Blockchain in Construction & Supply Chain Management: Blockchain technology can provide new solutions for supply chain management problems such as delays and mistakes in construction. This theme represents that there are 14 studies received the most citations in 80 publications. It is determined that 4 of the 14 most cited studies are literature reviews. Three of the remaining ten studies are semi-structured interviews. The methods used in the remaining studies are summarized as follows: Wang et al. (2020) developed a blockchain-based real time information model for precast component supply chain and designed a smart contract algorithm for its implementation. Lanko et al. (2018) combined blockchain technology with RFID in a case-based model to track the delivery of construction materials to construction site. Luo et al. (2019) studied on a case-based model to automate construction payment through smart contract-based blockchain framework for disputes, lack of trust and cash flow problems. Tezel et al. (2021) developed three payment prototypes for supply chain management. These are project bank accounts (PBAs) for payments, reverse auction–based tendering for bidding, and asset tokenization for project financing. Lu et al. (2021) explored blockchain-based construction supply chain system by smart construction objects enabled blockchain oracles framework. Li et al. (2022) investigated a case-based model that includes the integration of IoT and BIM to blockchain system in supply chain management for modular construction. Fitriawijaya et al. (2019) created a simulation of supply chain management using BIM, CDE, and blockchain, also, the smart contract system validated

every material and configuration of components within the model. According to Figure 6, smart contract technology is the most trending tool in supply chain financing. In addition, the sustainability of this system is another matter of discussion in terms of Industry 4.0. Also, the integration of BIM, IoT, and artificial intelligence can be seen as a new way of blockchain-enabled supply chain management with their yellow colors. The analysis of citations and journals that interested in these issues is shown in Figure 7. According to Figure 7, Automation in Construction has 142 citations, Frontiers of Engineering Management has 204 citations, Engineering Construction and Architecture has 49 citations and Building has 37 citations.

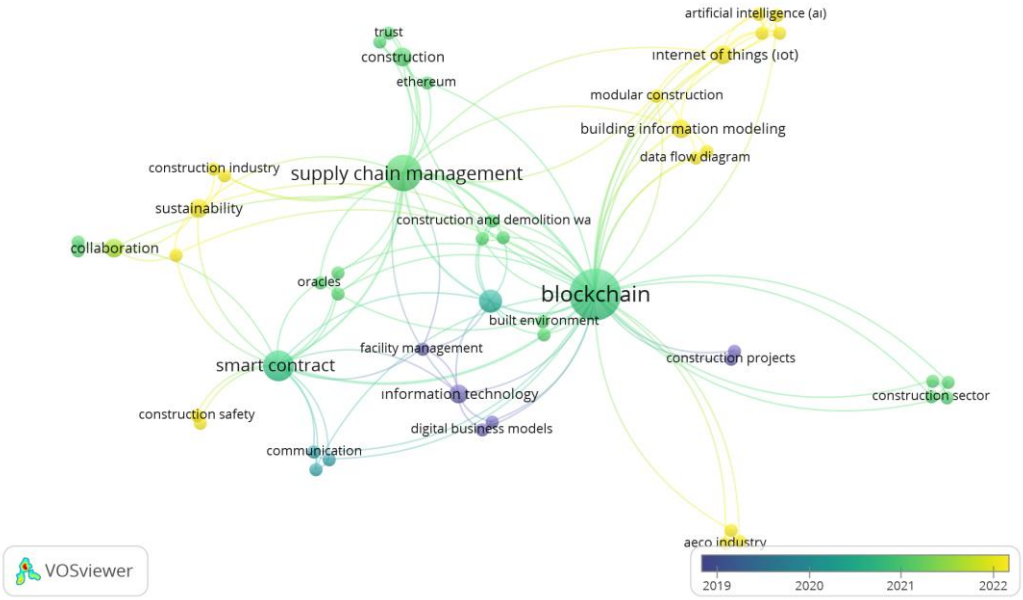

Figure 6: The science mapping of blockchain-related keywords in supply chain management by VOSviewer.

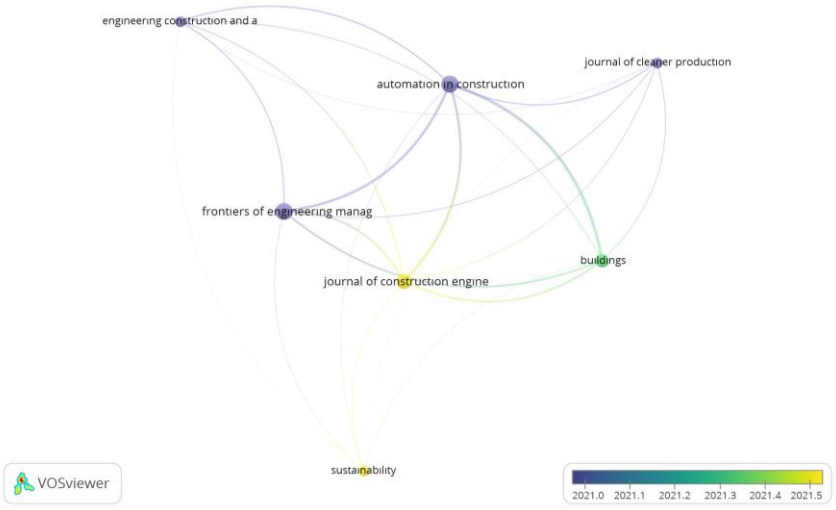

Figure 7: The analysis of journal and citations in supply chain management theme by VOSviewer.

Blockchain in Construction & Payment: Poor payment and contract problems have been causing numerous disputes and business failures. For this problem, digital contractual clauses can be developed and coded into blockchain-enabled smart contracts. Smart contracts can

work with fiat currencies and cryptocurrencies. In this theme, it is investigated that 14 studies obtained the most citations in 83 publications. The one of the fourteen most cited studies is literature review. The methods used in the remaining studies are developing models and the most cited remaining works summarized as follows: Elghaish et al. (2020) developed a payment model that executes all financial transactions by IPD smart contracts for IPD projects. Das et al. (2020) investigated an automated blockchain-based payment method for interim payment, sharing payment records at project-level transparently and securely. Ahmadisheykhsarmast and Sonmez (2021) focused on security system in smart contract payment named SMTSEC is presented for reducing payment problems. Hamledari and Fischer (2021) created an autonomous payment solution, integrating blockchain-enabled smart contracts and robotic reality capture technologies, payments with cryptocurrencies/tokens and non-fungible tokens (NFT) and implemented this model to implemented to seven subcontractors in two real-world commercial construction projects. Shojaei et al. (2019) developed a sample model including BIM, blockchain and current fiat currencies in transactions for dispute resolution. Lu et al. (2021) explored a blockchain based payment model for governmental supervision of construction work (GSCW) for policymakers, practitioners, and researchers to develop governance policies. According to Figure 8, smart contracts, cryptocurrency, asset tracking, digital signature, automated transactions and BIM keywords can be seen as popular research areas in construction payment theme.

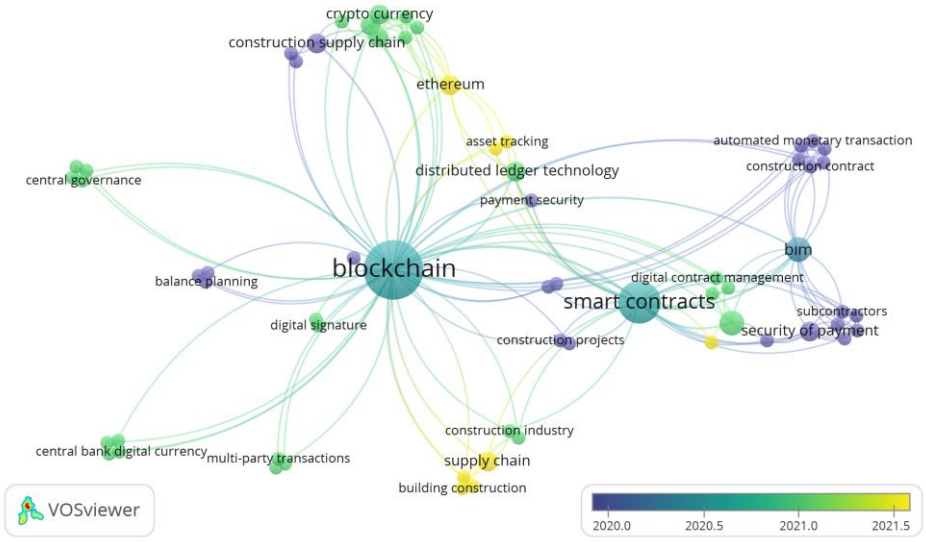

Figure 8: The science mapping of blockchain-related keywords in payment by VOSviewer.

Figure 9 shows the analysis of journal and citations network. In this analysis, it can be seen that Automation in Construction has 133 citations, IEEE Access has 32 citations, Informatics has 13 citations, Journal of Construction Engineering and Management has 10 citations. Moreover, Figure 9 can be interpreted as a timeline of this cluster. According to this timeline, it can be seen that blockchain-related tools have started to be published in the literature from 2019.

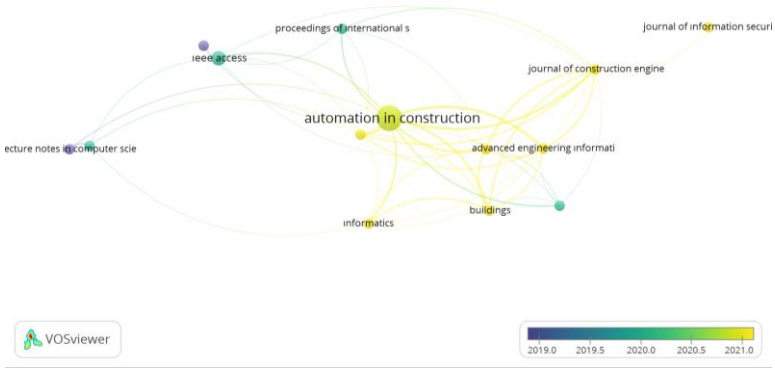

Figure 9: The analysis of journal and citations of payment theme by VOSviewer.

Blockchain in Construction & Information Management: Blockchain enables the storage of a wide range of know-how information in the construction in high security. In this cluster, 14 studies were investigated as the most cited works in 206 publications. Seven of the fourteen most cited studies are literature reviews. The methods used in the remaining studies are developing models and these works summarized as follows: Zheng et al. (2019) proposed BIM data organization based on blockchain model (BcBIM), to facilitate BIM data audit for historical modifications by blockchain with big data sharing on private and public blockchain. Sheng et al. (2020) developed a blockchain-based framework for managing quality information by smart contracts, referred to as "qualityChain". Lee et al. (2021) explored a model and implemented to a hypothetic case for traceable data communication by integration of digital twin and blockchain framework. Ye and König (2021) improved a billing model for checking the contract are defined on the basis of the building elements, determined quantities and defined construction works. Lokshina et al. (2019) designed a system that employs the blockchain as a measure to secure and control the information framework that involves integrated IoT and BIM technologies and this system was implemented to a case. Liu et al. (2019) developed a conceptual model to explore the potential roles of an integrated BIM-BC and smart contract approach for sustainable building design information management. As can be seen in Figure 10, the most popular research areas related information management are BIM, IoT, big data, smart contracts, digital twin, artificial intelligence and autonomous technologies. Also, construction safety and data management are trending issues in blockchain technology. Moreover, Figure 10 can be seen as a timeline of this cluster. According to this timeline, it is shown that blockchain-related tools have started to be published in the literature from before 2019.

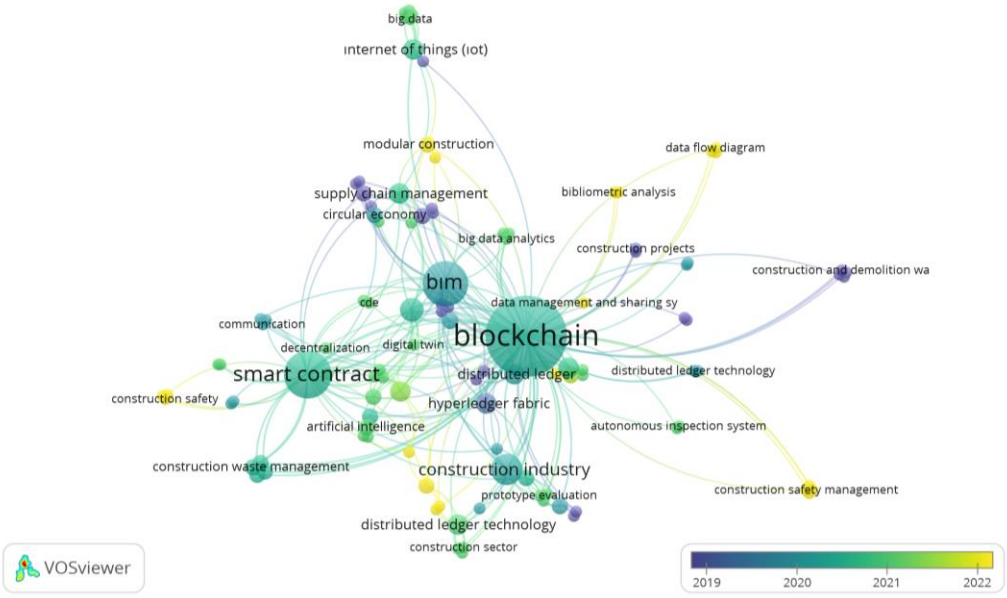

Figure 10: The science mapping of blockchain-related keywords in information management by VOSviewer.

Figure 11 presents the analysis of journal and citations network. According to this network analysis, it is clear that Automation in Construction has the highest citations that are 322, Journal of Building Engineering has 72 citations, Advanced Engineering Informatics has 53 citations, Engineering, Construction and Architecture has 48 citations, Journal of Information Technology in Construction has 47 citations.

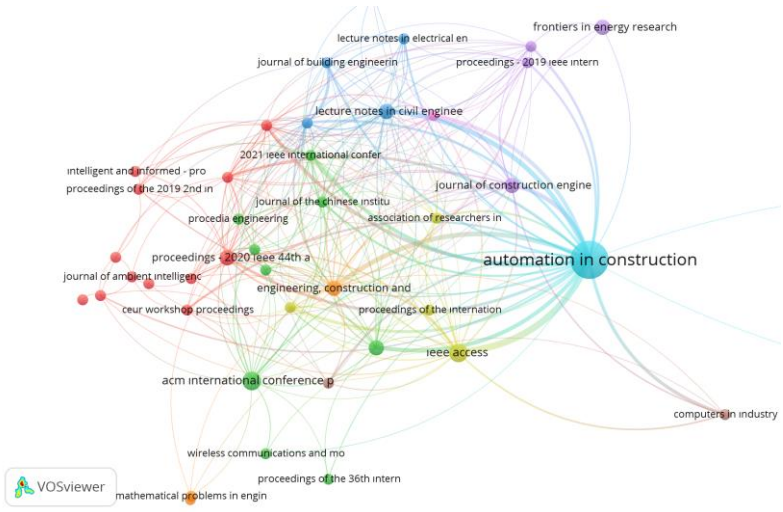

Figure 11: The analysis of journal and citations in information management theme by VOSviewer.

Blockchain in Construction & Facility Management: Blockchain in facility management is important for real-time data access, visualization and marketing, checking maintainability, creating and updating assets with the integration of IoT and RFID technologies. This issue is one of the latest topics in blockchain technology. Therefore, the least number of studies in this theme were found in databases. Four studies were discovered as the most cited works in 8 publications. All of these are literature reviews instead of developing the model. The most cited works are Turk and Klinc (2017) and Ye et al. (2018) suggested the integration of

blockchain-BIM-IoT; Shojaei (2019) added this framework to smart contracts for facility management.

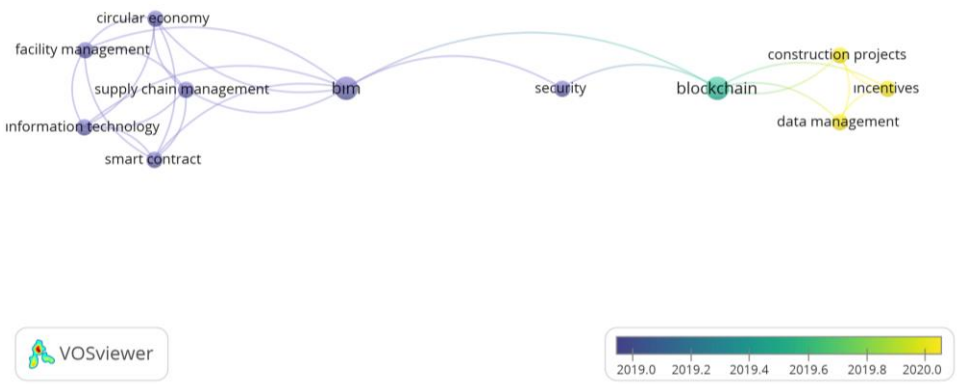

Figure 12: The science mapping of blockchain-related keywords in facility management by VOSviewer.

As shown in Figure 12, BIM is a tool between blockchain and facility management. In addition, smart contracts and circular economy are trending topics that are connected to facility management. According to the analysis of journal and citations network, it is found that there are four journals that are Proceedings of the 35th International Symposium on Automation and Robotics in Construction has the highest citations that are 33, Proceedings of International Structural Engineering and Construction has 24 citations. Science mapping analysis' of this theme cannot be shown since there was no citation link between the journals.

Blockchain in Construction & Contract Management: During the contract management procedure, any missteps throughout the bidding process can cause project delivery problems or planning and scheduling mistakes. These issues lead contract management to a fast, secure, immutable technology called blockchain and smart contracts. In this theme, 6 studies were examined as the most cited works in 132 publications. A literature review, a questionnaire model and four developing model were discovered in these six studies. The most cited researches were analyzed: Kim et al. (2020) made a questionnaire to experts to identify potential blockchain application areas in construction lifecycle and project management knowledge areas especially 'Procurement', 'Contract', and 'Cost'. Nawari and Ravindran (2019) developed a model for considering the potential incorporation within the BIM process to address post-disaster rebuilding problems and improving smart contract. Das et al. (2022) investigated a prototype of the proposed smart contract framework for document management. Sigalov et al. (2021) discovered a model and implemented a case that includes improving BIMcontracts, the blockchain container-based data exchange, and the digital contract management workflow. Ciotta et al. (2021) proposed a model and implemented a case that encompasses a proof-of-concept for the integration of blockchains and smart contracts into information flows used in various CDEs, information exchanged with data gathered by IoT sensors on site. Including these papers, 44 papers in Scopus and Sci-direct; 88 papers in Web of Science database were discovered and visualized by VOSviewer science mapping in Figure 13.

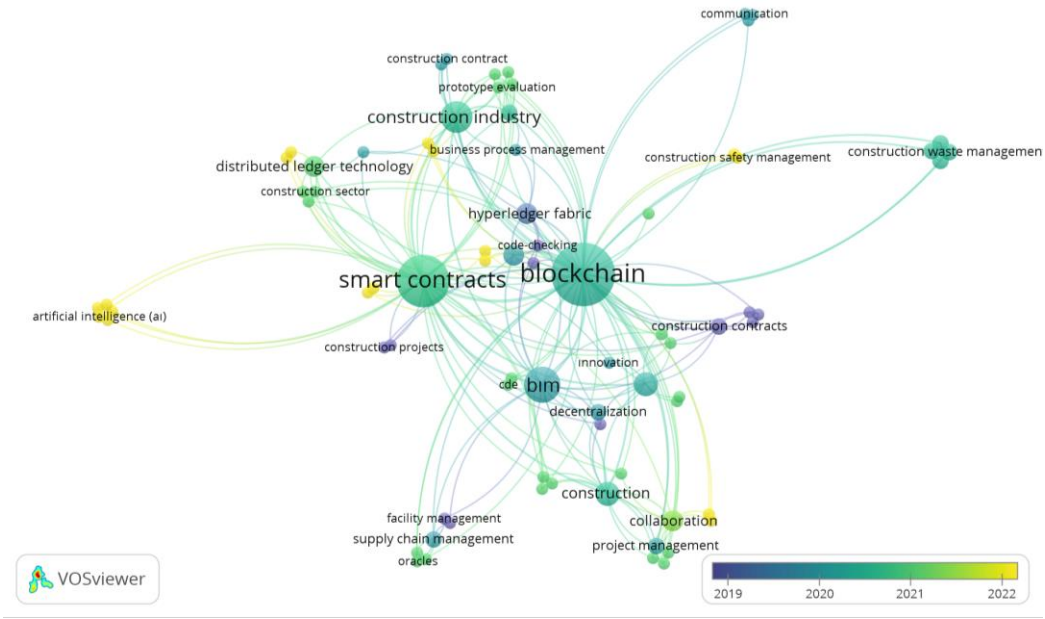

Figure 13: The science mapping of blockchain-related keywords in contract management by VOSviewer.

As shown in Figure 13, smart contract, artificial intelligence and BIM are seen the most trending digital tools related to blockchain technology. Also, smart contract is associated with business process management keyword. According to the journal and citations analysis that can be seen in Figure 14, Automation in Construction has 336 citations, Procedia Engineering has 176 citations, Journal of Building Engineering has 72 citations, Advanced Engineering Informatics has 53 citations.

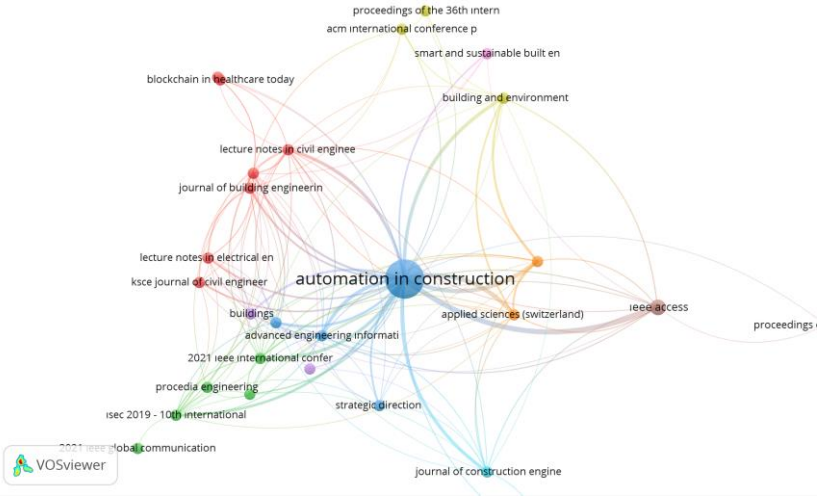

Figure 14: The analysis of journal and citations in contract management theme by VOSviewer.

Discussion and Conclusion

Digitalization era through Industry 4.0 was reflected in the construction industry as Construction 4.0. This era has various digital tools such as blockchain, big data, artificial

intelligence, IoT in construction. Despite the most of the sectors adopted digital tools, the construction sector lags behind the other industry. In order to implement these technologies, tools should be known in the sector and academia. In this purpose, this paper aims to identify blockchain technology that is the one of the popular digital tools and its five popular themes of applications in terms of Construction 4.0. In the research methodology, blockchain and related applications were clustered according to the main 'blockchain' keyword analysis in VOSviewer science mapping, and as a result of this step, five sub-keywords were grouped from prominent nodes in terms of management field. These are: supply chain management, payment management, information management, facility management, contract management. In the next step, five sub-keywords were refined by the keyword "construction". This phase demonstrated the thematic place of popular sub-keywords of the blockchain in the field of construction management. Various science mappings were generated in each theme by VOSviewer software. In addition, the analysis of journal and citations of studies were conducted by bibliometric network.

As a result, according to the cluster analysis of blockchain and selected five popular themes, it is found that most publications are in the fields of information management, payment, supply management, contract management, and facility management, respectively. These findings show that blockchain applications in facility management are limited and the information management area is a more trending issue than the others. Among the sources of these researches, China, the USA, India, and the UK stand out compared to other countries.

According to another result of the cluster analysis, the most popular and common blockchain-enabled tool in payment and supply chain management is smart contracts while the most trending blockchain-enabled topics in information management are BIM, smart contracts, IoT, digital twin and big data. Moreover, in payment theme, cryptocurrency, automated payments, asset tracking, and digital signature keywords seem to be open to development. In the cluster of facility management, the most trending blockchain-enabled tools are perceived as BIM and BIM related smart contracts. In the cluster of contract management, the most emerging tools are discovered as smart contracts, BIM, artificial intelligence and distributed ledger technology. As can be understood from cluster analysis, there are a few technological tools that come forward: blockchain-enabled smart contract, BIM, IoT, artificial intelligence and their combinations in hypothetical and real models.

In addition, according to the bibliometric analysis of five popular themes that are the limitation of the study, the number of articles developing a model and the number of the literature review articles were similar. But, in the facility management cluster, many literature reviews were found instead of developing a model based on blockchain. It has been inferred that there is a lack of model development in this area. The other clusters have developed hypothetical and real models. However, some of these hypothetical models can be interpreted as immature and open to development. As another result of the study, it has been determined that other technological tools such as IoT, artificial intelligence, big data and BIM in the literature can be linked with blockchain in various ways. For future works, it is recommended that thematic clusters can be expanded and detailed by using different software to understand blockchain's functions comprehensively. Moreover, it is suggested that to merge related technological tools within real prototypes by using thematic clusters to increase productivity of the construction industry in terms of Construction 4.0.

Evolution of the Building Sector from Building Catalogs to BIM Catalogs

D. Yıldırım and C. Ç. Çıtak
Yildiz Technical University, Department of Architecture, İstanbul, Turkey
dammlayildirimm@gmail.com, citak@yildiz.edu.tr

Abstract

Mass production that emerged with the Industrial Revolution has radically changed both the production and circulation of building elements and components in the market, as in all sectors and products. Since 1870, building elements have been produced in factories, cataloged, exhibited in fair areas, and begun to be sold in construction markets. Important developments in information technologies have revealed developments in computer software. Building Information Modeling (BIM), one of the important developments in the construction industry, has become the technology that enables the building system to be modeled with "BIM Objects" based on the building components that set up the building. Today, manufacturers design building components as "BIM Objects" and present them to users in international BIM libraries. In this study, the continuity of the international classification and standards of building elements formed in the printed catalog process in BIM catalogs was emphasized, and the studies were reached in terms of literature research. This has become a new marketing strategy for manufacturers. Throughout the historical development of the building industry, it is aimed to reveal the importance of the development of the tools of access to the building elements together with the technology for the manufacturer and the designer.

Keywords: *BIM library, building classification systems, building components, building information modeling, building products catalogs.*

Introduction

A building is the result of physically conflate many products together and is the final output of the production process. Building products constitute the physical corpus of the building. These products are classified according to their function, production and finish: material, piece, component, element and unit. The properties and classification of building products are important in terms of organizing information, comparison and selection (Balanlı, 1997).

With the Industrial Revolution that started in England at the end of the 18th century, social and individual values changed, and the effects of mass production showed themselves in architecture as well as in every field. Architectural practice required more housing and new building types. This situation has led to the development and standardization of existing materials, the discovery of new building materials and the emergence of new building production methods (Güvenli, 2006).

After the mass production, with the separation of the assembly processes from the design processes, the building elements, which are the main objects of architecture, were mass produced in the factories, identification with printed catalogs, and thus presented to the designer. Classification systems have been used since the 1950 to ensure coordination in industrial building production (Serter, 2020). Firms needed systems that process information and data in order to adapt to the constantly and rapidly changing environment and to reduce the uncertainties in their environment (Tarçın, 2007).

The development of Computer Aided Design (CAD) software in the 1980 enabled the computer to be used more effectively in architectural design and assembly. In today's widely used CAD software, the geometry of all parts of the building is defined based on a certain marking system. The architect benefits from representation techniques within this system. CAD software is built with a system that imitates previous analog drawing and modeling techniques. Building components are not defined separately in this type of CAD software (Karadağ, 2011).

Building Information Modeling (BIM), which started a new era in CAD software with the emergence of new technologies in the field of architecture, engineering and construction (AEC) industry, has become an integrated methodology that brings a new approach to design and documentation in building projects. BIM is a major technological and theoretical development for the AEC industry. Sacks et al. (2010) define BIM as a transformative information technology, as it is the integration of parametric AEC and Information Management which both took off concurrently in the late 1990s (Wierzbicki et al., 2011). Unlike the widely utilized CAD tools, BIM enables visualization of form, behaviour, function and various other information of building design and construction with its object-oriented properties. BIM, which enables the control of the life cycle of the building consisting of design, production and maintenance processes, also provides documentation and visualization by extracting the model containing all the information about the building (Bentley, 2011). BIM allows all actors involved in architectural design, production and maintenance to work together. At the same time, it models their relations with each other based on the components that make up the building (Yaman, 2010). The main building blocks of the BIM system are parametric BIM objects, which are model elements. In the BIM system, each object represents a building component and each building component has its own attributes (Baldwin, 2021).

The main features of BIM are that it works with a digital database that keeps all the data defining the building together, that the revisions are processed into the database and reflected to all other documents automatically, and that all data collected during the design process creates a forward looking information repository. Traditional drawing and CAD software portray a design as geometric shapes. BIM software defines design as smart objects and components such as walls, columns, work programs, plan views. All these parametric components and objects are gathered in a single model. BIM systems can be used not only as a digital visualization tool, but also as tools that can highlight the natural capacities of materials, manufacturing and construction processes (Karadağ, 2011). In BIM technology, it is not the architect's choice of building materials to be used as a product from a catalog, but the design of the building with the product presented in line with the technical data of the material and the possibilities of the tools used (Jensen et al., 2009).
With the use of BIM in the construction industry, the need for the formation and use of standards has emerged. In 2013, a Publicly Accessible Standard (PAS) was published by the British Standards Institute (BSI) with the sponsorship of the Construction Industry Council.

Standards play an important role in ensuring the same accurate data is available throughout the supply chain, enabling wider adoption of BIM technologies, processes and collaboration (BSI, 2013). The common goals of standards, classifications, codes of practice and regulations regarding BIM are to increase the performance of a process. Codes related to classification systems such as Omniclass or Uniclass related to BIM are used to code building components. The purpose of BIM classification systems is to advance the entire lifecycle of the vertical and horizontal built environment by providing a means to organize and classify electronic object data. It is desirable to increase regular communication between building owners, designers, material suppliers, builders, facility managers and all proprietary associated with the built environment. The purpose of the guidelines developed for all professionals in the industry is to encourage more efficient practices by all members of the team of architects, designers, engineers, contractors, owners and operators throughout the lifecycle of a project (NBIMS, 2015).

The building components that compose BIM systems are included in this technology with their classification systems. The BIM objects of the manufacturers of the building components can be accessed from the international online BIM libraries. The products in BIM libraries contain the information of many classification systems according to different criteria. BIM libraries work as online resources to create and share product models with users. These online resources are databases for building.

In this study, with the emergence of the BIM system by means of the technological developments in the building sector, the situations in which the information does not change, increasingly transforms, and the tools to access the information change in the system where the building components are defined as BIM objects are examined through classification systems and BIM libraries.

The literature studies consists of scientific articles, international classification systems, building catalogs, international online BIM libraries, BIM reports and books published by independent organizations. After the literature review, the content analysis method was used to examine the classification systems. Content analysis is one of the qualitative research methods. “The basic process in content analysis is to gather similar data within the framework of certain concepts and themes and to organize and interpret them in a way that the reader can understand” (Yıldırım & Şimşek, 2006). The study was carried out by following the principles of content analysis. For the examination, first of all, the classification systems of building components developed with the existence of building catalogs, and then the classification systems that continue to be used in BIM systems were investigated. The classification systems, which are in common use, were determined and their contents were compared. Various findings were reached by revealing similarities and differences.

Developments in the Building Sector

Mass production, which emerged with the Industrial Revolution, radically changed both the production and circulation of building elements and components in the market, as in all sectors and products. It not only changed the traditional understanding of architecture, but also caused a radical change in the role of the architect and architectural practices with new construction systems, material types, the use of computer technology and scientific studies. In the consumption oriented social structure created after the Industrial Revolution, it was expected that the buildings would be built faster, like all other production objects. This

situation, along with other factors, brought industrialization and standardization in building construction (Karadağ, 2011).

With the spread of innovations and inventions peculiar to modern times, the main phenomenon that left its mark on the transformation experienced by modern industrial societies after the 19th century was mass production. Since the beginning of mass production in the 1950s, the way in which user needs and demands are handled in the design, production and marketing processes of products has changed. In the 19th century, England pioneered the circulation of building materials in the market and innovations related to sales methods. In the past, the material was generally produced by the builders at the construction site, but now it is produced by the manufacturers in the workshops, introduced with catalogs, displayed in the exhibition and fair areas and sold in the construction markets. Catalogs issued by large companies, called Builder's Manual, have begun to replace the construction manuals prepared for contractors and builders (Bilgin, 1994). With the transition to industrial production after the developments in the building industry, the necessity of building centers has emerged. Building Industry Center (Yapı Endüstri Merkezi – YEM), which has an important place in the information center and building materials sector in Turkey, was established in 1968. In 1973, Building Industry Center established a publication order with the Building Catalog (Yapı Kataloğu), then the building magazine and professional books. Technical sheets of building materials produced in Turkey are classified according to the "SfB System" in the Building Catalog and are published every two years (Sey, 2008).

From the 1970s onwards, the Post-Fordist production system started to show its effects. With the production approach called "just in time production", it is aimed to produce maximum consumer satisfaction with minimum resources and time (Sarıyar, 2008). This production model aimed to be product-oriented rather than process-oriented.

With the development of computer technologies, the use of information technology tools in production has increased. Information technologies and flexible production methods that developed in the 1980s gave companies the ability to respond to the demand that has become fragmented. The common feature of these companies is that they divide their product systems into smaller components and then combine them to meet different consumer demands. In the 2000s, the rapid development of computer and communication technologies and the expansion of information networks accordingly increased the interaction between the supplier-manufacturer-consumer in the production processes and enabled the consumer to have an active role. The concept of mass production and standardization has been replaced by the idea of "mass individualization" as consumers differentiate and customize the product they buy according to their own needs and expectations (Sarıyar, 2008).

Building Components Information Systems

Companies need systems that process information and data in order to adapt to the constantly and rapidly changing environment and to reduce the uncertainties in their environment. Information systems have emerged to meet this need. It has been observed that reliable information support, a processing method that will ensure the usability of information, an effective arrangement and marking system, ease of use and a properly functioning distribution path are expected from information systems. The most powerful of these tools are CAD technologies and the internet that come with the use of computers today. The most important elements that ensure that the data is organized and transmitted correctly; classification method

and coding systems. Information systems have become a necessity in order to adapt to the development of technology, to provide the right information, to process and evaluate it, to determine the place where it will be used, to transmit the information, and to manage the projects in the basic sense. The use of information systems in the construction industry began in the 1940s. In Turkey, the information systems used or recommended to be used in the building sector first started in the 1970s (Tarçın, 2007).

Table 1. Chronological classification systems and BIM libraries.

CLASSIFICATION NAME	COUNTRY	YEAR	BUIDING CATALOG YEM / TR	INTERNATIONAL ONLINE BIM LIBRARY						
				BIMforum List			BIM Object	NBS BIM Library	ARCAT	MEP Content
				2019	2020	2021				
SfB	Sweden	1950	+							
CSI MASTERFORMAT	North America	1963					+		+	
BSAB	Sweden	1972								
CI/SfB	United Kingdom	1976								
CAWS	United Kingdom	1987								
UNICLASS	United Kingdom	1997				+	+	+		
UNIFORMAT	North America	1998		+	+	+	+			
ISO 12006-2:2015	Swiss	2001								
OMNICLASS	North America	2006			+	+	+	+		+

In Table 1, commonly used classification systems for building products are; short names, country and year of development are shown. At the same time, the classification systems used in the Building Catalog (Yapı Kataloğu - YEM) and BIM libraries, which are the most preferred by designers, are given in the table. Systems that continue to be used in common are indicated in bold. Within the scope of the study, common classification systems are included.

SfB system consists of three separate parts. In the first part, the functional elements of the building, the production method in the second part, and the classification of the resources in the third part are defined (Taş, 2002).

Masterformat is a master list of classified topics and numbers to organize information about construction conditions, products and activities. This system divides building production into 2 main groups, then these groups into 5 subgroups and subgroups into 50 classes in total (Tarçın, 2007).

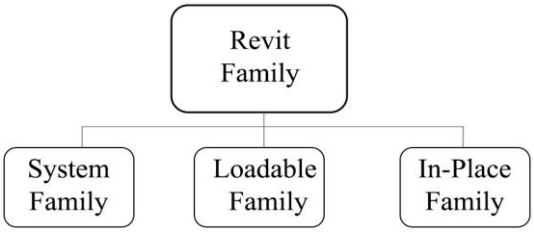
Uniclass is a product-based classification system. Containing the arrangement of specifications, cost information, project information structure, library documents; It is a classification system that can be used at every stage of the design and construction process (Serter, 2020).
Uniformat is a classification system in the building sector that aims to establish the link between the building-construction process, project specifications and cost calculations. In the Uniformat system, there are 5 stages created in the form of tables to classify the construction process (Tarçın, 2007).

Omniclass classification system is designed to classify all information about the production. The system is used in many execution, from classifying the structure of electronic databases to organizing product literature, project information and library materials. The system contains tables of used systems such as Uniclass, Masterformat, Uniformat, EPIC (Electronic Product Information Cooperation) (Serter, 2020).

The Relation of Building Information Modeling with the Building Components Classification System

The term of BIM first emerged with the development of solid modeling systems in the 1970s, but it became widespread in the 2000s (Eastman et al., 2011). BIM enables dynamic and direct collaboration, quick and accurate testing and validation of design decisions, participation of all project stakeholders, integration and analysis. It facilitates communication between project teams and supports quality management by automatically detecting design errors and clash detection. It is a project management tool that enables project teams to accurately estimate cost, reduce material waste, optimize work schedule, and streamline construction activities by simulating construction activities. It is also a mechanism designed to support contract management, monitor by assigning tasks, and plan and report on project progress by managing job changes (Baldwin, 2021).

In addition to the digital visualization of various forms, BIM software also contains all the information about the structure in the model elements. Thanks to the Computer Numerical Control (CNC) method, this information is sent directly to the machines and enables the production of building products. The transformation of the designs created in the free virtual environment offered to the designer by computer software to the final product can be realized as much as the materials, production tools and methods allow (Karadağ, 2011). BIM objects, which are the building blocks of the BIM system, are parametric. Computational infrastructure of material systems, which are constructed with complex relationships such as the combination of different parameters and data from material tests, is primarily created in the digital environment. However, the computational infrastructure based on material system logic should be able to integrate the geometric behavior, possibilities and limits of production methods, combination logic and material character, which are the main elements of material systems (Jensen et al., 2009).



The Revit software, which is one of the BIM based software and widely used in current BIM projects, was developed in the early 2000s and was purchased by Autodesk. The Revit software has an interface that facilitates the editing of parametric 3D building components. A change made in the 3D model can be reflected to all areas at the same time, such as images created in the program, annotations on the sheets, and lists.

In the BIM system, each object represents a building component. Each building component has its own qualities. Object defines the building component with its physical dimensions, material properties, function, cost and approval status. BIM objects have development levels. The levels of development of BIM objects are briefly defined as LOD (Level of Development). LOD defines the representation of the object for a particular phase or state. With the LOD levels, the detail levels of the model elements are defined, the geometric and textual information data that the model should contain is leveled. The LOD definition, created by the American Institute of Architects, uses a five-stage system associated with the five key phases of the project: concept design, design development, construction documentation,

fabrication drawings, and as-built. This is a fairly broad grouping that describes both the geometric and informational content of an object and its potential uses. Categories are not only a measure of object detail, but also their suitability for their intended use (Baldwin, 2021).

BIM objects are grouped as object families in the Revit software according to the function of the building components they represent. System families are used in building construction to represent basic building elements such as walls, roofs and floors manufactured on site. Loadable families are mostly used to represent building elements such as doors, windows, furniture, which are purchased ready-made and assembled on site. In-place families are used for objects modeled in the desired geometry and features within the project, according to the project (Autodesk Help, 2022) (Table 2).

Table 2. Object families with different properties in Revit software.

In BIM systems, designers access the building components of manufacturers through online BIM libraries. BIM object libraries work as online resources for creating and sharing product models with users. Products in BIM libraries can contain information of many classification systems or can be customized according to different criteria. BIM libraries present categorized information objects to users online. In the BIM library, the user can examine, download, and use objects from many manufacturers belonging to the same type of product. These online resources are databases for building. Objects in the online environment are updated quickly and the user can always access up to date content. Creating manufacturer specific BIM objects creates an online marketing environment for product manufacturers. Some of the commonly used BIM libraries and their subdisciplines are shown schematically below (Table 3).

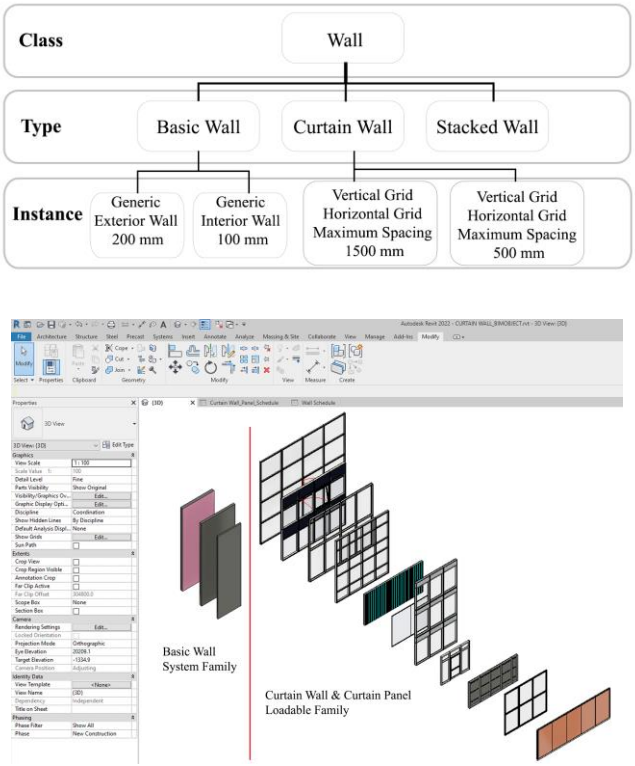
BIM softwares classify objects by class and type. Class is the highest category level of a building product. Primary relationships are defined at the class level. Type is a subcategory of model objects. Instance refers to individual occurrences of an object type in a project model.

“Class, Type, Instance” classifications (Table 4) explained over wall types are shown with wall examples in Revit program (Figure 1). Wall & Curtain Wall types belonging to different manufacturers were filtered from the “BIM Object” library and BIM objects were downloaded. Downloaded wall components are available as “basic wall” and “curtain wall” objects of different types.

Table 3. International BIM libraries and manufacturer sectors.

	BIM LIBRARY			
	BIM Object	NBS BIM Library	ARCAT	MEP Content
Architecture	+	+	+	
Structure	+	+	+	
Mechanical Electrical Plumbing	+	+	+	+

Table 4. Revit software classification systems.



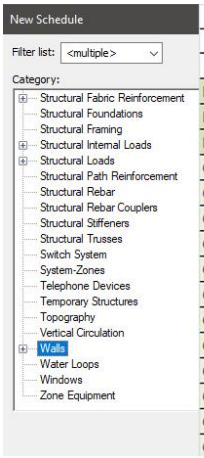


Figure 1: Wall examples in Revit program with BIM object.

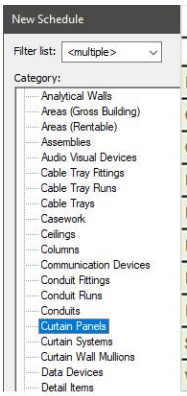
Revit program, the material list of the building components seen in the model; can be given automatically thanks to shared parameters containing geometric and text information. The important point is that the objects are created in the right category and with the right classification code. As can be seen in Figure 2, BIM objects are listed in the first step by selecting the "walls" class category from the schedule list. After this filtering, the Revit program gave the subcategory types of the wall elements created as "system family" as "basic wall (type) - curtain wall (type)".



WALL SCHEDULE

Family	Family and Type	Manufacturer
Basic Wall	Basic Wall: 3.1.2_Tabique Pladur® 240 (150) 6F MW	PLADUR
Basic Wall	Basic Wall: AU Hebel Powerpanel XL External Wall D=186 Mm R=2	HEBEL
Basic Wall	Basic Wall: SK Ytong Internal Wall U=0	YTONG
Curtain Wall	Curtain Wall: Laminam 1000x3000x3.5mm_Vertical Mechanical Fixing	RIVENTI FACHADAS ESTRUCTURALES S.L.
Curtain Wall	Curtain Wall: RIVENTI_System-R50SG_H70-V100	RIVENTI FACHADAS ESTRUCTURALES S.L.
Curtain Wall	Curtain Wall: Aluprof MB-SE75	ALUPROF SA
Curtain Wall	Curtain Wall: Wicona - WICTEC 50 - Double Glazed - Demo Frame - RAL 7016	WICONA
Curtain Wall	Curtain Wall: Curtain_System-CRL-3250-Curtain_Wall_System	C.R. LAURENCE - U.S. ALUMINUM
Curtain Wall	Curtain Wall: Curtain_System-CRL-3250-Curtain_Wall_System	C.R. LAURENCE - U.S. ALUMINUM
Curtain Wall	Curtain Wall: Curtain_System-CRL-3250-Curtain_Wall_System	C.R. LAURENCE - U.S. ALUMINUM
Curtain Wall	Curtain Wall: Aluprof MB-EXPO	ALUPROF SA
Curtain Wall	Curtain Wall: KINGSPAN COLDROOM VERTICAL	ALUPROF SA
Curtain Wall	Curtain Wall: Walls_Curtain-Walls_İnteral_MN60_Mullion-Transom	CUHADAROGLU
Curtain Wall	Curtain Wall: Ponzio WS 50 Curtain Wall	PONZIO
Curtain Wall	Curtain Wall: Lindner Logic 100-Situation4(A)_F30	LINDNER AG

Figure 2: List of system family models found in the wall category.

As seen in Figure 3, BIM objects are listed in the second step by selecting the "curtain panels" type category from the schedule list. After this filtering, the Revit program listed the “curtain panel” wall elements created as “loadable family” and the objects belonging to different manufacturers as “instance”. Since the selected BIM objects are designed after the "curtain panel" category is selected correctly in the Revit program, the same "OmniClass" codes can be seen even if they belong to different companies. The omniclass number of the curtain panel “23.25.20.14.11.11.17” consists of these codes.

REVIT_CURTAIN WALL_PANEL_SCHEDULE

Manufacturer	Family	OmniClass Title	OmniClass Number
KINGSPAN	Coldroom_Microcold_V	Infill Panels	23.25.20.14.11.11.17
C.R. LAURENCE - U.S. ALUMINUM	Crl-3250-Center_Glazed	Infill Panels	23.25.20.14.11.11.17
CUHADAROGLU	Interal_UCW72	Infill Panels	23.25.20.14.11.11.17
LAMINAM	Laminam Panel_Curtain Wall Vertical	Infill Panels	23.25.20.14.11.11.17
LINDNER AG	Logic100_Wood Panel_L-Corner(A)	Infill Panels	23.25.20.14.11.11.17
LINDNER AG	Logic100_Wood Panel_Spacer	Infill Panels	23.25.20.14.11.11.17
PONZIO	Pannelli Vetro_Glass Panes	Infill Panels	23.25.20.14.11.11.17
RIVENTI FACHADAS ESTRUCTURALES S.	Riventı_Curtain-Panel_System-R50sg_Glass-Pane	Infill Panels	23.25.20.14.11.11.17
SCHUECO INTERNATIONAL KG	Schueco_Fws-Glazing	Infill Panels	23.25.20.14.11.11.17
WICONA	Wicona - Wictec 50 - Single Glazing	Infill Panels	23.25.20.14.11.11.17

Figure 3: List of loadable family models found in the curtain panel category.

The OmniClass codes seen in Figure 4 after selecting the necessary steps to create a "curtain panel" object in the Revit program are as follows. The structural setup of the Revit program is

designed with the “OmniClass” classification system. This system contains tables of existing systems such as Uniclass, Masterformat, Uniformat.

In BIM technology, the appropriate classification system that the BIM object will contain can be selected according to the project objectives and country. Required classification codes can be added with text parameters to BIM objects that work with parameters. In this way, the code system of more than one classification system is contained in the digital BIM object (Figure 5).

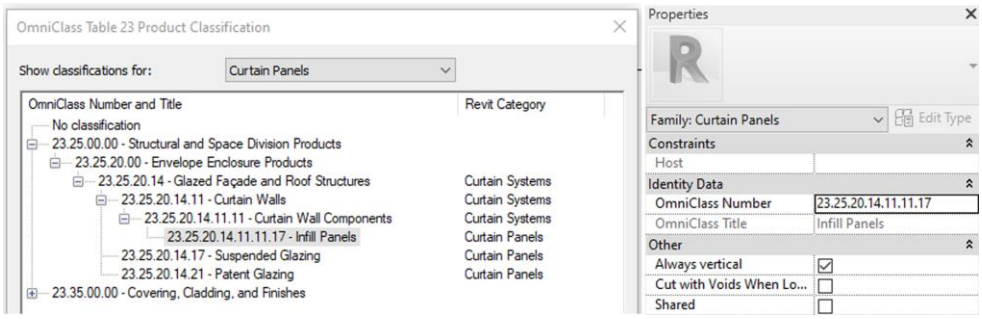


Figure 4: Omniclass code system within the Revit program.

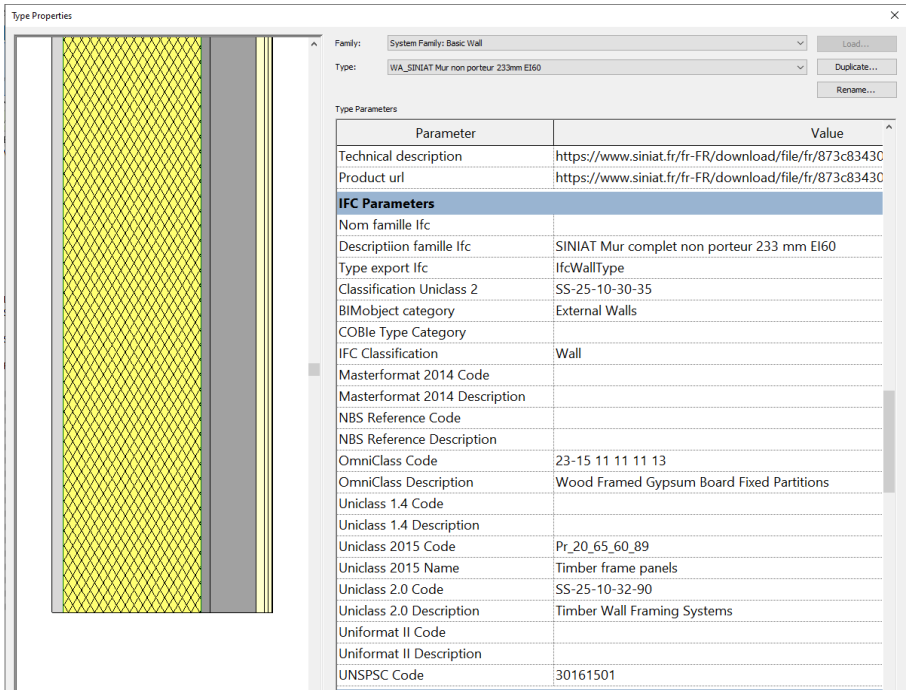

Figure 5: BIM object with different classification code parameters.

Conclusions

With the increase in the use of BIM technology thanks to the technological developments in the building sector, the work has progressed through classification systems and BIM libraries from past to present within the system where building components are defined as BIM objects.

Along with the industrial developments in the building sector, catalogs and brochures that provide information to users about building materials are presented as online resources instead of printed resources in order to be updated at the speed of new building materials that are rapidly spreading in the market. Today, with the widespread use of BIM technology, BIM libraries serve to share building components as BIM objects.

Within the scope of the study, classification systems and code data of BIM objects downloaded from the "BIM Object" library were examined. Thanks to BIM libraries, building components belonging to many different companies that can provide the same service in the

online environment can be used as BIM objects with 3D information, with correct technical and alphanumeric data. In this way, designers can reach manufacturers and their products from any location in the world. These conveniences may affect the decision of the designer from which company to choose the building element. Likewise, manufacturers can continue their competitive strategy on BIM platforms by expanding their market network. BIM libraries provide analytical data to manufacturers, giving data such as which product the user downloaded, when, how many times, from which location.

After the content analyzes made within the scope of the study, it was found that the use of building elements according to classification systems continues to be used in the structure of electronic databases. The classification systems used in the catalog system or traditional CAD systems continue their continuity in BIM systems. In BIM technology, these classification systems have added many values to digitalized building technology. In BIM technology, codes related to classification systems such as OmniClass are used to code building elements. Thanks to codes, electronic object data is organized. The classification data in the building elements enable the data shared on the common data environment to be used efficiently in the production of information, and the result information to be made into regular tables. Systems that classify building components with different methods can be used for classification of building elements. Categorizing by classification system in the BIM system details search and grouping activities, supporting subsequent sub-uses such as cost estimation and work schedule for objects that may be based on the same classification system. Data containing objects allow building elements to be produced and can directly initiate the fabrication process. Building data can be easily understood and shared among project participants thanks to digital parametric objects. Regular communication is maintained between building owners, designers, material suppliers, builders, facility managers and all stakeholders associated with the built environment.

Abstract

The construction industry is trying to adapt to the developing technologies day by day. One of these technologies is blockchain, a distributed ledger technology (DLT). DLT is a type of database that is decentralized in nature, eliminating the need for an intermediary to process, validate or authenticate transactions. This article aims to highlight the critical issues regarding the use of blockchain in the construction sector by analyzing the literature and shedding light on current research limitations and gaps. Blockchain technology provides advantages to different parts of the construction industry like quality inspection, smart contracts, supply chain management, intelligent transportation, project payments, tendering for bidding, knowledge management, sustainable waste management, and energy industry, etc., due to its decentralized, encrypted, and secured functionality. Integrating blockchain into construction works improves quality, efficiency, and capability through security and transparency. On the contrary, blockchain technology is not widely used in the construction sector for being costly, time-consuming, and cyber-attackable.

Keywords: *blockchain technology, digital authentication, knowledge management, online payment, project management, smart contracts, supply chain management*.

Introduction

Blockchain is a type of the distributed ledger technology (DLT) that can record data, assets, and all related transactions executed and shared between network participants with the characteristics of decentralization, immutability, transparency and traceability. There are key advantages in its inherent immutability, transparency, and the way it redefines the

trust relationship by offering fast and secure solutions that can operate publicly or privately (Underwood, 2016). Blockchain technology was devised from the first cryptocurrency known as Bitcoin. It was soon noted to have a much more full range of applications beyond serving as the platform for the digital cryptocurrency (Nawari & Ravindran, 2019). The adoption of blockchain technology in the construction industry takes time. Due to the fact that blockchain technologies are costly, time-consuming, and vulnerable to cyber-attacks, their use in the construction industry is not at a sufficient level. However, in recent years, an increase has been observed due to the severe impact of this technology on quality, efficiency, and capability. This study investigates what, how, and why blockchain technologies are used in the construction industry, such as digital authentication, knowledge management, online payment, project management, smart contracts, supply chain management, etc.

Literature Review

Studies on a blockchain between 2017 and 2022 were examined using the American Society of Civil Engineers (ASCE) and ScienceDirect (Automation in Construction) databases. As a result of a detailed scan, the branches of the construction industry with an application of blockchain technology have been classified into nine subject areas, which are (1) smart (intelligent) contracts, (2) financial management (payment), (3) design (BIM), (4) project management, (5) real estate management, (6) power engineering, (7) supply chain management, (8) urban management, and (9) knowledge management. The classification of studies is explained below:

Smart (Intelligent) Contracts

A smart contract is an executable code that runs on the blockchain to facilitate, execute, and enforce the terms of a contract. The main purpose of a smart contract is to automatically execute the terms of a contract when the specified conditions are met. Over the past decade, research into smart contracts has increased significantly with tremendous efforts from computer science and engineering fields. Smart contracts have received less attention in construction and engineering than in other areas. Using smart contracts increases productivity and transparency, reduces corruption, and contributes significantly to the project's success (Owusu et al., 2020). The study's hypothesis that the contributions of intelligent contract applications in the construction industry emphasize that certain aspects of the construction contract cannot be fully intelligent. Further, smart contracts should be considered part of the BIM-led revolution in construction and not considered separately from it (Mason, 2017). When a comprehensive literature search was conducted, applications of smart contracts in different areas in the construction industry were found.

Some of these applications are as follows:

- Energy Internet: The Energy Internet is a collection of networks covering clean and coal energy systems, power systems, energy transportation logistics networks, and natural gas and oil pipeline networks. Decentralized, open and transparent, secure and reliable distributed by blockchain technology, shared mechanisms, and smart contracts technologies, such as energy production and consumption that users can only reshape effectively reduce energy costs but also allows the use of energy (Zheng et al., 2019).
- Greenhouse Gas Emissions: Many countries have tried to reduce greenhouse gas emissions by implementing various mitigation plans. Blockchain applications in the

construction industry have a considerable potential to advance building energy performance and reduce fossil fuel consumption. With the energy use monitoring feature of the blockchain, fossil fuel use in the construction industry can be limited. In addition, the smart contracts feature of this technology makes it easier for contractors to fulfill their environmental obligations (Woo et al., 2020).

- Quality Inspection: Generally, on-site construction quality inspection is carried out manually, and its effectiveness largely depends on the self-discipline and evaluation criteria of the inspector. A prototype system was developed to vividly demonstrate the theoretical feasibility of using blockchain technology which records information immutable and transparently and automates some businesses with smart contracts (Wu et al., 2021).
- SC-based Planning Platform: The Ethereum Blockchain approach was chosen to create a Smart Contract (SC)-based planning platform since it can accurately and quickly get the preferences of project managers and transmit the resulting regulation to transactions. The research findings will help project managers to react quickly to unexpected changes in management preferences in manpower, field, or schedule by developing adaptive resource utilization solutions (He et al., 2022).
- Construction Business Process and Information Integration: The aim of the study is to investigate the feasibility of implementing both public blockchain and private blockchain technologies in the construction industry using two industry cases. This pilot study also demonstrates the process, benefits, and challenges of adopting private and public blockchain technologies in the field of construction (Yang et al., 2020).

Financial Management (Payment)

For the successful completion of construction projects, the project participants must be paid on time. In the construction project, participants with different financial capacities belonging to different organizations depend on contractual relations. Due to the organizational structure of such projects, the project participants do not completely trust each other, which prevents the adoption of centralized, automated frameworks available for pay decoupling (Das et al., 2020). Blockchain provides a reliable decentralized peer-to-peer electronic cash pay network with minimal transaction costs, providing a platform for digital transactions and applications to proceed using a trusted intermediary party (Berglund et al., 2020). When a comprehensive literature search was conducted, financial management applications in different construction industry areas were found.

Some of these applications are as follows:

- Blockchain Tokenization: Tokenization is the process of replacing sensitive data with unique identification symbols that retain all the essential information about the data without compromising its security. Tokenization in the construction industry is an innovative method of financing infrastructure. Tokenization as a derivative of blockchain technology and a creative means of financing improves transparency, increases access to alternative sources of capital and liquidity, and reduces counterparty risk through decentralizing the infrastructure project financial system (Tian et al., 2020).
- Payment Tools: Within the scope of smart city programs, electronic payment systems are used in parking lot routing systems, transportation agencies, and bicycle-sharing systems.

- Blockchain offers a platform for digital transactions and applications that new electronic payment systems are based on cryptographic proof rather than trust (Berglund et al., 2020).
- Governmental Supervision of Construction Work (GSCW): Blockchain technology has been explored for governmental supervision of construction work due to its merits of traceability, immutability, and transparency. The study states that across-sectoral learning is performed between GSCW and digital currency electronic payment systems. In addition, the authors adopted a design science research method to develop a dual-layer blockchain-based GSCW model integrated with an incentive mechanism. The model developed in this study can serve as a valuable reference for policymakers, practitioners, and researchers to develop governance policies or blockchain applications (Lu et al., 2021).
- Distributed Blockchain-Based Framework for Payment: This paper presents a distributed blockchain-based framework that does not require to be trusted for automatically enforcing the terms and conditions related to interim payments and sharing payment records at the project level transparently and securely. The proposed management strategy is designed to dynamically generate cryptographic keys from publicly sharable parameters so that storage and management overheads are reduced (Das et al., 2020).
- Integrated Project Delivery (IPD): The study aims to develop a framework proposing blockchain technology utilization in IPD projects. The presented automated financial system increases trust and transparency among IPD team members, providing them with the assurance that all approved transactions are immutable and allowing each team member to control the cumulative values of the paid cost, profit, and cost savings (Elghaish et al., 2020).
- Smart Contract Payment Security System (SMTSEC): Paying participants on time in construction projects is very important for the successful completion of projects. Few studies have proposed methods for eliminating the problem when studying the causes and consequences of the payment problem. The authors stated that SMTSEC provides for eliminating or reducing payment issues in the construction sector. The main contribution of SMTSEC is that it provides a new method of paying for construction projects on time and transparently, guaranteeing the payment security of works under construction without the need for administrative costs and burdens of trusted intermediaries such as lawyers or banks (Ahmadisheykhsarmast & Sonmez, 2020).

Design (BIM)

Having a more collaborative process in design holds the potential for more problems related to the ownership of the intellectual property of the design. Therefore, by moving to the new era of digital-based design, that is, building information modeling, the ownership problem may become more complicated as BIM-based designs involve more people in the design process (Adibfar et al., 2020). Existing platforms for collaborative BIM design, the design, and manipulation of data are exposed to cyber security risks such as denial, traceability, loss of data, and project delays, which can lead to a decline in productivity and a central design system architecture. Blockchain is a promising technology for solving such risks by providing decentralized and immutable data storage (Tao et al., 2021). When a comprehensive literature search was conducted, applications of design (BIM) in the construction industry were found.

Some of these applications are as follows:

- Design Development by Blockchain Concepts: By developing blockchain frameworks, researchers propose the potential application of blockchain technology in the design development phase of architecture, engineering, and construction (AEC) processes. One of them is aimed at categorizing the design data generated from the design development software and log files in order to have a secure ledger that has the potential to provide validation to an argument and determine the data encryption flow using blockchain concepts (Singh & Ashuri, 2019).
- Cyber-Physical Systems (CPSs): The study focuses on evaluating supporting technologies for CPSs in AEC projects. The study supports using the blockchain to verify shared information and thus maintain trust in information exchange by providing cybersecurity (Linares et al., 2019).
- Integration of Blockchain to BIM-based Design: The research aims to investigate how digital-based design can be protected from unauthorized use, including what considerations practitioners may take into account to ensure the protection of their intellectual property. Blockchain and BIM-based design improve security and prevent AEC industry copyright infringement (Adibfar et al., 2020).
- Technology Maturity Gap between Academia and Industry: The researchers investigated the acceptance levels of emerging technologies by the industry of academic research and architecture, engineering, construction, and facilities management through an on-site and online survey and classified the identified technologies as suitability and maturity. Technologies to consider high use in the near future were found to be blockchain, AR, and modularization, accounting for 47%, 44%, and 40%, respectively (Cho et al., 2019).
- Blockchain Technology-Based Solution in BIM (BIMCHAIN): The exchange of information in a BIM environment is critical but complex due to the multilateral cooperative nature of a construction project. The study explores a blockchain technology-based solution to increase trust in data exchange in BIM following a case study analysis of a commercial tool called BIMCHAIN. BIMCHAIN's analysis has concluded that it has fulfilled, inter alia, many of its objectives, such as improving data reliability, limiting the scope of responsibility, and clarifying stakeholder responsibilities (Paradeep et al., 2020).
- Semantic Different Transition (SDT) Model: A new Semantic Differential Transition (SDT) model has been developed by researchers to capture and block BIM changes instead of all BIM files. This model minimizes information redundancy and supports BIM and blockchain integration. While the traditional idea is to store an entire BIM model or its signature code on the blockchain, SDT captures local model changes as SDT records and combines them into a BIM modification contract. In this way, the version history of a BIM project becomes a time-stamped BCC chain, and stakeholders can instantly synchronize BIM changes on the blockchain (Xue & Lu, 2020).
- Distributed Common Data Environment (DCDE) Framework for Design: Existing platforms for collaborative BIM design, the design, and manipulation of data exposed to cyber security risks such as denial, traceability, loss of data, and project delays, which can lead a decline in productivity and a central design system architecture. A blockchain transaction data model and a smart contract have also been developed to support the DCDE functions in the proposed framework, blockchain, and the Interplanetary File System (IPFS) (Tao et al., 2021).
- Designing liability control and increasing claims and disputes: Although the parties cooperating in the project design are contracted with the client, they agree without any direct contractual relationship between themselves when using BIM and other

collaborative applications. It leads to a lack of design responsibility control and increased claims and disputes. The researchers have argued that with three project processes (design review, design coordination, and request for information), it will demonstrate the ability to record snapshots of individual design inputs to the overall project design and provide a clear and long-term record of significant change processes (Erri Pradeep et al., 2021).

Project Management

Inspection and project management are important construction processes that ensure that construction work and workers comply with the prescribed codes, standards, and construction progress. In addition, delays occur in most construction projects due to the fact that the project management is not done correctly. Therefore, improving the project management and control processes directly affects the project's success. In-depth study of blockchain articles in the construction industry for applications in project management. After reviewing the available literature, five categories were identified for blockchain technology in the construction industry: (1) secure data transmission and data ownership, (2) IT in construction, (3) quality information management, (4) stakeholders' collaboration, and (5) construction payments and trust. The findings indicated that BCT presented high promises to improve the overall efficiency of the construction industry (Wahab et al., 2022). When a comprehensive literature search was conducted, project management applications in the construction industry were found.

Some of these applications are as follows:

- Smart Construction Systems: The paper discusses smart construction top-level design and its system, summarizes its functions and application processes, focusing on the cost, quality, schedule, contract, safety, etc. The function of smart construction systems contains a capital chain management system and ID labor management system based on blockchain technology, a material procurement management system based on blockchain technology, and an intelligent contract (Shi et al., 2019)
- Adoption of Innovative Tools to Preplanning and Design Phases: The study analyzes the differences in perceptions between academics and construction industry practitioners regarding the 17 emerging technologies through survey data and identifies potential technologies for high cooperation from an academic perspective. Based on results, blockchain is useful for preplanning and design phases agreed upon between academia and industry (Jang et al., 2021).
- Delay Analysis: The article aims to create a step-by-step protocol for a delay analysis that will focus on combining two built-in techniques to fill the gap while combining their known advantages. It happens through a monitoring process that uses the floating-path interface on the Primavera P6 for an automated process. When paired with secure blockchain technology, an updated backlog of project delay information and an updated reserve are securely allowed for interested parties to access (Elazhary, 2021).
- Inspection of Construction Processes: Traditional examination is characterized by physical exertion and laborious paperwork. However, the COVID-19 pandemic has made it difficult to dispatch inspectors and encouraged governments worldwide to explore alternative inspection approaches that take advantage of the latest tamper-proof and traceability technologies, such as blockchain. The research reports the

urgent need for e-inspection 2.0 to guarantee construction quality, compliance, and progress amid pandemic conditions (Lu et al., 2022).

- Digital Transformation for Construction Management: The effect of digital transformation on the construction management process has been studied. The study contributes to the construction industry's digital transformation and adds to the literature of the related scholarship domain. The framework developed is generalizable, thus, entrancing its significance and impact in different jurisdictions (Owusu et al., 2022).
- Risk Assessment for Construction Projects: In order to receive risk input from multiple stakeholders, different systems have been developed to support collaborative risk assessment. In the study, the need for a new blockchain-based methodology for collaborative risk assessment is analyzed (Chung & Caldas, 2022).

Real Estate Management

One such area that can benefit from the benefits of blockchain technology is the real estate sector. Like many other sectors, real estate also faces major administrative problems such as high transaction fees, lack of transparency, fraud, and the effects of an intermediary, including undue influence and commissions. When a comprehensive literature search was conducted, real estate management applications in the construction industry were found.

Some of these applications are as follows:

- Benefits of Blockchain Technology in the Real Estate Sector: The real estate industry must be harmed by blockchain technologies to deal with major problems such as high transaction fees, lack of transparency, fraud, and the effects of an intermediary, including excessive penetration and commissions. The blockchain allows supporting technologies to overcome the obstacles inherent in the real estate investment market (Ahmad et al., 2021).
- Startups in Built Environment Sector: Startups have had an impact in recent years through the often innovative products and services they provide. While information and communication technologies form the core of innovative products and services, the built environment sector has also experienced a good share of benefits. However, the construction and real-estate industries have been rather conservative. The study mentioned the rise of blockchain technology, which may impact contracts in the real estate market, making them self-executable (Lam & Fu, 2019).

Power Engineering

Blockchain technology contributes to sectors such as energy storage, energy trading, efficient energy production and distribution, renewable energy and power systems, and internet technology. When a comprehensive literature search was conducted, power engineering applications in the construction industry were found.

Some of these applications are as follows:

- Using Blockchain in Energy Trading: For power engineering, a tremendous amount of data is collected from different devices, different geographical locations of the power grid, and different time scales, which creates a research opportunity for large power data. An article conducted a thorough current literature review and a preliminary

discussion of this emerging research topic. Using the blockchain, energy trade contracts negotiated by producing consumers can be automatically authorized and concluded in a cyber-secure manner, providing a promising solution to the second problem (Zhang et al., 2019).

- Smart Grid: A smart grid is a two-way communication distributed energy network that provides efficient energy generation and distribution. Blockchain is recognized as a promising approach to producing and transferring reliable decentralized energy using blockchain technology. The study proposes a new blockchain-based decentralized green energy distribution system for reliable energy exchange in a smart grid that is not reliable (Talat et al., 2020).
- Energy Sharing Platforms: The rapid growth of renewable distributed generation requires further development of the electricity market for distributed energy. Article distributed battery energy storage systems and renewable energy and distributed generation and energy management as a model of platform sharing; this platform proposes energy users, energy producers, energy producers, and energy storage devices, both Energy Transfer and price. The process is referred to as the blockchain method and the P2P energy trading model (Han et al., 2020).
- Feasibility of Blockchain Technology for Energy Trading: The article includes the feasibility of implementing blockchain technology as an accounting system for energy trading within each island and between interconnected islands. The feasibility of the proposed energy trading system has been confirmed using a realistic example of Egypt's Alexandria distribution system. The simulation results show the positive effect of blockchain-based energy trading on the cost of energy (El-Zonkoly, 2021).

Supply Chain Management

Supply chain management in the construction industry is the relationship between the suppliers and the contractors involved in the project. This integrated approach is the foundation of success whereby all the stakeholders fully understand of the resources, logistics, and people involved to ensure the project is delivered on time and within budget. Blockchain can significantly improve supply chains by enabling faster and more cost-efficient delivery of products, enhancing products' traceability, improving coordination between partners, and aiding access to financing. When a comprehensive literature search was conducted, supply chain management studies in the construction industry were found.

Some of these studies are as follows:

- Supply Chain and Intelligent Transportation: As a solution to difficulties in exchanging pallets through different information platforms, it has been put forward to realize the exchange of different platforms and pallets using blockchain technology. A more efficient pallet pooling logistics business system has been proposed. Finally, it is proposed to use blockchain technology, which can effectively solve the problems of difficulty in exchanging pallets between different information platforms in the pallet pool system (Chen et al., 2020).
- BIM+RFID+GIS+blockchain System for Industrialized Construction (IC): The effects of supply chain weaknesses and capabilities in industrialized construction are modeled with increasing challenges for supply chain resilience (SCR). An integrated software package (BIM+RFID+GIS+Blockchain) would increase supply chain capabilities and quality (Ekanayake et al., 2021).

- Reliable Digital Deliverable (RDD) Model: The aim of this study is to analyze the construction supply chain (CSC) data delivery challenges by providing a reliable digital delivery (RDD) with the integration of BIM and blockchain. The RDD model is an important step for construction enterprises to maintain their competitive advantage (Hijazi et al., 2021).
- Three blockchain-based Models for the Supply Chain of Construction Projects: In this study, some conclusions have been reached about the three blockchain-based models used for the supply chain of construction projects. Project bank accounts (PBAs) for payments, a ban on auctions based on reverse auctions, and asset tokenization for project financing are the three bases of the model. As a result, problems related to bidding processes can be solved with blockchain technology, and smooth and transparent payments can be made. In addition, easier access to project financing can be provided (Tezel et al., 2021).
- Off-site Logistics of Modular Construction: Off-site logistics, including complex module production, storage, and transportation processes, is very critical for the supply chain of modular building projects. The study aims to identify and classify the sources of uncertainty affecting the off-site logistics of high-rise modular building projects in high-density cities; a blockchain-based process management platform has been adopted for quality control and process management (Yang et al., 2021).
- Blockchain-Enabled IoT-BIM Platform (BIBP): The demonstrative case study in a modular student residence project evaluates the proposed BIBP system prototype with the performance analysis of storage cost, privacy, latency, throughput, and feedback from stakeholders. The results indicate that BIBP has an effective system architecture with acceptable throughput and latency, can save storage costs to achieve a single point of truth in BIM, and avoid a single point of failure for IoT networks with privacy and security-preserving mechanisms (Li et al., 2022).
- Precast Supply Chain: The study establishes a new blockchain-based information management framework for a prefabricated supply chain that expands blockchain applications in the field of construction supply chains. The performance of this framework is confirmed by a case study in which a visualization system is presented to provide (1) information sharing management, (2) real-time scheduling control, and (3) information traceability. Results show that the proposed framework facilitates the timely delivery of precast components (PCs) and tracks the causes of disputes in the precast supply chain, focusing on PCs (Wang et al., 2020).
- SCOs-enabled Blockchain Oracles (SCOs-BOs) Framework: This study provides an innovative solution that takes advantage of intelligent construction objects (SCOs). It develops a blockchain oracles (SCOs-CS) framework in which SCOs are active. To embody this framework, the system architecture of a blockchain-enabled construction supply chain management (BCSCM) system was developed and validated using a case study, whereby the four main smart contracts were examined in the context of off-site logistics and on-site assembly. The evaluation results show that the correct data were obtained for each request, and the corresponding reputation scores were successfully recorded (Lu et al., 2021).

Urban Management

Urban Management is a discipline that focuses on addressing the challenges of urban life and realizing opportunities. The few articles related to urbanization and Sustainable Urban Development discuss the unique characteristics of the blockchain-related challenges as well as implementation risks and explore potential blockchain applications in addressing the

challenges. For successful urban planning, human-centered approaches and robust business processes must also consider the capacity adequacy, including financial resources, human resources, local culture, infrastructure, and governance systems, while minimizing the exacerbation of inequality in access and benefits. When a comprehensive literature search was conducted, urban management studies in the construction industry were found.

Some of these studies are as follows:

- Urban Intelligent Transportation: Based on blockchain technology, smart urban transport big data platform, merging data from different sources of data and other advanced technologies, including unified control and operation, compatibility with many important should resolve the problem. In order to solve the problem that complicates data sharing, a large urban intelligent transportation data platform has been created using blockchain technology in the article. In this big data platform, block data is used as the core, thus eliminating the centralized data management of each organization (Gong & Liao, 2019).
- Blockchain Water Platform: Over the past decade, there has been a huge increase in the use of artificial intelligence technologies for hydrological and hydraulic modeling in the implementation of water resources management. The blockchain water platform approach to urban stormwater management integrates data collection, stormwater modeling, and automation of hydraulic structures. This approach will be the non-structural solution to rainwater management to improve the urban-regional ecology system and water quality and reduce the risk of flood hazards and the cost of operation (Cheng et al., 2020).
- Municipal Solid Waste (MSW) Projects: MSW projects require mixed bundling or unbundling to achieve efficiency by technologies such as blockchain instead of pure bundling. The researchers have presented a framework in which practitioners can begin to embark on the goal of supplying effective projects in the MSW sector based on detailed understanding (Dolla & Laishram, 2020).
- 3-Dimensional Printing (3DP): The speed with which families recover from natural disaster disruptions and return to normal daily operations is very important. The loss of housing and the need for temporary housing is the situation immediately after the impact of a natural disaster. When blockchain-based 3DP technology is evaluated and compared with traditional construction processes, it is found to be useful in five areas: duration, cost, environmental impact, security, and transportation logistics (Subramanya & Kermanshach, 2022).
- Blockchain-Based Telecommunication System: The article is aimed at creating theoretical foundations for a new decentralized and infrastructure-free communication system using a temporary mobile network, distributed ledger, and blockchain technology, as well as studying its performance (Ilbeigi et al., 2022).

Knowledge Management

Information management has been recognized as an important tool for improving organizational effectiveness (Jafari et al., 2013). According to the National Association of Professional Engineers, the lack of interaction between construction managers and project stakeholders made the flow of project information difficult and chaotic. Their contracts are generally weird and not comprehensive (Engineers, 2014). Implementing Knowledge Management (KM) processes at both the organizational and national levels requires innovation. With high security, blockchain can serve as a distributed, programmable and encrypted database for transferring, protecting, storing, and quickly accessing information

from one place to another (Tian, 2016). Blockchain technology can be used as a method to manage trust in the generation, storage, sharing, protection, and implementation of various information (Akhavan & Mahdi Hosseini, 2016). Several studies about blockchain application for knowledge management in construction projects were evaluated below:

- Modern data models with Industry Foundation Class (IFC): The industry basic class (IFC) dominates the architectural engineering and construction (AEC) industry as an open BIM standardized data model for storing and exchanging information. The purpose of this article is to analyze the current AEC data standards and propose a conceptual framework using modern data standards such as JSON and RDF with traditional IFC as a basis for different building automation system (BAS) use cases (Tang & Shelden, 2020).
- Regulatory Changes on Capital Projects: The purpose of the study is to help construction industry organizations match the regulatory compliance process with their capital projects better. Implementing a comprehensive and intelligent model allows companies to more effectively comply with regulatory changes to reduce risks and other commercial impacts. The construction industry is moving towards automation and adopting other technologies, such as artificial intelligence and blockchain (Rasoulkhani et al., 2020).
- Hydropower Projects: The uncertain construction of hydropower projects and fierce market competition impose more stringent requirements on the accuracy and competitiveness of cost forecasting for contractors. With the progress of construction technology, information about the construction process is gradually being shared. For example, the application of blockchain technology is changing the current state of engineering information. The information between the owner and the contractor becomes more transparent and robust (Chen et al., 2020).
- Cybersecurity of Operational Technology: Digital transformation in the construction industry affects how information is exchanged and disrupts the way construction sites work. The motivation of this study was to understand the current recent situation and identify gaps to propose future OT-related guidelines in construction from a cybersecurity perspective. Construction companies should consider the cybersecurity implications before utilizing blockchain technology to enhance their processes (Sonkor & Soto, 2021).
- Integrated Safety Management (ISM) System: A successful Construction Safety Management Process should include Security records of stakeholders, risk assessment, risk analysis, preventive control tasks, inspection procedures, and daily event reports. The study aims to develop a new information management framework for construction safety processes using blockchain. The results of this study contribute to the current knowledge and current state of practice in integrated safety management (ISM) systems aimed at protecting construction workers and the public by providing timely, reliable, and complete information to all organizations involved in a project (Morteza et al., 2022).
- Onsite Assembly of Modular Construction (OAMC): The study, which adopts the design science research (DSR) method, aims to investigate the use of blockchain technology to improve the accuracy of information sharing in the on-site assembly of modular structure (OAMC). It can serve as a valuable reference for future efforts to leverage the power of blockchain technology to mobilize information approval mechanisms, especially for various value-added applications (Wu et al., 2022).
- Integrated Digital Twin and Blockchain Framework: The study aims to develop and test an integrated digital twin and blockchain framework for traceable data

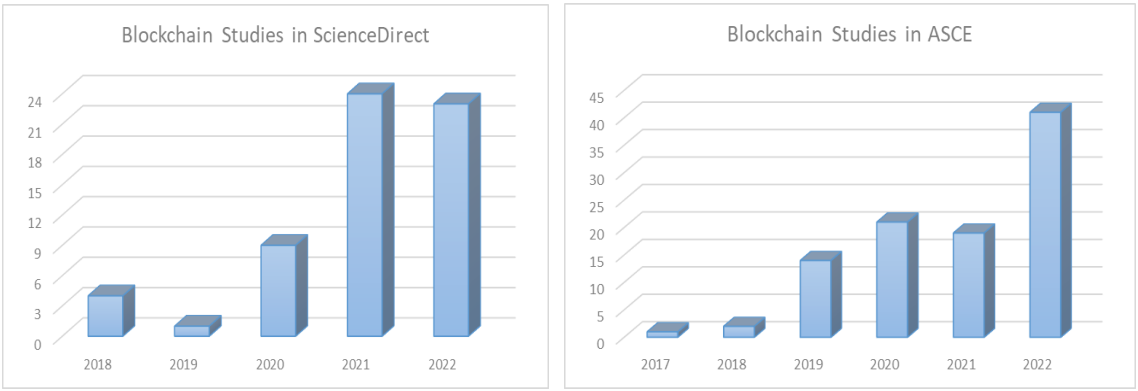
communication between stakeholders and project managers. The authors tested the framework with a case project in which virtual positioning data from a prefabricated brick is transmitted to the digital twin in almost real-time and recorded on the blockchain with time stamps. The results show that the integrated digital twin and blockchain framework makes all data transactions traceable (Lee et al., 2021).

Discussion

An exploratory approach was implemented in this review to understand which categories in construction are most studied by blockchain. Based on categorized subject areas, the potential and challenges of blockchain technologies are examined. The potentials of blockchain technologies are providing transparency, trust, and using and storing data securely. Moreover, this technology provides cost and time efficiency and workflow with its features of disintermediation, automation, and decentralization.

Table 1. Potentials and challenges of blockchain technology.

POTENTIALS	
Transparency	Savelyev (2018)
Trust	Rodrigo et al. (2018); Underwood (2016)
Data security	Coyne and Onabolu (2017)
Cost efficiency	Boonpheng et al. (2020); Sharma et al. (2020)
Work flow and time efficiency	San et al. (2019)
Disintermediation	Notheisen et al. (2017); Sun et al. (2019)
Automation	Nawari and Ravindran (2019); Kandiye and Artan (2021)
Decentralization	Dorri et al. (2016)
CHALLENGES	
Policy	Kiviat (2015)
Scalability	Jesus et al. (2018); Notheisen et al. (2017)
Privacy Leakage	Perera et al. (2020)
Initial cost	Kouhizadeh et al. (2021); Kandiye and Artan (2021)
High transaction confirmation time	Sunny et al. (2022)
Understanding	Gatteschi et al. (2018); Bag et al. (2020)
Storage problems	Lo et al. (2017); Lu and Xu (2017)
Cyber attackable	Penzes (2018)



On the contrary, blockchain technologies face some policy challenges due to the high initial investment cost, complexity, and vulnerability to cyber-attacks. Furthermore, its use has not become widespread in the construction industry due to problems such as high data storage requirements, privacy leakage, and high transaction approval times. The potentials and challenges of blockchain technology in the construction industry are listed in Table 1.

The exploratory approach was carried out by using the ASCE and ScienceDirect databases. In the ScienceDirect database, the count of review articles is 18, and the count of research articles is 43 in 61 studies related to blockchain technology between 2018-2022. In addition, when the ASCE database was scanned between 2017 and 2022, chapters/proceedings papers (35) and technical studies (26) constituted the majority of the 97 studies, as shown in Table 2.

Table 2. Article types and counts about blockchain in ScienceDirect and ASCE.

Databases	Article Type	Count
ScienceDirect	Review articles	18
	Research Articles	43
ASCE	Chapters/Proceedings Papers	35
	Technical Paper	26
	Front Matter	11
	Case Study	7
	State of the Art Review	6
	Editorial	4
	Technical Note	3
	Forum	2
	Back Matter	1
	Editor's Note	1
	Review article	1

Figures 1 (a) and (b) illustrate the count of blockchain studies of the two databases by year. The scanned blockchain studies on ScienceDirect between 2018 and 2022 show that the highest rank is in 2021 with a number of 24 articles, and in 2019 only one article was published. Additionally, when the studies related to the blockchain between 2017 and 2022 were scanned on ASCE, the highest count of articles with 41 were in 2022, and only one article was in 2017 (as shown in Figures 1 (a) and (b)).

(a) (b)

Figure 1(a), (b): The count of the article in ScienceDirect and ASCE by years.

The annual number of relevant literature analyses proves that the research results in this field have grown particularly rapidly in recent years. Then based on previous studies, the application topics are divided into; smart (intelligent) contracts, financial management (payment), design (BIM), project management, real estate management, power engineering, supply chain management, urban management, and knowledge management and the content is analyzed respectively. Figure 2 demonstrates that studies of blockchain technology in the construction industry published in 2022 highest article count were found to project management, smart (intelligent) contracts, and knowledge management which accounted for 6, 5, and 4, respectively. A total of 22 studies were carried out in 2022. In 2021, 19 studies were conducted in total, and 6 of these studies are related to supply chain management in the construction industry. In 2020, the highest blockchain studies were carried out with 23 studies, and 6 of them were published in the field of both financial management (payment) and knowledge management. In total, the subject areas with the highest number of blockchain

studies published are knowledge management (13), smart (intelligent) contracts (12), design (10), supply chain management (10), and finance management (9). On the contrary, the subject areas with the least study between 2017 and 2022 are real estate management (1), power engineering (5), and urban management (5). In 2018, no studies were conducted on these subject areas, as shown in Figure 2.

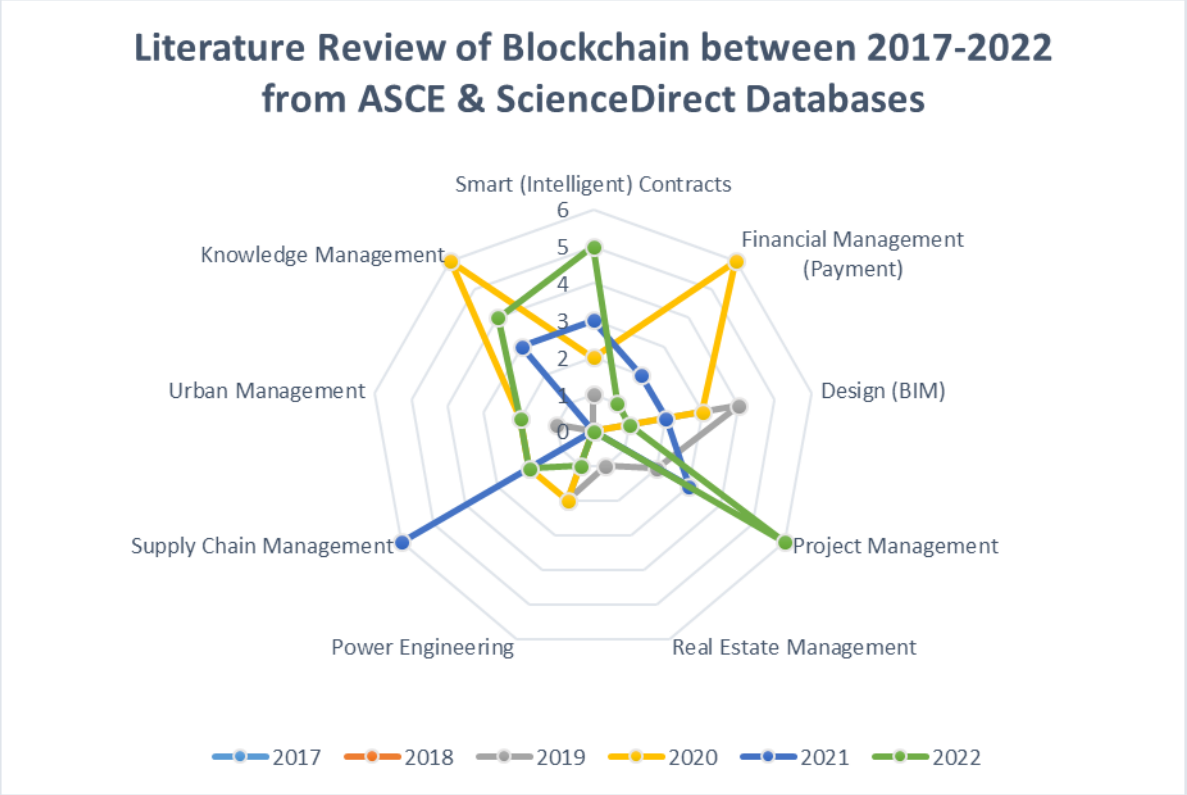


Figure 2: Categorized nine subject areas.

Most analyzed literature is qualitative, describing possible applications and intended effects. Only a few systems are applied to the construction sector. It is worth noting that the classification of the literature may not be correct due to the intersection of blockchain application in the field of civil engineering. At the same time, the lack of a specific research topic does not mean that there is no place for blockchain to play. On the contrary, this is the lack of the current research topic. Therefore, comparing the overview of blockchain application ideas with classified topics can help identify research gaps (Fu et al., 2021). The main contributions of this paper are: (i) to identify current blockchain applications in the construction industry; (ii) to help future researchers explore potential blockchain solutions.

Conclusion

Developing technologies play an important role in increasing overall productivity in the construction industry. Due to the advancement of technology usage in the AEC industry, more and more research is being conducted to explore the application of new technologies such as blockchain. Blockchain as a technology framework has the potential to solve some problems in the AEC industry by supporting processes related to data verification and advanced cybersecurity. Countries are trying to make the necessary legal and regulatory

changes to adapt to the new environment and make this change a reality. In the future, blockchain seems to be something we will hear a lot more about. It is evidenced by the fact that the number of articles on blockchain in the scientific literature in various scientific fields, including engineering, has been growing rapidly in recent years.

This study briefly examined the technical details, main concepts, and aspects of blockchain technology. It aimed to formulate a picture of the current state and application of its use in areas related to construction, architecture, and civil engineering. The study also has the potential to offer new solutions to construction industry-specific application areas, and related future performance, sustainability, and safety are outlined to improve how they are adopted. We identified nine important application areas and examined the relevant challenges and potentials ahead, namely in 1) smart (intelligent) contracts, 2) financial management (payment), 3) design (BIM), 4) project management, 5) real estate management, 6) power engineering, 7) supply chain management, 8) urban management, and 9) knowledge management. The conclusion of the study is that although blockchain technology is new and there are several early challenges that definitely need to be overcome, it has the potential to be an extremely positive force for change in the construction industry. As engineers, the construction industry must facilitate the digital transformation of the industry and prepare it for the challenges and potentials of the future. Blockchain must play a crucial role in this transformation.

Use of Visualization Technologies for Increasing Efficiency of Construction Industry

A. İ. Baki and B. H. Basri
Karadeniz Technical University, Department of Civil Engineering, Trabzon, Turkey
411601@ogr.ktu.edu.tr, hasanbb@ktu.edu.tr

Abstract

While efficiency increases in many industries with increasing technology, efficiency decreasing is being seen in the construction industry year by year. The most effective way of increasing efficiency is to increase technology adaptation in the construction industry. In the last decade, virtual reality technologies have been at the attention of the biggest technology companies and users. Using visualization technologies to adapt technology may be a great opportunity for the construction industry. Researchers, around the world, modelled projects with 3D virtual reality technologies and brought together stakeholders in the virtual environment. They tried to develop management and installation skills for projects. Many studies investigate the use of augmented reality technologies in the construction industry. The purpose of this study is to provide an objective summary of visualization technology studies related to Architectural Engineering and Construction. The most important points will be summarized by reviewing the literature studies. Studies will be analysed by grouping them according to their subjects. In this way, researchers who are interested in this subject can be found the right area to investigate. This study will contribute to determining the current position of the use of virtual reality technologies in construction projects.

Keywords: *augmented reality, BIM, communication, construction 4.0, construction planning, education, mixed reality, virtual reality, visualization technology.*

Introduction

The construction industry is one of the cornerstones of the world economy, with an annual income of 10 trillion dollars and employment of approximately %7 of the working population worldwide (Gerbert et al., 2016; Barbosa et al., 2017).

However, the construction industry loses value due to low labour productivity. While the labour productivity in the manufacturing industry and other industries has increased regularly in the last 20 years, the amount of labour productivity in the construction industry has remained almost the same. The labour productivity gap between the other industries and the construction industry is increasing every year (Japan Federation Industry Handbook, 2020).

Low labour productivity not only reduces the profitability and earnings of the construction industry, but also negatively affects the world economy. Low labour productivity leads to more labour employment than needed in the construction industry.

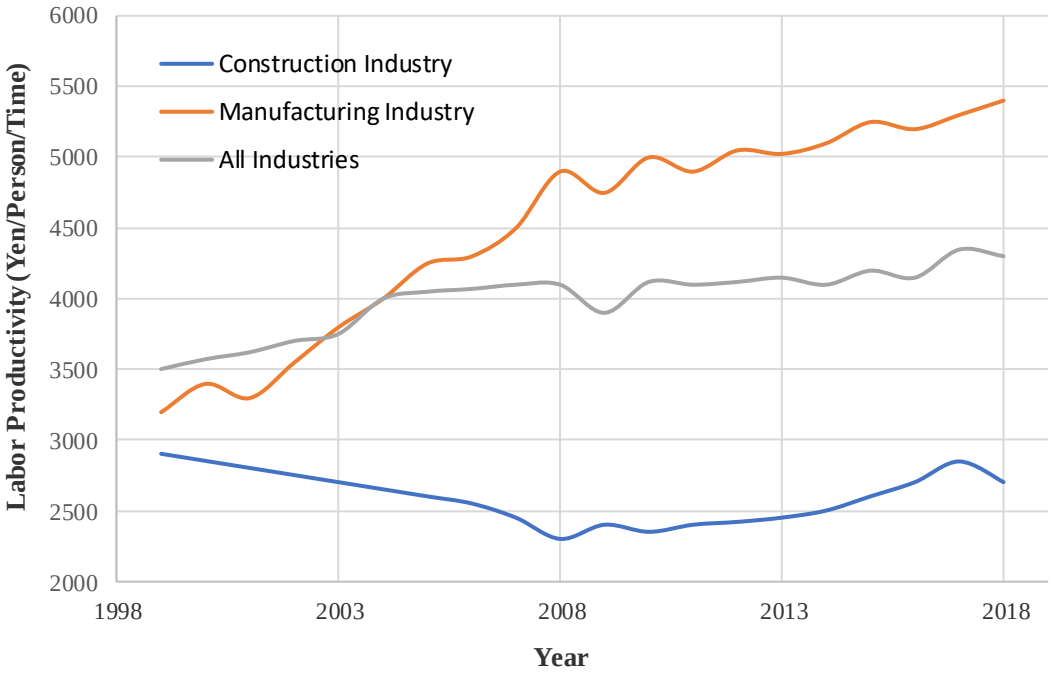

Figure 1: Labour productivity comparison between industries (Japan Federation Industry Handbook, 2020).

Employees employed in the construction industry without adding additional value are prevented from adding value to the world economy by being employed in another sector. As seen in Figure 2, the labour force that cannot be employed in other sectors will be prevented from adding new value between 1.6 trillion dollars and 2.3 trillion dollars to the world economy every year. (McKinsey Global Institute Report, 2017).

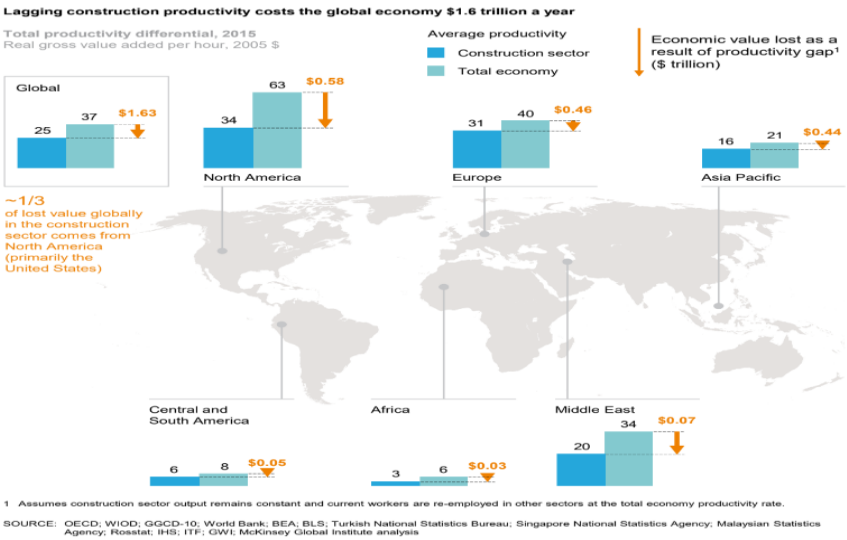

Figure 2: Delayed construction labour productivity costs the global economy 1.6 trillion dollar a year (McKinsey Global Institute Report, 2017).

One of the most important factors that affect the labour productivity of the construction industry and negatively affect the world economy is the low digitalization rate of the construction industry. As seen in Figure 3, there is a strong correlation between the labour productivity of the industries and the digitalization index. Both of digitalization index and labour productivity is lowest value in the construction industry among the other industries. (McKinsey Global Institute Report, 2017).

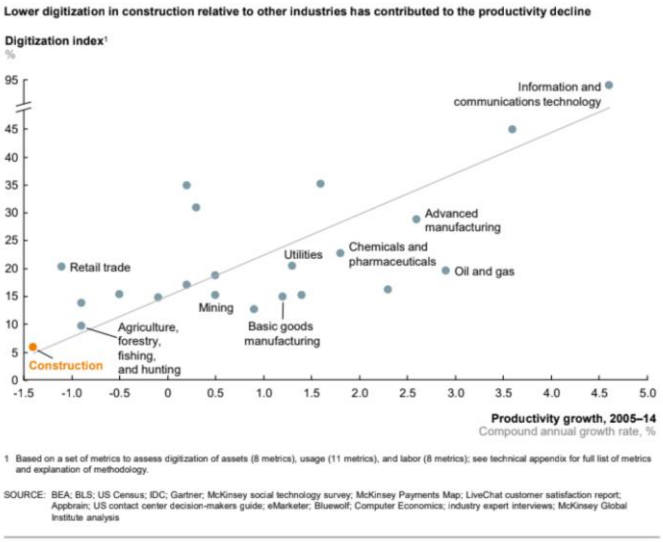

Figure 3: Digitalization index – labour productivity relationship between industries (McKinsey Global Institute Report, 2017).

Bock and Linner (2015) say that the problem of the construction industry with digitalization is that the products used by the industry do not complete the development stage. These two scientists applied Fuster's (1986) S curve plot of a product to the construction industry as seen at the Figure 4. According to this curve, a product initiative is developed in 3 periods. These are innovation, growth and maturity. At the innovation phase, products show lower performance than traditional methods. During this period, developers deal with technical and organizational problems and the challenges of the uncommercialized trial product. It cannot contribute to the performance as much as the traditional method. During the growth phase, performance increases and in the maturity period, it provides superiority to the classical application in terms of performance. Many technological products developed in the construction industry have not been able to contribute to the digitalization of the industry by putting them into practice because they have not yet overcome the technical and organizational problems.

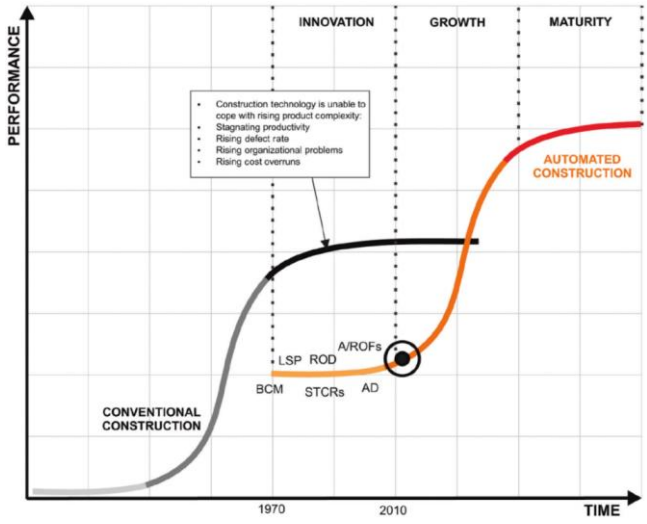

Figure 4: S curve applied to construction technology products (Bock & Linner, 2015).

German scientist Berger schematized the development stages of products in the construction industry and other industries that contribute to digitalization. As seen in the Figure 4, there is no product that has completed its development phase in the construction industry. According to Berger, the only way to increase labour productivity is digitalization. And Berger defined the works for the digitalization of the construction industry as Construction 4.0, inspired by Industry 4.0 (Berger, 2016).

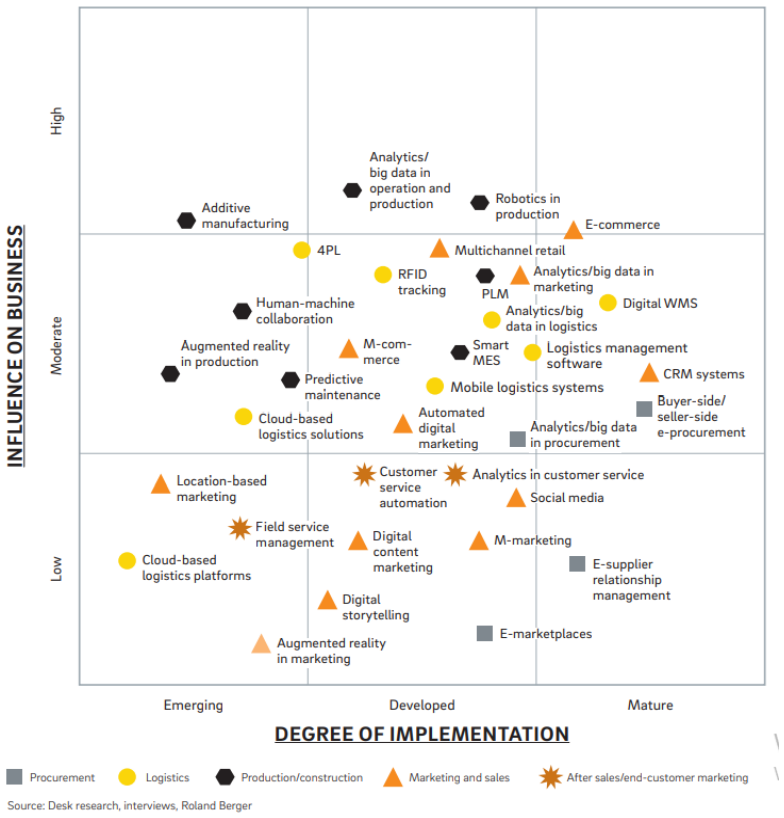

Figure 4: Development status of technology products in different industries (Berger, 2016).

Scientists work in 7 different fields of knowledge about Construction 4.0 to increase digitalization in the construction industry. These 7 knowledge areas are listed below as items.

- Robotic machines
- Artificial intelligence
- Data storage and cloud system
- Building information modelling
- Prefabrication
- Monitoring system (laser scanning, drone and cameras)
- Virtual, augmented and mixed reality.

As seen in Figure 4, virtual and augmented reality technologies have the lowest level of development among the digital products in the construction industry. However, virtual and augmented reality technologies are in the centre of attention of today's biggest technology companies. Facebook claims that virtual reality technology will create a new virtual universe called metaverse. The company attaches so much importance to this technology that it changed its name to "Meta". Meta also announced that they will invest 10 billion dollars in this technology and employ 10.000 highly skilled personnel to develop this technology. (Clegg & Olivan, 2021). Google and Microsoft are other big technology companies that focus on virtual and augmented reality technology.

In A Foster Total Economic Impact Study Commissioned (2019), Microsoft summarizes the benefits that a company will gain when investing in its own product, HoloLens glasses, with following items.

- Enhanced training efficiency
- Increased task efficiency for field workers and onsite workers
- Improved productivity for the project leader
- Improved productivity and avoided travel for specialized experts
- Reduced operational cost
- Protected and grew revenue.

These topics are improvements that will increase labour productivity in the construction industry. Studies that will expand the use of this technology in the construction industry will bring the development level of this product to the maturity level. In addition, the works to be carried out will contribute greatly to the digitalization of the industry, the increase in the labour productivity of the construction industry and the positive impact of the construction industry on the world economy. For this reason, the attention of scientists who works on Construction 4.0 should be get on augmented and virtual reality technologies.

Aim of the Study

Scientists have done a limited number of studies for the adaptation of augmented reality technology to the construction industry. The breakthrough of virtual reality and augmented reality products in recent years has added extra importance to the work done.

In order to augmented reality technology to reach maturity development level in the construction industry, the number and quality of the studies should be increased. For this reason, studies on augmented and virtual reality in construction industry should be reviewed and their deficiencies should be determined.

The aim of this study is to review the studies about augmented and virtual reality in construction industry and determined the deficiencies of these studies.

Methodology

For defining the main borders of studies about augmented and virtual reality in construction industry, eight scientific journal was reviewed. These journals are the most popular journals about digitalization of construction industry. The name of this journals is Automation in Construction, Advanced Engineering Informatics, Journal of Information Technologies in Construction, Journal of Computing in Civil Engineering, Buildings, Engineering Construction and Architectural Management, Journal of Construction Engineering and Management and Computer Aided Civil and Infrastructure Engineering. The searching was made by using augmented reality keyword. 238 article was found at these journals. Keyword relation analyse was made with these articles by using VOSViewer. Analyse report is showed as Figure 5.

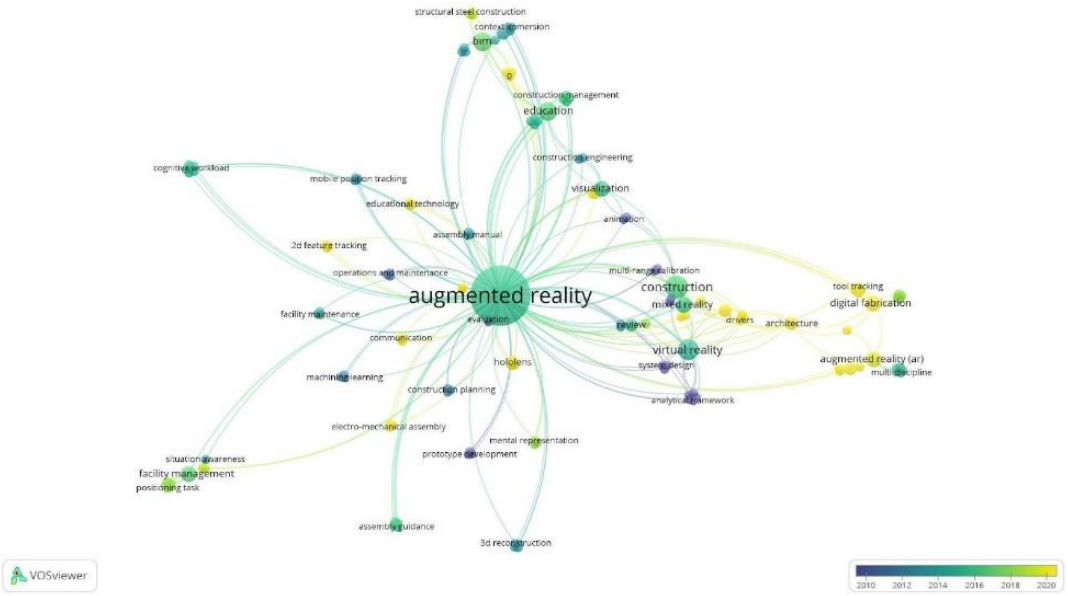

Figure 5: Keyword relation analyse between articles.

It can be seen that researchers generally had focused 4 main subjects at this articles. These are communication, construction planning, education and BIM. According to keyword relation analyse, these 4-research subject were specified as keyword of this research. Also 5 valuable words for this research was added to keywords list such as Augmented Reality, Construction 4.0, Mixed Reality, Virtual Reality and Visualization Technology.

By using these keywords, 50 articles were reviewed in detail. The aims, methods and outputs of each of the articles were determined and noted. The articles were divided into groups according to their area of interests. The aims and outputs of the grouped articles were converted into text to represent all the work done. Also, the pros and deficiencies of literature were specified.

Results

Looking at the writing dates of 238 articles, it is seen that research on augmented reality has increased in recent year. Figure 6 show the count of articles year by year for last 5 years. In 2021 the number of studies doubled compared to 2020.

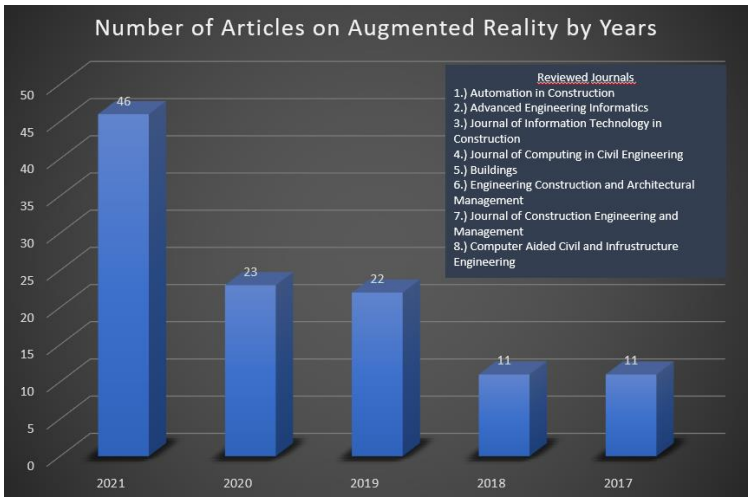

Figure 6: Number of studies in the last 5 years.

50 articles which represent literature was reviewed in detail. Studies on virtual and augmented reality are divided into 4 different groups according to their purposes. These groups are use of augmented and virtual reality in;

- Project Modelling
- Education
- Safety and risk determining
- Inspections.

The classification of these 50 articles according to subjects and years is shown in Figure 7.

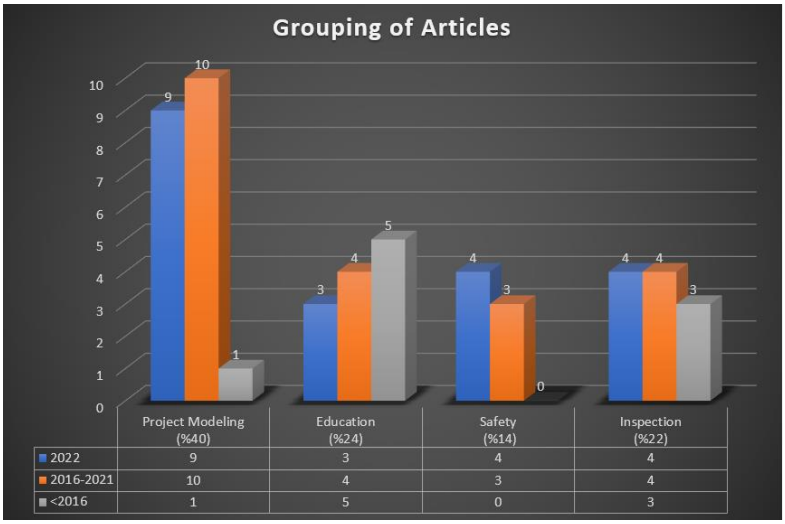

Figure 7: Classification of 50 articles according to subjects and years.

In this section, each group work will be given an overview with a few articles.

In Project Modelling Use of Augmented Reality and Virtual Reality

Scientists thought that people understood the project from the 2D project too late. By using augmented reality technology instead of 2D projects, they tried to make it easier for people to understand the project.

Carrasco and Chen (2021) modelled an office project with mixed reality and traditional 2D project. 42 participants were included in the study. 21 of them viewed the 2D traditional and other 21 of the viewed mixed reality model. After the review, the participants were asked question about the project. Reviewers with mixed reality answered 85% of the questions correctly. Reviewers with 2D traditional model answered 70% of the questions correctly. The difference between the correct answers shows the positive contribution of the mixed reality model to understanding the project.

Chalhoub and Ayer (2018) designed an electrical channel assembly project with traditional 2D project and augmented reality project model. Participants were divided into two groups. One of them made an installation by using a traditional 2D project and other group made an installation by using augmented reality project model. The time that both groups of users watched the project to understand the project was recorded. It was determined that the group using the augmented reality model understood the project in a shorter time. In addition, total project implementation times were recorded. It was determined that the group using augmented reality model, implemented project in a shorter time.

Shi et al. (2020) worked on the piping project. 120 participants were involved in the study. They prepared 2 D traditional simple content project, 2 D traditional detail content project, 3D projects and virtual reality model. Participants were divided into 4 groups. Every group installed pipe project by using different project type. The implementation times were recorded. The group which uses augmented reality project model finished their targets in shortest time.

Hartless et al. (2020) investigated whether the deficiencies in the project model could be better identified with the virtual model. A small building was modelled using virtual reality technology, ignoring the needs of the disabled. Participants tried to find deficiencies with virtual reality model. All of the participants could find all deficiencies.

Ewart and Johnson (2021) say that one of the biggest problems in the project is finding direction. They modelled the university building with virtual reality technology. They asked the participant to find a room. Some participants found room at real world and other participants found at virtual world. The participants which use virtual model found target room in a shorter time.

Du et al. (2018) enabled participants to interact in a virtual reality model. 71 participants were involved in the study. Participants using a virtual reality model detected errors in the project more easily.

In Education Use of Augmented Reality and Virtual Reality

Scientists have conducted research on whether the use of augmented reality technology as an educational tool will be beneficial. Especially, AEC industry students need to see what they have learned in the field. It is not always possible to see the field in the real world with all students because of cost and safety risks. But in the virtual world, it is possible.

Sampaio and Martins (2014) modelled the implementation stages of a bridge with a virtual reality model and used it as a training document. Students say that they understood better when they saw the implementation phases of bridge in the virtual model.

Vasilevski and Birt (2020) created a model where students can communicate with their avatars within the model. After the students' experiences, they took the students comments. Students said that learning with a virtual model is more fun.

Spesgozar (2020) developed a virtual reality model for students to learn how the tunnel boring machine works. 10 people can participate in the model at the same time and can be connected to the model via the internet. Students were able to discuss the subject in virtual environment. Students commented positively on the model as they learned in a risk-free and immersive environment.

In Safety and Risk Determining Use of Augmented Reality and Virtual Reality

In a construction project, risk assessment reports are prepared at the beginning of the project. However, it is not easy to imagine the risks that may occur in all phases of the project without seeing. Scientists have studied on the fact that it may be easier to detect safety risks in the virtual environment model.

Azhar (2017) created virtual reality models of 3 different projects in practice. He has given safety trainings and created safety plans based on these models. A survey was conducted with the project stakeholders about conducting the occupational safety communication with the virtual model. According to the project stakeholders, the communication channel in the explanation of the safety plan to the workers has been strengthened. Also, project safety communication network has been strengthened. And security related logistic materials were addressed in the pre-project phase.

Olurunfemi et al. (2021) worked on the office worker's transmission of safety directives to the site. Telephone communication and mixed reality model communication were compared. The question is that in which communication channel, site workers better understand the directives? After the applications, the participants were surveyed. 58% of the participants said that MR contributed positively to risk communication. 8% of participants said that it contributed negatively. 34% of participants remained neutral.

In Inspections Use of Augmented Reality and Virtual Reality

In many site applications, the construction industry is not digitalized. While many productions are made with machines in the production industry, even the most basic tasks in the construction industry depend on manpower. Site applications as well as site inspections affect labour

productivity. Often workers cannot work because the inspector cannot come for inspection due to busy. Scientists have worked on using virtual reality technology to automate inspections.

Kwon et al. (2014) designed a photo processing system. First, they designed a virtual project model and a mock-up model. They built a cloud system. The system matched photos and virtual model. They took a photo from mock-up model which its location was defined before. Photo was uploaded to the system. The system detected measurement errors.

Zhou et al. (2017) used augmented reality technology to control the segments of tunnel construction. Normally segment checks are done with meters. They modelled segments by using augmented reality technology. They checked whether the segment in the augmented reality glasses and the real segment overlapped. The segment control took less time than the traditional method.

Omer et al. (2021) created a virtual model of a bridge. The bridge was scanned with the laser scanner and compared with the virtual model. As a result of the comparison, cracks and other structural defects in the bridge appeared in different colours.

Conclusion

Studies on the adaptation of augmented reality and virtual reality technologies to the construction sector were reviewed in 8 journals, which include the most article about the augmented reality in construction. Looking at the years of publishing article, it was seen that the studies about augmented and virtual reality increase year by year.

To research in detail, 50 article which represent all literature were specified. These articles grouped according to their subject. It was seen that, the research about augmented and virtual reality in construction industry can be divide to 4 different research area. These are project modelling, education, safety and inspection.

All the articles at all research group show that augmented reality and virtual reality effect positively construction process. They make easier managers, inspectors or employers works compares to traditional methods and they give extra management qualifications to users. This means that augmented and virtual reality technologies need less labour for longer works in construction industry and increase the labour productivity.

The articles about visualisation technologies for construction process show that, users understand construction projects easily by using augmented and virtual project models compared to traditional 2D project. But the target users of these articles are generally construction managers instead of workers. But for the real adaptation this technology should be used at construction application sites. Employees should use visualisation technologies during the application and should take on site educations. These are the missing sides of research and these subjects are open to development.

This research show that, visualization technology contributes new properties to construction industry and these technologies will take more effective location at the sector at near future. In a limited number of studies show the contribution of visualisation technologies to labour productivity of construction industry. In order to eliminate the deficiencies of literature research

and increase the adaptation of visualization technologies to construction industry, researchers should increase studies about adaptation of visualization technologies to construction industry.

Use of Industry 4.0 Technologies in Stakeholder Management

J. Bulğan and E. F. Taş
Istanbul Technical University, Department of Architecture, Istanbul, Turkey
bulgan@itu.edu.tr, tase@itu.edu.tr

Abstract

Industrial revolutions have caused significant changes to the industries of their times. Industry 4.0 has made production systems more responsive, more agile, and leaner, reduced the need for human-workforce, and has increased connectivity. However, in the construction industry, the adoption of Industry 4.0 has not been as smooth as in other industries. There seems to be still quite a bit of resistance to new Industry 4.0 tools, especially in stakeholder management. This study aims to investigate and measure industry 4.0 awareness in stakeholder management in the construction industry. In order to do so, a survey is conducted both with professionals from Turkey and abroad. By analyzing the results of this survey, it is aimed to offer suggestions for better integration of Industry 4.0 into Stakeholder Management in the construction industry. Since understanding the stakeholders and meeting their expectations would determine the overall project success, integration of industry 4.0 tools for stakeholder management would benefit all construction projects.

Keywords: *big data, industry 4.0, integration, stakeholder management, text mining.*

Introduction

Industrial revolutions have caused significant changes in the industries of their time. Since the first industrial revolution, these revolutions have changed production systems and working methods to increase efficiency. The rapid development in digital technology has started a new industrial revolution called Industry 4.0. This revolution defines all modern technologies that strengthen the communication of all elements within the system and cause them to work more harmoniously together. Although the technologies used in Industry 4.0 vary, it aims to connect the components within the related industry to create an inclusive and sustainable production system (Hidayatno et al., 2019). Industry 4.0 refers to "a game-changing set of digital and physical technologies that deliver new values and services to customers and organizations." (Pacchini et al., 2019). Industry 4.0 has made production systems more responsive, more lean and agile, reduced the need for manpower, and aims to increase connectivity.

In the globalizing world, the ways of doing business are changing. Due to the increasing demands of the customers and the growth and complexity of the project scales, the current ways of doing business are insufficient. In this case, the use of industry 4.0 technologies in production systems creates the potential to meet these demands. In our constantly digitalizing world, all sectors are affected by these changes. Industry 4.0 is changing not only the manufacturing industry, but all other sectors, but also the construction industry and associated supply chains.

(Dallasega et al., 2018). The use of Industry 4.0 technologies not only increases the efficiency of the projects but also ensures that more agile, lean, and sustainable projects are produced.

Although it is indisputable that industry 4.0 can be used for and is beneficial to all aspects of the construction industry, this paper's research will be focusing on the use of industry 4.0 technologies in the field of stakeholder management since previous research proves that this is one of the least researched areas. Stakeholders make up all the actors in a construction project. Stakeholders are people who are involved in a project who have an interest in or a conflict with the process or the outcome of the project (Zidane et al., 2015). The involvement of stakeholders throughout the building lifecycle contributes to overall project success. However, simply discussing stakeholder involvement is not enough, it needs to be implemented. When there is more than one stakeholder involved in a construction project, their relationships must be managed carefully. Since the backgrounds of project stakeholders are very different, good stakeholder management is essential for clear communication between parties. If stakeholders are not managed carefully and successfully, their relationships can be harmful to project outcomes. A project's overall success depends on clearly defining and then satisfying the stakeholder expectations (Serrador & Turner, 2015).

Construction projects are usually very complicated and unpredictable, which makes Stakeholder Management challenging. However, "stakeholder involvement is important to project outcomes, and recognition of the concept of stakeholder management is growing" (Yang et a., 2011). Although project managers have tried various ways to engage some of the main stakeholders, the gaps in stakeholder management can cause unsuccessful projects (Oppong et al., 2017). Unsuccessful projects are often defined as projects that can't meet the predefined schedule, projects that are over budget, and projects with unsatisfied participants. Unfortunately, although very important, the shortage of research in this area and the lack of systematic methods for stakeholder management cause the adoption of inadequate methods (Yang et al., 2011; Oppong et al., 2017). During the literature research done for this study, it was realized that there is very fragmented and limited research in the field of Stakeholder Management. Also, it was realized that most methods are left at a theoretical level, do not involve all stakeholders, and do not include the benefits of modern technology.

Since stakeholder management is central to project success, there should be a constant effort to improve it. It is believed that just like other aspects of project management the use of industry 4.0 technologies can be very beneficial to stakeholder management. However, before suggesting ways to utilize industry 4.0 technologies for stakeholder management, first, the current situation should be assessed both in Turkey and internationally. In order to do so, a survey was conducted to see the current situation regarding the use of industry 4.0 technologies for stakeholder management.

Methodology

To observe the awareness of Industry 4.0 use in Stakeholder Management in the Turkish and international construction industries, a 22-question survey was designed and shared with real estate and construction professionals all over the world. The survey was distributed by online platforms, such as email groups regarding the construction industry and academia, LinkedIn connections working in the real estate/construction industry, and personal connections of the authors through the construction sector.

The questionnaire attempted to measure the general awareness of stakeholder management methods as well as the use of industry 4.0 technologies in this area both in the Turkish and international construction / real estate communities. A total of 67 participants responded to the questionnaire of which 31 was international participants and 37 were local from Turkey. Since the survey focuses on both local and international participants and aims to compare practices in Turkey vs. internationally.

The survey was composed of three sections. The first section included introductory questions to determine the suitability of the candidate by asking about which industry they work in, information about their company, and how experienced they personally are. The second portion of the survey measures the current situation of stakeholder management in the construction/real estate industry. It measures the connectivity of all stakeholders during different phases of the building life cycle by dividing it up into pre-construction, during construction, and post-construction phases. The survey also measures the barriers faced in stakeholder management as well as the frequency of use of the stakeholder management models. The third and final portion of the survey measures digital competency, the knowledge and use of industry 4.0 technologies for stakeholder management.

Analysis of Findings

In the first section of the survey, questions were aimed to better know the participants and make sure they are competent. All 67 of the respondents were university graduates, and 52 out of 67 had a graduate or post-graduate degree. All 67 of the respondents were actively working in the industry, and 60 out of 76 had more than 5 years of experience.

Figure 1 represents the distribution of participants' professions. By profession, 49% of the participants were architects, 18% were project managers, 12 % were civil engineers, 7% were business developers, and 4% were real estate/construction-related company owners. The remaining 10% were made of real estate sales/marketing professionals, quantity surveyors, BIM managers and safety consultants.

Figure 2 represents the distribution of where participants' countries of employment. By location, 54% of the participants were from Turkey, 12% were from Germany, 7 % were from the UK, 4% were from South Africa, 4% were from Belgium, 3% were from the USA, 3% were from Uzbekistan. The remaining 13% of the participants were from the Netherlands, Ireland, Sweden, Switzerland, Nigeria, Sri Lanka, and UAE. 36 out of 67 participants were from Turkey and 31 out of 67 participants were working internationally. The international nature of the participants also gives us the opportunity to compare the current situation in Turkey to the rest of the world.

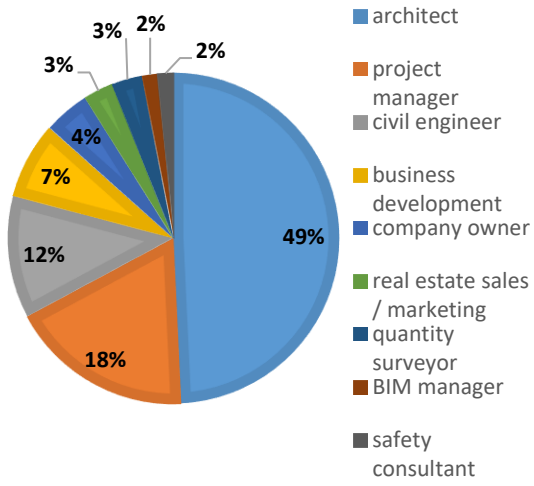

Figure 1: Participants by profession.

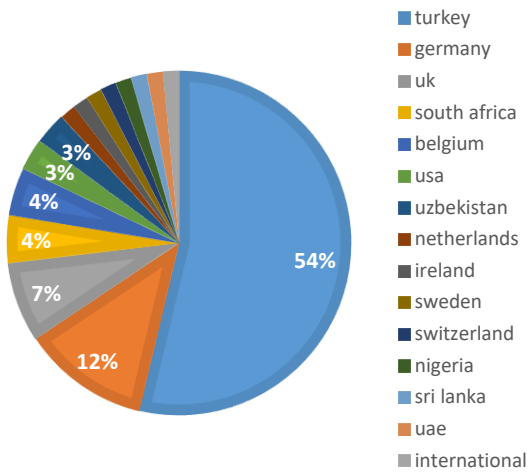

Figure 2: Participants' countries of employment.

Table 1 shows the size of the company in which participants currently work (or last worked). As can be seen, there is roughly an even distribution of small (1-49 people) and big (50-250+ people) companies. Table 2 shows the experience of the company in which participants currently work (or last worked). Only 25% of the companies had less than 10 years of experience. The companies that the participants work in provide the following services: Project management, engineering, contractor / sub-contractor, architectural, real estate development, real estate sales / rental, construction materials production/supply, retail services.

Table 1. Size of company.

Size of company	Number of answers	Percentage
1-9 people	15	22%
10-49 people	16	24%
50-250 people	13	19%
250+ people	23	34%

Table 2. Experience of company.

Experience of company	Number of answers	Percentage
1-10 years	17	25%
11-20 years	13	19%
21-50 years	21	31%
50+ years	16	24%

In the second portion of the survey, a 5-point Likert Scale (frequency scale) was used to measure the connectivity of 15 different stakeholder types during different phases of the building life cycle. The participants were asked, "How often do you communicate with your stakeholders?" The lifecycle of the project was divided up into pre-construction, construction, and post-construction. The list of stakeholders to be surveyed about was a combination of all stakeholders mentioned in previous literature research.

The results of this portion of the survey can be seen in Figures 3, 4, and 5. Although the level of connection with different stakeholders during different phases of the project with changed constantly, it can be easily seen that most answered "never" and "rarely" when asked about external (secondary) stakeholders such as end-users/customers, government authorities, community and public, non-government organizations, unions, and the media.

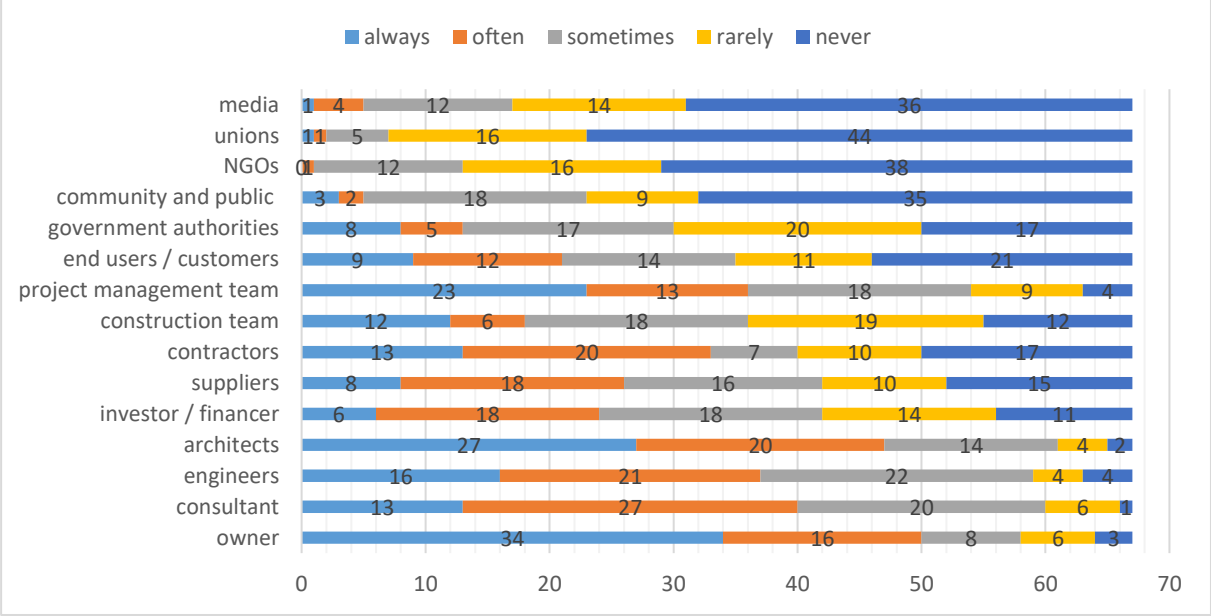

Figure 3: Connectivity amongst stakeholders during the PRE-CONSTRUCTION phase.

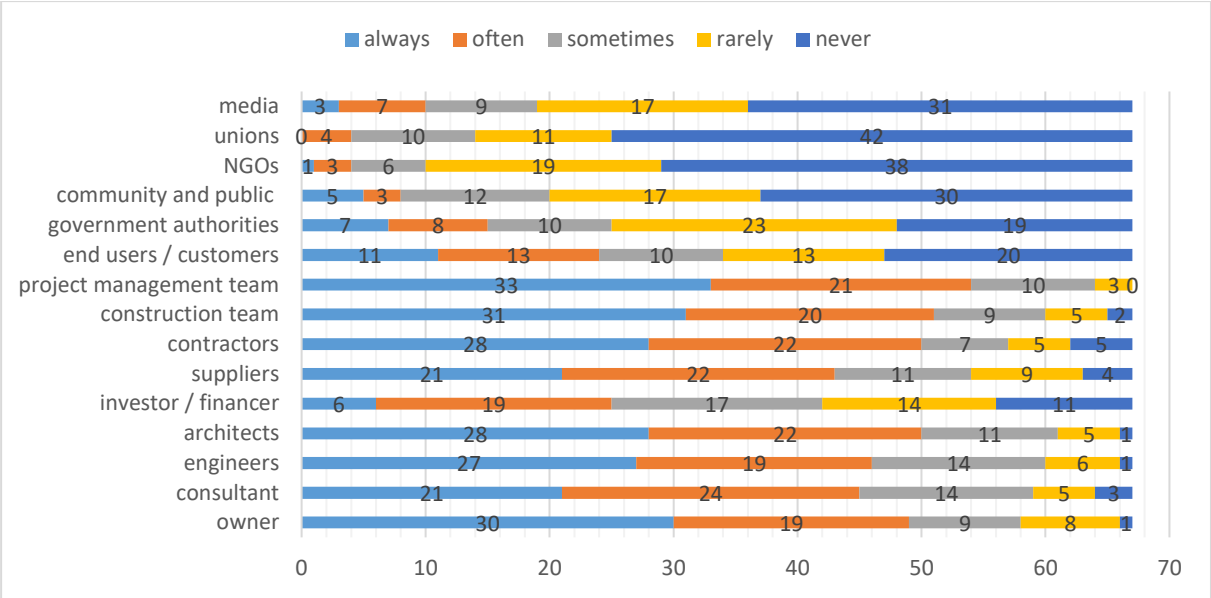

Figure 4: Connectivity amongst stakeholders during the CONSTRUCTION phase.

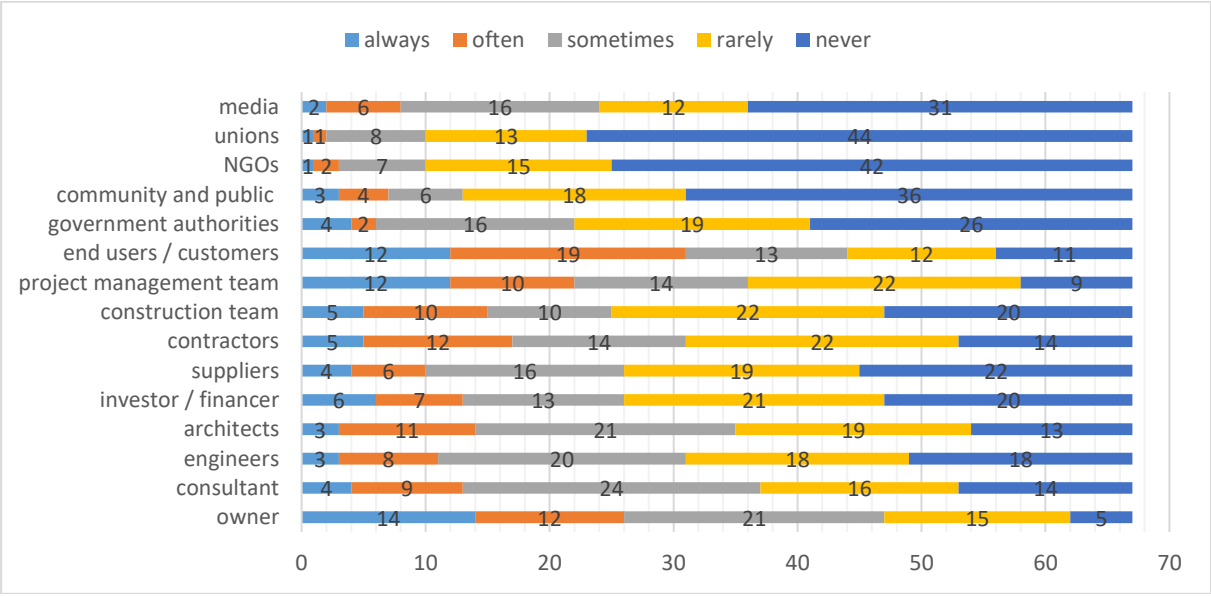

Figure 5: Connectivity amongst stakeholders during the POST-CONSTRUCTION phase.

Figure 6 shows the responses to the question “Is there someone specifically responsible for stakeholder management in your organization?” 57% replied “no” and 7% replied “no need”, totaling negative responses up to 64%. 31% replied “yes” and 3% said they outsource it, totaling positive responses up to 34%. The number of companies that do not have a Stakeholder Management responsible is double the ones that have. In the meantime when looked at geographically, Turkish and international responses were almost the same as can be seen in Table 3. From the 21 participants that answered “yes”, 10 were from Turkey, and 11 were international. Similarly, from the 38 participants that answered “no”, 19 were from Turkey and 19 were international.

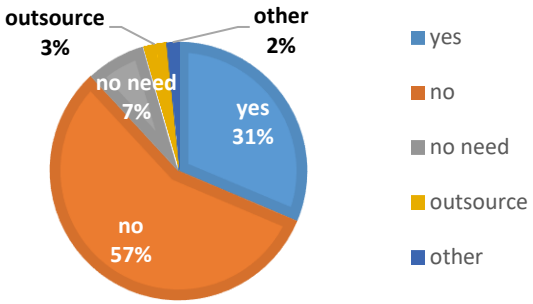

Figure 6: Presence of an employee-specific to stakeholder management.

Table 3. Distribution of responses according to country.

	Turkey	International	Total
Yes	10	11	21
No	19	19	38
No Need	4	1	5
Outsource	2		2
Other	1		1

As seen in Figure 7, when asked about barriers faced in stakeholder management the most common answers were that “the ideas/expectations of stakeholders are different”, “the ideas/expectations of the stakeholders change during the project”, and “the power imbalances amongst stakeholders”.

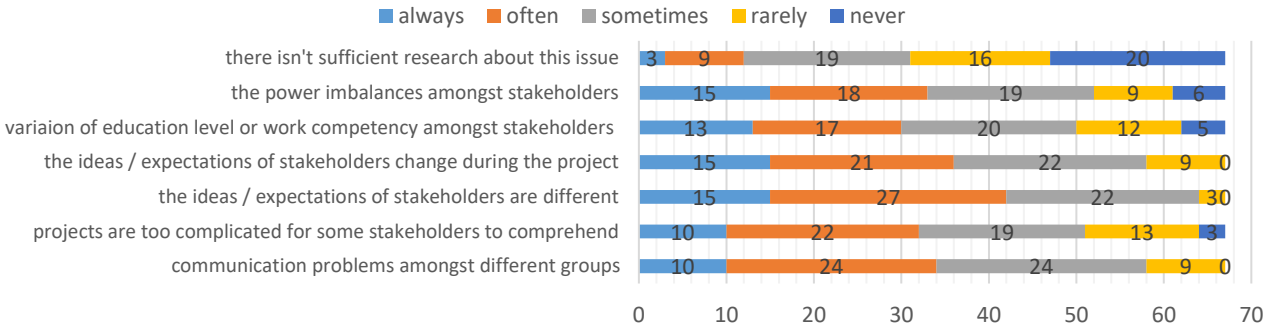

Figure 7: Challenges of stakeholder management.

Finally this portion of the survey wanted to measure the frequency of use for different stakeholder management methods/tools. As seen in Figure 8, when asked about which stakeholder management models are most commonly used the participants replied Building Information Modeling followed by Integrated Project Delivery. These methods are not stakeholder management specific but have a wholesome project management approach. This can be why they were most commonly picked.

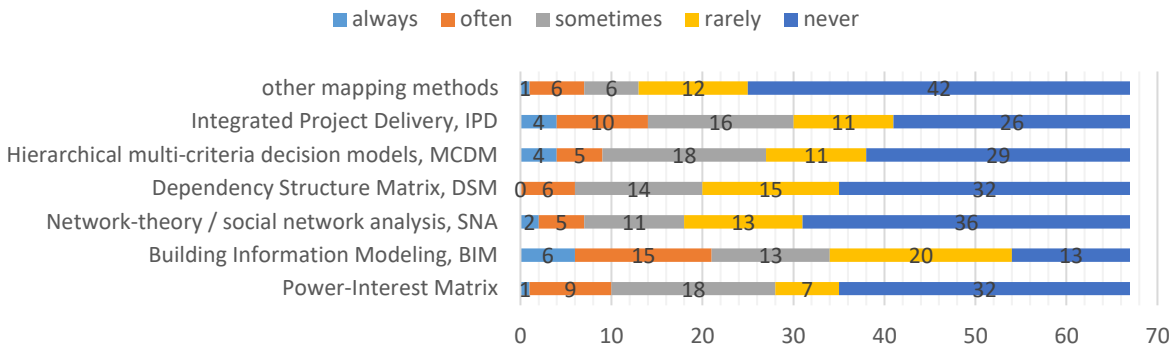

Figure 8: Frequency of use for different stakeholder management methods/tools.

The third and final portion of the survey was aimed to measure the level of digitalization in companies and the frequency of use of industry 4.0 technologies for stakeholder management. Figure 9 shows the responses to the question "Does your company have a staff member responsible for digitalization?" 33% replied "no" and 9% replied "no need", totaling negative responses up to 42%. 45% replied "yes" and 13% said they outsource it, totaling positive responses up to 58%. The number of positive replies is higher than the negative which can indicate a trend toward digitalization in the industry. In the meantime when looked at geographically, international participants were slightly more inclined towards digitalization. As can be seen in Table 4, from the 30 participants that answered "yes", 13 were from Turkey, and 17 were international. Similarly, from the 22 participants that answered "no", 15 were from Turkey and 7 were international.

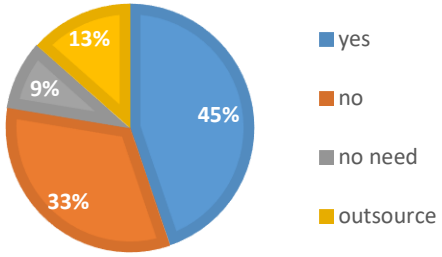

Figure 9: The presence of an employee-specific to digitalization.

Table 4. Distribution of responses according to country.

	Turkey	International	Total
Yes	13	17	30
No	15	7	22
No Need	2	4	6
Outsource	6	3	9

Figure 10 shows the responses of the participants when asked if they use industry 4.0 technologies for stakeholder management. The 15 industry 4.0 technologies that were surveyed about were the most commonly encountered technologies in the previous literature research. The results show that the most commonly used technology is BIM, followed by the cloud. This is understandable considering these technologies provide a wholesome aid to project management overall and therefore are also useful for stakeholder management. The least used technology was robotics followed by blockchain. As can be seen in Figure 11, when the responses were divided into 2 groups who answered as "always-often-sometimes" and "never-rarely", it was seen that more than 60% of the participants responded "never-rarely" to using industry 4.0 technologies except for BIM and the Cloud.

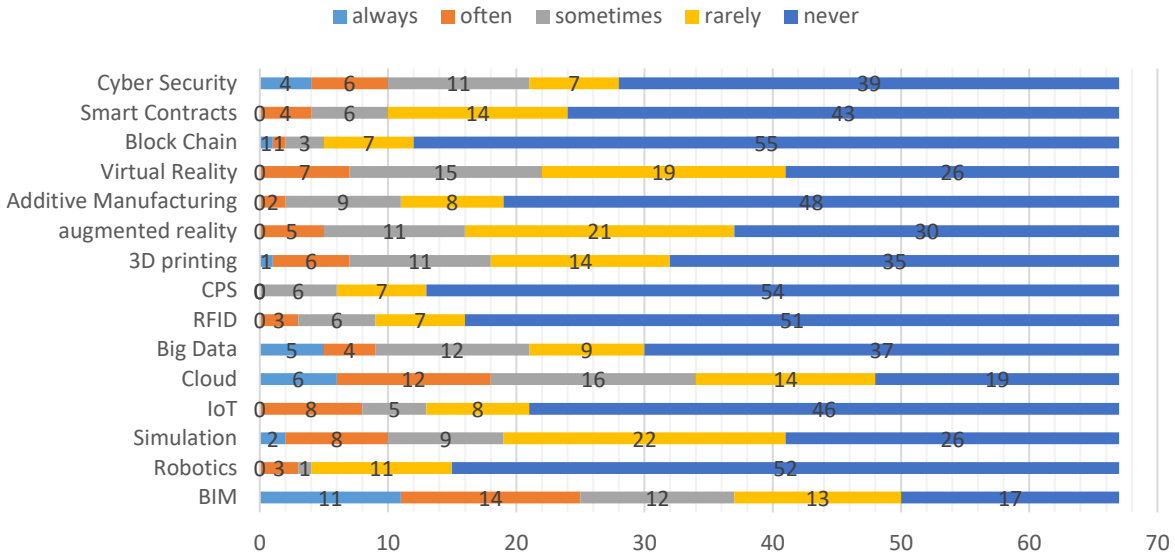

Figure 10: Frequency of use of different industry 4.0 technologies for stakeholder management.

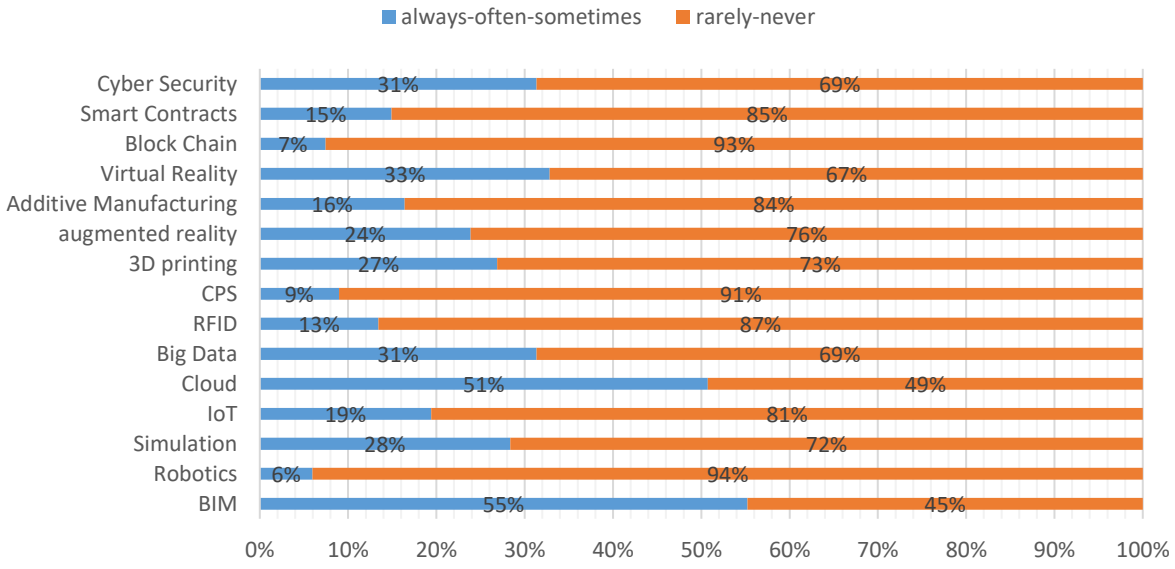

Figure 11: Percentage distribution of "always-often-sometimes" and "rarely-never" answers.

Figure 12 shows the percentage distribution of technologies used for gathering and distributing information amongst stakeholders. When asked "How often would you use the following tools to collect and distribute information among stakeholders?" the most common answer was internet technologies with 54 % answering "always" and 31% answering "often", followed by social media with 18 % answering "always" and 16% answering "often". The least used technologies were sentiment analysis with 72% answering "never" and 16% answering "rarely", followed by data/text mining with 63% answering "never" and 12% answering "rarely". Although participants claimed to use internet technologies and social media, the tools necessary to analyze the information gathered through internet technologies and social media, such as sentiment analysis and data/text mining, were mostly ignored and unused. It was also realized that automated systems, CRM systems, and satisfaction tracking dashboards that

systematize and organize the information flow through stakeholders were also hardly ever used, with more than 60% of participants answering “never” and “rarely”.

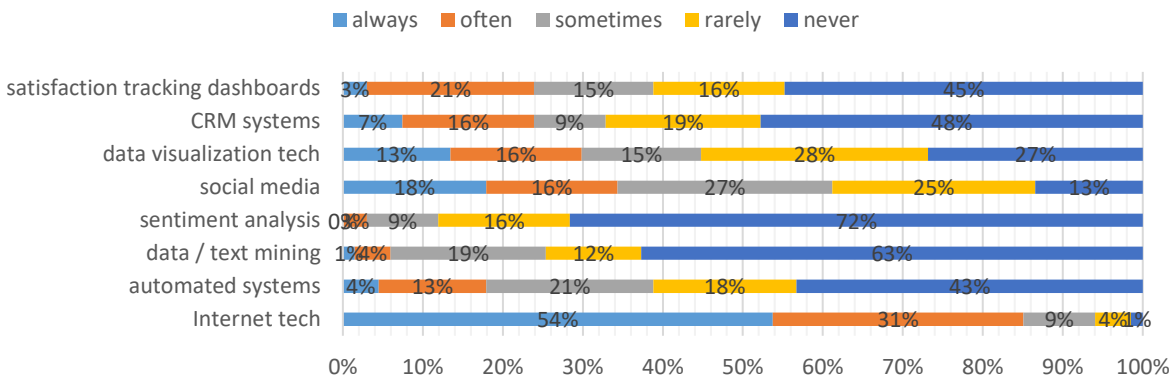

Figure 12: Percentage distribution of technologies used for gathering and distributing information amongst stakeholders.

Figure 13 shows the percentage distribution of ways to improve stakeholder management. The most common answer was that “digitalization should be prioritized and technology should be made more use of”, with 46 % answering “strongly agree” and 45% answering “agree”, followed by “stakeholder needs should be examined in more detail”, with 33% answering “strongly agree” and 58% answering “agree”. The least common answer was “decentralized (multiple) decision-making should be preferred”, with 16 % answering “strongly agree” and 31% answering “agree”.

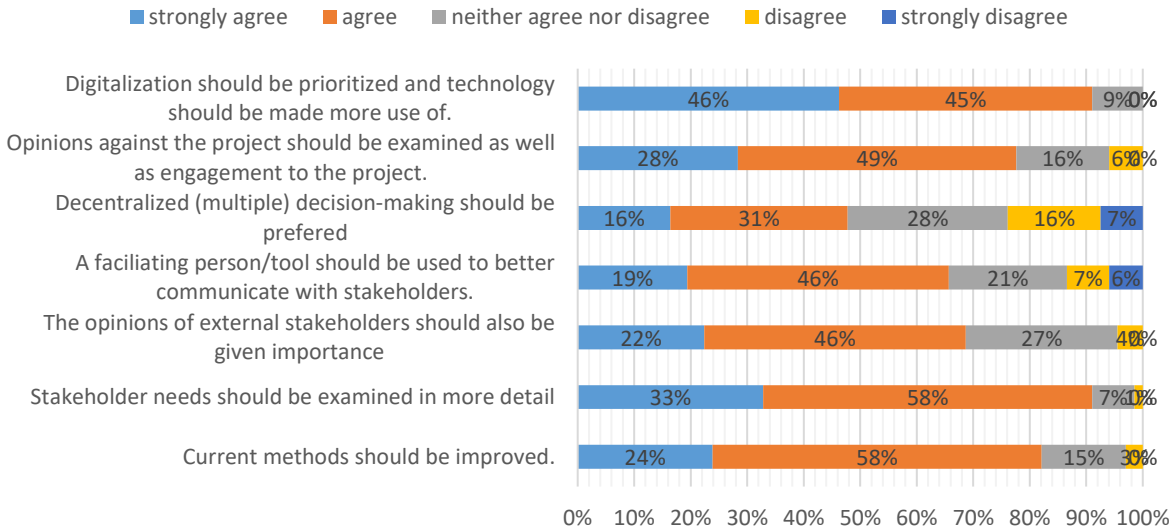

Figure 13: Percentage distribution of ways to improve stakeholder management.

Discussion

Throughout this survey there were two main questions to be answered: “What is the current situation of stakeholder management in the construction industry?” and “Are the industry 4.0

technologies being used to benefit stakeholder management?" Fortunately, answers were found for both queries.

Stakeholder management is mostly done pre-construction and during construction but it was seen through the survey that once the construction is over rarely any opinions of the users are considered post-construction. Throughout the 3 phases, it was realized that stakeholder management is mostly done between/for primary stakeholders but the secondary (external) stakeholders are ignored.

More than 60% of the companies did not have someone specifically responsible for stakeholder management. This didn't vary geographically since answers from Turkey and internationally were similar. The most common methods used for stakeholder management were Building Information Modeling and Integrated Project Delivery. However, these methods are not specifically stakeholder management methods, they facilitate stakeholder management as a part of their wholesome project management structure. When asked about barriers faced in stakeholder management the most common answers were about the constant change in stakeholder demands/needs and the power imbalances amongst them.

Unfortunately, although the participants surveyed hinted that there was an intention of going more digital in their companies it is not to the fullest extent to the benefits of today's technologies. When asked about digitalization, slightly more than half of the responses were positive, with international answers being slightly better than Turkish participants. However, almost none of the most common industry 4.0 technologies were used by the participants for stakeholder management. More than 60% of the participants responded "never-rarely" to using industry 4.0 technologies except for BIM and the Cloud.

When asked about using digital technologies for stakeholder communication such as gathering and distributing information it was realized that although internet technologies and social media were used by many, none of the tools to analyze and utilize the gathered information were used, such as sentiment analysis, big data analysis, etc. This shows that although companies have started to use some of the industry 4.0 technologies to communicate with stakeholders, they do not use (or are aware of) many of them and therefore do not experience the benefits to the full extent.

Finally when asked about solutions to better stakeholder management the most common answer was to make better use of digitalization and technologies, followed by examining stakeholder needs in more detail. Using current technologies of today not only can benefit stakeholder management but also achieve a deeper understanding of stakeholders since by using these new technologies more data from stakeholders can be gathered and analyzed. This idea was also supported by the responses received from the survey.

Throughout the survey, when responses from Turkish and international participants were compared there were no significant differences. It can be said that stakeholder management is lacking in both Turkish and international construction and real estate projects. Similarly, digitalization in stakeholder management in construction and real estate projects is slowly starting both n Turkish and international industries, with international answers being slightly more positive, but not significantly.

Conclusion

The construction industry has to change in order to improve itself. A long-time ignored aspect of project management has been stakeholder management, especially for external stakeholders. Not taking stakeholder needs into consideration has caused project delays and failures. In order to overcome the limitations of current stakeholder management methods, this paper suggests the use of industry 4.0 technologies. In order to do so, the current situation has to be assessed. While doing so it was realized that current methods of stakeholder management focus on a very limited number of stakeholders as well as being too static and not being able to track the changing needs of various stakeholders. Realizing that these problems can be solved by using industry 4.0 technologies, the survey also questioned if these technologies were being used effectively for stakeholder management. It was recognized that although there are a few participants starting to adopt some aspects of the modern technologies they are not used to (or known about) to the full extent. Further studies should focus on which industry 4.0 technologies would be more beneficial to stakeholder management specifically. Frameworks might be developed in the future to facilitate the use of industry 4.0 technologies for stakeholder management.

Big Data Applications in Construction Industry

K. Çimen and E. F. Taş
İstanbul Technical University, Department of Project and Construction Management, İstanbul, Turkey
cimen15@itu.edu.tr, tase@itu.edu.tr

Abstract

There is an exponential increase in the amount of data produced with the development of network and hardware technologies. The inefficient of traditional methods to process a large amount of data and extract useful insight from data has led to the development of big data technology. A wide assortment of industries including construction attempt to use big data technology to derive value and benefit from data. Big data is high-volume, high-variety and high-speed data. Construction data also indicates the characteristic of big data. It is high volume for including samples such as design and financial data and high variety for involving different formats such as dwg, dxf and rvt. As it is also high-speed on account of construction's dynamic structure, it is convenient for implementation of big data technology. This study intends to examine big data and its applications in the context of the construction industry. This technology has a remarkable potential to invent value from data. Moreover, the construction industry can increase its productivity in data management with the implementation of big data technology. Thus, there is a requirement for important research in this area. The study will give an overview of the literature about applications of big data in the construction industry.

Keywords: *applications, big data, big data analytics, construction industry, implementations.*

Introduction

The world is currently overfull with data and, many hardware transfers the data they produce to various applications with the rapidly advancing technology. The amount of data produced, stored and transmitted in this way is constantly increasing. Domo says that in 2021 every minute, 5.7 million searches are conducted Google, 575,000 tweets are posted on Twitter, 694,000 hours are streamed Youtube, and 6 million people shop online. The rising of digital devices such as smartphones and sensors has led to an unprecedented rate of data creation (Gandomi & Haider, 2014). This high speed creates an incredible amount of data. Besides, the generated data can be produced in a wide range of any type and format (jpg, pdf, word, excel etc.). As a result, a high variety of data is created. This increase in the speed, volume and diversity of data reveals the concept of big data. Basically, big data expresses as high-speed, high-variety, and high-volume data. The construction industry is suitable for the application of big data technology as construction data shows the characteristics of big data. Construction data is high volume for including samples such as design and financial data and high variety for involving different formats such as dwg, dxf and rvt. As it is also high-speed on account of

construction's dynamic structure (Bilal et.al, 2016). Big data technology provide efficiency and productivity for organizations; paves the way for developments in its products and services. The construction industry cannot be separated from this development (Madanayake & Egbu, 2019). Therefore, significant research is needed in this area. In this study, researches related to big data and the construction sector were obtained from the Scopus database and analyzed according to their keywords, the lack of studies on big data applications drew attention. This situation is one of the motivation sources for this study. The objective of this study is to carry out a systematic review of the literature dealing with the use of big data in the context of the construction industry. Firstly, related studies were obtained from the Scopus database. Using the Vosviewer application, a big data analytics tool, the most used keywords in related articles were grouped according to their relationships. After the groups were determined, each group was given a headline describing the application area in the construction sector according to the articles in it. As a result, the areas that benefited from big data technology in the construction sector were tried to be thematized five themes were determined as waste management, safety, project management, information management and risk management.

What is Big Data?

Data is raw information obtained from various media. Nowadays, the advancement of network and hardware technologies has led to an increase in the volume, speed and diversity of the data produced, and has brought the concept of big data (Zhang et al., 2015). There are different definitions for big data in the literature. According to Lu and Zhang (2021), this term refers to the storage, management, processing, interpretation and visualization of large amounts of data. Sang et al. (2020) expressed that big data is complex and interconnected volumes of information such as environmental, financial, geographical, social media information. With these definitions, big data is mostly explained through its properties. IT industry research group Gartner, big data; refers to high-volume, high-speed, and high-diversity information resources that require new forms of processing for knowledge discovery (Wessler et al., 2013). Similarly, the National Institute of Standards and Technology expresses that big data is high speed, high-volume and high diversity datasets (Chang & Grady, 2019). As a result, big data differs from simple data with its high volume, speed and variety; moreover, it is a concept about storing and managing datasets and making them meaningful by processing them with various methods and technologies.

Big data and Construction Industry

Construction data is large, heterogeneous and dynamic, so it shows the characteristics of big data (Bilal et. al, 2016). The construction industry has important data from different disciplines over the life cycle of a facility (Yousif et al., 2021). By discovering hidden patterns, trends, and correlations within this data, good management can help gain social, economic, and environmental insights that will support data-driven decision making for competitive advantage (Madanayeke & Ebgu, 2019). This is possible with the use of big data analytical techniques. Although the use of big data in the construction industry is not yet widespread, there are examples, and it is predicted that these examples will increase as technology becomes more involved in our lives (Ram et al., 2019). For example; Lu et al (2016); conducted a study to compare construction waste management performance between public and private projects. They did this using big data in the form of two million waste

records from around 5700 projects undertaken in Hong Kong in 2011-2012. As a result, they found that there is a remarkable construction waste management performance difference between the public and private sectors. Cheng et al. (2012); Taiwan has conducted a study using big data techniques to determine the factors that cause occupational accidents in the construction industry. Among all accident types, the most common cause of injury was fall/ tripping (47%). Collapse of objects (19%), electric shock (13%) and falling objects (5%) were recorded as other important causes. Kim et al. (2007) conducted a study using big data analytics to determine which factors are causing delays in an ongoing construction project. In this study, using the data of a drainage project in the USA, they identified nine important factors that caused the delay. These factors were defined as temperature, material delivery, weekend, faulty site survey, subcontractor delay, incorrect towing, safety, weather, and seasons. Carrillo et al. (2011) also analyzed the pre-project review reports from the two companies using big data methods to find out if there are certain trends that could provide useful information for future construction projects. As a result of the research, the words that are frequently used in the reports for both companies were determined and the relationship of these words was examined, and it was determined where the companies made mistakes in their previous projects and an awareness was created for them to pay attention to these issues in their future projects.

Barbosa et al. (2017); sees big data and analytics methods as a sensible way to alleviate some of the pressures faced by the construction industry. While the use of big data in the construction industry is still in its infancy, numerous studies show that the potential is huge if construction big data is fully utilized (Munavar et. al, 2022).

Research Method

Big data and construction industry related studies were acquired from the Scopus database. In order to see the interests of the researchers, all document types including conference paper, article, conference review, review, book chapter, book and editorial were included. It was only focused on studies written in the English language. The retrieval was conducted using the following code: TITLE-ABS-KEY ("big data") AND TITLE-ABS-KEY ("construction industry" OR "construction sector" OR “construction project” OR “construction projects”) AND (LIMIT-TO (LANGUAGE, "English")). 338 publications were reached as a result of the search. Figure 1 shows the publications by years. According to the Figure 1, big data in the construction industry had more attention in 2012 and onwards. For this reason, it is meaningful to examine the studies on big data applications in the construction sector that is main topic of this article for 2012 and after.

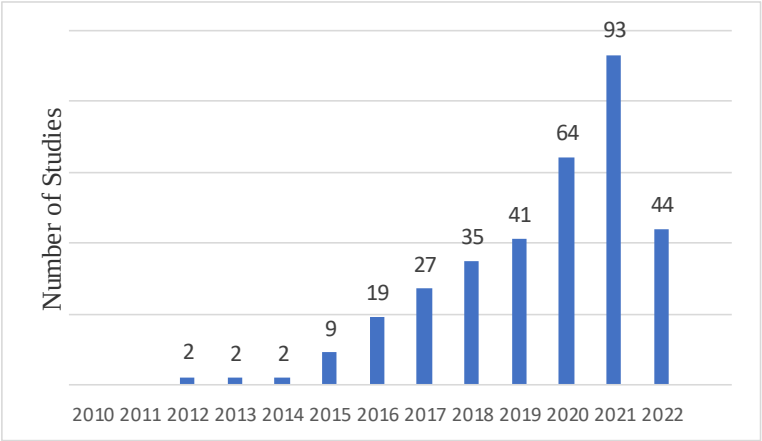

Figure 1: The numbers of studies in Scopus between 2010-2022.

The software VOSviewer that is a tool used to produce meaningful information from big data was used to analyse 338 publications in order to determine the most frequently used keywords in the research. The texts in the title-abs-key section of the publications were analysed according to co-occurrence. 108 keywords were found that repeated at least 2 times out of 908 keywords used in the title-abs-key section of 338 documents. The 103 concepts with the highest relationality are included in the network map. Figure 2 demonstrates network analysis of co-occurring keywords. The total link strength shows the total strength of the connections of an item with other items. Big data and construction industry are keywords having the largest number of total links, 166 and 52 respectively. Other remarkable keywords are BIM (37), industry 4.0 (35), construction (33), blockchain (32), machine learning (31), big data analytics (30). Application keyword has only 4 total link. It shows that there is a lack of studies directly related with big data applications in the construction industry. This encourages the topic of this research. Besides, the “application” item is associated with big data analytics, one of the items with the highest total link strength. Big data analytics contributes to the application of big data. Thus, this keyword was also used for finding articles pertaining to big data applications in the construction industry in the following step.

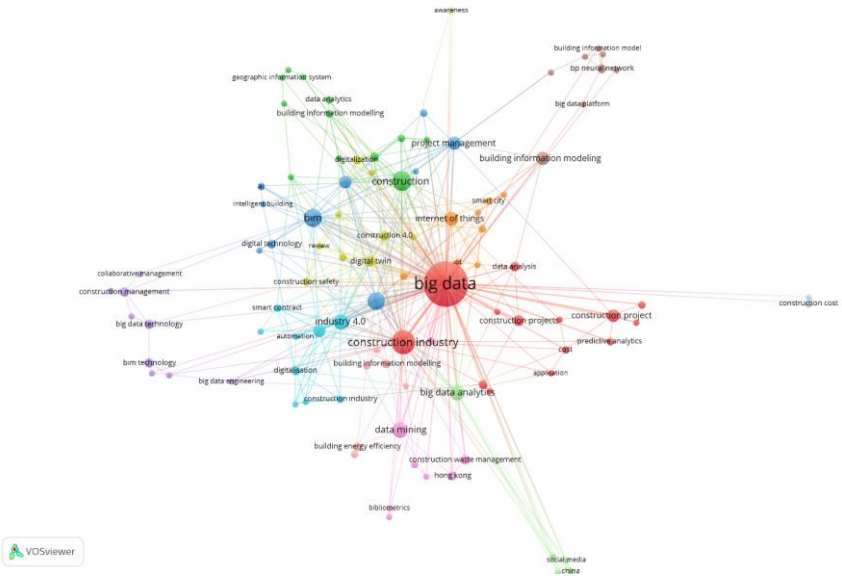

Figure 2: The network analysis.

In the next step, publications pertaining to big data applications in construction industry were acquired from Scopus. The different keyword combinations were developed to reach the most useful and relevant publications and the following code was used for retrieving: TITLE-ABS-KEY ("big data" OR "big data analytics") AND TITLE-ABS-KEY (application OR applications OR implementation OR implementations) AND TITLE-ABS-KEY ("construction industry" OR "construction sector" OR "construction project" OR "construction projects") AND (LIMIT-TO (LANGUAGE , "English")). 152 publications were reached and Vosviewer was used to analyse results. The texts in the title-abs-key section of the publications in the Scopus database were analysed according to co-occurrence. 51 keywords were found that repeated at least 2 times out of 404 words used in the title-abs-key section of 152 documents. Besides, Vosviewer was grouped keywords focused on frequency of together usage and displayed each group with a specific colour. 49 keywords were grouped under 11 clusters. In the continuation of the study, the articles within the clusters were analysed and names were given to these groups in a way to express the big data application areas in the construction industry. Table 1 shows the clusters and cluster names showing areas of the big data applications in the construction industry. Clusters of 'big data and blockchain', 'big data and artificial intelligence', 'big data and BIM', 'big data and internet of things', 'big data and neural network', 'big data and cloud computing' can be associated with the digital technologies pertaining to big data. Therefore, they are out of scope for this study.

Table 1. Clusters on the Vosviewer.

NO	KEYWORD	NUMBER OF LINK	TOTAL LINK STRENGTH	CLUSTER NAME
C01	application	3	3	BIG DATA and WASTE
	big data analytics	13	18	
	building information modelling	6	6

	construction projects	2	3	

In the next step, the research was restricted only research papers and reached 42 articles. In order to determine how big data is applied in the construction industry, content of the 42 articles was analysed. 20 articles were found eligible. Table 2 shows only the original research papers that uses big data technology as a tool in the construction industry with the

purpose of use. At this stage, it was also determined which of the clusters the articles belonged to in the previous step.

Table 2. Research papers that uses big data technology as a tool.

NO	TITLE OF ARTICLE	AUTHOR	PURPOSE OF USE	CLUSTER
1	Developing a Geospatial Framework for Severe Occupational Injuries Using Moran's I and Getis-Ord Gi* Statistics for South-eastern United States	Fahad et al., 2022	. to analyse the severe injury reports	BIG DATA and SAFETY
2	Applications of Smart Technologies in Construction Project Management	Zhu et al., 2022	. to estimate and schedule in project time management . to estimate and control cost . to predict potential quality issues and trace the root causes of the issues to improve quality assurance	BIG DATA and PROJECT MANAGEMENT
3	Analysing the Freight Characteristics and Carbon Emission of Construction Waste Hauling Trucks: Big Data Analytics of Hong Kong	Wei et al., 2022	. to monitor the effectiveness of policy interventions related to construction waste transportation planning and carbon emission	BIG DATA and WASTE
4	Construction Project Cost Management and Control System Based on Big Data	Chen et al., 2022	. to process large-scale data for construction project cost management	BIG DATA and PROJECT MANAGEMENT
5	Towards sustainability evaluation of urban landscapes using big data: a case study of Israel's architecture, engineering and construction industry	Yoffe et al., 2022	. to enhance sustainability rating systems in landscape development	BIG DATA and KNOWLEDGE MANAGEMENT
6	Handling missing data for construction waste management: machine learning based on aggregated waste generation behaviours	Yang et al., 2021	. to pinpoint the potential of waste big data in portraying project behaviours	BIG DATA and WASTE
7	A BIM and machine learning integration framework for automated property valuation	Su et al., 2021	. to manage information exchange between AEC projects and property valuation and to support automated property valuation	BIG DATA and KNOWLEDGE MANAGEMENT

8	Life Cycle Assessment of Bridges Using Bayesian Networks and Fuzzy Mathematics	Zhou et al., 2021	. to reduce traffic pollution emissions for reducing the impact of the construction industry on the environment	BIG DATA and KNOWLEDGE MANAGEMENT
9	The Impact of Organisational Resilience on Construction Project Success: Evidence From Large-Scale Construction in China	Yang et al., 2020	. to identify organisational resilience factors that affect construction project success	BIG DATA and RISK MANAGEMENT
10	Factor-based big data and predictive analytics capability assessment tool for the construction industry	Ngo et al., 2020	. to develop a capability assessment tool that highlights the strengths and weaknesses of construction organizations and can measure their capabilities in big data and predictive analytics	BIG DATA and RISK MANAGEMENT
11	Social Risk Early Warning of Environmental Damage of Large Scale Construction Projects in China Based on Network Governance and LSTM Model	Fang et al., 2020	. to analyse characteristics of the social risk of environmental damage of large-scale construction projects	BIG DATA and RISK MANAGEMENT
12	Application of remote electron microscope technology in construction management of building engineering	Xu et al., 2020	. to better monitor the quality of the project and ensure the construction safety	BIG DATA and PROJECT MANAGEMENT
13	A Big Data and FMEA-based construction quality risk evaluation model considering project schedule for Shanghai apartment projects	Ma & Wu, 2019	. to predict the relationship between the planned schedule and the project quality risk	BIG DATA and RISK MANAGEMENT
14	Investigating profitability performance of construction projects using big data: A project analytics approach	Bilal et al., 2019	. to create a project analytics approach to understand the profitability distribution of different types of construction projects	BIG DATA and KNOWLEDGE MANAGEMENT
15	A Big Data Analytics Approach for Construction Firms Failure Prediction Models	Alaka et al., 2019	. to reduce the unfavourable waiting time during construction firms failure prediction models	BIG DATA and RISK MANAGEMENT

16	Research on Optimization of Big Data Construction Engineering Quality Management Based on RNN-LSTM	Wang et al., 2018	. to predict the quality problems of steel bars, formworks, concrete, cast-in-place structures, and masonry in the construction project	BIG DATA and RISK MANAGEMENT
17	Mining big building operational data for improving building energy efficiency: A case study	Fan & Xiao, 2018	. to utilize big building operational data effectively	BIG DATA and KNOWLEDGE MANAGEMENT
18	RFID Enabled Knowledge-Based Precast Construction Supply Chain	Wang & Hu, 2017	. to utilize RFID in knowledge-based precast construction supply chains	BIG DATA and KNOWLEDGE MANAGEMENT
19	Big data architecture for construction waste analytics (CWA): A conceptual framework	Oyelede et al., 2016	. to analyse construction waste	BIG DATA and WASTE
20	A Big-Data-based platform of workers' behaviour: Observations from the field	Guo et al., 2015	. to classify, collect and store data about workers' unsafe behaviour in construction site	BIG DATA and SAFETY

Conclusion

The age of big data has begun with the development of network and hardware facilities such as sensors and servers. In order to create an understanding of big data from the perspective of the construction industry, this study examines the applications of big data technology in the construction industry. These studies obtained from the Scopus database were analyzed using the Vosviewer tool. The most frequently used words in related studies were grouped according to their relations and the articles in these groups were analyzed according to their content. As a result, these groups were given titles to express the application area in the construction industry. According to the data obtained, the most common areas of big data applications in the construction industry are waste management, safety, project management, information management and risk management. When only the original research articles are examined, it is seen that the most studies have been done on information management and risk management, followed by waste management and project management. Safety is another area of research. It is obvious that the adoption of big data technology will have positive contributions to the construction industry. Bilal et al. (2016) argue that the optimal use of big data will arguably be the next front of innovation in the construction industry. Yousif et al (2021); the adoption of big data in the construction industry will improve sustainability, become more knowledgeable in decision-making processes, and improve safety and working conditions; It claims that costs and timeouts will be reduced, project delays will be eliminated and risks will be reduced. The broad applications of big data can encompass many perspectives of the construction industry.

A Brief Summary on Facilities Management Technologies and BIM-FM Integration

E. Tezel and H. Giritli
Istanbul Technical University, Department of Architecture, İstanbul, Turkey
tezele@itu.edu.tr, giritli@itu.edu.tr

Abstract

Built environments need countless facilities management (FM) services to ensure functionality, comfort, safety, and efficiency for their occupants. Formerly, FM practices have relied on hard copy documents. Following the development of computer-aided systems, the FM industry has started to embrace digital transformation. Nowadays, advanced methods such as building information modeling (BIM) are playing a crucial role in the efficient delivery of FM services. Yet, diverse information needs of different services throughout the operational phase constitute the major hindrance in the BIM and FM integration. This research aims to investigate the widely used FM technologies and identify their synergy with BIM. First, inclusive analysis of scientific literature, as well as industry-specific reports and best practice documents, reveals common FM technologies together with their role in the operational phase of built environments. Then, a questionnaire survey with FM professionals identifies the required building information for efficient FM practices. The final discussion emphasizes the potential of BIM for FM by highlighting the information that BIM can provide for efficient FM practices.

Keywords: *Building Information Modeling (BIM), facility management (FM), BIM-FM integration, digital transformation.*

Introduction

A facility, often used as *facilities*, is something that is built, installed, or established to serve a particular purpose. Architecture, Engineering and Construction (AEC) industry professionals work together to design and construct various facilities to provide a suitable environment for diverse human activities. *Facilities management*, which is synonymously used with workplace management, involves the services to maintain, improve, and adapt the buildings of an organization in order to create an environment that strongly supports the primary objectives of that organization (Barrett & Baldry, 2003). Today, FM refers to an organizational function which integrates people, place and process within the built environment with the purpose of improving the quality of life of people and the productivity of the core business (ISO, 2017). Undoubtedly, FM services differ depending on the needs of organizations. A broad list of those services includes but is not limited to daily operations (i.e., cleaning and catering), administrative services (i.e., security), maintenance and repair works, energy management, occupancy planning and space management, architectural and engineering services (i.e., renovation, refurbishment and retrofitting), financial management, emergency management and

disaster recovery, and FM personnel training (Springer, 2001; Chotipanich, 2004; Atkin & Brooks, 2021).

Until recently, facilities managers have been relying on blueprints, printed manuals, and records to understand the building's history and make future decisions. However, due to the increasing adaptation of technological developments within the AEC industry building projects become more complicated and technology oriented. On top of that, the deepening role of buildings in the climate crisis, cost escalations, human resource limitations, increasing competition and decreasing business profits lead facilities managers to implement innovative technologies to work efficiently. As a result, the FM industry has started to embrace computer-integrated facilities management (CIFM) environments (Yu et al., 2000). A typical list of CIFM environments includes computerized maintenance management system (CMMS), computer-aided facilities management (CAFM), and integrated workplace management system (IWMS). In the early 2010s building information modeling (BIM) concept emerged with the promise of integration and efficiency (Becerik-Gerber et al., 2012; Gao & Pishdad-Bozorgi, 2019). ISO defines BIM as the use of a shared digital representation of a built asset to facilitate design, construction and operation processes to form a reliable basis for decisions (ISO, 2018). Since its first introduction to the industry, numerous studies have shown that FM can utilize BIM to create digital assets, visualize the exact locations of critical equipment, plan and monitor maintenance work orders, manage workspace, control indoor environmental conditions, monitor building performance, and give training to FM personnel, all in a 3D environment (Becerik-Gerber et al., 2012; Pärn et al., 2017). The literature identifies various reasons that are hindering BIM-FM integration (Korpela et al., 2015; Patacas et al., 2015; Pärn et al., 2017; Durdyev et al., 2022), yet digitization in FM, particularly BIM-based FM, is a globally evolving phenomenon.

The present study investigates the major FM software systems that are frequently used by facilities managers with a special focus on BIM and BIM-FM integration. First, some background information on the key characteristics of CMMS, CAFM, IWMS, and BIM technologies is provided. Then, a survey of FM professionals determines what information is required to efficiently carry out FM tasks. Finally, this study discusses how BIM can respond to FM needs.

FM Technologies and BIM-FM Integration

The list of FM technologies involves numerous software solutions in sophisticated abbreviations, such as CMMS, CAFM, IWMS, building automation system (BAS), energy management system (EMS), enterprise asset management (EAM), enterprise resource planning (ERP), BIM, digital twins, Internet of Things (IoT) and sensors, virtual reality (VR) and augmented reality (AR), and artificial intelligence (AI). Although each of these technologies is notably important for the efficient operations of built environments, they play different roles in the whole FM ecosystem. The previous study by Ebbesen (2016) categorizes these technologies into seven groups and illustrates the relationship among them as seen in Figure 1. Typically, an unexpected issue is detected by an FM staff during inspection or other data capturing systems (i.e., RFID, sensor, IoT, drone, etc.), then it is issued to the facilities manager as a work request, then the facilities manager needs to analyze associated building data located in different platforms (i.e., database, spreadsheet, CAD, BIM, etc.) to make a decision, and issues a work order to the associated personnel through the workflow system (i.e., CMMS, CAFM, or

IWMS). As illustrated in the figure below, there is a continuous data flow among these systems and facilities managers must have the right data at the right time to make the right decisions.

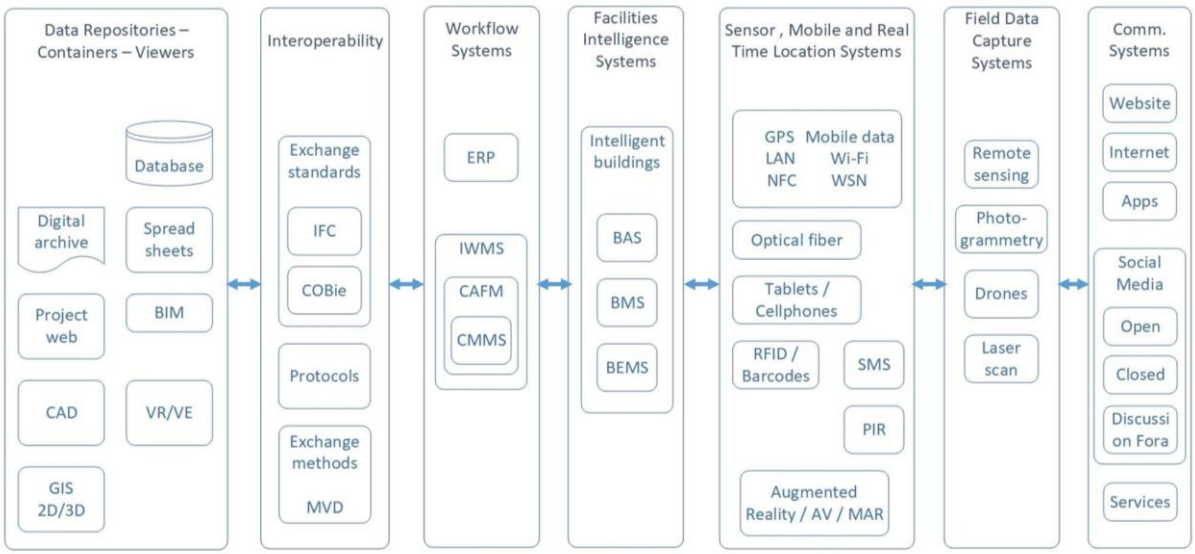

Figure 1: FM technologies.

Among these technologies, the computerized maintenance management system is a software system that supports the maintenance of key equipment and physical assets within buildings. CMMS is essentially a database that stores maintenance operations data such as asset registers (individual records of each asset), work orders, assigned and completed tasks, equipment availability, and inventories. Facilities managers utilize the mentioned data to schedule preventive maintenance, make purchase decisions or generate labor and material use reports. Winker et al. (2016) emphasize the key role of CMMS in lowering the hidden costs of maintenance. Similar to CMMS, computer-aided facilities management is one of the core software solutions for facilities managers. It supports different FM tasks such as space (or workplace) management and asset management. A CAFM system can incorporate CAD or GIS to store floor plans, therefore it is mainly used for planning and allocating space, tracking equipment, physical and technical assets, and monitoring space occupancy (Mohanta & Das, 2016; Zvirbule & Kirikova, 2018). Besides, it enables facilities managers to manage planned, reactive and corrective maintenance works of critical equipment in buildings (Whittaker, 2017; Maslesa, 2019). An integrated workplace management system, as the name suggests, integrates facilities management, real estate management, maintenance management, energy management, and project management functions within a single platform. An IWMS, mostly referred to as a developed version of CAFM, supports facilities managers to make space management decisions, assign and track maintenance work orders, monitor energy metrics and carbon emissions, and design and construct new facilities or remodel existing ones.

Most of the time, facilities managers have to spend extra time and effort to transfer the unstructured data they received at the project completion into the mentioned FM systems (Patacas et al., 2015). This process is tedious and inherently error-prone. However, BIM-based projects store whole building lifecycle data into a repository and interoperability standards enable seamless data exchange between BIM and FM software systems. BIM-FM integration studies and practices are gaining popularity over the last decade (Tezel & Giritli, 2021). Evidence shows how BIM can support maintenance management, indoor environmental quality monitoring, space management, emergency planning, and FM personnel training (Korpela et

al., 2015; Merschbrock et al., 2016; Lavy et al., 2019; Jung et al., 2020; Kula & Ergen, 2021). Diverse FM services utilize different software systems with different information requirements. This prevents a single software solution to respond all types of FM services (Wong et al., 2018). Still, BIM offers great potential to FM professionals as it provides a collaborative platform to create, coordinate and store building information throughout the whole lifecycle of the building.

Research Method

A questionnaire survey was developed to identify the most important information for facilities managers. Respondents were questioned about the necessity of the given 15 items for effective FM practices in buildings, and they were asked to rate their importance. There was an additional open-ended question for the respondents to indicate further items. They were able to select the level of importance for each item among the following three categories: (0) not needed, (1) better to have, and (2) must have. The survey also collected a set of information regarding respondent characteristics, namely, position, years of industry experience, years of experience in the latest company, and their BIM-based FM background.

Table 1. Respondent characteristics.

Characteristics	**Categories**	**Response count**	**Response rate**
Position	Founder/General Manager	16	43%
	Vice General Manager	6	16%
	Director/Leader/Manager	9	24%
	Consultant	2	5%
	Specialist	2	5%
	Other	2	5%
	Total	**37**	**100%**
Experience in the FM profession	< 5 years	4	11%
	6-10 years	11	30%
	11-15 years	10	27%
	16-20 years	5	14%
	21-25 years	4	11%
	> 26 years	3	8%
Years in the current company	< 5 years	14	38%
	6-10 years	11	30%
	11-15 years	5	14%
	16-20 years	6	16%
	21-25 years	1	3%
	> 26 years	-	-

The online questionnaire invitation was shared with the members of three major FM associations in Turkey, as this study adopts an expert sampling (or judgment sampling) strategy. Expert sampling ensures that individuals who are associated with the study subject are present within the targeted sample (Thieart, 2001; Taherdoost, 2016). Even though FM is a relatively new industry in Turkey, it plays a significant role in the O&M of millions of square meters with diverse needs. Within the scope of this study, 90 members of the Turkish Facility Management Association (TRFMA), Professional Facility Managers Association (PTYD), and Urban Facility Management Association (TRKTYD), and local offices of 3 well-known international

FM provider organizations were invited to the questionnaire between February and March 2021. A total of 37 valid responses were received with a response rate of 40%, approximately. Table 1 below shows the general characteristics of the respondents.

The largest group of survey respondents (43%) are Founders or General Managers within the Turkish FM industry, followed by Directors, Leaders or Managers (24%), and Vice General Managers (16%). The remaining groups include Consultants (5%), Specialists (5%), and other experts in different FM service areas (5%). On this account, it is evident that the survey drew the attention of high-ranking FM professionals. The respondents were able to choose their years of experience within the FM industry in general, and within the latest company in particular from the following categories: (1) less than 5 years, (2) 6 to 10 years, (3) 11 to 15 years, (4) 16 to 20 years, (5) 21 to 25 years, and (6) 26 years and more. It is seen that the majority of the respondents (60%) have more than 10 years of experience in the FM industry and again the majority of them (62%) have been working in the same company for at least 5 years. The descriptive findings regarding respondent characteristics imply that the study sample is highly representative of the industry.

Findings

Collected data were analyzed in terms of frequency, mean, rank, and comparison. Figure 2 illustrates the BIM-based FM background of survey respondents. Given the frequencies in Figure 2, it is seen that almost 20% of the respondents (8 out of 37) did previously use or are actively using BIM in at least one project. More importantly, a significant number of the respondents (70%) are willing to work with BIM even though they did not work with it until now. This finding is great evidence of the growing tendency of BIM-based FM services in the country.

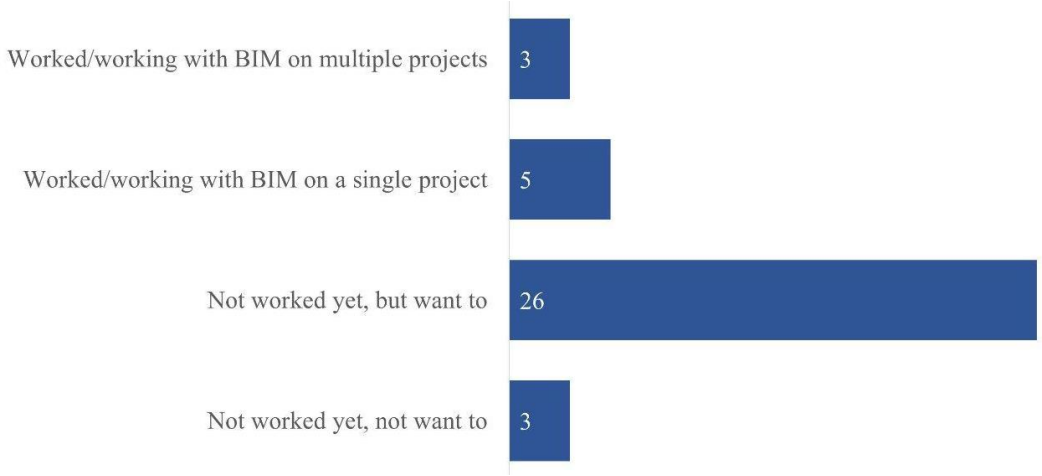

Figure 2: BIM use of the survey respondents.

Table 2 shows the responses given to the question of how necessary it is to have the listed data and information for efficient and effective FM services. Contrary to common expectations, FM professionals prioritize an emergency plan, a document that describes the actions to take during emergency cases, and emergency scenarios at the top. Then, they look for equipment lists, manuals and warranties, equipment logs, maintenance and repair records, and the locations of emergency equipment (i.e., fire extinguisher, first-aid kit, etc.) within the building. It is

interesting to note that, 2D as-built drawings such as floor plans and sections and 3D as-built models that show the exact representation of the buildings do not seem to be as crucial for the facilities managers as the above-mentioned documents. There may be two underlying reasons explaining this outcome. First, the data were collected between February and March 2021, when all industries were still struggling with the COVID-19 pandemic, yet they were continuing business under unstable economic conditions. Therefore, they may ask FM service providers to be prepared for emergencies. Secondly, facilities managers generally receive the major construction drawings, but the inaccurate or outdated floor plans or models do not help them to make further decisions regarding the building. Thus, they may not find these documents as useful as they were expected to be.

Table 2. Data and information requirement rank.

	Responses				
	not needed	**better to have**	**must have**	**Mean**	**Rank**
Emergency plans	-	2	35	1.95	1
Emergency scenarios	-	3	34	1.92	2
Equipment lists and manuals	1	2	34	1.89	3
Equipment logs	1	2	34	1.89	3
Locations of emergency equipment	1	2	34	1.89	3
Regulations and standards	1	3	33	1.86	4
Specifications	-	5	32	1.86	4
Financial information	1	4	32	1.84	5
2D as-built drawings	-	7	30	1.81	6
Occupant information	2	3	32	1.81	6
Policies	2	7	28	1.70	7
Energy consumption logs	-	11	26	1.70	7
Personnel training documents	2	8	27	1.68	8
Certificates (energy, green building)	-	14	23	1.62	9
3D as-built models	-	17	20	1.54	10

In addition to the listed items, open-ended responses emphasize the importance of an adequate FM plan, a clear definition of the FM service scope, and interoperability standards for different FM technologies for better services. Based on the findings, it can be concluded that the FM industry suffers from poorly defined contracts, unavailability of documents regarding critical assets, and technological discrepancies.

Figure 3 compares the answers of the non-BIM-user and BIM-user facilities managers to the question of what the "must have" data is for efficient FM operations. For all BIM users (100%), equipment lists, and regulations and standards are the absolute must documents to have when operating buildings, followed by 2D as-built drawings, equipment logs, emergency plans and scenarios, and financial data (88%). On the other hand, most of the non-BIM users require emergency plans first (97%), followed by equipment logs, emergency equipment locations, and emergency scenarios (93%).

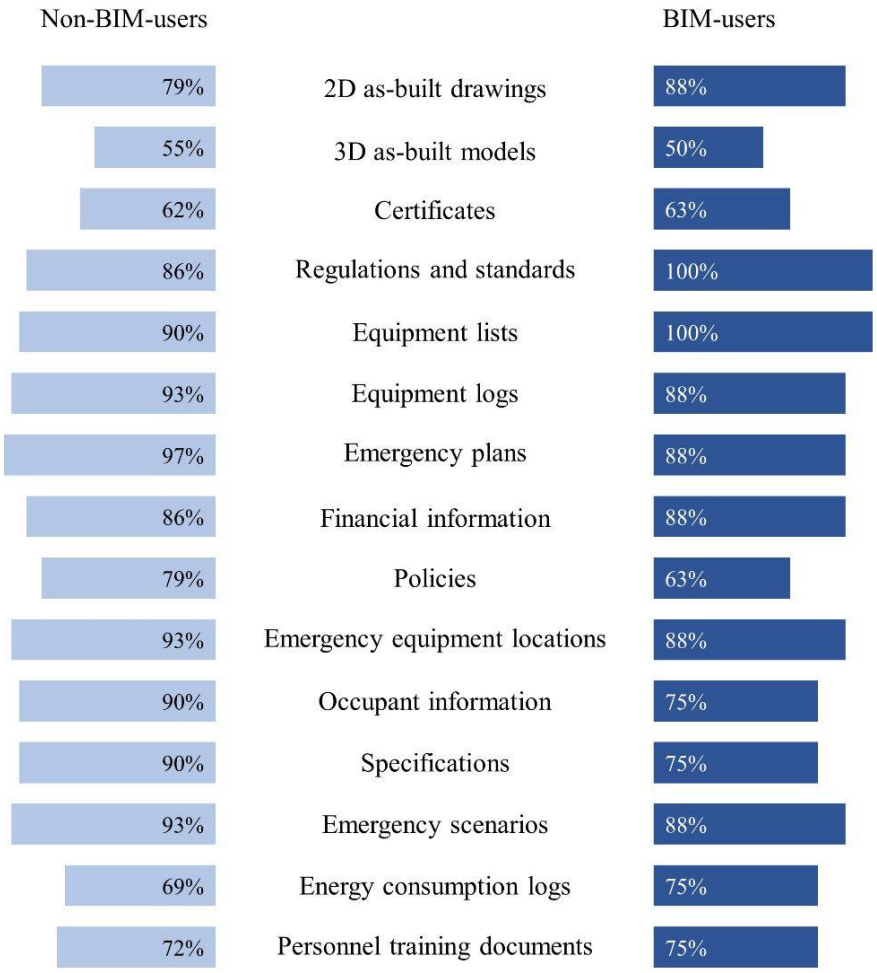

Figure 3: “must have” information for non-BIM-users and BIM-users.

It is interesting to note that none of the two groups look for 3D digital models of the building, in contrast only half of the respondents in each group believe that 3D models are necessary, and the remaining half do not need them at all. This finding may result from the limited BIM understanding of the respondents. According to the National Institute of Building Sciences (NIBS), equipment checks, facility maintenance, and repair activities take half of the time of FM personnel every day (NIBS, 2015). Thus, accurate 3D representation of each component with non-geometric details (i.e., manufacturer, install/replace date, manual, warranty, etc.) will be a time saver, especially in urgent cases. However, in most cases, BIM is accepted as a 3D visual without the associated “information”. Therefore, respondents may not find 3D models as necessary as other documents.

Conclusion

BIM is increasingly diffusing into the AEC practices to improve communication and coordination, reduce errors and rework, and increase efficiency. The more we design and construct buildings with BIM, the more we have BIM-based data to support FM services. Recognizing these developments, countries are taking various steps towards the spread of BIM and promoting BIM-FM integration. On the other hand, the FM industry in Turkey has a great

appetite for BIM, yet BIM diffusion within the industry is still very limited due to numerous reasons.

This study focuses on the most popular FM technologies and their synergy with BIM-based practices. The questionnaire survey with FM industry professionals unexpectedly reveals that documents concerning emergency planning and building equipment are the most required information by facilities managers in place of major construction documents such as as-built drawings and models. Previous studies show that inaccurate and outdated data are a hindrance to healthy decisions about building operations and maintenance. Thus, there may be distrust towards the architectural and construction drawings. However, in all work request facilities managers have to handle different documents at a time, and manually coordinating these documents is tedious and error-prone. BIM-based technologies ensure coordination and synchronization of all building data in a single platform.

BIM has been changing how the AEC industry works, and it changes how the FM industry works as well. ISO has been developing the 19650 series to guide the BIM implementation process for the actors in the entire building lifecycle. ISO 19650 series highlight the influence of industry-specific conditions and suggest associated adaptations on the given documents to ensure a smooth implementation process. The findings of this study support BIM integration within the FM industry in Turkey by identifying the most necessary information for efficient FM services.

Digital Twin Practices for Enhanced Construction Management: A Literature Review

B. Aktürk and P. Irlayıcı Çakmak
Istanbul Technical University, Department of Architecture, İstanbul, Turkey
akturkb19@itu.edu.tr, irlayici@itu.edu.tr

Abstract

Effective construction management plays a significant role in overcoming challenges the industry faces including low efficiency and productivity, inability to control processes, low profit, etc. In the digital transformation era, several interrelated aspects such as competition, changing customer demands, new generation employees and stakeholders, presented new instruments which have started to become widespread in construction management. Extensively applied in the automotive and manufacturing industries, Digital Twin (DT) has emerged as a technology-based innovation as one of the advances of the digitalization journey to improve and support construction practices. DT is a virtual system that brings design, construction, and operation together by data-linking to its real and physical assets bidirectionally with combined technologies. To answer key questions -namely "What is the definition of Digital Twin (DT)?", "What are the elements, technologies, and applications of DT in the construction industry?", and "How DT can be used for enhanced construction management?"- a synthesis of the digital twin literature through the lens of construction management will be made and the high potential of DT to improve construction management practices will be demonstrated. Furthermore, the frequency of consideration of DT practices and the level of awareness in the industry will be increased.

Keywords: *construction management, cyber-physical system, digital twin, information technology, literature review, project lifecycle.*

Introduction

On a global scale, the construction industry has a bad reputation for productivity and efficiency. According to the McKinsey Global Institute report, the cost of inefficiency in the construction industry to the global economy is approximately 1.6 trillion dollars, and it is stated that companies and regions that adapt to digital technologies and have an improved management understanding can increase productivity by 50 to 60 percent (Barbosa et al., 2017). In the last few decades, the construction industry has started to look for solution in digital tools such as mass production industries to increase its efficiency and productivity. The acceptance of building information modeling by the entire industry has become a catalyst supporting the digitalization effort in construction processes (Shahzad et al., 2022). Thus, newer and more advanced concepts emerged.

The emergence of the term Digital Twin (DT) is actually not so new. Widely accepted as the first definition of DT, the “digital equivalent to a physical product” was introduced at the University of Michigan in 2003 (Grieves, 2019; Opoku et al., 2021). However, within the scope of the current industrial revolution (industry 4.0), the increasing use of trends such as cloud computing, predictive maintenance, 3d printing, and smart sensors in the manufacturing, defense and space industries accelerated the introduction of the DT concept into our lives. Pan and Zhang (2021) states that a great impact on the rapid growth of interest in digital twins is caused by the work of the National Aeronautics and Space Administration (NASA) aimed at continuously simulating, predicting, and evaluating spacecraft condition, reducing vehicle errors. In general terms, the DT concept is a provision of uninterrupted and bidirectional data flow between a physical entity and its virtual representation. Accordingly, the three main elements that make up the digital twin: the physical entity in the real world, its virtual counterpart in the virtual world, and the data collection that connects both. DT receives the data from the physical entity and applies it to the virtual model. In this manner, a digital twin enables the cyber part of a cyber-physical system to be managed by assisting decision-making and giving functions for real-time prediction, development, monitoring, and control of the physical asset (Camposano et al., 2021). In the literature, presently, it has been revealed that there are DT applications to all life-cycle phases of construction projects except the demolition and recovery phase (Opoku et al., 2021). A variety of data-related, high-fidelity modeling, and simulation technologies are needed for the implementation of DT (Opoku et al., 2021). Building Information Modeling (BIM), Internet of Things (IoT), Artificial Intelligence (AI), Smart Contracts, Blockchain, Augmented Reality (AR), and Virtual Reality (VR) can be cited as examples of these technologies and concepts that support digital twin and offer different advantages from each other. The required data is produced with a series of sources like RFID tags, sensors, gauges, unmanned aerial vehicles and drones, laser scanners, cameras, etc., and in different types of formats.

With this background, the purpose of this paper is to create a guide by examining the literature on the DT concept, and its associated technologies from a construction management perspective for those who will work on digital construction management. Thus, the current applications of DT, the potentials and benefits it offers directly and indirectly have been revealed.

Methodology

A comprehensive literature review was conducted to examine in detail the existing studies on digital twin and its applications. Scopus was chosen as the database because it has a wider scope and provides access to newer publications (Opoku et al., 2021). Title-Abstract-Keywords filtering in Scopus' advanced search engine was used with 2 separate parts. The first and changing part was "digital twin" or its practices such as "artificial intelligence OR ai", “internet of things OR iot" etc., while the second and unchanged part was "construction management" for every search run. The papers obtained in the search results that are not related to the construction industry were eliminated. The remaining relevant papers were read by categorizing them according to DT and its practices. Finally, the current status, potentials, and benefits offered to construction management for each practice were compiled.

Literature Review of Digital Twin Practices from Construction Management Perspective

Building Information Modeling (BIM)

BIM is a methodology of using a digital 3D representation of a structure to simplify construction processes from design to maintenance. BIM, which increases efficiency by managing information in a digital environment and allows more than one discipline to work together, has been frequently studied in the literature in the last 20 years due to the many opportunities it provides. The development of BIM standards, the research of formats in which information will be exchanged, and the continuation of the examination of real projects are constantly improving BIM technology (Jiang, 2021). Working as a dataset of a digital model, the system provides a reliable basis and source of information for decisions to be made throughout its lifecycle. Unlike 2D drawings, the approach to the building takes place as a combination of building components such as walls or windows. Before actually building the structure, it is aimed to prevent conflicts by establishing a simulation environment where different disciplines work together, strengthen communication by keeping project stakeholders on the same page, and enable the development of the project by testing real-life events and conditions. Considering that 3D is only a geometric dimension, BIM models with added data such as time, cost, energy or facility information have dimensions from 4D to 7D according to the data they have. These data determine how much benefit the BIM model can provide in construction management. For example, Agostinelli et al. (2019a) have shown that when the concept of time is treated as the fourth dimension, BIM technology can prevent waste of time, materials, and resources and improve adherence to the schedule by enabling better risk management. The use of a 5D model makes it possible to uncover and analyze costs and alternative scenarios, allowing for more precise material, labor, and resource estimation as well as cost control and planning (Agostinelli et al., 2019a). It has been revealed in the literature that BIM provides efficient processes by providing better information management to the site, project team, and stakeholders in every phase of the project, increases coordination, productivity, quality, safety, and energy efficiency (Goyal et al., 2020; Liu, 2021; Ma et al., 2020; Michalski et al., 2021; Onungwa et al., 2017; Sepasgozar et al., 2021). Many construction management topics such as risk, cost, quality, time, etc. are related to each other and these benefits reveal positive outputs with BIM.

Internet of Things (IoT)

The concept of IoT represents the network in which physical objects (mechanical or digital tools, living beings, or objects etc.) supported by sensors and by technologies such as software and data processing are connected and exchanged data via the internet or other connection/communication types. Administration and examination of multi-source data collecting, automated monitoring, and predictive warning can be given as examples of usage purposes (Han et al., 2020). Gaining importance with the technological possibilities in the 21st century, IoT facilitates processes in many industries, even in our homes and cars, with the uninterrupted communication offered by interconnected objects. The development of Artificial Intelligence (AI) and other technological possibilities has enabled it to be tried as a solution for different purposes and quickly popularized (Liang et al., 2021). As Zhang et al. (2022) have shown us, IoT continues to be studied for many disciplines as well as for construction, to support and facilitate management processes. The fact that IoT resources

provide instant and real data can improve the monitoring of almost every preferred construction element and make it easier to manage. In addition, to enhance it, new positive outcomes may emerge by working together with technological processes such as BIM and GIS (Han et al., 2020; Qian, 2021). With the use of IoT in steel structures, it is possible to monitor the heat, environmental, and health status of the structure, thus making it safer to use, and improving operation and management processes (Liu et al., 2020). With the help of RFID systems, Yu et al. (2019) were able to provide information management of the precast elements to be used in a metro construction through information collection, production management, transportation, and application processes, and provided the necessary data for the quality improvement and maintenance stage. In addition, it has been examined in the literature that working with technologies such as BIM, in which IoT is integrated, contributes to many construction management areas such as maintenance and repair, safety of workers and work-site, inventory management with equipment, material and worker monitoring, and it has been revealed that it increases construction management efficiency by reducing waste generation while increasing productivity (Han et al., 2020; Oke et al., 2020; Qian, 2021; Reinbold et al., 2019).

Artificial Intelligence (AI)

Although its roots date back to the 1940s, AI, which is still one of the most puzzling computer science topics of today, was coined as a term for the first time by John McCarthy at the conference held on the subject in 1956. AI is the ability of a computer or computer-controlled robot to perform and simulate the processes or tasks that human intelligence is related to. The main expected benefit of AI is that it reduces the workload on tasks that require time for a human to think, calculate and control. AI uses a wide range of disciplines applicable to the construction industry such as automation, deep learning, machine learning, robotics, and decision trees (Hooda et al., 2021). Nguyen (2021) defined machine learning as a system that learns from data and mentioned that the quality improvement of the information management system and more precise cost estimation can be made by machine learning in the construction industry. In addition, machine learning and deep learning make it possible to fully automate the processing of data from devices such as robots or UAVs to enhance life-cycle management processes (Jang et al., 2021). If we consider that the main purpose of project management is to maximize quality while minimizing time and cost, for overall improvement (Aziz et al., 2014) developed a smart optimization model named "Smart Critical Path Method System" using AI to support balance between construction time, cost and quality for the decision-makers. Hooda et al. (2021) have compiled the most important applications of AI in the construction industry; (1) Decision making using the parameters of project characteristics, risk, environment and organization, location and workers with artificial neural network (ANN), (2) sticking to the project plan from concrete production to handover with the aid of robotic and machine learning, (3) structural health monitoring with ANN, and (4 and 5) real-time monitoring and smart city opportunities with AI-IoT cooperation. In addition, it has been seen that costs can be controlled more easily with precise looking, more precise forecasts and risk analyzes with ANN (Cao et al., 2021; Nguyen, 2021). Many AI applications have been presented in the literature to increase project quality and productivity, make the construction site safer, and support project managers in decision-making (Alheeti & Aldaiyat, 2021; Wang & Hu, 2022).

Virtual Reality (VR)

VR is a technology that allows users to experience a computer-generated and simulated environment. The virtual environment with realistic scenes and objects, grants users perceptions like vision, hearing, and smell to provide an immersive experience (Xu, 2021). Currently, this environment can be provided with wearable devices called VR Headsets or multi-screen digital rooms. At first, VR became popular in the gaming and entertainment industries, but its entry into the architecture, engineering, and construction (AEC) industry did not take long since the discovery that VR applications allow better visualization and simulation of various scenarios (Pour Rahimian et al., 2020). VR technology, on its own or in combination with model-supporting technologies such as BIM, can act as a guide for better construction management. Allowing users to experience a project that has not yet been built, VR enables the visualization of project design, construction plan, schedules and different activates, thus, helps to spot potential risks, optimize processes, create design prototypes, and facilitate communication between stakeholders (Ozcan-Deniz, 2022; Pour Rahimian et al., 2020). The created virtual environment accelerates material, manpower, and financial resource and time-consuming processes by providing a training field for safety practices or applications such as HVAC and a vision for hard-to-reach areas (Ozcan-Deniz, 2022; Wang, 2021; Xu, 2021). Furthermore, continuing to review the literature from a construction management perspective, Shojaei et al. (2021) state that, this technology improves decision making and productivity while reducing on-site injuries. It has been revealed that VR technology directly contributes to areas such as quality management, cost management, safety management, time management, and logistics management and has a positive effect on Key Performance Indicators (KPIs), which are the outputs of these areas (Bhadaniya et al., 2021; Dallasega et al., 2020; Ghanem, 2022; Zhong & Hao, 2014).

Augmented Reality (AR)

AR refers to an enhanced version of the real physical world through technologies that bring computer-generated objects such as visual elements and sounds, into the user's physical environment. As with VR, smart devices such as mobile apps and headsets are used to support the users' AR experience. Different from VR, to improve the experience, augmented reality overlays virtual data on top of the real and physical world. At its core, AR strengthens understanding by providing detailed visualization of plans or any elements in the construction industry. In the literature, it is stated that there is an increasing interest in AR in the AEC industry and examples of application areas such as education, damage measurement of buildings, risk management, energy control, facility management, synergic site visualization (i.e., tracking or determining the position of the components behind the finished wall), site planning, examining the consistency of what is planned and built and equipment operation are given (Karji et al., 2017; Kim & Irizarry, 2021; Pour Rahimian et al., 2020; Rohani et al., 2014). Improving the visualization, it provides more understandable 3D project data, and sharing this data with stakeholders over the internet creates a more efficient and easier construction management system (Bhadaniya et al., 2021; Kim et al., 2011; Zhong & Hao, 2014). Thus, information such as quality, safety, and process monitoring can be monitored live. In addition, allowing to investigate possible scenarios, these visualization and simulation methods allow AEC professionals to prevent potential conflicts, detect clashes and construction defects in the pre-construction stage, and export quantities from the model (Rohani et al., 2014; Tayeh & Issa, 2020). Thus, a shorter construction time is ensured (Dallasega et al., 2020). AR applications are applied not only in the construction phase, but also in the design, procurement, and maintenance phases (Rankohi & Waugh, 2013). It facilitates decision-making by visualizing care data, enabling faster and more accurate

information sharing, and saving time by accelerating results (Chung et al., 2021). Moreover, Mirshokraei et al. (2019) stated that it offers a better quality management environment by revealing that AR reduces delays, improves quality, provides cost control, and strengthens communication between parties.

Smart Contracts and Blockchain

A smart contract is a computer program that, under specific circumstances, executes the terms of a contract between the parties. Smart contracts execute exactly as they are coded. Working with the if/then concept, SC is coded to follow or execute the next action when a task is completed (Owusu et al., 2020). Smart contracts are connected to a blockchain to keep track of the pertinent data for each user within the network. Users no longer have to rely on a centralized system for their exchanges and transactions, and a decentralized chain is created as a result. Blockchain is a secure distributed file system in which a chain of nodes rather than a single one controls communication between nodes (Darabseh & Martins, 2020). Three characteristics of the Blockchain are summed up by Turk and Klinc (2017): (1) the content is chained across several devices; (2) the chained data cannot be changed and (3) the copies across various sources are identical. And the 6 characteristic features according to (Lin et al., 2021) are: (1) openness; (2) anonymity; (3) safety and reliability; (4) immutability; (5) traceability, and (6) automated information processing. Blockchain technology can advance the digital twin concept by enhancing the transparency of the digital construction industry, data, and communication (Ni et al., 2021). Of course, by enabling a more secure data flow. One of the 7 categories in Li et al. (2019) study, which deals with the built environment applications of blockchain, is construction management. After 2 years, the authors reviewed the literature with 153 sources and listed the construction applications of blockchain and smart contracts as follows: information management, payments, procurement, supply chain management, regulations and compliance, contract management and delivery, dispute resolution, and technological systems (Li & Kassem, 2021). In addition, managerial problems such as data insecurity, delayed payments, poor collaboration, low data quality, and overall project quality can be eliminated with blockchain (Lin et al., 2021; Wahab et al., 2022). When DT applications such as BIM and IoT are integrated with blockchain, it has been shown to have great effects on construction applications such as reduced rework, cost reduction: reliable data monitoring (i.e., air quality), better information sharing, increased trust, strengthened procurement and supply chain activities, automated facility management, traced changes, better data ownership, automated payment (Darabseh & Martins, 2020; Li et al., 2019; Turk & Klinc, 2017).

The Contribution and Use of Digital Twin Practices to Construction Management

In the previous titles of the research, BIM, IoT, AI, AR, VR, and Blockchain practices were examined within the framework of construction management, and their potential, status, and benefits were gathered together by reviewing the existing literature. In the light of the research and the data obtained, in Table 1, the critical problems and main topics of Construction management and the corresponding digital twin applications are brought together. Although the number of proven case studies and DT projects is limited, it has been revealed that DT can be applied in the design, construction, or operation & maintenance

phases of the construction project and provide a variety of benefits, depending on the technology added and the level of data collected.

Table 1. The relevance of digital twin practices to construction management.

Construction Management Related Topics and Technics	DT Practice(s)	References
Alternative Scenarios and Estimations	AI, BIM, VR	(Agostinelli et al., 2019a; Cao et al., 2021; Hooda et al., 2021; Nguyen, 2021; Pour Rahimian et al., 2020)

As the Digital Twin concept increases and diversifies the data flow with the help of various technologies and practices it offers, it has been seen that it also reveals, diversifies and multiplies the benefits that may correspond to many critical keywords of construction management.

Conclusion

This research reviewed and analyzed the current applications of technologies and concepts that the digital twin will bring to the construction industry. To serve as a guide for those who want to work in the field of digital construction. By examining its practices under separate headings, the benefits that emerged when they worked alone or in pairs were analyzed in the light of current literature. However, when these results are put together, it has been revealed

that DT practices, which have so far been studied singly or in pairs in construction practice and academia, can improve construction management more broadly in response to more problems if they work together and with more data. With an overview, digital twin concept facilitates the decision-making processes, which is the main element of construction management, by offering much faster and more efficient monitoring. Also, a strong positive effect has seen on the project management triangle (cost, time and scope within quality needs) by allowing to simulate and traceability of each desired element in the construction environment enables cooperation and better communication between the parties involved. Thus, it has been demonstrated that it can be a tool for the goal of better construction management that can eliminate the low efficiency and lack of productivity faced by the construction industry.

Investigation of BIM Perception in Metro Projects

İ. Akgüneş Ahmed and E. Ergen Pehlevan
İstanbul Technical University, Department of Civil Engineering, İstanbul, Turkey
akgunes@itu.edu.tr, esin.ergen@itu.edu.tr

Abstract

Building Information Modelling (BIM) has led to technological and procedural shift within the construction industry. Since 2015, BIM has been made mandatory in metro projects in Istanbul. BIM adoption and implementation involves key components, including the perceptions of the professionals according to which BIM can either be adopted or rejected. This study aims at presenting professionals' perception on BIM from numerous aspects as revealed in six real-life metro projects based in İstanbul to comprehend in what ways the implementation has affected the work practices, future expectations and barriers. To achieve the aim of the study, two survey studies are conducted among the professionals working in the metro projects in Istanbul. The first study surveyed 279 professionals of all technical staff involved, and the second study surveyed 164 professionals, who are actively using BIM in their day-to-day tasks. This paper presents the similarities and differences of BIM perception between these groups in terms of different profile characteristics of the participants (i.e., age, organization). The study argues that working on BIM-based projects is becoming less challenging and the expectation and understanding of BIM varies from one stakeholder to another.

Keywords: *BIM, BIM adoption, building information modelling, metro projects.*

Introduction

Management of the digital essential aspects of building design and project data has resulted in the emergence of numerous methodologies that rely on certain interacting policies, processes and technologies including Building Information Modelling (Penttia, 2006). Building Information Modelling (BIM) within the Architecture, Engineering, Construction and Operations (AECO) industry is a potential development that has lately gained more attention (Barlish & Sullivan, 2012; Charef et al., 2019). Adoption of BIM is a relatively new area, and it presents its own set of challenges for the AECO industry (Charef et al., 2019). Similar to many other developing countries, BIM implementation remains challenging for the Turkish construction industry.

BIM experience in the construction sector indicates the application of BIM in various domains, and it may be utilised to guide the early phases of BIM growth in the infrastructure field (Shou et al., 2015). Particularly in developed countries, there have been several studies on the use of BIM (Eadie et al., 2015; Chong et al., 2016; Li et al., 2017; Zhang et al., 2020). Likewise, in developing countries, there have been studies conducted regarding the BIM

implementation (Masood et al., 2014; Elyamany, 2016; Hanafi et al., 2018; Al-Ashmori et al., 2020). They emphasize the advantages, disadvantages, critical success factors, and, in particular, the lessons acquired through case studies. As a consequence, all of these research studies enable us to recognize the existence of various levels of adoption around the world.

The applications of BIM are not limited to buildings and are applied within infrastructure projects. The majority of previous BIM studies have mostly focused on buildings, with only a few studies covering the adoption and usage of BIM in infrastructure projects (Chong et al., 2016). Since 2015, BIM has been made mandatory in metro projects in Istanbul. In order for an implementation to be successful and in contrast to the comprehensive application, a thorough understanding of the current state of BIM should be considered (Kim et al., 2016). Despite the fact that BIM has been in use for seven years on several metro lines with various stakeholders, such knowledge has yet to be assessed. Due diligence must be performed on the adoption and execution of completed projects. BIM adoption and implementation involves key components including the perceptions of the professionals according to which BIM can either be adopted or rejected. This study aims at presenting professionals' perception on BIM from numerous aspects as revealed in six real-life metro projects based in İstanbul to comprehend in what ways the implementation has affected the work practices, future expectations and barriers.

Research Methodology

In this study quantitative research method is used. Two survey studies are conducted among the professionals working in the metro projects in Istanbul. The first study surveyed 279 professionals of all technical staff involved, and the second study surveyed 164 professionals, who are actively using BIM in their day-to-day tasks. The metro projects that are covered are Kabataş-Mecidiyeköy-Mahmutbey, Ataköy-İkitelli, Dudullu-Bostancı, Ümraniye-Göztepe-Ataşehir, Çekmeköy-Sultanbeyli, Kaynarca-Pendik-Tuzla metro line projects in İstanbul, Turkey.

A simple random sampling is used for survey 1 to represent the overall population's viewpoint by providing participants equal odds of being picked from the population of metro projects (Kish, 2004). The first survey is administered to professionals who work as technical staff on metro projects and are not among the responders of the second survey. A purposive sampling method is used for survey 2 to obtain the opinions of competent persons that are actively using BIM. The second survey is administered to professionals who are constantly working with BIM to perform one of the following activities; design authoring, design documents creating, design reviews, cost estimation (quantity take-off), record modeling, site utilization planning, digital fabrication, construction system design, 3D coordination, engineering analysis-energy, engineering analysis-structural, phase planning (4D modeling), sustainability evaluation and existing conditions modeling. Surveys were administered over a 3-month period using Google Forms and an online link sent to participants. 757 experts from six metro projects were contacted for survey 1 and 229 professionals were reached out for survey 2. In survey 1, 279 professionals responded, yielding a 37% response rate, while for survey 2, 164 responses were received, yielding a 72% response rate. The response rate for surveys should be at least 35-40%; and as the response rate for both sample techniques is greater than that, the criteria was satisfied (Baruch et al., 2008).

On a five-point Likert scale, survey respondents are required to score their perceived BIM usage, how the adoption has influenced work practices, future expectations, and barriers. In the scale, 1 refers to “Strongly Disagree”, 2 refers to “Disagree”, 3 refers to “Neither agree nor disagree”, 4 refers to “Agree” and 5 refers to “Strongly Agree”. The data collected from the surveys were analyzed and the findings are triangulated.

Data Analysis

The Likert-type data demonstrated within the surveys are analyzed by using the IBM® Statistical Package for Social Sciences (SPSS®) version 27. The normal distribution test was used. In this study the Shapiro-Wilk normality test has become the preferred test because it is a precise test for normality whereas the Kolmogorov-Smirnov Test is more general but less effective (Mendes & Pala, 2003). The Sig. value of the Shapiro-Wilk Test for surveys data is less than 0.05, indicating that the data deviates considerably from a normal distribution. Since the study's data were ordinal and did not have a normal distribution, non-parametric tests were performed (Mircioiu & Atkinson, 2017). These were; 1) the Kruskal-Wallis, 2) the Mann-Whitney U test, 3) the Kendall’s concordance analysis, 4) Spearman's rank correlation test.

Kruskal Wallis H Test is performed to discover inferences within the data since such is judged an adequate statistical mean to compare three or more groups (Kruskal & Wallis, 1952). In other words, it is carried out in order to evaluate the examined phenomenon if it varies according to participant profile parameters. The Kruskal-Wallis H test is a non-parametric variant of ANOVA and it is a modified version of the Mann-Whitney test since it allows for the participation of two or more groups. In this study, the significance threshold is set at 0.05. (Ostertagova et al., 2014). The basic premise is that the null hypothesis (H0) can be rejected if the estimated p-value is less than the allowable significance threshold (e.g., 5%).

Mann-Whitney U test is used to evaluate statistically significant differences or divergences between the median values of the same item between two different respondent groups (Kasuya, 2001). The Mann-Whitney U test is used on the responses in this study, which demonstrates discriminating qualities according to the Kruskal-Wallis H test. The basic premise is that if the computed ρ-value is less than the acceptable significance threshold (e.g., 5%), the null hypothesis (H0), which states that there are no significant variations in the median values of the same item between the two respondent groups, can be rejected (Chan et al., 2010). In the study, the significance level is set at 0.05.

Kendall’s coefficient of concordance test is used to assess respondents' agreement on the examined phenomenon within each respondent group (Legendre, 2005). In this study, consensus among organizations-client, construction manager, designer, contractor-, was investigated. Kendall's coefficient of concordance has a dimension ranging from 0 to 1. The greater the value of the coefficient, the greater the level of agreement among survey respondents within the group (Chan et al., 2010). Because there were more than seven items, the $\chi 2$ test was applied.

Spearman's rank correlation test is used to assess the strength of a relationship between two groups (Chen & Popovic, 2002). In this study it is applied to see if there was a statistically significant association between the age variable and the responses to the research questions. Spearman's rank correlation coefficient (rs) has a dimension ranging from -1 to 1. The greater the coefficient value (positive or negative), the stronger the positive or negative linear

association (Schober et al., 2018). There is no linear association if rs = 0. (Chan et al., 2010). The basic premise is that if the estimated ρ-value is less than the allowable significance threshold (e.g., 5%), the null hypothesis (H0), which states that there are no significant differences in ranks between the two groups, can be rejected (Chen and Popovic, 2002).

Results and Discussion

The survey results are presented at Table 1. This study demonstrates that BIM is being heard more and more, and according to the majority of the professionals in metro projects it is the future's project management system (survey 1;78% (median=4); survey 2;91% (median=5)). The item "The industry is not clear enough on what BIM is yet" had the highest (strongly agree/agree) agreement in Survey 1 with 84% (median=4). On the same item, 90% (median=5) of survey 2 respondents strongly agree/agree. Results from both surveys show that the majority of specialists say that the industry's concept of BIM remains ambiguous.

Survey respondents indicate that with the help of BIM, they face far fewer problems in the field. This benefit was further emphasized among survey 2 respondents. However, the participants state that the design process takes longer due to BIM. This negative effect was emphasized more by survey 2 participants (strongly agree/agree; 56%) than by survey 1 participants (strongly agree/agree; 28%). Professionals who have responsibilities in their daily work related to BIM and therefore use it more, have different evaluations as they experience BIM more in their work. Organizational structure to support BIM within the company is one of the critical success factors for implementation (Morlhon et al., 2014; Tsai et al., 2014; Ozorhon and Karahan, 2017; Chan et al., 2019). Although many studies have noted that one of the most evident advantages of BIM is its ability to accelerate up and simplify the design process (Yan & Damian, 2008; Barlish & Sullivan, 2012), the reason why the design takes longer is that while the project outcomes are delivered by meeting BIM requirements, a new design processes are not developed, and the necessary durations are not allocated for project delivery. Operations continue as in the traditional method although BIM requirements demand a change in how professionals work. Furthermore, the item "Much more difficult to work on BIM-based projects" has the largest (disagree/strongly disagree) disagreement, with 51 percent for survey 1 (median=2) and 73 percent for survey 2 (median=2). Majority of experts believe that working on BIM-based projects is no more difficult. Working on BIM-enabled projects is not perceived as more difficult by professionals than working on non-BIM-enabled projects.

As a result of the Kruskal-Wallis H Test, it can be concluded that the questions with a significance level (Sig.) of less than 0.05 differ based on organizations of the participants (Table 2).

Table 1. Frequency distribution.

n	Statements	Survey 1 Frequency (%)					Median	Mode	Survey 2 Frequency (%)					Median	Mode

Table 2. Kruskal-Wallis H test results.

n	Statements	Survey 1	Survey 2
1	You hear more and more about BIM these days	0.000*	0.656
2	BIM is the future of project information	0.028*	0.23
3	The industry is not clear enough on what BIM is yet	0.902	0.000*
4	I think BIM will be used in all projects in the medium term	0.312	0.298
5	I think BIM will be mandatory in public projects in the near future	0.062	0.000*
6	Design process takes longer due to BIM	0.000*	0.021*
7	With the help of BIM, we face far fewer problems in the field	0.000*	0.647
8	BIM-used projects are more difficult to manage	0.001*	0.000*
9	Much more difficult to work on BIM-based projects	0.000*	0.000*

The Kruskal-Wallis H test determines which questions have a significant difference based on profile characteristics, but it does not determine which groups vary from the others. The Mann-Whitney U test was used to assess whether groups had differences in the questions for which a significant difference was identified based on the participants' organizations (Table 3 and Table 4). The client's acceptance of the use of BIM in their projects is among the three most significant critical success factors in the implementation of BIM (Tsai et al., 2014; Chan et al., 2019). Working on BIM-based projects is more challenging for the client group than for the construction manager group. This result reveals the need for more competent professionals about BIM for client in the projects. Because the implementation process is still new and there is a great need for client guidance, standardization, establishment of procedures and identification of needs (Abubakar et al., 2014; Rogers et al., 2015).

Construction managers and contractor group experts placed a greater emphasis on "BIM will be necessary in public projects in the near future" than client groups. The reason for this is because the client group professionals, who are IMM specialists in this project, believe that the industry is not yet ready for this. Public bodies are reluctant to accept BIM and resistant to change. Similarly, construction managers and contractors place higher emphasis on the statement "The industry is not clear enough on what BIM is yet" than the client group.

When compared to client and construction manager group professionals, designers claim that the design process takes longer owing to BIM. Designers naturally perform more modeling than that of in the prior procedure. This increases their workload and results in longer design timelines in the short term, however, it saves them more time in the long run (Barlis & Sullivian, 2012; Charef et al., 2019). However, it appears that they are still getting adjusted to this circumstance. On the other hand, the employers and construction managers can spot problems more readily and present alternate designs from the designer in less time.

Project management with BIM is more challenging for the designer than for the client, construction manager, and contractor groups. Project management using BIM is more challenging for the contractor than for the construction manager group. The reason for this is because BIM procedures in projects are not yet developed. It is expected that the designer will handle all aspects of BIM in the projects. On the other hand, unclarified demands from the client and construction manager in terms of contractual and project BIM procedures put more pressure on the designer and contractor than that of in the prior system. Furthermore, in order to meet the needs of the clients and the construction managers, they must train specialists and resolve challenges.

Working on BIM-based projects is more challenging for the designer group than for the construction manager and client groups. Designers are allocated more throughout the project's design phase, and they are the team that creates the model in the first place, as opposed to other groups. More than construction managers and contractors, designers believe BIM is the project management system of the future. Designers that are increasingly involved with BIM implementation want to use it in their new projects as well.

According to client group professionals, they meet considerably less challenges in the field with the use of BIM than construction managers and contractor group professionals. This demonstrates that, according to the client, the last stakeholder to whom the outcomes of the BIM process are conveyed, the adoption of BIM has resulted in fewer difficulties in the field.

Table 3. Mann-Whitney U test results, survey 1 (organization vs organization).

n	Item		Organization group pairs	N (gr.1/gr.2)	Mean Rank (gr.1/gr.2)	Mann-Whitney U	Z-value	p-value	Conclusion to Ho

Table 4. Mann-Whitney U test results, survey 2 (organization vs organization).

n	Item		Organization group pairs	N (gr.1/gr.2)	Mean Rank (gr.1/gr.2)	Mann-Whitney U	Z-value	p-value	Conclusion to Ho
5	I think BIM will be mandatory in public projects in the near future	1	Client/Construction manager	41/37	29.09/51.04	331.5	-4.547	0,000*	Reject
		2	Client/Contractor	41/43	33.84/50.76	526.5	-3.369	0,001*	Reject
3	The industry is not clear enough on what BIM is yet	1	Client/Construction manager	41/37	31.05/48.86	412	-3.89	0,000*	Reject
		2	Client/Contractor	41/43	34.93/49.72	571	-3.064	0,002*	Reject
6	Design process takes longer due to BIM	1	Client/Designer	41/43	35.46/49.21	593	-2.669	0,008*	Reject
		2	Construction manager/Designer	37/43	33.24/46.74	527	-2.681	0,007*	Reject
8	BIM-used projects are more difficult to manage	1	Client/Designer	41/43	34.91/49.763	570.5	-2.882	0,004*	Reject
		2	Construction manager/Contractor	37/43	33.81/46.26	548	-2.58	0,010*	Reject
		3	Construction manager/Designer	37/43	28.03/51.23	334	-4.666	0,000*	Reject
		4	Contractor/Designer	43/43	37.29/49.71	657.5	-2.375	0,018*	Reject
9	Much more difficult to work on BIM-based projects	1	Client/Construction manager	41/37	46.34/31.92	478	-3.075	0,002*	Reject

Designer group professionals also report less issues in the field when using BIM than construction manager and contractor group professionals.

The value of Kendall's coefficient of concordance (W) for all respondents, according to organizations, is shown in Table 5. The null hypothesis should be rejected since the levels of significance for all of the groups are less than the acceptable significance level (5%). The findings give adequate evidence to indicate that the respondent's sets of question rankings are interdependent, with a significant degree of agreement within each group.

Age variable's normality distribution is examined and no normal distribution is detected since the Shapiro-Wilk p-value is $p=0.000<0.05$. There was no statistically significant difference between the age variable and responses in survey 1 ($p>0.05$). On the other hand, for survey 2, the age variable has a statistically significant relation with items 3 and 4. Item 3 and 4 had significance levels of 0.034 and 0.045, respectively, which are lower than the permitted threshold of significance (0.05). As a result, the null hypothesis must be rejected. There is a statistically significant, negative relation between 3 and 4 items and the age variable at a weak level ($r3=-0,165<0.2$; $r4=-0,157<0.2$; $p<0.05$). According to younger respondents, who are more hopeful than older respondents, BIM will be employed in all projects and will become essential in the near future.

Table 5. Kendall's coefficient of concordance test results.

	Organizations	N	Kendall's W	Chi-square	df	p-Value	Conclusion to Ho
Survey 1	Client	23	0.475	87.34	8	0.000	Reject
	Construction Manager	112	0.463	414.55	8	0.000	Reject
	Contractor	91	0.24	175.08	8	0.000	Reject

	Contractor	43	0.419	324.21	18	0.000	Reject
	Designer	43	0.291	224.97	18	0.000	Reject

Conclusions

This study presented professionals' perception on BIM from numerous aspects as revealed in six real-life metro projects based in İstanbul to comprehend in what ways the implementation has affected the work practices, future expectations and barriers. Different perspectives are presented based on professional's organizations. The study argues that working on BIM-based projects is getting less challenging, and stakeholders' expectations and knowledge of BIM varies based on their BIM utilization and changes in their processes.

The study confirms that with the help of BIM, professionals face far fewer problems in the field. However, the designers claim that the design process takes longer due to BIM compared to the clients and construction managers. The reason for this is that while the project outcomes are delivered by meeting BIM requirements, new design processes are not developed, and the required durations are not allocated for project delivery. Operations continue as in the traditional method although BIM requirements demand a change in how professionals work. And also, it is revealed that working on BIM-based projects is more challenging for the designers than for the construction managers and clients since designers

are assigned more detailed BIM-related tasks throughout the project's design phase as opposed to other groups, and they are the team that creates the model in the first place.

Similarly, project management with BIM is more challenging for the designer than for the client, construction manager, and contractor. Also, project management using BIM is more challenging for the contractor than for the construction manager. The reason for this is that operational BIM procedures in projects are not yet fully developed. It is expected that the designer will handle all aspects of BIM in the projects and unclarified demands from the client and construction manager in terms of contractual and project BIM procedures put more pressure on the designer and contractor than that of in the prior system.

Furthermore, the study reveals that working on BIM-based projects is more challenging for the client group compared to the construction manager group which points out the need for more competent professionals about BIM for client in the projects. And the implementation process is still new and there is a great need for client guidance, standardization, establishment of procedures and identification of needs.

Client group professionals meet considerably less challenges in the field with the use of BIM than construction managers and contractor group professionals. This demonstrates that, according to the client, the last stakeholder to whom the outcomes of the BIM process are conveyed, the adoption of BIM has resulted in fewer difficulties in the field. Designer group professionals also report less issues in the field when using BIM than construction manager and contractor group professionals.

As per the majority of professionals, the study highlights that the industry's concept of BIM remains ambiguous since it is agreed that the industry is not clear enough on what BIM is yet. However, BIM is becoming increasingly used in the industry, and according to the majority of specialists, it is the project management system of the future.

Challenges of BIM Implementation in Airport Projects

A. Karacigan and B. Ozorhon
Bogazici University, Department of Civil Engineering, İstanbul, Turkey
ahmet.karacigan@boun.edu.tr, beliz.ozorhon@boun.edu.tr

Abstract

Digitalization forces the Architecture, Engineering and Construction (AEC) industries to change, and adapt new technologies that intensely affect the traditional way of collaboration in projects. Among these technologies, Building Information Modeling (BIM) is one of the most predominant by enabling project parties to collaborate within a shared environment that includes the entire project data. AEC companies spend massive amounts of resources on BIM implementation and encounter many challenges. Due to their large scale and complexity, BIM implementation in airport projects is critical. The main objective of this paper is to investigate the barriers to the BIM implementation process in airport projects. In this respect, a comprehensive literature review has been conducted and a total of eleven barriers were identified; six at the industry, one at the firm, and four at the project level. Interviews were conducted with the construction professionals to analyze the BIM implementation process in four airport projects. The findings of the study revealed that the top three barriers are; the fragmented nature of the industry, project specific problems, and collaboration problems. This research is expected to facilitate the BIM implementation process in the AEC industries and guide the industry professionals on the most significant barriers to focus on.

Keywords: *airport projects, building information modeling, challenges, construction industry.*

Introduction

In the recent years, construction projects have become more complicated and demanding. This situation puts an emphasis on the new technologies regarding the project management approach and the tools to be utilized. Building Information modeling (BIM) is one of the most fascinating technologies in the Architecture, Engineering, and Construction (AEC) industries. AEC companies are in a transition process to keep pace with the digitalization of the industries and seek to develop BIM capabilities for competitive advantage (Eastman et al., 2011).

BIM represents not only the physical components of the building but also the construction process with the cost and time aspects and the facility management process with sustainability and maintenance aspects (Ozorhon & Karacigan, 2019). BIM is proven to be an effective tool that strengthens knowledge, and communication and advances information sharing within the risk management processes (Kaya et al., 2020). BIM has been defined as a crucial technology for the project lifecycle that may substantially influence a project's lifecycle (Kaewunruen & Lian, 2019). In the literature, it has been stated that improved quality, reduced duration and

costs, and increased collaboration are among the benefits of BIM implementation in the AEC industries (Olawumi & Chan, 2019).

Consequently, BIM implementation has reached a new level across the globe. NBS (2021) reported that the BIM adoption rate in 2021 was 71% globally. During the BIM adoption process, AEC companies spend massive amounts of resources and encounter various challenges. These challenges cause slowness in the adoption of innovation and prohibit BIM to be fully functional (Ozorhon & Karahan, 2016). In order to enjoy the full benefits of BIM, the barriers in front of the implementation should be identified and eliminated.

Mega projects in construction are naturally complex, large scaled, and involve multiple parties which increase the chance of failure (Akcay, 2022). Hence, implementing new technologies such as BIM in mega projects is much more important than a regular construction project. Airport projects are a good representation of mega construction projects since they involve complex systems that require innovative solutions.

In order to ensure a seamless BIM implementation in airport projects, challenging factors need to be identified. This study aims to investigate the barriers to the BIM implementation process in airport projects at three different levels including the project, company, and industry levels. In this respect, a systematic literature analysis has been conducted to identify the challenging factors. A total of eleven barriers were identified; six at the industry, one at the firm, and four at the project level. The identified barriers have been examined on four different airport projects and evaluated via the interviews that were held with professionals from these projects. Distinguishing the barriers based on their influence levels will help the professionals to identify the parties that are responsible for certain barriers and take remedial actions.

Research Background

BIM implementation has been investigated extensively within the literature. Various research focuses on different aspects of the BIM implementation process such as drivers, inputs, and enablers. However, there is also a vast of research on the challenging factors also called barriers.

A group of studies in the literature focus on the barriers against the BIM implementation process in a more general aspect. Based on a research study that analyzed four case projects, there are many barriers that keep project parties from using the most advanced technology including the risk of failure, high initial investment costs, the learning curve for the software, and lack of support (Migilinskas et al., 2013). In another study conducted by Dawood et al. (2012) to investigate the barriers and drivers of BIM, “time and cost”, “resistance to change” and “lack of experience” have been identified to be the biggest barriers to a successful process of BIM implementation.

Barriers to BIM implementation in South Australia have been examined in a study conducted by Newton and Chileshe (2012). The researchers argued that lack of understanding and awareness acts as a challenging factor for BIM implementation. Accordingly, Gerrard et al. (2010) reveal that lack of BIM knowledge and expertise is the greatest barrier. In business organizations, decisions are made with financial concerns by focusing on profits. It would be

hard to convince investors to implement BIM unless there is case study evidence about the financial benefits of BIM (Yan & Damian, 2008).

On the other hand, some research in the literature investigated the BIM implementation process for special cases such as the project's type, company's size, or the country where the project is being built. Olanrewaju et al. (2022) conducted a research study to investigate the barriers to BIM implementation in developing countries and collected data from 90 experts. The findings of the study showed that cost and standards, process and economy, technology and business, and training and people are the most critical barriers. In another study, researchers gathered perceptions of 228 companies (small and medium-sized enterprises (SMEs) and large firms) regarding the challenges of BIM implementation. The results showed that there is a general digital divide as regards to BIM implementation between SMEs and large firms (Saka & Chan, 2021). Akcay (2022) investigated the challenges of BIM implementation in mega construction projects and argued that lack of skilled staff and lack of knowledge were the major barriers.

Although numerous studies have investigated the barriers to BIM implementation, more research is required to clearly identify the challenging factors. In addition, there is no research that specifically focused on airport projects. Based on the research background provided, the current study aims to investigate barriers against BIM implementation in airport projects. To this end, an extensive literature review has been conducted and 38 research papers have been examined in detail. The barriers that are mentioned in the literature are noted and have been re-assessed and merged according to their similarities. In addition, barriers are grouped together according to their level of influence as; industry, firm, and project levels. The importance of the identified barriers is determined by examining four different airport projects. Interviews were held with industry experts, and they are asked to evaluate the factors based on a 1-5 Likert Scale. In addition, experts' opinions are gathered based on their own experiences.

Methodology

Barriers to BIM implementation are defined as the main challenges encountered during the implementation process which make the BIM implementation process complicated and risk its success. Based on this definition, a comprehensive literature review has been conducted to identify the barriers that are mentioned in the literature. A total of 38 research papers have been examined in detail and the factors that are matched with the previously determined definition are noted.

An initial list that consists of 35 barriers was created based on the literature review. The frequency of the identified barriers was counted to find how many papers have referred to each barrier. Following this, similar factors are merged or redefined under a more general name and irrelevant factors are deleted in order to refine the initial list of factors. As a result, the final list of barriers consisted of eleven factors which are defined as; "unavailability of knowledge based on experience", "unclear benefits", "lack of best practices", "high costs", "technology related problems", "change process problems", "legal & protocol problems", "fragmented nature of the industry", "collaboration problems among different parties", "project specific problems" and "lack of government support".

One of the objectives of this study was to distinguish the roles/responsibilities of the industry, companies, and project teams. For this purpose, different influence levels are defined as; industry level, firm level, and project level. The influence level of each barrier is determined, and the barriers are divided into three groups. The influence levels of the barriers are aimed to be logical and consistent with the literature. Table 1 elaborates the final list of barriers to BIM implementation in this study.

Table 1. The final list of barriers to BIM implementation.

No	Barriers to BIM Implementation	Influence Level	Source Number
1	Unclear benefits	Project	12, 14, 16, 17, 23, 24, 25, 27, 40
2	High costs	Project	4, 6, 7, 9, 10, 11, 12, 13, 14, 16, 17, 20, 23, 24, 25, 26, 27, 28, 30, 32, 40, 41, 42, 43, 44, 45, 46, 47
3	Collaboration problems among different parties	Project	3, 5, 7, 8, 9, 12, 14, 16, 17, 22, 24, 28, 30, 32, 38, 39, 43
4	Project specific problems	Project	3, 4, 5, 7, 8, 9, 10, 11, 12, 16, 17, 21, 22, 23, 24, 25, 28, 32, 41, 42, 43, 44, 45, 46, 47
5	Unavailability of knowledge based on experience	Firm	3, 6, 7, 8, 9, 10, 11, 12, 14, 16, 17, 20, 23, 24, 25, 26, 27, 28, 30, 32, 42, 43, 44, 45, 46
6	Lack of best practices	Industry	6, 10, 11, 12, 13, 14, 17, 21, 23, 24, 25, 26, 27, 30, 32, 36, 43, 44, 45, 46, 47
7	Technology related problems	Industry	3, 4, 7, 8, 9, 10, 11, 12, 13, 14, 17, 20, 21, 22, 23, 24, 25, 26, 27, 28, 30, 32, 38, 39, 41, 42, 43, 44, 45, 46
8	Change process problems	Industry	1, 3, 4, 7, 8, 9, 10, 12, 13, 14, 17, 20, 21, 22, 23, 24, 25, 26, 28, 29, 30, 32, 38, 40, 41, 42, 43, 44, 45, 46, 47
9	Legal & protocol problems	Industry	3, 7, 9, 10, 11, 12, 14, 17, 23, 24, 26, 28, 29, 30, 32, 36, 38, 40, 41, 42, 43, 44, 45, 46
10	Fragmented nature of the industry	Industry	7, 10, 12, 16, 22, 23, 30, 32, 41, 42, 46
11	Lack of government support	Industry	16, 23, 24, 43

Four airport projects have been selected as case studies to investigate the effect of challenging factors on airport construction projects in reality. The projects were chosen by considering some project specific factors such as location, size, budget, ownership, and purpose of BIM utilization. In addition to that, the interviewed companies were also chosen by considering the companies' role in the project, size, and BIM experience. The case projects were expected to represent a mixture of the mentioned project and company specific factors.

The first project had a total construction area of 12 Million sqm. The scheduled construction duration of the project was 24 months, and the general contractor was sole ownership. The project utilized BIM in both design and construction phases and employed various software such as Revit, Dynamo, Bentley, Navisworks, Tekla, Synchro, 3DS Max, Sap2000, X Steel, AutoCAD, and BIM360. The total BIM investment is stated as less than 1% of the project budget and the size of the BIM team was 30 people. The interviewed company's role was the architectural consultant for the project. The company had more than 30 employees and 6 years

of BIM experience. The interviewed industry expert was the company's partner and had 18 years of construction experience.

The second project had a total construction area of 76 Million sqm and the project's budget was more than 35 Billion Liras. The total duration of the project was scheduled as 42 months only for the first phase. The general contractor was a consortium and they utilized BIM in both the design and construction phases. The software that has been utilized are; Revit, Dynamo, Bentley, Navisworks, Tekla, AutoCAD, Primavera, and BIM360. The interviewed company was the general contractor of the project and was responsible for architecture, engineering, and construction work. The company had more than 5 years of BIM experience. The interviewed industry experts were the company's BIM team leaders and had 6 to 8 years of construction experience.

The third project was an additional terminal building for an existing airport and had a total construction area of 700,000 sqm. The project's budget was more than 2 Billion U.S. Dollars, and the duration was 60 months. The general contractor was a joint venture. The project utilized BIM only in the construction phase and had a BIM team of 40 people. Bentley, Synchro, and Micro Station were used as BIM software. The interviewed company was the general contractor for the project and had 8 years of BIM experience. The interviewed industry expert was the company's director of engineering & design and had more than 20 years of experience.

The fourth project was also built by the same company as the third project. It had a total construction area of 60,000 sqm and a budget of more than 200 Million Euros. The duration of the project was 24 months. The general contractor was a joint venture and had a BIM team of 15 people. They utilized BIM only in the construction phase and used; Revit, Dynamo, Navisworks, Synchro, Primavera, and Aconex.

Face to face interviews were held with the industry professionals working on the selected case projects. During the interviews, the interviewees were expected to rate the level of significance for listed barriers on a 1-5 Likert scale (1: very low, 5: very high) based on their experiences in that case project. The average values for each of the challenging factors were calculated and compared with the previously counted frequency in the literature. Moreover, interviewees were also asked to share their own experiences during the BIM implementation process for that particular project.

Findings and Discussion

Within the scope of this research study, challenges of BIM implementation for airport projects have been identified via an extensive literature review including 38 research papers. Identified barriers were divided into three groups based on their influence levels to distinguish the responsibilities of the industry, companies, and project teams. The significance of the barriers was evaluated via the interviews that were held with the industry experts working on four different airport projects. The experts also shared their own experiences with the particular project. Table 2 shows the identified factors with a brief description, their frequency in the literature, and the average significance score based on the interviews.

Table 2. Findings for the Barriers to BIM Implementation.

No	Barriers to BIM Implementation	Description	Literature Frequency	Case Study Rating (Avg.)
1	Project specific problems	Delivery method, contract type, unique requirements	25/38	4.25/5.00
2	Fragmented nature of the industry	Number of parties getting involved to the process	11/38	4.25/5.00
3	Collaboration problems among different parties	Low collaboration, lack of coordination	17/38	4.00/5.00
4	Unavailability of knowledge based on experience	Lack of experience, awareness within the company	25/38	3.50/5.00
5	Unclear benefits	Lack of tangible benefits	9/38	3.50/5.00
6	Change process problems	Resistance to change, company culture, fear of failure	31/38	3.25/5.00
7	Lack of best practices	Lack of cases, benchmarks, universal use	21/38	3.25/5.00
8	High costs	Time, HR, software & hardware investment	28/38	2.50/5.00
9	Technology related problems	Licensing, interoperability, reliability	30/38	2.25/5.00
10	Legal & protocol problems	Lack of legal protocols, ownership, responsibilities	24/38	2.00/5.00
11	Lack of government support	Lack of incentives, initiatives	4/38	1.50/5.00

Based on 38 studies that have been reviewed, “unclear benefits” has a very low frequency of 9 out of 38. In contrast, the industry experts evaluated the barrier to have a mid-high level of significance with an average score of 3.5 out of 5. The factor comprises two initial barriers “lack of tangible/measurable benefits” and “BIM deliverables are not clear”. Jin et al. (2017) stated that clearly defined BIM deliverables will enhance the returns from BIM implementation. It is hard to measure the benefits of BIM and people do not know what to expect. Since it is identified as a project level barrier, the project team should clearly identify their expectations from the BIM implementation.

Although high costs are one of the top three mentioned barriers within the literature with a frequency of 28/38, industry professionals evaluated it as 2.25/5. This is an expected finding for airport projects where the project budgets are very high compared to regular construction projects. It should be noted that high costs include “cost of time”, “cost of human resources”, and “cost of software & hardware” as the initially identified barriers. The interviewee from the second case project stated that “there was a specific budget allocated for BIM implementation in that particular project.”

“Collaboration problems among different parties” is one of the most important barriers to BIM implementation in airport projects with a ranking of 4 out of 5 while having a low-mid level literature frequency (17/38). This factor is mostly related to the lack of coordination and collaboration and BIM itself is a catalyst for collaboration. Thus, this barrier can be eliminated with increased coordination among the project parties.

One of the two most important barriers turns out to be project specific problems. It has a literature frequency of 25/38 and consists of four initial barriers; “contract type/delivery method is not suitable”, “unique project requirements make it harder”, “BIM implementation

is not suitable" and "lack of initially integrated models (for construction phase)". Since airport projects are unique, project specific problems are crucial for them. The average ranking of industry experts for this barrier is 4.25 out of 5.

As the one and only firm level barrier, "unavailability of knowledge based on experience" has a mid-high level of frequency (25/38) in the literature which is in parallel with the rating of industry experts (3.50/5). The factor has been generated by merging two initial barriers; "lack of knowledge (awareness) of benefits/rewards" and "lack of experience and skilled personnel". Regarding this particular barrier, interviewee for the second case study project stated that "This was not an important barrier for the core BIM team, however, in an airport project, it was hard to adapt people from too many different disciplines to the BIM process who have no BIM experience." In order to overcome this barrier, companies should hire experienced BIM experts to learn from their experiences and create an awareness within the company.

The "lack of best practices" has been generated by combining four initial barriers; "lack of case study evidence/benchmarking", "lack of universal use", "lack of demand" and "rapidly growing technology/innovations". The frequency among the literature was counted as 21/38 and industry experts rated 3.25/5 on average based on case projects. Arayici et al. (2011) stated that there has been a lack of consistent benchmarking for BIM implementation, and it was critical to review new processes. This barrier will be dismissed by itself as the BIM adoption among the AEC industries increase.

Software compatibility restricts the use of BIM and is required to be solved to maximize the benefits that BIM offers (Stanley & Thurnell, 2014). Based on the literature analysis, "technology related problems" is the second most mentioned barrier with a frequency of 30/38. It has been determined as an industry level barrier and generated by merging five initial challenging factors; "incompatible software", "safety and reliability of the information/cyber security", "user friendliness", "software adoption rates" and "license compliances". On the contrary, industry professionals rated the barrier among the least three important factors with an average ranking of 2.25 out of 5. The interviewee from the third and fourth case projects stated that "technology related problems can be overcome when you are a part of a huge airport project and working with information management experts."

The most frequently mentioned barrier in the literature is the change process problems with a score of 31/38. Change process problems are mostly related to the project people and human nature. It consists of six different initial barriers as "resistance to change", "belief that the current technology is enough", "company culture/business model", "lack of will", "fear of failure" and "training process". Accordingly, it has a relatively high ranking of 3.25/5 for industry experts. Independent of the project type, whether an airport project or a residential building project, people resist changes, and it is hard to interfere with someone's way of doing business.

"Legal and protocol problems" has been identified as an industry level barrier. It has a medium literature frequency, mentioned 24 times out of 38 in the literature. It was determined by merging three initial barriers; "lack of standards/protocols", "legal issues" and "uncertainty of level of responsibility and data ownership". On the other hand, industry experts evaluated the legal and protocol problems as the second least significant with a ranking of 2 out of 5. Incorrect use of BIM models may cause significant and complicated claims due to blurred

responsibility and ownership (Sun et al., 2017). Developing industry wise protocols for the BIM implementation process could eliminate this barrier.

Although the fragmented nature of the industry has the least frequency within the literature (11/38), industry experts evaluated it as one of the two most significant barriers (4.25/5). This was an expected finding because of the multidisciplinary nature of the airport projects. Keskin et al. (2021) stated that "airport projects encompass a higher variety of stakeholder work processes that require more strategic efforts in diffusing BIM in comparison to regular building projects". Similarly, the interviewee working for the first case project stated that "in airport projects, there is a different designer and consultant for each special part such as runway construction or apron lighting." Findings show that more research is needed regarding the fragmented nature of the industry for the airport projects.

Lack of government support is the least mentioned barrier within the literature and also ranked as the least significant barrier by the industry experts. This finding was also expected since airport projects are generally public projects and there is continuous support for BIM implementation. BIM usage for airport projects is even stated as a clause in the contracts. However, interviewees also argued that offering incentives such as tax reduction, etc. may boost the BIM adoption rate in the construction markets.

Conclusion

Airports are large scale infrastructure projects that require the adoption of the most recent innovations regarding digital construction. BIM is the most adopted tool which will become an industry standard in the near future. However, certain barriers hinder the BIM implementation process and cause companies to spend massive amounts of effort and money. This study revealed the challenging factors based on an extensive literature review and showed their perceived significance based on experiences from four different airport projects. In addition, the responsibilities of the industry, firms, and project teams are distinguished to eliminate the barriers.

At the project level, project specific problems can be eliminated during the contract phase by choosing the most suitable delivery type. In addition, collaboration and coordination are the keys to eliminate the other project level barriers and this can be assured via strong communication among project parties. At the industry level, when the fragmented nature of the airport construction industry is considered, it is recommended to increase BIM awareness with industry-wise events. Last but not the least, the only firm level barrier is identified as the unavailability of knowledge based on experience and this can be achieved by hiring experienced staff or external consultancy.

Interview responses showed that the fragmented nature of the industry, project specific problems, and collaboration problems among different parties are crucial barriers to BIM implementation in airport projects. All the top-rated barriers are common characteristics of problems faced in mega construction projects. Hence, it is clear that the BIM implementation process for mega projects is tough and the identified challenging factors need to be eliminated to fully enjoy the benefits of BIM.

This study shed a light on the BIM implementation process in airport projects that have different sizes and locations. Based on the comparison of results for the case projects, it is

observed that the crucial barriers to the BIM implementation are the same regardless of the size and location of a project.

Consequently, the findings of this study will guide the companies willing to implement BIM for airport construction. However, the number of cases within the scope of this study was limited and there are certainly other factors to be considered. Further studies might analyze the identified factors on different types of projects and make comparisons.

Abstract

Blockchain technology (BT) has started to be used in many areas, industries, and geographies. It is relatively not widely used nor researched in the construction industry. Based on the literature review, this paper aims to examine potential contribution(s) of the BT to the construction industry and to its stakeholders. Furthermore, within the scope of this paper, the potential benefits and contributions of the use of the BT in other industries will be examined to enable construction industry professionals and managers to consider how to and why to use the BT benchmarking from other industries. All stakeholders of the construction industry, supply chain and construction project management are expected to get benefit from this paper.

Keywords: *blockchain, construction industry, construction project management, stakeholders.*

Introduction

The construction industry (CI) is known to face many difficulties, such as low productivity. One of the challenges preventing the modernization of CI is its inability to embrace digital developments compared to the successes in some other sectors (logistics, automotive and mechanical engineering, etc.) (Cardeira, 2015). Use of innovative technologies by construction stakeholders can increase process efficiency, support synergetic effect, and development of the entire industry through network interaction between stakeholders and the use of digital platforms/payment systems (Ablyazov & Petrov, 2019).

Blockchain technology (BT), which was initially conceptualized by Nakamoto (2008) as an electronic payment system, became famous with the cryptocurrency bitcoin (Beck & Muller-Bloch, 2017). The first venture capital (Willett, 2012) turned into a development and funding instrument for entrepreneurs, thanks to Buterin (2013)'s Ethereum initiative and smart contracts considering its possible contributions to the solution to many problems encountered in CI with autonomous, decentralized and distributed database applications. For this reason, in-depth research should be carried out on where the BT can be used in the construction

project life cycle, its adaptation and its effects. This paper examines potential contribution(s) of the BT to CI and to its stakeholders.

Blockchain Technology and Applications

Blockchain (BC) refers to the decentralized system technology that allows transfers of digital values without relying on trust and conducts transactions with transparent records in distributed databases (Nakamoto, 2008). In Mattila (2016)'s study, which deals with blockchains in three layers: application, protocol and network communication, value-oriented transactions. In some researches, blockchains are handled at 3 levels, namely: cryptocurrencies (i.e., Bitcoin, Ethereum, Ripple etc.), smart contracts and industrial applications (Hoy, 2017). Dresher (2017) mentioned the application areas for blockchain value transfer as cryptocurrencies, digital assets, payment rails, digital identity, compliance, micropayments, and notary services.

Networks used in the network communication layer of blockchains are considered in 3 types (Nanayakkara et al., 2019);

1. public networks with limited personal data (e.g., Bitcoin, Ethereum), where participants are open to unauthorized participation and data access (Lewis et al., 2017);
2. private networks, where participation is permission-based and enterprise-level secure applications and authorized participants can be included (Martinovic et al., 2017);
3. consortium networks, which does not have a single owner, and which are suitable for the development of partial private blockchain solutions at the enterprise level (Nanayakkara et al., 2019).

Blockchains, which were initially a platform where crypto financial products were developed, have become a tool that develops different solutions in many industries, especially with smart contracts (Cardeira, 2015). Smart contracts are defined by Gronbaek (2016) as "computer protocols in which contract terms are converted into computer codes running on a network". Rudolf (2017), on the other hand, defined smart contracts as a set of self-executing contracts or rules in a distributed, decentralized blockchain network on which the terms of the agreement among the parties are transformed into the codes. Many of the modern or new generation blockchain networks support smart contract and enable development of decentralized applications (DApps) on blockchain networks with the help of these contracts (Nanayakkara et al., 2019). There are studies on some potential application areas in the literature such as digital rights (Ma et al., 2018), increasing flexibility in supply chain management (SCM) (Min, 2018) and fraud prevention (Khan, 2015). Nanayakkara et al. (2019) stated that smart contracts provide many positive effects such as effectiveness, integrity, accuracy, uniformity.

Blockchain in Construction Industry

Thanks to smart contracts, the way of doing business in the financial sector is changing and it is considered to have a potential impact on many sectors, including CI. (San et al., 2019). The studies of some researchers on the possible impacts of BT on construction business processes were reviewed by Yang et al. (2020). These studies are reviewed under the titles of blockchain-enabled contract management (Wang et al., 2017) also SCM (Luo et al., 2019),

autonomous payment systems (Shojaei, 2019) and construction information management (Liu et al., 2019).

Considering construction project's lifecycle, construction project stakeholders make temporary cooperation for project delivery processes, but this causes complexity in the project supply and management processes data, trust issues among stakeholders, and conflicts (Lamb, 2018). According to Hijazi et al. (2019), a digital twin of the physical building can be created with BIM model to eliminate these problems through integration of blockchain-based decentralized data management systems. Thus, all data can be stored in this model and transparent property/facility management can be achieved (Hijazi et al., 2019). In the literature, there are studies on blockchain integration into BIM-based applications. These are the studies on the applicability of the ethereum protocol (Salmon, 2017) and blockchains in BIM management in BIM transactions (Turk & Klinc, 2017), real estate investments (Trofimov et al., 2016). There are also studies such as the one of Barnett (2016), which focuses on many topics, on blockchains for BIM, property rights management, dispute resolution and its applicability in smart city models. On the other hand, studies on use of BT in CI focus on research areas such as payment/prepayment systems (Yang et al., 2020), funding management (San et al., 2019), and facility management (Shojaei, 2019).

Blockchain for Construction Stakeholders

Researches in the literature concentrated on the final product, production process, management model and stakeholders in the CI (e.g., Nanayakkara et al., 2019). In addition, the adaptation of blockchain to construction processes is investigated in research areas such as supply chain and/or project management processes/models/approaches/systems (e.g., Yang et al., 2020).

Complex and dynamic features of the CI may adversely affect supply chain stakeholders such as contractors, subcontractors, suppliers and customers in CI projects (Nanayakkara et al., 2019). Danuri et al. (2015) stated that the negativities arising from payment inefficiencies in the supply chain; is the most fundamental of the disagreements between the stakeholders. In the design of construction contracts, while determining the terms of payment, additional payment, prepayment and partial payment, non-payments and delayed payments are ignored and the resulting disputes can affect financing, reduce efficiency and delay project deliveries (Danuri et al. 2015). For this reason, the effects of blockchain applications should not be ignored to regulate the relations between stakeholders in the SCM and to eliminate the negativities (Danuri et al. 2015). On the other hand, according to Gouin (2018), even in the most basic construction project management model, at least 5 different contracts must be prepared and executed among project developer, project manager, contractor, architect, engineer and other stakeholders (Gouin, 2018). Furthermore, many aggreements or contracts are executed in procurement and delivery processes, relationships between supply chain stakeholders, vendors and/or suppliers and procurement teams (Yang et al., 2020) and logistics (Lanko et al., 2018), contractor subcontractor relations. Also many contracts are used in relations between investors and crowdfunding stakeholders, possible maintenance processes in project life cycle (Giuda et al., 2020), inter-stakeholder relations from design to ending of project life cycle.

How to Use and Applications Areas

In studies dealing with blockchain applications in the CI, their applicability is mainly investigated (i.e., Nanayakkara et al., 2019). These studies focus on how blockchain tools can be used to regulate stakeholder relations (i.e., Yang et al., 2020). San et al. (2019) discussed potentials in construction contracts (Design, Bid, Construction, Life cycle [Giuda et al., 2020]), electronic document management (EDM), BIM, property management, SCM, and funding management. Besides the official stakeholders of the projects, if each participant who may have an impact on/contribution to or relationship with the project is considered as a stakeholder, each of them will be a contracting or agreement party with the help of smart contracts (San et al., 2019). Therefore, smart contract applications in all management areas will be the most important field of study (San et al., 2019). With the help of these autonomous contracts embedded in digital codes, relations and workflows between stakeholders such as investor/investors, project developer and manager, design planning/management and implementation teams, contractor/subcontractors and suppliers, consultants and auditors able to have opportunities for cooperating on a fair, decentralised autonomous platform (Yang et al., 2020). The smart contracts on which the duties, responsibilities and interactions of each of these stakeholders/team are determined taking into account many possible scenarios (Gouin, 2018).

Blockchain-based platforms are handled in 3 different groups (Nanayakkara et al., 2019). Among these platforms, platforms that can support smart contracts and enable the DApps are important in solutions (Nanayakkara et. al., 2019) to be developed for the CI. In determining the platforms and tools to be used for these purposes, it is important to specify which problem of CI is aimed to be solved (Cardeira, 2015). Ethereum protocols (ERC20, ERC75) or public or consortium platforms such as EOS.IO or consortium platforms such as R3 Corda may be beneficial for solutions to be developed in venture capital and funding (Nanayakkara et al., 2019). On the other hand, private platforms such as Hyperledger Fabric may be useful for information management/sharing in SC issues such as inter-stakeholder payment / prepayment (Abrishami and Elghaish, 2019).

Why to Use BT and Its Potential Benefits/Contributions

According to Gouin (2018), blockchain-based solutions have the potential to contribute to the execution of financial transactions and processes in the CI, invoicing and fast payments, and implementation of contract rules and agreements. In this context, especially in terms of transparency and trust, time and cost efficiency, data/information security and international investability, suggestions, which are mostly at the conceptual level, need to be developed with field applications (San et al., 2019).

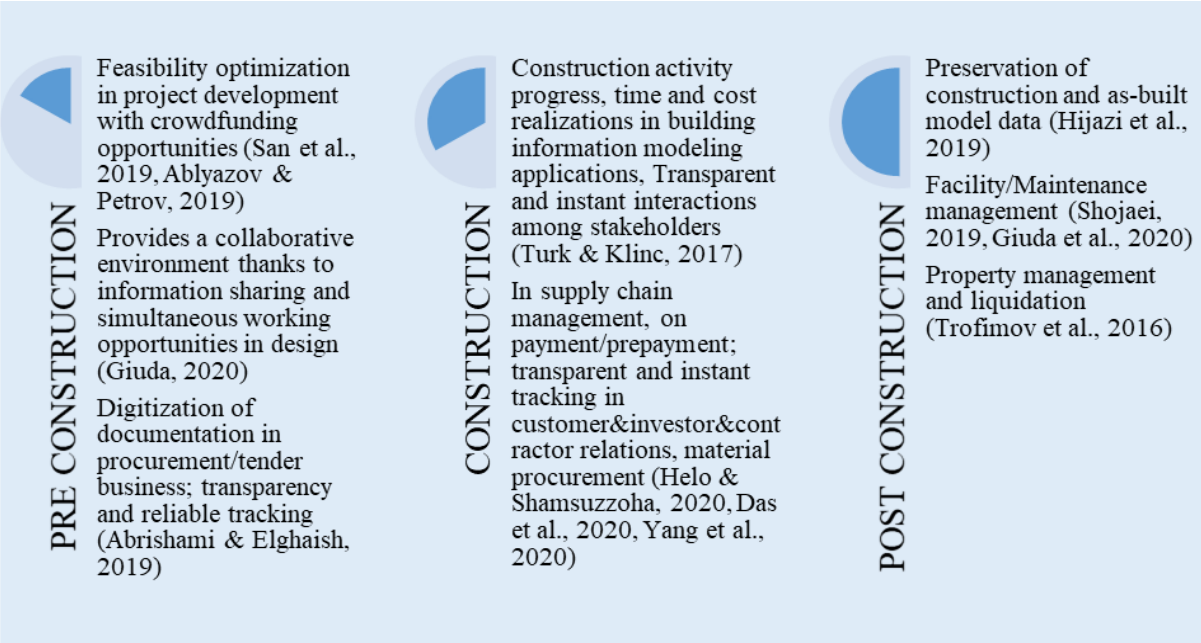

Figure 1: Potential contribution of BC to construction processes.

Nanayakkara et al. (2019) examined perceptions of stakeholders on blockchain adoption to the CI. As a result of their research, the most charming factors for the execution of blockchain in the CI were determined as efficiency, trust, fairness, security and transparency, respectively (Nanayakkara et al., 2019).

In studies (e.g., San et al., 2019; Turk and Klinc, 2017; Hijazi et al., 2019) on the adaptation of blockchains to the CI, it is emphasized by researchers and project stakeholders that this adaptation has important opportunities. For this reason, this issue should be investigated and discussed in depth.

Discussion

BT is applied to CI with limited tools, even though BT can offer opportunities in resolving financial, legal and governance issues to avoid wasted time and money, and quality depreciation/defects Yang et al. (2020). Benefits of this new technology can provide to the construction project life cycle and its stakeholders need to be explored.

The unique nature of construction projects and project-based collaborations of construction project stakeholders; causes confusion, trust problems and conflicts in the construction project life cycle and project delivery processes (Lamb, 2018). In this context, especially in the construction supply chain, the complexity encountered in data management will be solved by securing data on decentralized platforms with blockchain-based BIM applications, and the processes will be carried out transparently (Hijazi et al, 2019). In addition, it is necessary to focus on different solutions for agreements and contracts executed at every stage from design to the end of the project life cycle. San et al. (2019) discussed potentials of BT in construction contracts (Design, Bid, Construction, Life cycle [Giuda et al., 2020]), EDM, BIM, property management, SCM, and funding management. Besides these; Subject-specific researches focuses on; relationships between supply chain stakeholders, vendors and/or suppliers and procurement teams (Yang et al., 2020), contractor-subcontractor relations; investors-

crowdfunding stakeholder relations; maintenance processes (Giuda et al., 2020). Smart contract solutions can be developed for construction project life cycle phases, in which the project/supply chain stakeholders participate.

The negativities experienced in the interactions between the stakeholders in the CI can affect the quality of the product and process, and as a result, cause inadequacies in meeting customer expectations. On the other hand, according to stakeholders, through use of blockchain and smart contract in CI; positive results can be obtained in factors such as efficiency, trust, fairness, security and transparency (Nanayakkara et al., 2019).

As adaptation of BT to the CI has important tools/components that can contribute to the effective and efficient execution of digital platforms/applications/systems and to reduce disputes/conflicts, how and with what applications this adaptation can take place, as well as the potential benefits/contributions it may provide need to be studied. Within the scope of this study, at which stages in the construction project life cycle, blockchains can be used and the contributions they can provide in terms of processes and stakeholders at these stages were determined (Figure 2).

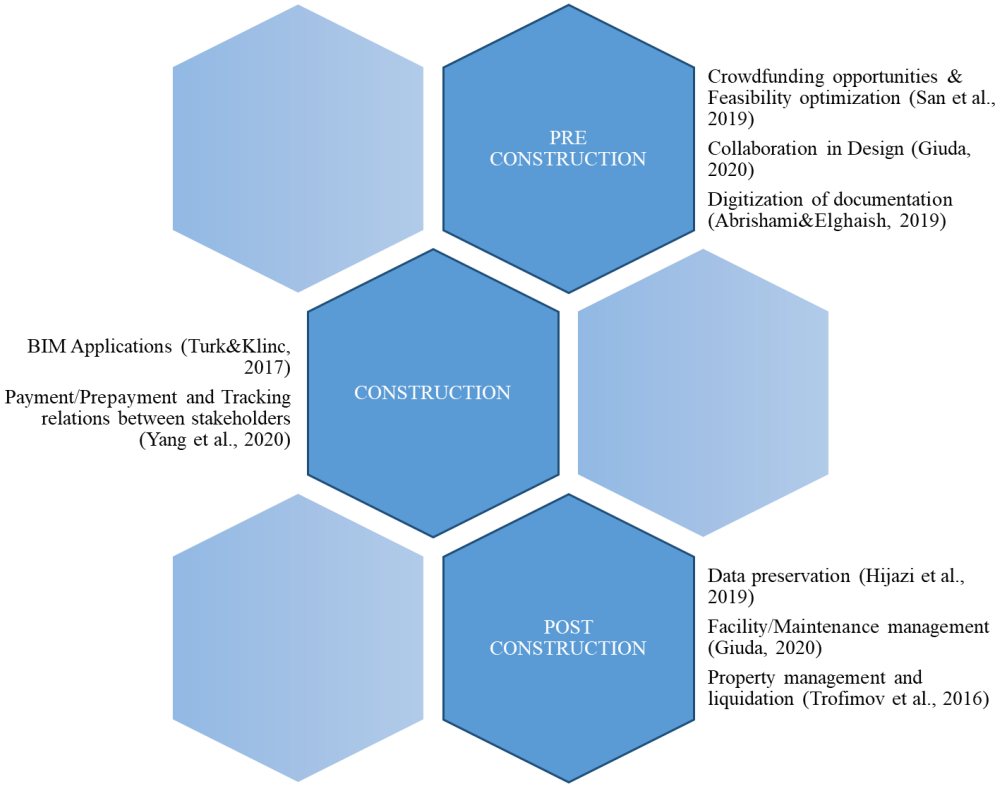

Figure 2: Contribution areas of BC in Construction processes.

The contributions of BT adaptation to the construction project life cycle, specified as follows;

- in the pre-construction phase; funding benefits, collaboration in design and digitization in documentation;
- in the construction stage; time/cost optimization and instant/traceable interactions between stakeholders with blockchain-based BIM applications;

- in the post-construction phase; data preservation of projects, property management and liquidation

Conclusion

The project and supply chain relations of the construction industry, which is negatively affected due to its project-based nature, complex and dynamic features; can be regulated by blockchain platforms, tools, system components and algorithms (Nanayakkara et al., 2019). In this context, Based on literature review, this study investigated properties of blockchain, its possible implementation areas, its effects/contributions to construction project management and supply chain stakeholders, how and why it should be adapted to the CI.

As a result of the study, it was seen that there are researches on blockchain solutions for different issues at different stages in the construction project life cycle (Figure 2). When these studies are examined, it is understood that there are different concentration areas from funding problems to collaboration in design, from Bim applications to payment/prepayment issues, from data security to asset management. The studies on the applicability and adaptation of BT in CI are largely based on literature research or conceptual models. Since real case applications are very limited, more applications and in-depth studies are needed.

Abstract

Smart megaprojects are constructed and accomplished increasingly affecting all construction project management processes. This paper examines the concepts of megaprojects and smart megaprojects, need for and drivers for smart mega projects. Based on literature review, the objective of this study is identification of smart megaprojects affecting construction project management. This paper underlines and examines different aspects of megaproject and smart megaprojects with respect to the construction project management. This research is expected to be beneficial to the Architecture-Engineering-Construction industry professionals and academics especially with respect to smart megaprojects' and their construction project management.

Keywords: *construction project management, megaprojects, smart city, smart megaproject*.

Introduction

In accordance with a report released by PwC (PricewaterhouseCoopers) in 2018, the market for smart cities worldwide is anticipated to increase by roughly 16% yearly (Kim, 2022). The Architecture-Engineering-Construction industry plays a significant role in establishment of new smart cities and development of existing smart cities by providing input to infrastructure and superstructure development (e.g., roads, skyscrapers) for the smart cities (Brad, 2020). Sarkheyli and Sarkheyli (2019) also mention that many projects such as infrastructure, commercial buildings, city centres, transportation structures are required for smart cities. Based on this, each of these infrastructure or superstructure projects can be considered as megaprojects by the definition of megaprojects. Considering the needs of megaprojects developed for smart cities such as data collection and transfer, real-time data, communication and information management, these projects can be defined as smart megaprojects. (Sarkheyli & Sarkheyli, 2019). This research aims to determine smart megaprojects' requirements affecting construction project management.

Megaprojects

There are several definitions about the concept of megaprojects. Megaprojects are large scaled, and complex, have high-budget (minimum of $1 billion), take long-term with multiple stakeholders, and are transformational (Flyvbjerg, 2014). Jia et al. (2022), similarly, consider megaprojects on the basis of their multi-stakeholder nature, high political sensitivity, long-term duration, technical challenges, important external influences, complex design and high stability requirement. Zhai et al. (2009), on the other hand, discuss megaprojects emphasising their complexity and challenging nature, long-duration, impact on the community, technology, region and even on the entire country (Zhai et al., 2009). In the literature, different authors have approached the definition of megaprojects from different angles.

Due to the complex nature of megaprojects, the activities related to the management are more challenging and difficult compared to small scale projects (Jia et al., 2022). He et al. (2021) emphasise that megaprojects have a reputation for disappointing performance in their management. Most megaprojects are over-budget due to lack of realism in initial cost estimates, ignoring changes in currency exchange rates, price changes and expropriation costs (Marrewijk et al., 2008). Average cost overrun rate of highway projects varies between 20% and 96% depending on the type of project such as bridge, tunnel, railway and dam (He et al., 2021). On the other hand, delays in the schedule are a separate issue for megaprojects, causing both cost overruns and benefit shortfalls (Marrewijk et al., 2008, as cited in Flyvbjerg, 2017). Reasons behind delays include uncertainities, poor consideration of project specifications and designs, security and environmental requests (Marrewijk et al., 2008, as cited in Flyvbjerg, 2017). Kipp et al. (2008) also argue that technological challenge is accepted as an important issue in megaprojects. For instance, Taib et al. (2014) note that ICT (Information and Communication Technology) contractors in megaprojects can face the problem of the inability for ICT work to be delivered as part of construction project in a systematic, efficient and effective manner. Therefore, analyzing megaprojects according to their characteristics, establishing project management systems in accordance with these characteristics and encouraging these management systems aim to increase the success of the project (He et al., 2021).

Smart Megaprojects

The variety of initiatives such as roads, highways, intersections, airports and other transportation systems, skyscrapers, multi-purpose complexes, shopping malls, renewal of city centers are required for the development of smart cities (Sarkheyli & Sarkheyli, 2019). These projects can be considered as megaprojects by definition due to time and budget consumed (Zhai et al., 2009; Flyvbjerg, 2014; Jia et al., 2022). Based on this definition, it can be considered that it is required to comprehend relationship among megaprojects and smart cities to understand smart megaprojects.

Sarkheyli and Sarkheyli (2019) define megaprojects as urban catalysts that can increase sustainable development and ultimately enable smart city visions to be realized. Although megaprojects constitute this input for smart cities, it is deficient because smart city construction is a complex infrastructure development initiative where various stakeholders of the smart city offer integrated city services with advanced technology. (Kwak & Lee, 2021). Considering the data, information and technologies underlying smart cities, smart mega-projects can be suggested as a means of achieving the goals of smart cities (Sarkheyli & Sarkheyli, 2019). Kwak and Lee (2021) referring to the incorporation of ICT with a building

and becoming a smart building, claim that smart megaprojects can be formed with the inclusion of ICT.

Smart megaprojects are essential for smart cities. It is proposed as mediators of smart cities to achieve their objectives (Sarkheyli & Sarkheyli, 2019) such as providing energy efficiency and carbon reduction, providing high quality of life for citizens, developing green areas and accessible infrastructure in the city, ensuring social equality among citizens and economic growth (Ojo et al., 2015). Apanaviciene et al. (2020) emphasize that smart buildings not only improve the concept of smart city but also urban development, national economy, use of resources and quality of life of citizens. Serteser et al. (2020) also mention that smart structures are the components of smart city which aims to minimize pollution and waste, improve user comfort and safety, save energy and improve air quality. Based on the statements of Ojo et al. (2015), Apanaviciene et al. (2020) and Serteser et al. (2020) it can be considered that smart megaprojects are an important need for smart cities, recognizing that smart mega-projects are smart building and smart construction on a larger scale.

Research Method

This study aims to identify smart megaprojects requirements affecting construction project management. An extensive evaluation of the literature on the subject of this study was conducted using the Science Direct and Google Scholar databases for researches published between 2010 and 2022. Megaprojects, smart city projects, smart construction projects, sustainable construction projects and urban projects have been chosen as keywords, considering that they have similarities with smart megaprojects. The requirements of smart megaprojects and their effects on construction project management were determined by using the selected keywords.

Results

Tables 1, 2, 3, 4 and 5 show requirements of megaprojects, urban projects, smart city projects, smart construction projects and sustainable projects that can affect construction project management. The description of the requirements found in the literature are provided in the middle columns of Tables 1, 2, 3, 4, and 5, and the requirements are classified according to their description in the left columns. The right columns of Tables 1, 2, 3, 4 and 5 provide the relationship among the project knowledge areas in PMBOK (Project Management Institute, 2017) and the requirements identified in the literature.

The requirements of megaprojects are presented in Table 1. These requirements are classified in the literature as: resources (Aiyetan & Das, 2022); internal and external stakeholders (Aiyetan & Das, 2022; Damayanti et al., 2021; Flyvbjerg, 2014); technology and expertise (He et al., 2021; Locatelli et al., 2017; Aiyetan & Das, 2022); planning (Flyvbjerg, 2014); government (Ahmadabadi & Heravi, 2019); rules and regulations (Flyvbjerg, 2014; Mišić & Radujković, 2015). Aiyetan and Das (2022) focused on the necessity of a certain number of resources such as people, money, equipment and machinery, time and materials for a very long time for megaprojects. This affects planning, estimating, acquiring and controlling resources (Aiyetan & Das, 2022). External and internal stakeholders can affect megaprojects (Aiyetan & Das, 2022; Damayanti et al., 2021; Flyvbjerg, 2014). Aiyetan and Das (2022) mention that it is very important for all stakeholders of a megaproject to pursue synchronized

project goals and objectives. Moreover, an effective communication, transparency between stakeholders, strong cooperation and coordination can directly affect project success (Damayanti et al., 2022; Aiyetan & Das, 2022). On the other hand, lack of cooperation between stakeholders having different interests can result in complexity (Kardes et al., 2013).

New technologies and operation improvements can affect monitoring and controlling the project work (He et al., 2021). Locatelli et al. (2017) also mention that there is a relationship between technological characteristics of megaprojects, and delay and cost overruns. On the other hand, sufficient and competent workforce, technical personnel, equipment and machinery can also affect megaproject through the application of new technologies (Aiyetan & Das, 2022). Ahmadabadi and Heravi (2019) have emphasized government intervention and government commitment is important for megaprojects. Moreover, Flyvbjerg (2014) and Mišić and Radujković (2015) state awareness of and compliance with rules and regulation affect project success.

Table 1. Megaprojects' requirements affecting construction project management.

Requirements	Description of Requirements	PMI (2017)'s Relevant Knowledge Areas
Resource	Needs huge quantities of resource for a long period of time (Aiyetan & Das, 2022)	Resource Management
External/ Internal Stakeholders	Stakeholder engagement (Aiyetan & Das, 2022)	Stakeholder Management
	Communication (Aiyetan & Das, 2022), cooperation and coordination (Damayanti et al., 2021) Effective partnering among project participants (Flyvbjerg, 2014)	Stakeholder Management
Technology & Expertise	New technologies and operation improvements (He et al., 2021; Locatelli et al., 2017)	Integration Management
	Sufficient and competent workforce, technical personnel, equipment and machinery (Aiyetan & Das, 2022)	Resource Management
Planning	Pre-project planning (Flyvbjerg, 2014)	Project Integration Management
Government, rules & regulations	Awareness of and compliance with rules and regulation (Flyvbjerg, 2014; Mišić & Radujković, 2015)	Scope Management
	Government intervention in operation (Ahmadabadi & Heravi, 2019)	Integration Management/ Cost Management
	Government commitment (Ahmadabadi & Heravi, 2019)	

Table 2 presents the requirements of urban projects affecting construction project management processes found in the literature. They are stakeholders, technology & expertise, organizational structure, government, rules and regulations (Curran & Spillane, 2016; Curran et al., 2018; Kroh, 2021; Yu & Kwon, 2011; Zhang et al., 2011). Identifying and early involvement of key stakeholders from the very beginning of the process is important for project success (Kroh, 2021). Besides, stakeholder engagement, stakeholders' cooperation and communication is another requirement of urban projects (Curran & Spillane, 2016; Curran et

al., 2018; Kroh, 2021; Yu & Kwon, 2011) On the other hand, it is necessary to establish an appropriate organizational structure as different key players are required at each stage throughout the project life cycle (Yu & Kwon, 2011). Besides, Zhang et al. (2011) argued that the competence and experience of customers is another requirement affecting the design. Moreover, appropriate organizational structure (Yu & Kwon, 2011) and team composition (Kroh, 2021) can contribute to the project integration management, creating organizational chart in the project charter. Government commitment is also required for urban projects (Kroh, 2021).

Table 2. Urban projects' requirements affecting construction project management.

Requirements	Description of Requirements	PMI (2017)'s Relevant Knowledge Areas
Stakeholders	Stakeholder engagement (Curran & Spillane, 2016; Curran et al., 2018)	Stakeholder Management
	Early involvement of stakeholders (Kroh, 2021)	Stakeholder Management
	Stakeholders' cooperation and communication (Yu & Kwon, 2011)	Stakeholder Management
Technology & Expertise	Client's qualification (Zhang et al., 2021)	Integration Management
	Qualification of project team (Kroh, 2021)	Stakeholder Management
Organizational Structure	Appropriate organizational structure (Yu & Kwon, 2011)	Integration Management
	Team composition (Kroh, 2021)	Integration Management
Government, rules & regulations	Government commitment (Kroh, 2021)	Stakeholder Management

Table 3 shows requirements of smart city projects affecting construction project management. Alshahadeh and Marsap (2018) state that ICT system knowledge and the privacy and security of the system are technology-related requirements that affect the project management of smart city projects. Furthermore, project stakeholders are another requirement (Alshahadeh & Marsap, 2018; Woods et al., 2016; Kogan & Lee, 2014; Ojo et al., 2014). Monitoring the behavior and movements of citizens in smart cities (Woods et al., 2016; Kogan & Lee, 2014; Ojo et al., 2014), enabling citizens to make decisions on city-related issues, and producing real solutions for citizens' needs can affect design management (Woods et al., 2016; Kogan & Lee, 2014; Ojo et al., 2014; Cardullo & Kitchin, 2019). Developing a common perspective from the aims, opportunities and challenges facing all stakeholders involved in the smart city project may be essential (Woods et al., 2016).

The importance of financing for smart city projects was emphasized by Pétercsák et al. (2016) and Jayasena et al. (2019). He et al. (2021) support this by proposing partnership of a strong local government as key stakeholder and a private partner with expertise in technology and finance. Moreover, Pétercsák et al. (2016) indicate that proposing creative financial instruments that can support the effective and timely implementation of projects is another

requirement. Jayasena et al. (2019) also mention that government support and funds are crucial for the development of smart city projects.

Table 3. Smart city projects' requirements affecting construction project management.

Requirements	Description of Requirements	PMI (2017)'s Relevant Knowledge Areas
Technology & Expertise	ICT system knowledge (Alshahadeh & Marsap, 2018)	Integration Management
	Security and privacy (Alshahadeh & Marsap, 2018)	Stakeholder Management
Stakeholders	Citizens' behaviors and movements in the city (Woods et al., 2016; Kogan & Lee, 2014; Ojo et al., 2014)	Integration Management
	Citizens' decisions about city (Woods et al., 2016; Kogan & Lee, 2014; Ojo et al., 2014; Cardullo & Kitchin, 2019)	
	Citizen needs (Pétercsák et al., 2016)	Scope Management
	Common aim and objectives (Alshahadeh & Marsap, 2018).	Scope Management
	Collaboration between private and public industry (Alshahadeh & Marsap, 2018).	Stakeholder Management
	Partnership local government and a private partner (He et al., 2021)	
	Early involvement of project team (Olawumi & Chan, 2020)	Integration Management
Financing	Creative financial instruments (Pétercsák et al., 2016)	Cost Management
	Partnership with funding from subsidies (Jayasena et al., 2019)	Cost Management
Government, rules & regulations	Support from municipalities (Jayasena et al., 2019)	Cost Management

Table 4 demonstrates requirements of smart construction projects affecting the construction project management. Technology and expertise, stakeholders, financing, government, rules and regulations are requirements found in the literature for smart construction projects (Carlander & Thollander, 2022; Opoku et al., 2022; Reddy & Kone, 2019; Gbadamosi et al., 2019; Olawumi & Chan, 2020). Stakeholders' cooperation (Carlander & Thollander, 2022) and stakeholders' commitment (Opoku et al., 2022) can be crucial for stakeholder management. It can provide information and knowledge sharing between teams (Olawumi & Chan, 2020). Besides, early involvement of stakeholders in the project can affect project management success (Carlander & Thollander, 2022). Moreover, stakeholders' clear targets and client's willingness and requirements are important (Carlander & Thollander, 2022; Opoku et al., 2022).

In terms of technology and expertise, implementation of IoT (Internet of Things) tools and sensors can be quite critical (Reddy & Kone, 2019; Gbadamosi et al., 2019; Olawumi &

Chan, 2020). Technology and expertise can help at increasing work productivity, allocating resources, providing a safety working environment in the site, improving the site supervision, tracking the materials, reducing and controlling project cost, operation and maintenance cost (Reddy & Kone, 2019). On the other hand, Gbadamosi et al. (2019) highlight data ownership, security of data and privacy of users as requirements that should be considered during the management of smart construction projects. Moreover, service availability and power consumption requirements are other requirements that can effect project management of smart construction projects (Gbadamosi et al., 2019).

Table 4. Smart construction projects' requirements on construction project management.

Requirements	Description of Requirements	PMI (2017)'s Relevant Knowledge Areas
Stakeholders	Stakeholders' cooperation and cross functional teams (Carlander & Thollander, 2022)	Stakeholder Management
	Early involvement in the project (Carlander & Thollander, 2022)	Integration Management
	Clear targets of stakeholders (Carlander & Thollander, 2022)	Scope Management
	Stakeholders' commitment, demand (Opoku et al., 2022)	Stakeholder Management
	Client's willingness, requirements (Opoku et al., 2022)	Scope Management
Technology & Expertise	Implementation of IoT tools and sensors (Reddy & Kone, 2019).	Integration Management
	Privacy and security (Gbadamosi et al., 2019)	Stakeholder Management
	Service availability, connectivity, power consumption requirements (Gbadamosi et al., 2019)	Integration Management
	Data ownership (Gbadamosi et al., 2019)	Stakeholder Management
	Technical competence of staff (Olawumi & Chan, 2020)	Stakeholder Management/ Integration Management
	Information & knowledge sharing (Olawumi & Chan, 2020)	Stakeholder Management/
Organizational Structure	Supportive organizational culture and effective leadership (Olawumi & Chan, 2020)	Stakeholder Management/

Table 5 shows requirements of sustainable construction projects affecting the construction project management. As in other project types, stakeholder is also a crucial requirement for sustainable construction projects (Lia et al., 2019; Sang & Yao, 2019; Opoku et al., 2022). Firstly, owner's commitment about sustainability is crucial for the implementation of sustainable construction projects (Opoku et al., 2022). Moreover, effective communication and cooperation between various participants improve the success in sustainable construction projects (Lia et al., 2019). Furthermore, Lia et al. (2019) argue that owner's active involvement in the project can encourage cooperation among the project stakeholders.

Moreover, definition of clear goal and objectives for stakeholders can help to reduce the chance of design changes or change orders (Lia et al., 2019; Sang & Yao, 2019).

Adoption of technology is required for project management of sustainable construction projects (Olawumi & Chan, 2022). Olawumi and Chan (2020) highlight implementation of BIM in project management process can contribute to design analysis, evaluation of energy performance, carbon emissions, daylight analysis, sustainable material selection in the design phase. On the other hand, Lia et al. (2019) mention sustainability implementation plan as a requirement which helps to reduce risks and provides smoother implementation plan.

Table 5. Sustainable construction projects' requirements affecting construction project management.

Requirements	Description of Requirements	PMI (2017)'s Relevant Knowledge Areas
Stakeholder	Clarity in requirements and measures for achieving (Olawumi & Chan, 2020)	Scope Management
	Communication and cooperation between stakeholders (Lia et al., 2019)	Stakeholder management
	Clear goals and well-defined goals by stakeholders (Lia et al., 2019; Sang & Yao, 2019)	Stakeholder management / Design management
	Owner's involvement (Lia et al., 2019)	Stakeholder management
	Owner's commitment about sustainability (Opoku et al., 2022)	Stakeholder management
Planning	Effective project planning and control (Lia et al., 2019)	Integration management/
Technology& Expertise	BIM integration (Olawumi & Chan, 2020)	Integration management/

Discussion

Smart megaprojects are megaprojects and urban projects in terms of scale, budget, time, complexity (Flyvbjerg, 2014; Jia et al., 2022). The characteristics of megaprojects and urban projects can be considered also for smart megaprojects. On the other hand, the smartness and green requirements of smart megaproject also reveal the need to evaluate these projects from a different perspective. Therefore, within the scope of this research, besides megaproject and urban projects; smart city projects, smart construction projects and sustainable construction projects were also evaluated. Figure 1 shows the relationship of smart megaproject with these project types. Besides, it also demonstrates these projects' requirements affecting construction project management.

Technology is one of the most critical requirements, as smart megaprojects involve the integration of smart city technologies, both smart buildings and smart construction projects (He et al., 2021; Locatelli et al., 2017; Aiyetan & Das, 2022; Zhang et al., 2021; Kroh, 2021; Alshahadeh & Marsap, 2018; Reddy & Kone, 2019; Gbadamosi et al., 2019; Olawumi &

Chan, 2020). Smart megaprojects aim to collect data from environment, city through various services and systems and use this data in the construction management process (Sarkheyli & Sarkheyli, 2019). According to Reddy and Kone (2019) and Alshahadeh and Marsap (2018) IoT tools and sensors will directly affect the project management of smart city projects and smart construction projects. Based on these findings, technology and expertise can have an impact on the project management of smart megaprojects. Technology requirement of smart megaprojects can affect integration management and stakeholder management of their construction project management (He et al., 2021; Locatelli et al., 2017; Aiyetan & Das, 2022; Zhang et al., 2021; Kroh, 2021; Alshahadeh & Marsap, 2018; Reddy & Kone, 2019; Gbadamosi et al., 2019; Olawumi & Chan, 2020). Gbadamosi et al. (2019) also argue that technology contributes to design decision making, monitoring and controlling activities, improving the work schedule, thus helping to increase project performance by improving resource management and schedule management. Moreover, use of technology and data require data ownership, privacy and security (Gbadamosi et al., 2019). Therefore, data and information security is crucial to achieving smart management's optimum results. (Sarkheyli & Sarkheyli, 2019). On the other hand, the installation of these systems can create the need for a competent and experienced workforce (Olawumi & Chan, 2020; Aiyetan & Das, 2022).

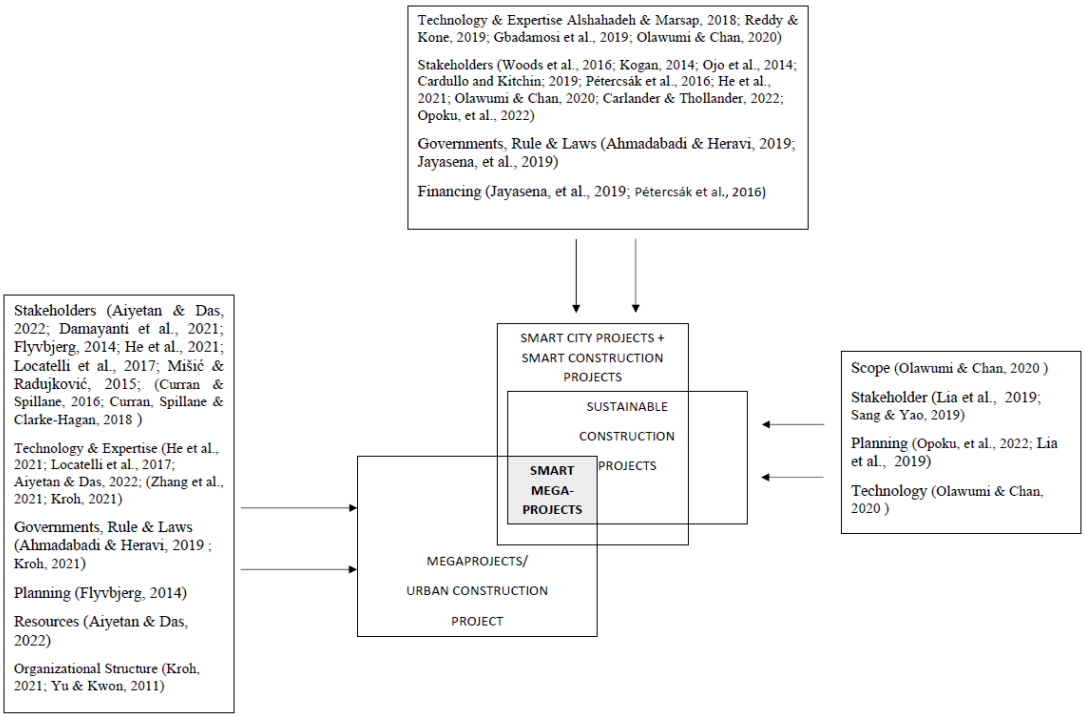

Figure 1: Requirements of smart megaprojects affecting construction project management.

Stakeholders are emerged as a common requirement affecting construction project management of megaprojects, urban projects, smart city projects, smart construction projects and sustainable projects (Lia et al., 2019; Sang & Yao, 2019; Opoku et al., 2022; Carlander & Thollander, 2022; Curran et al., 2018; Yu & Kwon, 2011; Kroh, 2021). From this point of view, it is revealed that it is an important requirement for smart megaprojects. Stakeholder engagement, collaboration and communication among project stakeholders, clear purpose and target definition for all stakeholders are some of the stakeholder requirements (Lia et al., 2019; Sang & Yao, 2019; Opoku et al., 2022; Carlander & Thollander, 2022; Curran et al., 2018; Yu & Kwon, 2011; Kroh, 2021). These requirements affect directly stakeholder management. Clear purpose and target definition of the stakeholders (Carlander & Thollander,

2022) is expected to contribute to scope management of smart megaprojects. Furthermore, as the data collected from the citizens and the citizens' footprints in city (Woods et al., 2016; Kogan & Lee, 2014; Ojo et al., 2014; Cardullo & Kitchin, 2019; Pétercsák et al., 2016) citizens become an internal stakeholder in smart megaprojects. In this case, this should be evaluated within the integration management since it may indirectly affect design decisions. Other requirements found in the literature such as organizational structure, planning, resource, financing and government, rules & regulations can affect the construction project management of smart megaprojects (Ahmadabadi & Heravi, 2019; Flyvbjerg, 2014; Aiyetan & Das, 2022; Yu & Kwon, 2011; Kroh, 2021; Lia et al., 2019; Opoku et al., 2022). The effects of these requirements focus on knowledge areas such as scope management, integration management and stakeholder management.

Conclusion and Recommendations

This study identified the preliminary requirements of smart megaproject affecting construction project management. The definition of megaprojects and smart megaproject were explained highlighting the similarities and differences between them. Requirements of megaproject, smart city project, urban project, smart construction project and sustainable construction projects on project management were investigated (Tables 1, 2, 3, 4 and 5). These highlighted requirements may have an impact on Project Management Institute's knowledge areas like scope management, integration management, and stakeholder management. (Tables 1, 2, 3, 4 and 5). As smart megaprojects are similar to megaprojects and urban projects, the requirements of these projects can also be valid for smart megaprojects. However, since smartness becomes important, it can have similar features with smart city projects and smart construction projects. Furthermore, smart megaprojects must comply with sustainability requirements. Figure 1 shows the requirements of smart megaproject. This paper can be useful for AEC industry professionals, municipalities, governments and academics in the construction project management processes of smart megaprojects. As this study identifies the requirements of smart megaprojects that affect the construction project management, it has a potential to provide input to put forward construction project management models for smart megaprojects. This input can be considered as a future work direction.

Potentials of VR and AR in Pre-Construction Phases

T. Seyman-Güray and B. Kısmet
Beykoz University, Department of Architecture, Istanbul, Turkey
tayibeseymanguray@beykoz.edu.tr, burcukismet@beykoz.edu.tr

Abstract

VR and AR technologies are among the digital tools and techniques of Construction 4.0 which is a new term reflecting the effect of Industry 4.0 digitalization transformation in the construction industry. VR is identified as a digital-driven experience on which the user is transferred into a simulated virtual environment while AR is an interactive experience of a real-world environment whereas AR involves superimposing computer-generated images and information on real-world environment. By increasing complexity and high requirements of buildings, the construction management actions of pre-construction phases play a crucial role on the efficiency and the effectiveness of the building projects. Since the pre-construction phase is mainly associated with its uncertainty; the decisions to be made at this stage brings high risks. This study aims to evaluate the potentials of VR-AR technologies in order to show how VR-AR can be used in various management areas of pre-construction such as feasibility, programming, cost-budget, scheduling, constructability review, communication and coordination. By employing a through literature review, it is also targeted to provide the applicability areas of VR-AR technologies in pre-construction phases.

Keywords: *AR, augmented reality, pre-construction, vr, virtual reality, construction management.*

Introduction

Pre-construction phase plays a crucial role in the whole building project process. Efficiency of the construction phase is related to the accuracy of pre-construction decisions. Pre-construction is the phase of uncertainty involving main services as design review, constructability review, scheduling, cost estimation & budgeting, coordination. Due to the uncertainty and complexity of construction projects, proper planning of each stage is a necessity to deliver the building successfully. A comprehensive and accurate pre-construction process is significantly important to secure the project goes as planned and all project outcomes successfully delivered. In order to prevent delays, cost over-runs, errors in design decisions, wrong detailing, improper material choices, this study aims to investigate the potentials of Virtual Reality (VR) and Augmented Reality (AR) technologies in pre-construction phases. VR is identified as a digital-driven experience on which the user is transferred into a simulated virtual environment while AR is an interactive experience of a real-world environment whereas AR involves superimposing computer-generated images and information on real-world environment.

Research Gap

Previous studies mainly focused on VR-AR applications in the construction phase, however there is a gap to examine the stages of the pre-construction process in this manner. This study targets to respond to this gap. On the other hand, there are some studies, such as Biocca et al. (2013), Noghabaei et al. (2020), and Park et al. (2013), indicating the general advantages of VR-AR technologies such as providing improvement in communication and visualization. However, there is a need of necessity of specifying these advantages connected to the stages of the pre-construction phase. Ultimately, the purpose of this paper is to investigate solutions by utilizing VR-AR technologies in relation to the pre-construction phase problems. As these technologies create immersive environments, in this study it is focused on the potentials of providing improved perception of the project requirements to be able to reach sufficient decisions and planning steps before the construction start. Thus, this study aims to contribute to the whole project life cycle by overcoming the problems arising from the pre-construction process which will impact the construction process negatively in time and the building as a final product.

VR-AR Technologies in the Construction Industry

VR-AR technologies are becoming widespread, and every industry will be affected by the rapid adoption of them (Delgado et al., 2022). Due to the rising popularity of mobile learning and distant working in the last years, usage of AR has drastically increased (Emiroğlu & Kurt, 2018). Moreover, Covid-19 Pandemic has brought new normal conditions which required professionals adopts these technologies widely.

VR-AR technologies are among the digital tools and techniques of Construction 4.0 which is a new term reflecting the effect of Industry 4.0 digital transformation in the construction industry. These technologies identified as one of the top 10 Gartner strategic technology trends for 2019 (Panneta, 2018). According to American Institute of Architects' (AIA) Firm Survey Report (2018), more than 25% of firm leaders surveyed state that VR- AR are having an important impact on the AEC (Architecture Engineering Construction) industry today, and 66% believe that the technology will have a significant impact within the next five years. Noghabaei et al. (2020) indicate that the AEC industry experts foresee strong growth in the use of VR-AR technologies over the next 5–10 years.

The Pre-Construction Phase Problems in The Literature

The pre-construction phase services cause some problems which could affect the overall project outcomes dramatically. Based on a study by Olanrewaju et. al (2017), more than 95% of construction professional had faced communication problems in the construction organization (Abd Rahman et al., 2019). Besides, in pre-construction of a project, people are likely to communicate through paper documents if they are using traditional method. However, misunderstandings can be occurred frequently.

The traditional methods are limited for visualization, understanding, and collaboration within a complex project (Abd Rahman et al., 2019). The lack of coordination results in losses construction phase which was indicated by Peniel Ang, 2013. According to Nassereddine et al. (2019), between $17-36 billion are lost each year because of the omitted information while

transforming design documents into construction documents. Also, some studies about construction efficiency indicate the waste of 25-50% in coordinating labor and management (Modular Building Institute, 2010). According to a report by the US Government Accountability Office (2013), the time overruns faced in construction projects resulted in approximately 35 months per project. The report compiled by Indian Ministry of Statistics and Programme Implementation (2016) declares that the completion delays in construction projects differ from 1 to 261 months.

VR-AR Usage Potentials in the Pre-construction Phase

This study investigates the potentials of VR-AR in the pre-construction phase considering the previous studies. As Table 1 illustrates, the pre-construction phase main services defined as design review, constructability reviews, cost estimation & budgeting, scheduling, and coordination.

Table 1. VR-AR in the pre-construction stages according to literature review.

Design Review

The early usages of VR mostly refer to visualization as Bouchlaghem et al. (2005) defined VR as a collaborative visualization tool for improving the design process. Another VR application in the pre-construction phase related to the design stage is a VR 3D sketching interface for the conceptual architectural design process to increase design creativity in the early stages (Rahimian et al., 2011). VR technologies provide environments for better collaboration among participants, enable a better understanding of complex designs, identify design issues, depict building geometry so that users can make sense of a project and reach a better design decision and aid collaborative decision-making (Alizadehsalehi et al., 2019). According to the research of El Jazzar et al. (2020), VR and AR can be suitable to improve processes and deliverables in planning and design phases. The results showed that VR-AR adaptations are effective in obtaining user feedback which improves the end-user satisfaction rate and performance in design (Shakil, 2019). In a study conducted by Alsafouri and Ayer (2019), the efficiency of AR usage in constructability and design review sessions was compared with the use of BIM, VR and physical mock-ups during these sessions (Hajirasouli et al., 2022). AR extends the opportunity to evaluate different design alternatives. Researchers developed a mobile AR application that can augment BIM models on top of the real-world

building, which helps technicians to optimize and visualize the data and the model (Williams et al., 2015). The proposal of Park and Kim (2013) for visualization system integrates AR, BIM and gaming.

360-degree visualization and AR model rendering features (Index AR Solutions 2018; Gheisari et al. 2016). It can provide project participants with an integrated view of the components in real scale and real time (Wanget al. 2014; Shanbari et al., 2016) while permitting access to the information in an augmented workspace (Wang, 2009; Lin et al., 2015). AR 'popup' models link AR models with physical 2D drawings to help clients and professionals to understand the drawings comprehensively (Dunston & Wang, 2005). Wang et al. (2014) mentioned that the synergy of BIM and AR opens new possibilities in the field of architectural visualisation, navigation, and interaction with a real time modelling facility. Furthermore, it provides early identification of design clarification.

Constructability Review

According to the previous studies, constructability review activities have a significant role in detecting and identifying errors, conflicts and inconsistencies (Abrishami et al., 2015; Carneiro et al., 2019; Foroughi Sabzevar et al., 2021; Rajaratnam et al., 2021; Hajirasouli et al., 2022). Additionally, by walking through the 4D-BIM model in VR, constructability analysis contributes to productive and efficient planning of a project (Du et al., 2018). Alsafouri and Ayer (2019) ran constructability and design review sessions with industry partners and practitioners to analyse their actions during these sessions while using AR as a means of communication (Hajirasouli et al., 2022).

Scheduling

VR-AR scheduling activities are interrelated with 4D BIM which provides environments to communicate and collaborate visually while scheduling sequences of work items by linking the BIM model (Crowther & Ajayi, 2019), Shakil (2019), Wang et al. (2019), and Charlesraj and Dinesh (2020) mentioned that AR integrated 4D BIM is useful in project scheduling. Wong et al. (2014) stated that both time and cost-saving opportunities are available to the project managers by using AR technologies. There are wide range of software for scheduling such as Navisworks, Synchro, Bexel, Fuzor and Visual 5D. Even though their interfaces are differentiated, aim of these tools are to eliminate rework, protect the budget by finding problems in advance, save time & resources by optimizations. Ikerd (2013) developed a framework to integrate 4D BIM with VR applications.

Cost and Budget

In pre-construction phases, VR-AR is beneficial for cost estimation in management for construction projects (Alizadehsalehia et al., 2020). In the study of Balali et al. (2018), a framework for cost estimation in construction using VR technology was developed which used a real-time VR model that provides the ability to change the building materials with the real-time price impact. VR-AR technologies in cost estimation extend its usage thanks to 5D BIM which involves cost planning and budgeting through linkage with BIM model. Davidson (2009) and Aouad et al. (2007), focused on cost and BIM relation in early phases. Xu (2017), Wong et al. (2014) and Smith (2014) emphasized VR-AR and 5D BIM interactions which result in accurate estimations.

Coordination

As VR-AR technologies create a virtual environment and enhance real world, they increase the perception and understanding of the project both for the professionals and the clients. Issa (2000) mentioned VR technologies are not limited to only a presentation tool but could also act as the main interface used to facilitate communication of construction information and cooperation among project participants. According to Shen et al. (2013), if design requirements are not sufficiently managed and client viewpoints are not fully understood, conflicts often arise among the designers and clients, especially in the pre-contract stage (Gunarathna et al., 2018). Thus, design knowledge acquisition (knowledge and experience of the designer and client) and knowledge negotiation (design understanding among the stakeholders) must be well-coordinated (Norouzi et al. 2015). Moreover, Alizadehsalehia et al., 2020; Bille et al., 2014; Romano et al., 2019; Sutcliffe et al., 2019. Du et al. (2018) proposed a BIM-related VR system to achieve collaborative decision-making, which enables users to revise modifications in BIM models concurrently from VR headsets. Additionally, to improve communication among participants, researchers introduced a cloud-based VR system called CoVR by integrating a multiuser interactive virtual environment with BIM data (Du et al., 2018). Besides these technologies provide virtual walk-through tours for clients while in the office before construction started.

Table 2: Potentials of VR-AR for the activities of the pre-construction phase (by authors)

	Problems caused in the Pre-construction phase	**Problem Area**	**Potentials of VR-AR**	**Tools**	**Software**
Design review	Errors in design documents Low performance in design End-user dissatisfaction Overloaded revision requirements	Quality	• Proper design deliverables • Providing real time experience in early stages • Increased perception of drawings • Better performance in design • End-user satisfaction • Less revisions in the upcoming stages of the project	Headsets, Handsets, Desktop Mode Mobile	Unreal Engine, Unity, Sim Lab
Constructability Review	Unproductive and inefficient planning Errors, conflicts and inconsistencies Mischoice of systems/detailings Rework	Quality Time Cost	• Productive and efficient planning • Detect and identify errors, conflicts and inconsistencies • Proper detailing and system selections	Headsets, Hand Sets, Desktop Mode Mobile	Unreal Engine, Unity, Sim Lab, Bexel Manager
Cost Estimation and Budgeting	Mistakes in cost estimation Cost overruns	Cost	• Accuracy in cost estimation • Better cost- budget control • Compatibility with 5D-BIM	Desktop Mode Mobile	Synchro Primavera BIM 360 Bexel Manager
Scheduling	Errors in schedule Need of extra resources Delays	Time	• On time delivery • Better resource assignments • Time efficiency	Desktop Mode Mobile	Synchro Primavera Bexel Manager
Coordination	Conflicts among participants Clashes in drawings Misunderstandings Limited communication with clients	Quality Time Cost	• Better communication • Better cooperation among participants • Better visualization and presentation options for clients • Elimination of misunderstandings	Headsets, Handsets, Desktop Mode Mobile	Unreal Engine, Unity, Sim Lab Revit BIM 360 Bexel Manager

Table 2 represents the problems, problem areas, VR-AR potentials, tools and software. The problems were defined according to the literature review. Problems were categorized in three areas as; quality, time and cost. Potentials of VR-AR were composed and interrelated with each problem. Additionally, the most common tools and software were listed in Table 2 for each activity of the preconstruction phase.

Discussion and Conclusion

This study discussed the current problems of the pre-construction phase in terms of design review, constructability review, cost estimation & budgeting, scheduling and coordination. Accordingly, the potentials of VR-AR technologies were investigated based on a comprehensive literature review, to provide an insight for researchers and the AEC professionals. Pre-construction problems affects the quality, time and cost of the whole project lifecycle and this study evaluated the adoption of VR-AR technologies before construction starts.

VR and AR technologies are not only visualization tools but also, they are increasing design abilities by creating a virtual environment or a virtual object. This augmentation real environments results in increased creativity and accurate choice among design alternatives. Additionally, these technologies can help to handle uncertainties of the pre-construction phases. Budgeting and scheduling of can be more precise to minimize the cost and time overruns during construction phases. On the other hand, according to client's point of view, can give some advantages in communication of design with the professionals, moreover they can virtually experience the design which increases their perception and understanding.

But the potentials of VR/AR in early stages of building projects can further be explored. Especially activation of 5G technology is expected to enhance the performance of VR and AR usage in near future. Also, companies such as Microsoft, Google, Apple and Facebook are investigating on these technologies as well as many start-up companies are focusing on them recently. In this regard, participants of AEC industry need to emphasize on technology solutions and establish research development departments. Integrating these technologies in construction industries can be reconsidered as a new career path for architects and/or engineers. In order to reach success in construction projects, the pre-construction phase should be empowered with these recent technologies.

Abstract

Construction simulations are helpful in analyzing construction steps, designing construction processes and related steps in the most effective way which increases the productivity to the maximum level possible. These simulations can be used for all repetitive processes of construction. As a repetitive work subject, a tunneling operation in which precast pipe sections are used is chosen. Tunneling operations are frequently used repetitive works in construction industry and a study for productivity may be useful in prospective works. In this paper, an EZStrobe simulation is modeled for a tunneling operation with the help of the data obtained from site. Also, productivity and effectiveness, ways of increasing productivity, and solutions to possible problems are discussed. Outputs of this study can be used to estimate and increase productivity in tunneling as well as different kinds of repetitive construction works.

Keywords: *construction simulations, simulations, Stroboscope, tunneling.*

Introduction

The simulation tool has been used for more than 50 years in the design and development of technical processes, as well as in the analysis and optimization of the processes. Resources such as workers, equipment, and management included in the simulation are important for the simulation to work. Simulation models provides an understanding of the logic of the works and the specific processes. Analyzing model results is important to understand factors such as efficiency (Thanh, 2017). One of the main purposes of creating a simulation is to compare alternative situations (construction methods, etc.) by modeling (Ioannou & Martinez, 1995).

Simulations are also extensively used in construction work. With the use of simulations, some situations in construction works are compared and the decision-making process is carried out in a sufficient way. The processes in the construction are repeated both in terms of the works (formwork manufacturing, etc.) and in terms of fields (construction of high-rise buildings, etc.). It is seen that they are repetitive within the scope of the foundations on which the construction operates. For this reason, simulations created for construction work need to be cyclical and scalable. (Martinez, 1996).

It can be difficult to create simulations about the complex construction operations. There seem to be three major obstacles in the way of modeling construction works in a simulation. One of these obstacles is that the language created by the simulations is shaped according to production needs, and not construction processes. CYCLONE, RESQUE, COOPS, etc., the emergence of simulation types as such has helped to overcome this problem. These simulations are similar to CPM in that they are based on their scans of activity in construction works. The fact that these simulations are not a language makes it incomplete for modeling complex construction processes. With the advent of STROBOSCOPE, this problem has been largely resolved (Ioannou & Martinez, 1996).

One of the processes applied in construction works is the process of opening micro-tunnels with micro-tunnel tunneling machines. It has been seen that more than a thousand sales of microtunneling machines have been made in the last 20 years. The usage of microtunneling methods is increasing day by day. Microtunneling is carried out with MTBM. The efficiency of the MTBM is affected by factors and components such as weather, equipment adequacy, design changes, rework status, space flexibility (Thanh, 2017).

Microtunneling is a complex process involving personal experience and the interaction of various equipment. Regulating this complex process can help to understand the factors affecting productivity (Dang et al., 2013).

The aim of this study is to model a pipe jacking operation and discuss results for the possibility of increasing the efficiency of the operation.

Pipe Jacking Operation

The history of pipeline jacking goes back almost more than a hundred years. Pipe jacking was first used in the United States in 1896 to place a concrete culvert beneath the Northern Pacific Railroad, but it did not become widespread in the United States until the 1950s. (Sterling, 2020). It was 30 years later where microtunneling technology, which is a type of pipe jacking, first entered the market. The first microtunneling machine was developed in Japan in 1972 by Komatsu and the first job was completed in 1974. Microtunneling spread slowly but gained popularity in Europe specifically in Germany and the United Kingdom starting in 1981 and 1984, respectively (Hafez et al., 2022).

Microtunneling is a tunnel construction technique used to construct an auxiliary tunnel with a diameter of approximately 0.5–4 m. Because of their small diameter, it is not possible for an operator to operate the tunnel boring machine, so they must be operated remotely.

Micro-tunnel boring machines (MTBM) are similar to larger tunnel boring machines (TBMs). The methodology starts with the installation of MTBM and hydraulic thrust frame on a shaft at the required depth. The operator monitors the position, orientation and hydraulic devices of the MTBM via a computer console, a CCTV camera or a Gyro unit. Gyro Control has often replaced cameras for location and digital feedback.

The pipes, which are lowered into the shaft with the help of a crane, are driven into the tunnel by the pushing force performed by hydraulic pistons in the microtunneling method. The control of the system is made from the control cabinet on the surface.

The microtunneling machine needs to excavate the tunnel and the hydraulic rams in the jacking frames simultaneously pushes the pipes in the excavated part. While the cutter head is pushed forward with the hydraulic pushing system, a new pipe is connected to the system when there is enough space for a new pipe to be driven, and the pushing process continues this way.

After the micro-tunnel machine excavates the soil with cutters and hammers, pressurized water is used to remove the excavation from the system in the form of a slurry. This slurry is sucked by the existing discharge pipes in the system and taken to the discharge tank on the surface or inside the shaft.

Measurement processes in the micro-tunnel method takes place with the help of continuous data exchange between the machine and the control panel in the control cabinet on the surface. These received data are evaluated instantly by the operator who manages the control panel on the surface, and the machine is prevented from going beyond the prescribed deviation limits.

The data is evaluated on the computer in the control cabinet, and the horizontal and vertical position of the machine is displayed numerically and graphically on the control panel. In the graphic display, the position of the main body of the machine, the position of the cutter head and the fixed position of the machine are displayed in different colors on the screen on the control panel. Control system, operates with +/- 0.01% sensitivity with immediate intervention.

Equipment Used in Microtunneling

There are various equipment and tools used in the operation of microtunneling. The ones that are explained are the main procedures that effects the microtunneling simulation.

- Pipes and Concrete Segments: Concrete pipes and segments used for tunnels must be of high quality without surface defects. The stock should be ready next to the shaft.
- Transport of Segments: With the help of a crane, the segment stones are carefully placed on the guide rail.
- Cutter Head: It is a steerable mini drilling machine equipped with a suitable cutter head at the front for excavating small diameter tunnels. It uses a laser guidance system to transmit instant feedback. The blades of the cutter head can be changed according to the floor type and usage time. Different types of cutter heads can be seen at Figure 1.

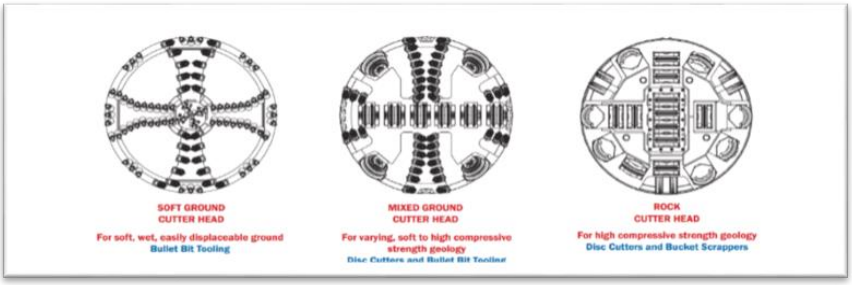

Figure 1: Cutter heads for different soil conditions (Akkerman, n.d.).

- Lubricant Bentonite Mixture: Automatic Bentonite Injection System – Remotely controlled delivers oil directly to the pipe ring at predetermined pressures and intervals to reduce friction forces.
- Slurry: A mixture is created by injecting a mixture of water or bentonite clay into the crushing cone of the MTBM. This sludge-like mixture is carried to the return lines and passes through the sludge transmission pipes so that it can be removed from the system. The weight can be sent directly out of the shaft with the help of the pump, it can also be filled into the carrier feet inside the tunnel.

Stroboscope and EZStrobe

Models were created using EZStrobe. Stroboscope is a programming language used to simulate repetitive and common processes in construction works (Martinez & Ioannou, 1994). Stroboscope is a discrete event simulation system for creating simulations of complex construction works (Ioannou & Martinez, 1996). The processes to be simulated consist of complex structures containing different resource types (Martinez & Ioannou, 1994). Models of this programming language, which are similar to activity loop diagrams, consist of node and connection networks (Ioannou & Martinez, 1996). Efficient and effective results are obtained by analyzing the simulation outputs (Martinez & Ioannou, 1994). It can be said that Stroboscope is a scalable monitoring system that complements existing tools (Tilmans et al., 2018).

Accessing the resources and the appearances of these resources in the construction processes is the main basis of the simulation. Elements in the modeling are assigned properties that define how they should behave. There are characters that represent situations such as the duration of an activity, the amount and direction of flow of resources and the order of activities. The simulation considers the order of the elements and how they should follow each other. Examples of these situations are: until the crews leave the field or until the cables are examined (Martinez & Ioannoui, 1994).

Ioannou and Martinez (1998) demonstrate by modeling the link and correlation between the activity durations of STROBOSCOPE. In addition, a sample highway project is modeled using an additional program with CPM planning. Martinez and Ioannou (1994) created an aircraft service center simulation model to demonstrate the programming language of STROBOSCOPE. Ioannou and Martinez (1996) gave examples of simulations created with STROBOSCOPE in complex construction processes. Tilmans et al. (2018) created a declarative network monitoring on a budget with the help of STROBOSCOPE.

EZStrobe is a straightforward yet powerful general-purpose simulation system created for modeling construction activities, although it is domain independent and hence applicable to a wide range of systems in any discipline. EZStrobe works with Microsoft Visio, hence it is based on visual modelling and easier to use. The Three-Phase Activity Scanning paradigm is used by EZStrobe, which is based on Activity Cycle Diagrams. (Martinez, 1998) As a result, it's well-suited to complicated systems with several resources working together to complete tasks, such as those found in construction. The paper also explains the fundamental concepts of the system.

To express the essentials of a model, these systems make use of a network based on Activity Cycle Diagrams. These systems are intended for both simple (e.g., CYCLONE) and

complicated (e.g., STROBOSCOPE) modelling programs. EZStrobe is intended to bridge this gap in currently available simulation tools and to ease the transfer to more complex tools as the system matures. Also, other programs that do not meet the demand for a tool that is simple to learn and capable of modeling somewhat complex situations with little effort. (Martinez, 1998).

Following are the basic modeling elements for EZStrobe shown in Figure 2, as well as the precedence rules that govern them and their explanation:

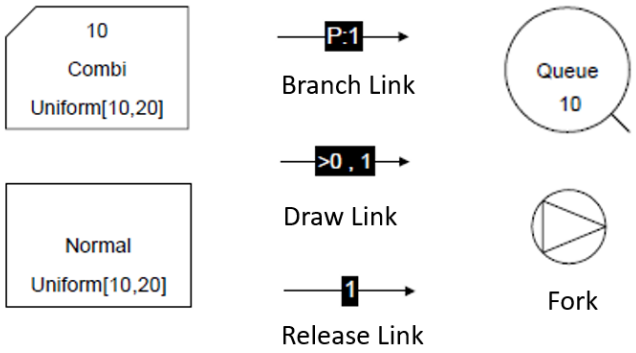

Figure 2: EZStrobe modeling elements.

- *Queues* are named elements that contain idle resources. The Queue's name is displayed in the center. Queues have a limited quantity of resources at the start of a simulation.
- *A Conditional Activity (Combi)* is a named element that specifies tasks that can begin whenever the resources in the queues preceding it are sufficient to support the task.
- *A Bound Activity (Normal)* is a named element that represents tasks that begin when any previous activity instance expires. The Bound Activity's name is displayed in the center.
- *A Fork* is a component of probabilistic routing. It usually follows an activity, but it can also be followed by another Fork.
- *A Draw Link* is a link that connects a queue to a conditional activity.
- Except for conditional activities, a *Release Link* connects an activity to any other node.
- On the other hand, except for a conditional activity, a *Branch Link* connects a fork to any other node (Martinez, 1998).

Project and Modelling

In this paper a simulation model of the microtunneling operation is conducted based on EZStrobe methodology for modeling and simulation. The specific operation discussed in this paper was taken from the book ‘Planning and Analysis of Construction Operations’, in which CYCLONE was used to create a model of this tunneling work. A visual explanation of the operation was shown on Figure 3.

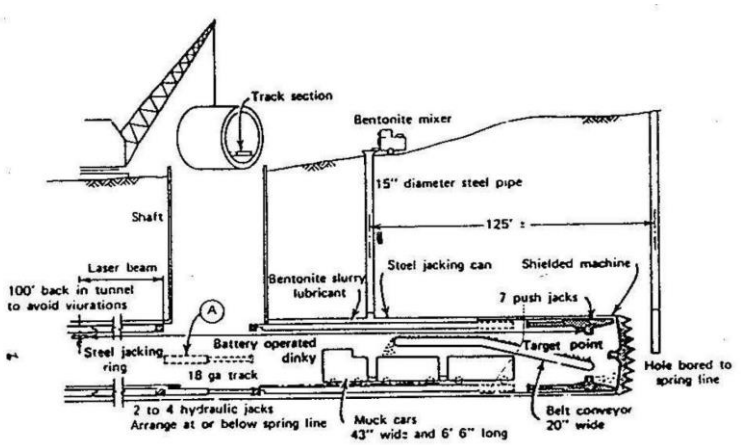

Figure 3: Microtunneling operation shown in Planning and Analysis of Construction Operations (Halpin & Riggs, 1992).

The operation that is simulated includes the previously discussed equipment and procedure. For this operation, instead of removing the excavated soil by pressurised water, 6 ft. long muck cars are used with the help of 20 in. wide conveyor bands. There is a 15 in. diameter steel pipe to pour the bentonite lubricant for a 125 ft. long microtunneling operation. The concrete pipes are pushed by 4 hydraulic jacks.

For modeling the process, duration data gathered from the book "Planning and Analysis of Construction Operations", various articles and a real site in Istanbul, Turkey. The simulation outline was taken from the book, and additions were made according the engineers from the site. Duration of activities were obtained from different articles and from the site. Then model was created and possible efficiency improvements were discussed with the engineers.

An EZStrobe simulation in Figure 4 was created and results were discussed using Stroboscope. EZStrobe was used for modeling for modeling this pipe jacking process. Simulation was made for only 2 pipes cycle because EZStrobe was unable to reach the total duration of this model. To reach the total duration, SimTime of the simulation will be multiplied with a number, thus this model can be used for projects at different lengths.

Activities (cornered elements) throughout the process are;
1) Lowering the Pipe (LowerPipe)
2) Positioning the Pipe (PstnPipe)
3) Replacing Jacks and Collar (RplcJackscollar)
4) Jacking 6 ft Forward (Jack6ftFwd)
5) Emptying the Muck (Empty)
6) Removing Jacking Collar (RmvJckngCollar)
7) Reset Jack Rams (ResetJackRams)

For lowering the pipe,

a) Crane must be in idle position (CrnIdle=1)
b) There must be a pipe in stockpile (PipeStckp>0)
c) Crew 1 must be in idle position (Crew1Idle=1)
d) After the first cycle, jack rams must be in reset position and thus, NewSctnRqrd, which is a messenger element, must be 1.

Positioning will start directly after lowering the pipe is completed.

For replacing jacks and collar to start,

a) Pipe must be in position (PipeinPstn=1)
b) Collar must be removed after the first cycle (CollarRemoved=1)

For jacking to start,

a) Jacks must be in position (JackinPstn=1)
b) Muck cars must be empty (MuckCarsEmpty=1)

For emptying the muck cars to start

a) Muck cars must be full (MuckCarsFull=1)

For removing jacking collars,

a) Jacking must be completed, so CollarMustRmvd must be 1
b) Crew 1 must be in idle position

Resetting jack rams will start directly after jacking 6 feet forward.

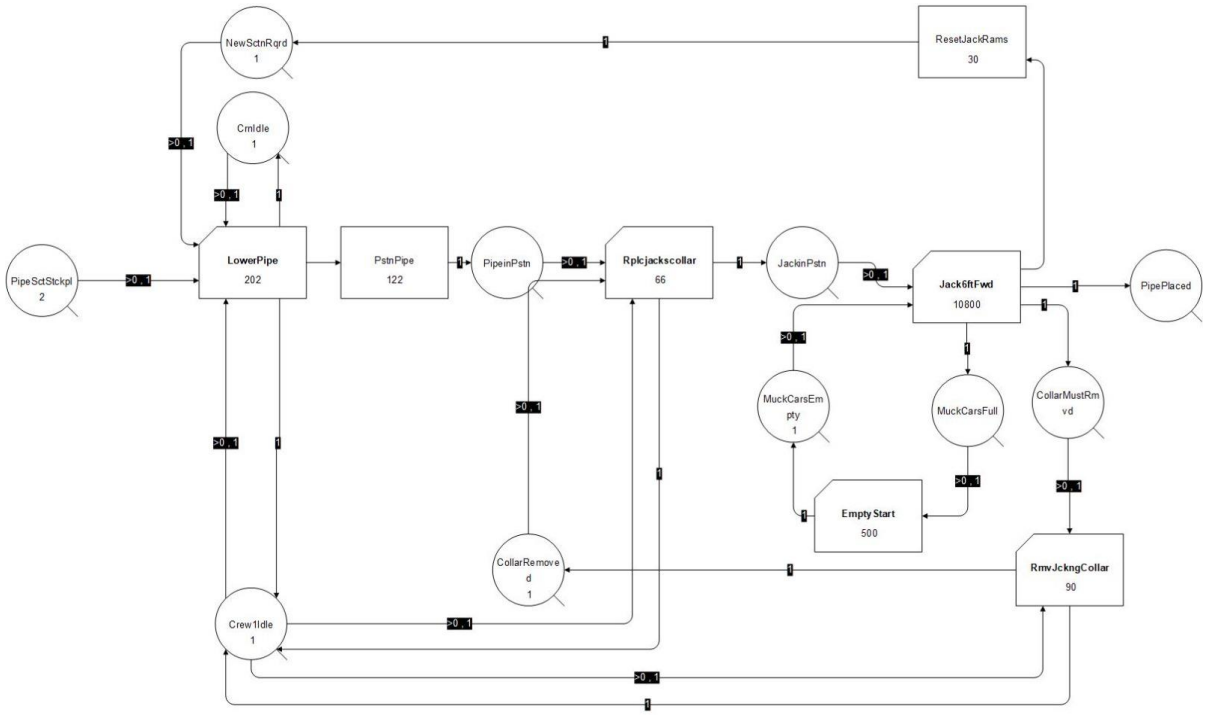

Figure 4: EZStrobe model for pipe jacking operation.

Results

Simulation time was calculated as 22990 seconds for 2 pipe cycles. In this project, there are 19 pipes, so total time required is 3640 minutes. Results are given in Figure 5.

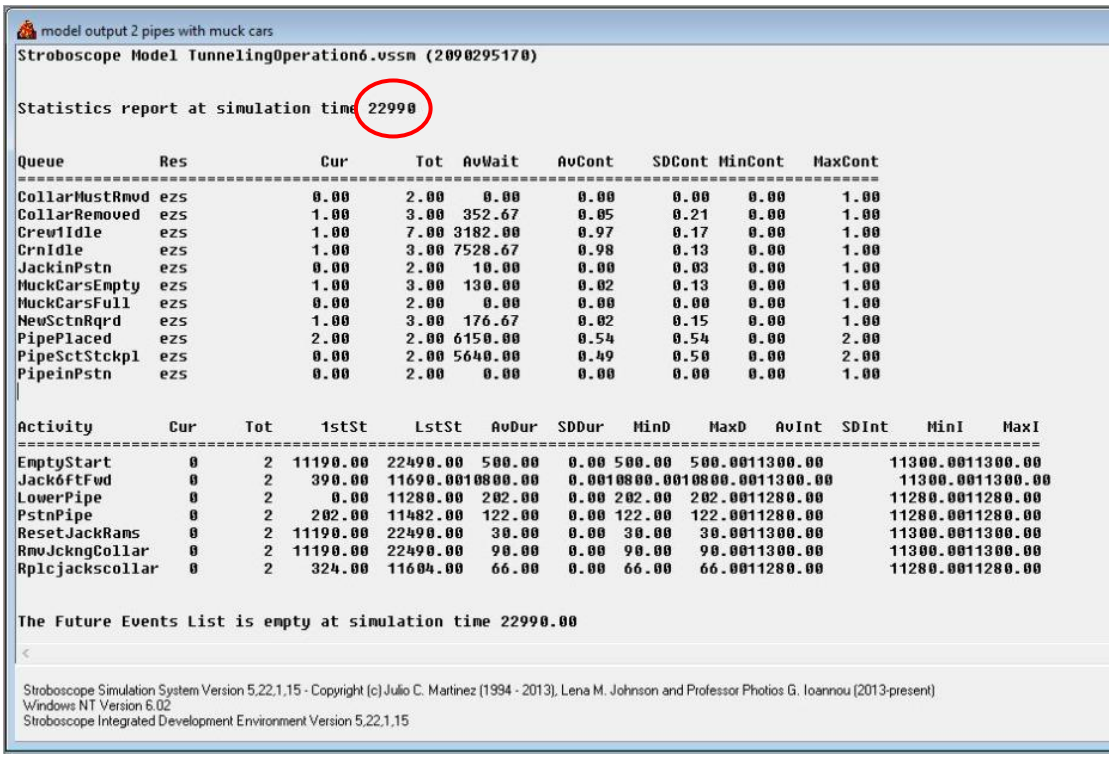

Figure 5: EZStrobe simulation results.

As a result of the simulation, it was seen that 94% of the duration is due to jacking activity, and none of the other activities can take place at the same time with this activity. However, it is not possible and efficient to reduce the duration of this activity, because one of the factors affecting the duration is the soil type, which cannot be changed. The other reason is spread rate of bentonite. Bentonite should be evenly and deeply spread and reach far points of the pipeline to jack the pipes properly. Even in soils have less density, jacking must be done at a certain speed for spreading the bentonite. Different possible improvements are explained in the Discussion section.

Discussion

Numerous factors influence the productivity of microtunneling operations. The productivity of microtunneling is primarily influenced by the underground circumstances, operator experience, pipe conditions, obstructions, use of lubricant, and main jack capacity. Geotechnical challenges, soil conditions, and impediments are some examples of underground circumstances, which is not possible to change. On the other hand, experience of crew and operators can play a significant role in productivity enhancement. Pipe conditions include alignment and diameter of the pipe and the cutter head. Main jack capacity includes the torque of the machine, shape and diameter of the cutter head. Based on computer simulations, the significance of the elements was explored in this paper. These elements should be taken into account by owners, engineers, and contractors who are aiming to increase project productivity.

Conclusion

In this paper, pipe jacking operation and modeling this operation using EZStrobe was discussed. In research, activities and durations were taken from different studies and also an actual pipe jacking project in Istanbul, Turkey. After running the simulation, possible restorations for efficiency were discussed. 94% of the duration of a cycle is caused by Jacking activity, which cannot be affected unless some parameters hard to change such as pipe diameter, torque of the machine or fluidity of bentonite used changes. Various improvements can be done for the other 6%, such as adding crew members or using a better crane operator.

Using Blockchain Concept in Smart Home

D. Savur and Ş. Emekçi
Ankara Yıldırım Beyazıt University, Department of Architecture, Ankara, Turkey
duygusavur92@gmail.com, semekci@ybu.edu.tr

Abstract

The growing population has created new challenges, although expanding technology has provided numerous benefits over the previous two decades. Some of those; excessive and rapid consumption in line with their needs and new rational areas that we need to create for these consumptions. Buildings utilize up to 40% of global energy and are predicted to reach 50% by 2030. Energy consumption in buildings has led to an increased interest in smart home technologies. As they used automation systems that can become passive at certain times by adapting to environmental factors, reducing energy consumption throughout the life of the building. These systems provide monitoring energy requirements and consumptions so facilitating the controllability of energy. However, there is a need for a transparent, decentralized and constant system in order to monitor the energy needs throughout the life cycle of the building. Blockchain technology (BTC) is seen as a solution to the question marks such as how to follow all these processes, data storage, and transparency in data. The study aims to discuss how smart homes (SH) can be managed with blockchain and how to cycle using devices from the preliminary design stage to the end of their lifecycle.

Keywords: *blockchain, energy management, life cycle, smart home.*

Introduction

Since the beginning of the universe, the world has undergone regular changes. However, in the last half-century, humanity faced crucial problems with a rapidly growing population. It was triggered by fast consumption and require new places for shelter. Thus, with the global warming caused by climate change emerged another problem like agricultural land declining as glaciers melted, the resulting food supply problems, loss of biodiversity, pollution of the air, water and ground (Cilingir, 2020; FAO, 2019). Besides, starting with industrial revolution period, human had transferred to the city center from town and village. Today, world populations live in cities approximately 50% (IPCC, 2014). This causes trouble decreasing raw material production and increasing of energy consumption. These are totally domino effects for world. Because of this, the construction industry has the most crucial point in energy consumption. According to the statistics, it consumes %30 of energy in global energy consumption, and also more than %50 of electric in the worldwide (Santamouris & Vasilakopoulou, 2021). Approximately, it has one-third of carbon emissions (Santamouris & Vasilakopoulou, 2021). When we look at water consumption, the construction sector is consuming one-fourth of the total water consumption. Another important statistic is about waste, %25 of solid waste and %20 of liquid waste has produced in the buildings (Kabakçı, 2019).

With all these adverse effects seen, concepts such as sustainability and renewability began to be discussed (United Nation, 1987). As a result of developing technology, that is, digitalization, building businesses that are out of human management started to be used. These building systems are also called smart home (SH) or smart buildings. Smart homes (SH) are different from green buildings. Although green buildings have entered our lives as a concept which is environment, economy and social sustainability as an ideology, with the developing technologies have been integrated into the building sector. In other words, the smart homes (SH) can be considered as the integrated version of the developing technologies in the building field. Even though this system has many positive aspects, some problems have emerged regarding the operation of the system and the storage of data in process of time (Türkyılmaz & Altındag, 2022).

With studies in recent years, our perspective has changed about the data and data warehousing. Blockchain technology (BTC) is novel in this fields. First definition or ideas came in 1990s by a group of researchers. However, first real definition is come from Satoshi Nakamoto in 2008 (Kandiye, 2020). He adapted the old version for himself.

Consumption is advancing in many sectors which are occurred food industry, clothing meaning the fashion sector (Castagna et al., 2022), technological inventions and also construction. Humanity needs to control their consumption. In the study, it will be discussed how smart homes (SH) can be operated with blockchain technology (BTC) and how to energy cycle used items from the preliminary design stage to the end of their lifecycle.

Blockchain Background

The system that allows tracking of all assets and transactions in a business network is called the blockchain. Another definition is a decentralized distributed ledger technology that faultlessly creates, confirms and records encrypted processes of digital assets (Owens, 2017).
System is working in this way;

- Each process saves as a data block
- Each data block has a connection with before and after
- Any operation can't be undone, and it has saved into a chain in a blockchain, which is a chain (Nakamoto, 2009).

In the traditional system, databases have used, and it works on a server, and other channels connect with host server. However, blockchain technology (BTC) means decentralized systems. It can also define that this network occurs on many computers, although in a way that the data cannot shifted without the unanimity of the whole network. Each block has a hash and connect with previous block or hash (Owens, 2017). So, blockchain has proof of work for recording all steps in detail.

When examining the chronology of blockchain, there are three plunge points.

1. Blockchain 1.0: Decentralization of money and payment
2. Blockchain 2.0: Decentralization of markets
3. Blockchain 3.0: Decentralization of government, science, health, art, culture. Meaning is that applications beyond money and market (Kandiye, 2020).

There are 3 main elements for working: block, chain and network. Block is where places of transactions are recorded. Chain is that connection of the creation blocks each other. Network namely the whole system (Kandiye, 2020).

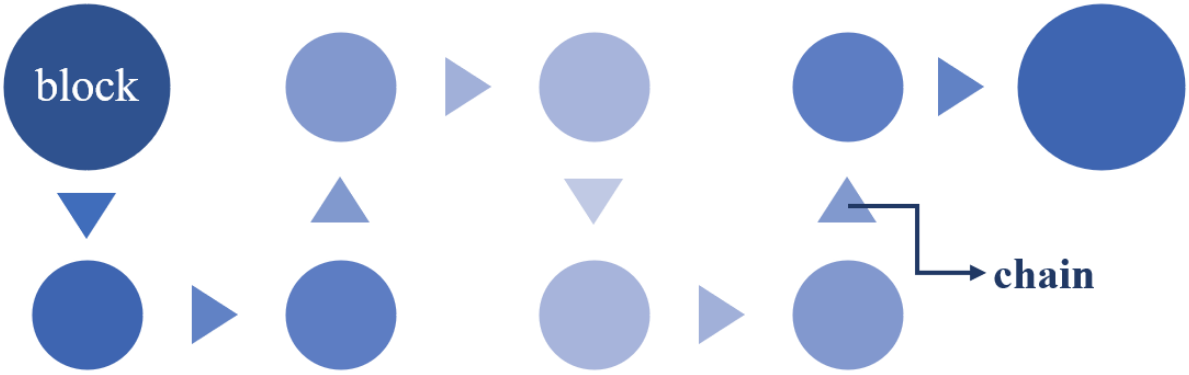

Figure 1: Blockchain main elements diagram.

Although blockchain technology (BTC) is a solution to many problems, its main subjects are 3 topics which are scalability, reliability and decentralization. In order to create a good system, these 3 main issues should work together (Kandiye, 2020).

A survey has done which conducted asking about the main supporting elements of blockchain technology (BTC) that is being used by businesses in which more than 50 companies participated. The survey participants answer that 61.5% of the respondents said transparency, 58.5% immutability, 40.8% trust, 33.7% of them answered decentralized and 20.1% of them as cost reduction, intermediation, and automation, which are described as other (Sebastian, 2019).

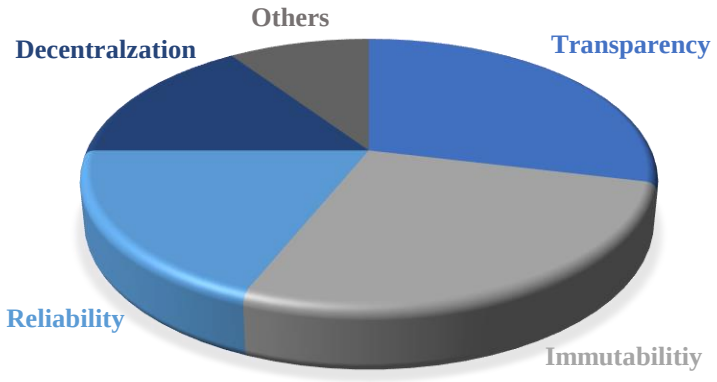

Figure 2: Main supporting elements of blockchain technology.

Types of Blockchain

a) Public Blockchain

This type of the blockchain is a network that anyone can join without restrictions. Most types of cryptocurrencies operate on a permission-less blockchain governed by consensus or rules algorithms (Solomon, 2019). In construction sector, public contract applications can be suitable for this type of blockchain technology (BTC), inasmuch as, public blockchain is transparent (Kandiye, 2020).

b) Permissioned or Private Blockchain

In the Permissioned blockchain, only authorized participants can join the network. However, participation is just by invitation. Transactions can only take place on approved participants, not on every participant (Solomon, 2019).

c) Federated or Consortium Blockchain

The consortium blockchain does not have a single owner, so it is somewhat similar to a private blockchain. This blockchain network is closely controlled by a preselected set of nodes or a preselected number of stakeholders in which the mining process (Solomon, 2019).

One of the sectors that the developing blockchain technology (BTC) can adapt to is the construction sector. With this technology, we can determine how we will use the accumulated data from the preliminary design stage to the end of the building's life cycle. Blockchain technology (BTC) is a very important innovation, especially in order to follow the energy efficiency issue, which is one of the biggest problems of today. Blockchain technology (BTC) will be a very important technology in matters such as the monitoring of the energy produced by the buildings, the list of needs, and if there is unnecessary energy production, its supply to the necessary places.

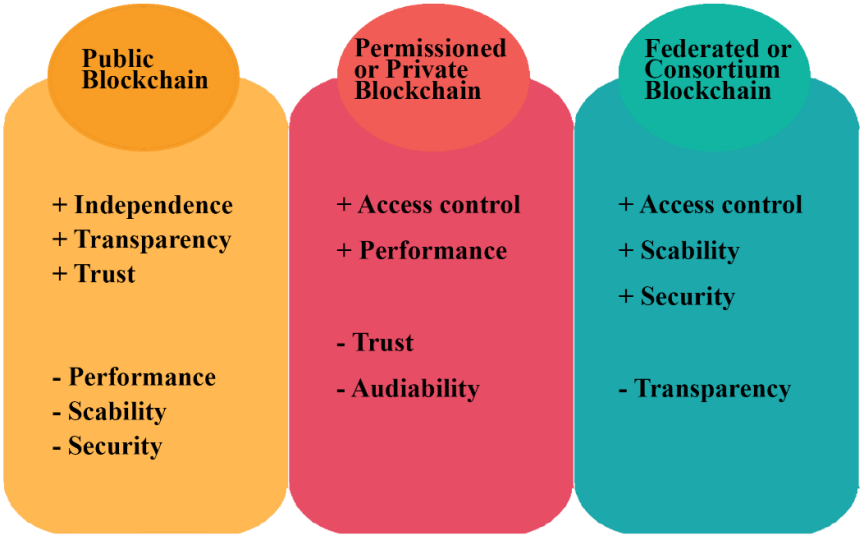

Figure 3: Types of blockchain and pros and cons.

Smart Home Background

Smart homes (SH) can be expressed that automatically controllable buildings distantly. Devices or appliances need a connection network which can be managed via mobile phone or monitoring vehicle. Internet technology is the most important invention for this. All home vehicles can be added control plugs and connected with smart phone. Distances are not important for most duties, user can open or close electrical vehicles or can control times or issues can command working time. Control capacities can list like security accessing, lighting, temperature, vehicle control and home theater (Smart Home, n.d.).

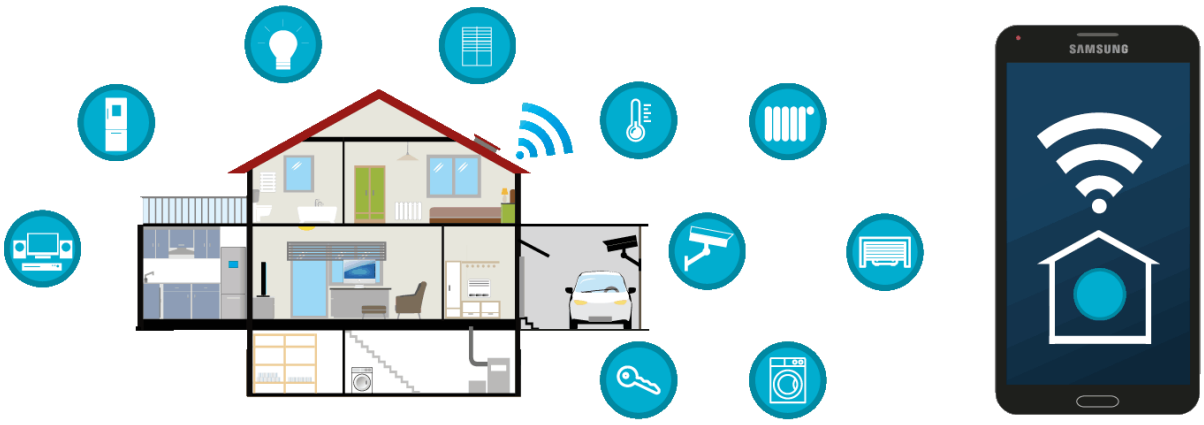

Figure 4: Smart home systems (Blog de Trisacor, 2017)

Another definition;

"Smart homes are, in their simplest definition, the computerization of housing. They gather data on inhabitants and their habits with a range of sensors; by analyzing these collected data, they respond to these actions and events by controlling certain mechanisms built into the housing." (Emekci, 2022).

These systems, which can be self-supporting, have to use some sources. These are energy and network connection with the outside world and between each other. So, after the energy, the most important requirement in using smart home systems is internet infrastructure. The theoretical name of this is Internet of Things (IoT). What is the IoT?

Internet of Things (IoT)

IoT is the most significant technology in this century. It can describe in this way; the network of a material object. IoT is using a vast amount of fields nowadays. Since, new technology brings us new requirements and humanity needs to connect and swap data with other gadgets and systems via the internet (Oracle, n.d.).

Nowadays, IoT has lots of benefits these are access to low-cost and power sensor technology, connectivity, cloud computing platform, machine learning, analytics and conservations artificial intelligence (AI) in these matters.

The studies on the use of the IoT system in the smart home were examined in 3 groups (Sepasgozar et al., 2020).

1. The energy management processing, provide today's smart home applications from the point of energy efficiency and energy consumption following
2. Applications of artificial intelligence in smart homes, such as deep learning algorithms and machine learning can be applied in divergent contexts
3. Aged care systems can be adapted in different places and can be learned from these practices.

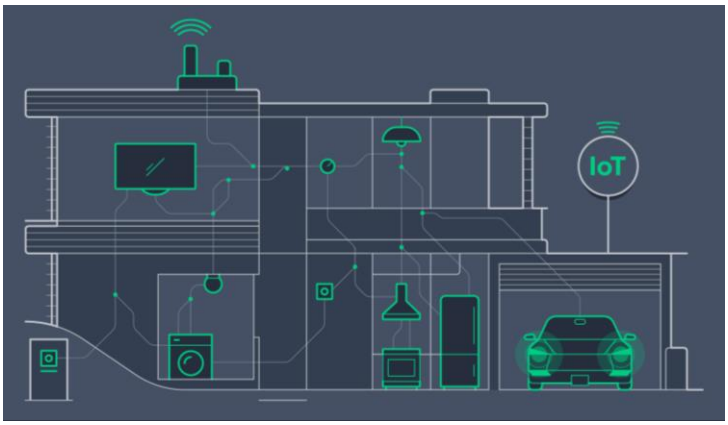

Figure 5: IoT in the smart home (SH) (Mundle, 2020).

The reason for the need for the computerization of houses is the global climate problems. The climate crisis and the rapid increase in population have pushed people to use their resources more efficiently. It would be more explanatory to consider these resources as production waste rather than evaluating them only based on raw materials. The carbon that comes out while processing any raw material used, the water used and the energy we burn are buried energy that no one thinks of. When a construction evaluation after construction terms is just looking but it's totally wrong energy efficiency has to start from scratch. Inasmuch as, carbon emission starts with the first step and continues until the end of the life of the building and its demolition.

Blockchain Technology (BTC) in Smart Home (SH) Life Cycle

The cradle-to-grave concept, which is frequently used in sustainability, has been the best technology that can define and follow the life cycle. Starting from the very beginning of the process, that is, the agreement of the parties, design, construction, delivery, placement of the users and the active use of the building, etc. It has become mandatory today to record the list one by one and follow up on the needs of the users in light of these data.

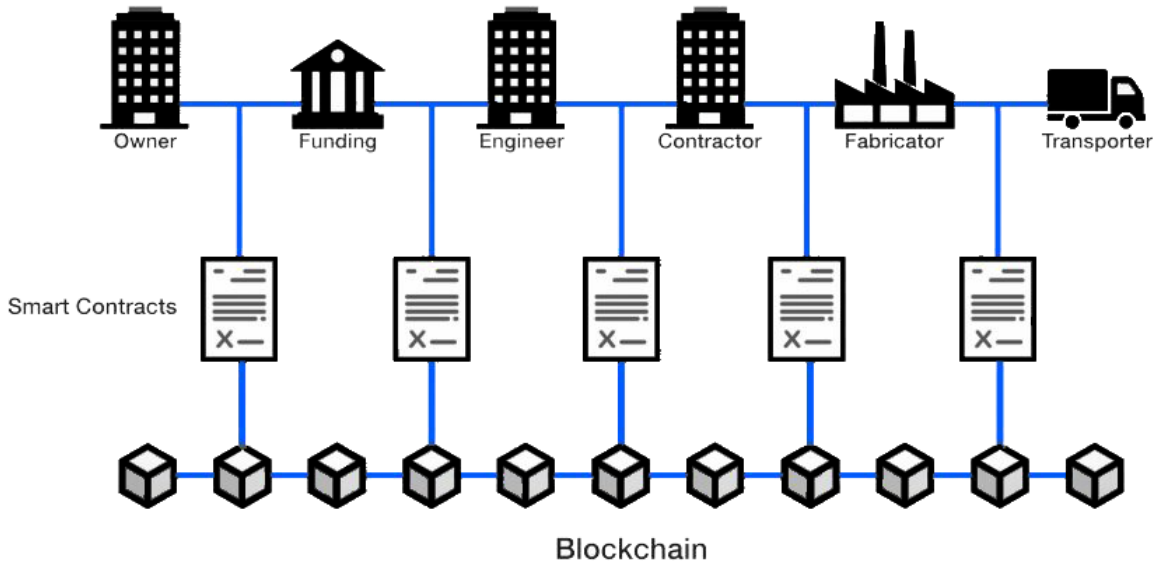

Figure 6: Blockchain network.

In smart home systems, if we start from the user's location, innovations such as the maintenance of the devices used, the monitoring of the energy they consume, the easy monitoring of the safety of the individuals in the house, the automatic provision of appropriate temperature and lighting will be appropriate for this era.

There are some timed intervals used in the structure. These are dishwashers, cloth washers, plug-in hybrid electric vehicles (PHEV). The promptitude of these tools plays an important role in saving electricity usage, that is, in bills (Sethi et al., 2020). At the same time, all vehicles have vital importance for managing energy consumption automatically. The user can see vehicles working conditions and how much time can be taken or how much energy will consume. Thus, of vehicles can be changed or renewable some problematic parts.

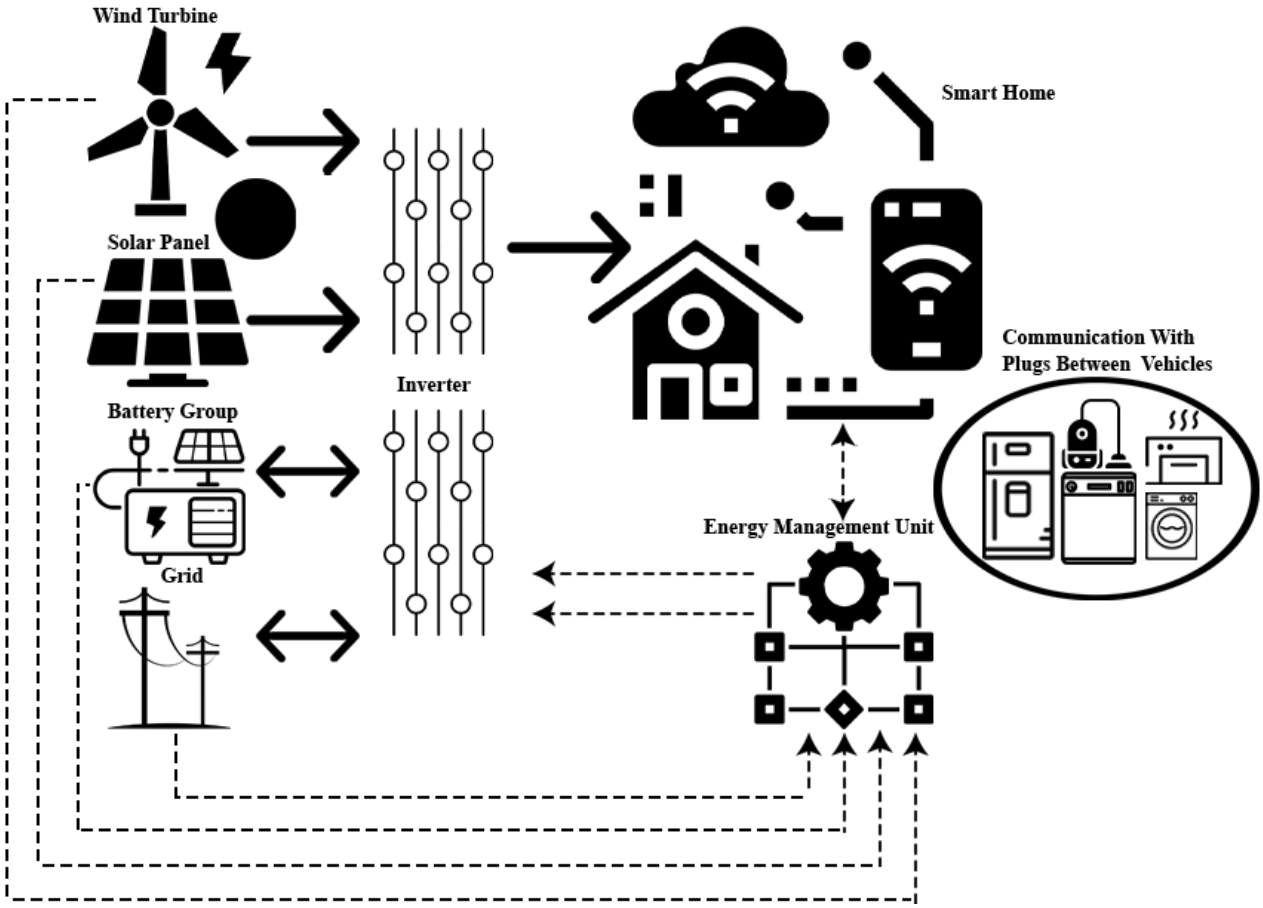

Figure 7: Energy management systems in smart homes (SH).

Building life cycle can be divided 3 main parts. Design and construction phase, user phase and completing its life. These all phases are consumed energy and they can be monitories via blockchain interface.

The use of blockchain technology (BTC) in the building life cycle begins at the stage of deciding on the construction of the building. During the construction phase, it creates a safe and systematic organization between the parties. The reason is that the system is transparent, and everyone can participate in the blockchain network at equal distance. When accessibilities and control panels are easily, energy consumptions can be organized easily. This is mutualist relationship between consumer and system.

In the using phase, it continues in parts such as the control and maintenance of smart home systems, automatic provision of material-based needs, resource and waste management. The energy needs registered in the system or the transfer of wastes to the relevant places will be carried out automatically, thanks to an open contract. The electricity produced by the building itself is directed to the needs as a priority. If there is excess electricity storage, it is sold to the relevant units and the building is ensured to sustain itself economically. Another way is If-This-Then-That (IFTTT). This method, which stands for "if-this-then-that", is the algorithm-generated version of the system known as a "smart contract". It can be argued that this system should be used in the construction industry.

In blocks in the blockchain, codes can be generated that automatically arrange the necessary messages and payments using the “if-this-then-that” logic. It is an undeniable fact that the use

of smart home devices will be more efficient thanks to the created algorithm. The reason is that the maintenance in Decentralized Autonomous Organization (DAO) smart home systems can automatically set the repair order. In this way, issues such as the maintenance of the vehicles in the building, equipment needs, and waste management can be carried out automatically.

If-This-Then-That (IFTTT) can also be defined as the adaptation of smart contracts to blockchain technology (BTC). However, it is certain that transparency will be ensured in the contracts. Therefore, it is argued that the adoption of If-This-Then-That (IFTTT) in the construction sector will increase the trust environment between the parties. If-This-Then-That (IFTTT) will increase efficiency in many fields, from vehicle and equipment rental to waste management.

The most important features that make this system powerful are; efficiency, automation, privacy, transparency, decentralization and auditability. On the other hand, their weak features are; scalability, low performance, high energy consumption over time, having a complex structure. Although these technologies, which have been in our lives for the last two decades, have many positive and negative features, the most crucial feature is to control energy management and thus reduce it. Nevertheless, it will take time to eliminate all negative features and maximize efficiency.

At the last stage, it can be easily determined that the productive life of the building has been completed. All processes in the building are recorded and it is automatically known which systems are efficient and at what level. If the building's general life is over, and there are still usable vehicles, these are determined and transferred to the centers where they can be used. The same applies to the materials used in the construction of the building. Therefore, energy management is possible to make a complete follow-up from the cradle to the grave by using blockchain technology in smart homes.

Discussion and Conclusion

System Requirements

Some minimum conditions are required for the use of blockchain technology (BTC) in smart home systems. The most basic of these is the internet infrastructure. Smart home (SH) and blockchain technology (BTC) work on totally electric and internet infrastructure. Therefore, in cities, the internet and electric infrastructure have to strengthen. On the other hand, these requirements provide preparation for smart city grounds. Inasmuch as, smart home devices can access each other, and they have to connect their relation units and services.

In this era, thanks to the technological invention, human life has been both easier and harder. Although machine learning or smart technologies make human life easier, it is possible for all systems to fail and shut down in the smallest infrastructure problems. This shows that these systems require very clever and reliable design. Considering the smart systems to be used only as simple machines in residential buildings is due to the insufficient perception of the scope of these systems. Although the use of smart technologies in the field of health aims to minimize human error, it can be predicted that system failures caused by infrastructure problems may lead to greater losses.

To sum up, smart home technologies can be applied easily and can adapt lots of place but it requires hard infrastructural technology. If there are any basic insufficient, smart technologies will be unmeaningness.

Management of Energy, Material and Time

Blockchain technology (BTC), which started in the 1990s and has gone through many leaps to the present, has become inevitable to be used in the building sector and construction. The energy and material management in the building's design phase, starting from time management and in the advancing processes, is very valuable and has become very easily controllable thanks to blockchain technology (BTC). The use of blockchain technology can make all processes fast, transparent, reliable and effective. Choosing a blockchain at a scale suitable for the area to be used and using it can be said to be the only condition necessary to ensure the flow of work.

In a globalized world for any project managed, there is no chance of progress accidentally. The carbon, water and energy emissions that occur in every project consume the natural resources of the world. In order to prevent these, highly controlled and reliable methods should be used. The first condition to reduce the effects of increasing population and climate change problems should be to minimize the margin of error in the selected methods. It is seen that the real purpose can only be achieved by the continuity of the positive features of the methods used and the development of the negative features in the positive direction.

In this study, the positive and negative features of the use of blockchain technology (BTC) in smart homes (SH) were investigated. In line with the results obtained from the research, it was concluded that the positive features are efficiency, time, energy and material management. It is foreseen that the system will be able to operate with full efficiency as a result of the elimination of negative features such as the need for internet infrastructure and the need for permanent energy.

Major Research Areas in Smart Factory Research

G. B. Ozturk and B. Ozen
Aydin Adnan Menderes University, Department of Civil Engineering, Aydin, Turkey
gbozturk@adu.edu.tr, 1911900118@stu.adu.edu.tr

Abstract

The rapid and continuous development in Information Technologies (IT) has led to the 4th industrial revolution which triggers the Construction 4.0 approach in the Architecture, Engineering, Construction, and Operation (AECO) industry. Digitalization, as the major step for technology adoption, increases in the AECO industry as in all other industries throughout the world with the help of improvements in computer and data sciences. This revolution may be defined as the transformation of production systems from automated to digitalized smart production. Smart production may increase the quality, cost, sustainability, and efficiency via the new revolutionized production environment, tools, techniques, and methods within the Smart Factory concept. This article focuses on Smart Factory research in the literature. Bibliometric research and scientometric analysis were conducted to figure out the research areas in the Smart Factory concept. The research areas in the Smart Factory subject were clustered under six main headings. In the light of the findings, the Smart Factory subject is the focus of scholars since it triggers efficiency in production and facility management.

Keywords: *cognitive systems, Construction 4.0, data management, digitalization, Industry 4.0, smart facility management, smart factory*.

Introduction

Digital production has begun to evolve into smart manufacturing with the rapid development of information technologies (Chen et al., 2017). Industry 4.0 is based on smart production and aims to transform into smart factory (SF) that make resource management more efficient than traditional factories. This goal integrates factories with the product lifecycle and activities (Fernandez-Carames & Fraga-Lamas, 2019; Kang et al., 2016). SF covers networked manufacturing systems for smart manufacturing. To implement SF, smart objects must be combined with big data analytics. Smart objects may be configured dynamically, while big data analytics can provide feedback and coordination to achieve high throughput. Thus, SF can produce products efficiently, profitably, and in a short time (Wang et al., 2016). In addition, production processes can be physically monitored in these facilities and a digital twin of the physical world can be created. In this way, SF can make smart decisions through real-time communication and collaboration (Zhong et al., 2017). This innovation has emerged thanks to developments in artificial intelligence (AI) and automation and new digital technologies connected to the Internet of Things (IoT) (Sjödin et al., 2018). IoT refers to objects that communicate with each other to create a dynamic network (Borgia, 2014).

The most relevant term for SF is Cyber-Physical Systems (CPS) (Xu & Duan, 2019). Computing and networking may be integrated with physical processes, dynamics can be controlled and managed, and more efficient and reliable next-generation Information and Communication Technologies (ICT) systems can be achieved via CPS (Mittal et al., 2019). Better data collection and faster communication networks can be established with CPS, thereby increasing the formation of interconnected physical facilities to generate large amounts of data. Such big data in CPS of SF have great potential for better supply chain management, reducing failure rate, improving production speed and quality (Xu & Duan, 2019). In recent years, the cheapening of sensors and ICT, the success of machine learning (ML) and AI plays an important role in the implementation and development of SF. AI is important in smart production because of features such as learning, smart execution (Zhong et al., 2017). The success of these technologies has also triggered the dawn of the digital twin concept. A digital twin (DT) is the creation of a virtual representation. It aims to improve the operations of the product throughout its lifecycle and provides real-time inspection of the product (Rasheed et al., 2020). Representing the conceptual ideal for product lifecycle management, the DT allows for virtual representation with data bidirectionally integrating the physical asset at any time (Ozturk, 2021).

Data in SF flows over the internet. As a result, threats to security and privacy have increased. It is important to ensure security and confidentiality, especially apart from issues such as data integrity and data redundancy. This challenge can be overcome with blockchain technology, which can eliminate the need for the central authority to perform various transactions (Bodkhe et al., 2020). Blockchain can keep a permanent and tamper-proof record of transaction data. Each node of a blockchain maintains a copy of the ledger to prevent a single point of failure. All copies can be updated and verified simultaneously (Hammi et al., 2018). Blockchain helps automate industrial processes involving multiple companies. Therefore, the concept of smart contracts is important. The smart contract relies on data connected to external services that receive real-world data and store it on blockchains (Fernandez-Carames & Fraga-Lamas, 2019).

This paper aims to classify the mainstream research areas in SF research to capture the gaps and current research tendencies and to make projections for prospective research areas in the field. Thereby, scholars, industry experts, managers, and the SF research society would profit from the results by creating an understanding of the future to shape and clarify the research and development path of implementing SF tools, techniques, technologies, and philosophies.

Methodology

This research utilized bibliometric search, scientometric mapping, and scientometric analysis to provide an overview of current Smart Factory research areas. (Represents articles published up to October 2021). Bibliometric data was acquired from the SCOPUS database, which contains more information than any other database due to the ever-growing resource (Aghaei Chadegani et al., 2013). The SCOPUS search API uses a system called Boolean Syntax to combine search results for sensitive data (Cobo et al., 2011). Since the data collection is a one-time snapshot of the literature, it only includes research patterns, gaps, and trends for that period. Providing a dynamic data graph can be more effective for the presentation of the research. Language limitations, including only articles, are other limitations for the study. Scientometric Mapping analyzes bibliometric data to show the relationship between research areas through keyword co-occurrences. VOSviewer software was used to analyze the data

collected from the Scopus database. This research involves clustering keyword combinations to visualize, analyze and explore the research areas of Smart Factory. However, future research can reveal more insight about Smart Factory by further analyzing publication sources, citation, co-citation, co-authorship, and bibliographic matching of articles, authors, organizations, and countries.

Scientometric Analysis and Results

Bibliometric Search

The Boolean search was used to consolidate search output and to find results related to the research area. A summary of the bibliometric search entry showing other limitations of the keywords is shown in Figure 1. This research resulted in 9038 articles. Additional limitations such as language, document type, document source, and subject area were applied. Then, 3229 articles that were highly relevant to the research topic remained.

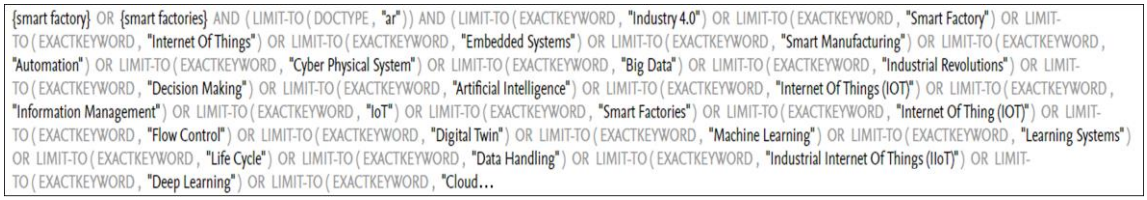

Figure 1: Summary of bibliometric search input.

Scientometric Analysis and Mapping of Keywords

Keywords play a key role in identifying important points in research (He et al., 2017). Using Vosviewer enabled natural language processing and text mining methods application. A network visualization map was established to show the relationship between keywords and cluster main research areas (Eck & Waltman, 2014). In this research, the keywords that were overlooked were prevented by using index keywords other than the keywords used by the authors. Filtering Figure 2 shows the network visualization map of keywords co-occurrence analysis results. The keyword list is shown in Table 1.

Related keywords were clustered with VOSviewer, thus allowing comments on sub-areas of the research field. Each color in the image given in Figure 2 belongs to a separate cluster. The clusters were given names after the keyword sets' related research areas. Accordingly, the clusters are named Information Management (red-coded), Data Utilization (green-coded), Cognitive Smart Systems (blue-coded), Smart Facility Management (yellow-coded), Information and Communication Technologies (purple-coded), and Information Security (turquoise-coded).

The red-coded cluster called "Information management" is related to collecting, processing, and managing data for a predictive decision-making process in order to enhance efficiency throughout the product life cycle. In the Smart Factory implementation, all systems and products are equipped with sensors to acquire and update information. The management of consists of ensuring the quality and accessibility of the acquired information to share it with all stakeholders. IoT sensors and actuators are among the most widely used technologies for

collecting data. The collected ‘big data’ is handled such as categorization, analyze, and evaluation to manage data to information cycle in order to establish a robust decision-making process. This cluster consists of the basic elements necessary for the formation of a Smart Factory and smart manufacturing.

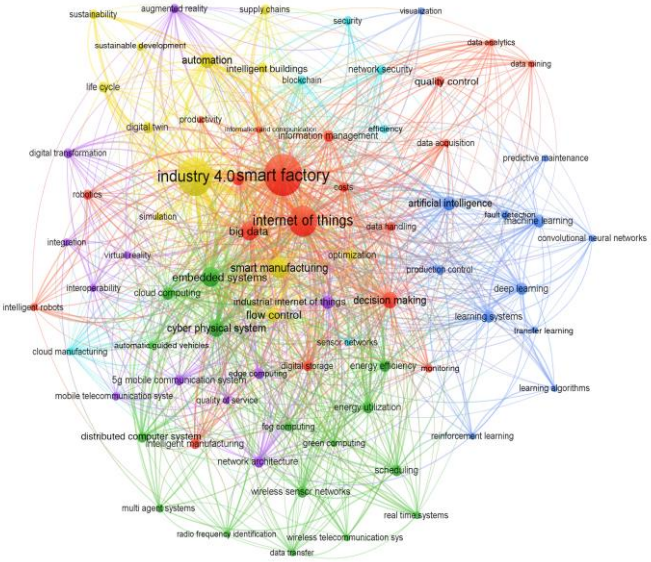

Figure 2: Network visualization map of keyword co-occurrence analysis of Smart Factory.

The green-coded cluster called “Data Utilization” is related to how the collected data will be used. It is possible to reduce error rates in production, produce with less cost and higher efficiency with the use of data collected and managed by sensors. Better data can be collected; production speed and quality can be increased with CPS. Thus, energy efficiency is ensured to a great extent.

The blue-coded cluster called “Cognitive Smart Systems” is related to systems that can learn by themselves and produce what they learn. These systems are developed using AI technologies. Sub-fields of AI such as deep learning and machine learning in this cluster show that intelligent systems are being used.

The yellow-coded cluster called “Smart Facility Management” is related to the smart product at each AI level. With the implementation of AI technologies in SF, the idea of real-time monitoring of production emerged. This has triggered intelligent facility management. Smart facility management (SFM) ensures the integration of systems, processes, technologies, and people to improve management in facilities. Providing SFM increases productivity by reducing costs and manpower. In order to achieve this, DT technology is used.

The purple-coded cluster called “Information Communication Technologies” is related to collaborative and integrated systems. ICT can realize the connection in production systems at any time and place. ICT was used in order to communicate systems with each other and therefore, increase interoperability between the systems used in SF.

The turquoise-coded cluster called “Information Security” is related to emerging cyber security limitations against rapidly revolutionizing technology. Information security is the protection of the integrity and confidentiality of data during the storage and transfer of

information. The flow of data over the internet in systems used in SF has made the issue of data security important. Blockchain technology aims to reduce threats to data security.

Table 1. Keyword co-occurrence analysis results for Smart Factory.

Clusters	Keyword Group	Link	Total Link Strength	Occur-rences	Average Citation	Average Normalized Citation	Average Published Year
Information Management (red-coded)	*Big data*	59	244	65	55,14	1,81	2018,65

Discussion

Through the triggering of the Industry 4.0 concept in recent years, smart production has become the focus of attention of the business world and academics. Smart systems have attracted great interest in many sectors with the new information technologies offered by Industry 4.0. The AECO industry has also benefited from these developments. The fact that the AECO industry plays an important role in the economies of countries and consumes raw materials very quickly is an indication that digitalization plays a key role in the sector. Using smart production technologies in the sector, the optimization of time, cost and quality parameters in project management can be achieved. Materials and resources are correct; labor

and machinery can be used efficiently via smart production technologies. In addition, by providing integration between stakeholders, delivery times can be reduced, quality and cost can be increased.

The collection and processing of data necessary for the development of the SF has been the primary focus of the research area. For this reason, technologies that enable data collection with sensors such as IoT are attracting more and more attention. Data collection alone is not enough to build a SF. The correct processing and management of this data has been achieved with the development of ICT. After collecting and managing the data, the next step is to set up a learning system on its own and produce it more efficiently. With AI technologies, human participation in production can be minimized in order to provide a more sustainable and efficient product life cycle. Exchange of information over the network in SF jeopardizes data security. This is one of the biggest challenges in implementing the SF. In recent years, the number of researches in the direction of blockchain and network security has increased. Collecting and processing data, developing self-learning systems, ensuring inter-system communication and ensuring data security will ensure the full realization of the SF. Thus, with the smart production provided by the SF, energy efficiency and a sustainable product life cycle can be achieved.

Conclusion

This study aims to reveal the scientific trends of research on SF in the literature. For this purpose, bibliometric research and scientometric analysis were performed. As a result of the research, it has been revealed that SF can provide sustainability and energy efficiency in production. According to the Scientometric mapping results; research on SF seems to focus on collecting and managing data and ensuring security. Research has shown that there is a trend towards integrating SF with AI technologies, which minimize errors in production and may increase productivity. In addition, a virtual representation of the product can be obtained and the product life cycle can be followed in real-time. ICT can be used to enable systems used to communicate among themselves. Thus, inter-system integration and interoperability can be achieved. Ensuring information security management in SF is a challenging task. By ensuring information security management and interoperability of systems, the difficulties in implementing SF can be overcome. Thus, future studies may be aimed at increasing the contribution of SF to sustainability and energy efficiency.

Abstract

Digital age of the architectural, engineering, operation, and facility management (AECO- FM) industry fosters knowledge management with the extensive and inclusive data acquisition and information transformation for better management throughout the building life-cycle. The transformation of data into knowledge enhanced via the data acquisition, data retrieval, data store, information share, knowledge generation, knowledge utilization. Information management is the creating, sharing, using and managing the information from concept creation to demolition of a building. However, the diverse nature of the building information complicates the management of building knowledge in terms of interoperability, transparency, time, accountability, customization, size, linguistics, and diverging needs. The chaotic environment triggers safety, transparency, speed, accessibility needs throughout all information sharing processes. Therefore, distributed ledger technologies become prominent for building information management, to provide security of data. Our objective in this paper is to show different distributed ledger types and their usage in the AECO-FM industry.

Keywords*: construction industry, data security, digital twins (DTs), distributed ledger technology (DLT), internet of things (IoT).*

Introduction

The AECO-FM industry has been modified through technological developments within the last decades that results in the AECO-FM industry managing building assets throughout their lifecycle, automating facilities management activities to increase business potency.

Industry 4.0 emerged as a set of systems consisting of three stages: the Internet of Things, Internet services and cyber-physical systems. In general, the traditional construction industry was beginning to be integrated into industry 4.0 and its components. The information sharing structure in project management, which was applied in the traditional method, contained deficiencies in terms of security, integrity and applicability. With Industry 5.0, there were also new developments to eliminate these shortcomings. Industry 5.0, which stands out with its unmanned technologies, virtual realities and sustainability solutions, started to work rapidly on

solution proposals that were aimed to be applied to the construction sector as well.

The digital twin is one of the most prominent issues in the construction industry. Digital twin technology, which aims to minimize error, loss of time and danger by working on virtual structures before starting real construction, is seen as a groundbreaking progress. However, although it solves many problems, this technology has its own shortcomings. The biggest handicap is the lack of security in sharing information.

This study examines the distributed ledger approach to develop DT technologies and synthesize the findings from these cases to propose an abstract implementation framework that might be used as a catalyst for raising the potency of AECO-FM.

Distributed Ledger Technology

Digital systems that provide decentralized databases are called Distributed Ledger Technology (DLT). These digital systems eliminate the central authority hence it spreads digital data across multiple places at the same time. DLT controls against manipulation of the network and allows for record keeping of all information in the system safe and secure with cryptographic algorithms. Every record keeping part of the network is called node. These nodes replicate, share and synchronize digital data through the network. To ensure replication across nodes is undertaken, distributed ledgers require a peer-to-peer network and a consensus algorithm.

Classification of DLTs

It is crucial to choose the right DLT type for an application. Most of the cryptocurrency and virtual applications couldn't succeed in the area just because they don't understand the importance of the right DLT type. DLT classification depends on its information sharing structure. In Figure 1 whole database types are shown with their examples. For DLT there are 3 main types:

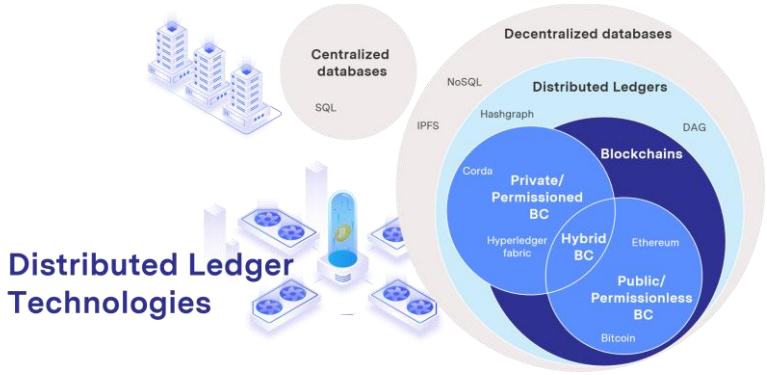

Figure 1: Taxonomy of distributed ledger technologies. Graph from Raphael Iten and Severin Kranz, Different Types of Blockchain, (mm1 consulting, Jun 26, 2019).

Public, Permissionless distributed ledger systems do not require any permission from an authority. All nodes in the network are able to maintain and operate public distributed ledgers. Public DLTs are, due to their structure, available to anyone who wants to get access to it.

Most well-known public ledger is Bitcoin. It was originally designed with public parameters, however lots of the on-ramps and off-ramps for Bitcoin are increasingly permission-based recently.

Private, Permissioned distributed ledger systems, on the contrary, require permissions. Authorized nodes are mandatory for validation of blocks. Hence authorized nodes maintain the ledger, determining restriction, like read and write access, is also possible in private distributed ledgers. It is feasible to identify users whitelisted or blacklisted through KYB (know your business) or KYC (know your customer) procedure which is a common method in traditional finance. Transaction costs and data redundancies are less than public ledgers. On the other hand, it needs a manager for determination of authorized nodes.

Hybrid distributed ledger systems are the combination of public and private DLTs. With the privacy utility of private ledger and with the security and transparency utilities of the public ledger, hybrid ledger gains significant flexibility for businesses.

Features of DLTs

Following features are common in all kinds of DLTs:

A. Distributed: makes possible multiple parties collectively enabling multiple parties to collectively generate, edit and operate a shared set of records (the ledger).
B. Multi-party consensus: enable all parties to come to agreement on a shared set of records
C. Independent validation: verification of transactions and integrity of the system is enabled by each participant.
D. Tamper evidence: non-consensual changes applied in the records are detected by each participant.
E. Immutable: make it hard for a single party to unilaterally change past records (i.e. transaction history).

DLT Criteria

A. Consensus Algorithm

In the network some rules and processes are needed to add, validate new assets to that network. This set of rules, to reach an agreement in the network, are called consensus. The most well-known consensus algorithm is PoW, depending on complex computational problems. Based on the consensus, the faster participant in the network solving the problem first gets the creation right for the next block. Since this consensus depends on computation power, energy consumption of it is very high. Alternative consensus mechanisms have been launched according to created DLTs need and usage area. They affect transaction time, security level, scalability and many properties of DLTs.

B. Protocol

In the network some rules are needed for communication between participants. This set of rules determine how systems work together and how they understand each other. Protocols affect integrity, security, robustness and many properties of DLTs.

C. Data structure

Very basically data structures declare the aim of DLTs. The specific kinds of information and data structures that are held by a node, are always specific to the DLT system. Data structures affect durability, transparency, standardization, tamper resistance and many crucial properties of DLTs.

D. Cryptography

In the network, secure communication and data exchange is provided by different cryptographic algorithms, encryption methods and key types. The method used in a DLT depends on system requirements and field of study. Cryptography is also involved in some of the consensus protocols and is the primary vehicle in achieving consensus. Also, encryption is possible in different layers of the system as shown in Figure 3. Cryptography affects security, integrity, confidentiality, authority and many properties of DLTs.

E. Mining

Process of generation of new blocks is called mining. New transactions' sender, receiver and data values are sent in encrypted form. Miners, also referred to as validator nodes, go through some processes to add the transaction to the block which vary depending on DLTs mining protocol. For example, in Bitcoin, miners have to solve complex algorithmic problems to get the writing turn of the block. Miners are also rewarded for encouraging the mining process in some DLTs.

F. Transactions per second

The number of transactions in one second, as a measuring concept, is called transactions per second (TPS). It is used for all kinds of actions in the computational field as TPS. In this paper it is used to measure the duration of between two transactions of DLTs. TPS affects speed, energy consumption of DLTs.

G. Validation of transactions

The action of checking or proving the validity or accuracy of transactions. Verification is done in the network if transactions and records are valid, consistent and conform to the set of rules in the system. Some DLT types rule that validated transactions can never be reversed. Validation of transactions can affect immutability of DLTs.

H. Energy Efficiency

Concept of decreasing energy bills, and increasing sustainability by getting the same result with less energy consumption is called energy efficiency. Although power is a must for DLT systems infrastructure it is possible to reduce waste of energy by choosing better options for DLTs.

I. Security

It is stated as being free from danger or threat. Cryptography, hashing algorithms and public/private keypairs are used to provide security in DLTs. It signs and encrypts messages (transaction) with public/private keypair. When the message is sent to the network, the encrypted version can be seen by other nodes. This is called asymmetric cryptography and DLTs' security depends on it. Based on ledger implementation scale key size varies.

J. Scalability

The capacity to be changed in size or scale in a system is called scalability. If a DLT don't structured on the correct requirement, the need to store all data pertaining to that DLT, may grow to be unmanageable in size for individual end-users.

K. Platforms

Technologies or groups that are using DLTs for their applications, processes.

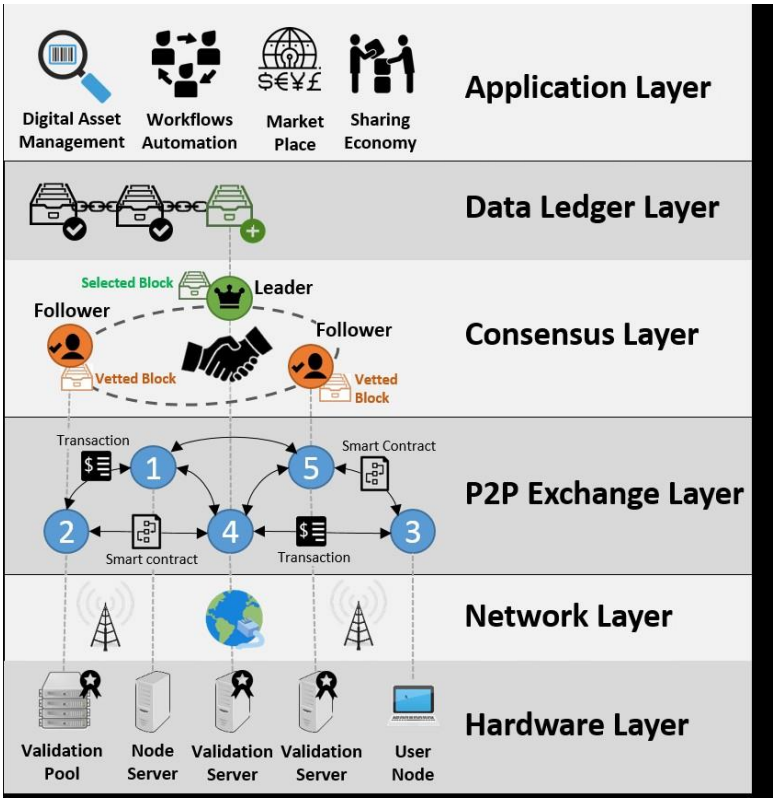

Figure 2: Blockchain high level architecture (graph from: Omar Dib et al, Consortium Blockchains: Overview, Applications and Challenges, iariajournals, Sept 2018).

Types of DLT

Blockchain Features

- Immutability: Since validation of transaction is irreversible and one valid chain exists, that ledger cannot be changed. This makes the system immutable.
- Enhanced security: Due to its infrastructure and cryptographic methods used it's very hard to interfere with this DLT type.
- Consensus: First blockchain application launched with PoW consensus. However, the consumption of energy led producers to use alternative consensuses. Currently it supports a wide range of consensus algorithms that help the nodes to make the right decision.
- Mining: Similarly, it started with Bitcoins mining algorithm. Nowadays participants have the ability to mint new tokens via different consensus algorithms.
- Transactions per second: Highly limited in terms of scalability and TPS
- Data Structure: Hash of current and previous block, time-stamp and data is the basic elements of a block. These blocks added to each other and created blockchain after validation by miners.
- Validation of Transactions: A transaction can be validated or canceled by miners in the network.
- Time of launch: Despite the first known blockchain proposal being launched in 1982 by

cryptographer David Chaum, popular usage and common knowledge of real-world application blockchain was Bitcoin in 2008.

- Speed: Slow to medium speed
- Platforms: ethereum, corda, hyperledger fabric

Directed Acyclic Graph(DAG)Features

Connection directed in one-way and with none cycles is called directed acyclic graph generally. This means irreversibility of blockchain provided by benefits in transaction rules, is coming from the data structure of DAG itself. All nodes in the network can commence transactions in DAG, however benefits in transactions is only probable if the nodes confirm at least two prior transactions on the ledger. Validation of recent nodes is formed by a process which arbitrarily selects the two transactions of interviewee nodes and checks them with valid node's transaction records. However, a process randomly selects the prior two transactions for each participant to validate. Due to measurability facilities, this DLT type is appropriate for large volume transactions including systems.

- Scalability: Validation time reduces as the number of nodes in the network increases. In theory it can reach an infinite extent of scalability for this reason.
- Micro-Nano Transaction: Every transaction in the network is confirmed by the nodes without any size restriction. Thus, even micro and nano transactions are confirmed directly.
- Quantum-resistance: Conjointly DAG uses one-time signature (OTS) that is difficult to break in even using quantum-computers.
- Parallelly lined transactions: Another feature increasing speed of the transaction. Validated transactions are aligned parallel with alternative transactions. To prevent maintenance problems there are some regulations in the structure.
- Mining: All nodes in the network act like miners and verify transactions to attain consensus. This provides high speed.
- Transactions per second: Unique data structure via directed acyclic graph guarantees that scalability and TPS are high.
- Data Structure: Each transaction is independent owing to directed acyclic graph structure.
- Validation of Transactions: The efficiency of a present transaction depends on its capability to validate two prior transactions.
- Everything as a Service: Any device with a chip can work as a service. Conjointly computational power, PC storage, Wi-Fi bandwidth, etc. can also be leased.
- Time of launch: IN 2013 NXT is launched as a DAG-based payment network.
- No Transaction Fees: It does not charge any transaction fees from their users.
- Platforms: NXT, Iota, byteball

Hashgraph Features

Hashgraph was invented in 2010 by a computer scientist Dr. Leemon Baird, also founder of Swirlds. Hashgraph is patented technology for an authorized ledger which is called Hedera Hashgraph. It was aimed to propose a solution for the scalability issue in the blockchain. DAG's structure for speed and PoS's voting mechanism for security are used in hashgraph. Addition to them, time-stamping is shared to the nodes in the unpredictable order which makes the system 'fair'.

- Enhanced Fairness: Compared to other DLTs, hashgraph has the most reliable consensus algorithm. Time-stamping architecture makes it so special. Each transaction is distributed to the nodes in a random order. Hence, any adversarial attempt to

manipulate transactions is not possible. To verify the transactions, all time-stamps in each node are going through a process and calculated with an algorithm.

- Gossip about gossip: History of the ledger is meant as gossip here. Therefore, nodes exchange what they tell to whom in the past. It makes the exchanged information very small, not more than a few bytes, which provides speed. Same as the gossip algorithm, gossip about gossip is made randomly. Gossip spreads binary, so as the network grows, the time required for a transaction decrease. Nodes randomly gossip about what they know with the other nodes to spread to information until every node knows the information.
- Virtual Voting: Prediction of what other nodes would have been voted for is what virtual voting is. Very basic and efficient way of verification. When the transactions reach a specific number, determined in the structure, each node checks its data, which is collected from gossip about gossip protocol. Since all nodes have the history of other nodes, it is possible for that node to predict what the other nodes are kept in their ledger. If a malicious node tries to interfere it is detected by other valid nodes during voting. Vote of majority is accepted as valid in the ledger. With virtual voting also zero bandwidth is used.
- Mining: Energy consumption free mining is possible with DAG structure.
- Transactions per second: Contrary to blockchain, as the number of nodes increases, TPS decrease in the network.
- Data Structure: Virtual Voting and Gossip about Gossip ensures that transactions are validated by the majority. The ledger logs down every gossip sequence on the network in an orderly fashion.
- Validation of Transactions: Validation of transactions is as per consensus.
- Time of launch: Available for public use as of August 24 2018.
- aBFT (asynchronous Byzantine Fault Tolerance) = the highest degree of security a consensus algorithm can provide.
- Energy efficiency: Hashgraph is more than hundreds of thousands of times more energy efficient than blockchain. Due to its consensus algorithm, transactions can be done constantly with 100% efficiency.
- Speed: Very fast up to 500.000 transactions per second.
- Security: Asynchronous byzantine fault tolerance (aBFT) is claimed as the best security measure. All participants, none of whom trust each other, have to come to an agreement for validation of a transaction. When a participant reaches a decision, it's irreversible. Then all participants have to do a mathematical calculation to ensure all participants reach the same agreement in their computer without using any bandwidth. Eventually they decide if that transaction is valid or not. Decision of majority accepted as correct.
- Platforms: Hedera, noia, minga

Holochain Features

Holochain is a technology that is totally different from all other DLTs, and offers improved transfer and data storage. There is no consensus algorithm in this DLT because every node has its own chain locally. It's inspired by nature and it has no consensus in self. Just two parties involved in that transaction keep the record of that transaction in their local chain. All of the records are cryptographically signed by two sides to provide security.

- Agent-centric: Agents mean nodes and they can run their ledger in their local computer without any consensus forced.
- Energy Efficient: Energy consumption of DLTs comes from running complex consensus algorithms, spreading data to other nodes and so holochain doesn't have none

of these, it's much more energy efficient.

- True Distributed Ledger: Each ledger is kept and maintained in local computers so this is only true distributed ledger launched.
- Configurability: Since participants control their own data in this DLT, user empowerment is provided. It is possible for each app to have its protocols, standards, and choice of the consensus algorithm. This means that every dApp created on the chain can maintain a customizable interoperable network.
- Microservices: Every node, which keeps its own chain, also serves for a bigger purpose of the system. As a server, bridge, edge for a network they all work voluntarily. When it's considered there's a big network, there is no big burden for nodes and the network can even work when the nodes are offline.
- Mining: Nodes run on individual chains hence miners are not needed to validate transactions.
- Transactions per second: Each node processes its own ledger hence limitless scalability and TPS. Only limit is the local computer's capacity.
- Data Structure: Data is not distributed through nodes. They are stored in local chains and one public center of holochain
- Validation of Transactions: Validation is not a process since every transaction is kept in local chains.
- Time of launch: Alpha1 product released on May 26, 2018.
- Platforms: holochain

Tempo Features

- Sharding: Every node on the network keeps a shard (smaller section of the global ledger) with a unique ID.
- Gossip Protocol: Nodes send out all their information to synchronize their own shards.
- Logical Clocks: Rather than time-stamping the transactions, this DLT remembers the sequence of the transactions to reach consensus.
- Platforms: radix

SWOT Analysis of DLT Types

Blockchain is the first invented and developed distributed ledger type in all. There are many commercial decentralized applications (DApp) based on blockchain. For the beginners and last users, blockchain could be the best DLT type since there are plenty of sources and examples of it. Yet, it is the slowest and most expensive one.

Dag is a good option for industrial usage of DLT. Since it doesn't have mining there are no transaction fees. It provides quantum-resistance since it has one time used signatures. The possible problem with DAG is scalability. Quite the contrary of blockchain DAG scalability improves when the network grows. So, for small projects it might be a problem to use this type. And even though transaction per second is better than blockchain, it's the second slowest DLT type.

Hashgraph reduces computational burden through its unique consensus mechanism. It's also the second fastest DLT type. However, it's created by a professor and now controls this DLT type in one company and this can cause some trust issues in the future work.

DLT TYPE / PROPERTIES	Blockchain	DAG	Hashgraph	Holochain	Tempo
Mining	Participants have the ability to mint new tokens via different consensus algorithms	The previous transaction validates the succeeding to achieve consensus. No new tokens to discover	Nodes create energy-intensive mining	Nodes process their own ledger hence there is no need for miners	Developer Royalty System
Transactions per second	Highly limited in terms of scalability and TPS 4 to 7 TPS	Unique data structure via directed acyclic graph ensures that scalability and TPS are high 500 to 800 TPS	Unique consensus mechanisms reduce computational burden hence high scalability and high TPS. >200.000 TPS	Each node processes its own ledger hence limitless scalability and TPS. infinite scalability	More nodes increase the number. 20.000 TPS
Data Structure	Data structured in blocks in order of transactions which are validated by miners in the ecosystem.	Data structure follows the directed acyclic graph mechanism where each transaction is independent.	Virtual Voting and Gossip about Gossip ensures that transactions are validated by the majority.	Data is distributed among various nodes on the platform hence there is no problem of network congestion.	Every node on the network keeps a shard (smaller section of the global ledger) with a unique ID.
Validation of Transactions	Miners have the power to postpone a transaction or cancel it entirely.	The success of a present transaction relies on its ability to validate two previous transactions.	Nodes do not have to validate the transactions. Validation of transactions is as per consensus.	Distributed hash table (DHT) sends transactions to random neighbours for validation.	The system only processes transaction if, for every input object with a validated owner , the owner validates the transaction.
Speed	Slow comparing to other DLTs	Faster than blockchain	Very fast, more than BC, DAG and Tempo	Very fast since ledgers are locally process and validation is random	Faster than BC and DAG
Energy Efficiency	High energy consumption comparing other DLT's	More energy efficient than BCT	As there is no consensus algorithm for mining, you don't have to waste powers	The different nature of the ledger makes the system much more energy efficient than others.	Energy efficient
Consensus	PoW, PoS, etc.	Pow, GoF(Grades of finality)	aBFT(asynchronized Byzantine Fault Tolerance)	Agent-centric instead of data-centric	Cerberus(aBFT, PBFT)
Security	Hacking this DLT is nearly impossible due to its decentralized nature and cryptographic encryption.	One time used signatures make structure quantum-resistant	aBFT makes it robust against the cyber-attacks	Every node on the network maintains their own ledger, which creates a true distributed system.	Message authentication codes, digital signatures, or threshold signatures
Accessibility	Private, public, hybrid	Public or Private	Public or Private	Private	Public
Protocol	Bitcoin, Corda, Ethereum	Gossip protocol	Gossip about Gossip & Virtual Voting	Hydro Protocol	Multi-shard transaction processing protocol variants using the original Cerberus protocol
Scalability	Scalability issue with increasing number of nodes. It needed to be downloaded all ledger to become a valid node.	Scalability improves as the network grows.	Only 128 bytes of data need to be downloaded which contains events and signature.	No scaling limit	Unbounded scalability
Expenses	High transaction fees	No transaction fees	USD $0.0001	Almost non-existent	Very low currently
Time of Launch&Platforms	2008 Ethereum, Bitcoin, Corda	9 Nov 2015 Iota, byteball	24 Aug 2018 Hedera, noia, minga	26 May 2018 Holochain	2012 Radix

Figure 3: DLT types and properties.

Holochain offers the best solutions to all imaginable problems with infinite scalability, fast structure by local processing and a true distributed system by every user having their own ledger. Only problem with holochain, because it wants to change the whole internet concept rather than offering an adaptable solution to the existing environment, it doesn't look applicable for commercial use.

Tempo, although better than most of the other options, because it doesn't have enough sources about it, it is hard to be evaluated as an option for industrial use. In theory, it has a different sharing structure which gives high scalability and security to this DLT type.

DLT Type Selection Proposal for Design Team

Distributed ledgers are needed to be chosen carefully depending on usage areas. In the AECO-FM industry there are numerous departments, teams and responsibilities for every phase. There is limitless information in every project for each department and keeping track of these connections is vital for information security. To make the correct decision of DLT type, it is needed to evaluate every information and every project separately depending on the priorities.

Problem of the BIM model is that the data cannot be controlled strictly in project phases by stakeholders, therefore the quality of the BIM model and included documents are limited and disordered. Redefining structure of the BIM, data storage, data update and data transfer, is the solution proposal of this paper. Lack of security and trust in the BIM structure will be improved with this new way of data sharing and storing method. Decentralized decision- making processes and even no administration systems can be possible with this kind of solution.

To sum up, digital twins will be in common use sooner than thought. That's how the dangerous and long processes can be handled more securely and in the short term. One big issue with digital twin technology is the way of information sharing and storing. Distributed ledgers offer many options for different usage purposes. As in other areas of technology, it is critical to determine the needs and priorities in the selection of DLT. Since the project in question is information security, it would be more rational to prefer applicability and security rather than speed. Most prominent type of DLT is DAG with its nano-transaction structure. Also, since there is no mining it's free. With the high level of configurability, DAG can be transparent and private at the same time. Yet, different DLT types can be chosen for one project but different parts of it through its interoperability structure. Even though many practices are required in the field, it would not be wrong to say that it is a groundbreaking development already.

Development of BIM-Based 3D Visualization and Quantity Take-off Calculation Software

F. Ergen and Ö. H. Bettemir
Inonu University, Department of Civil Engineering, Malatya, Turkey
faruk44.mlt.23@gmail.com, onder.bettemir@inonu.edu.tr

Abstract

Determination of the material requirement and cost of a construction project is the most important part of the design process. Presently, quantity takeoff and cost estimation can be made much faster than traditional methods by using Building Information Modeling (BIM) software. However, the quantity take-off data obtained by considering only the geometric shapes without determining the intersections of the structural and architectural elements with each other cannot have satisfactory accuracy. The state-of-the-art BIM software cannot detect the dimensions of the intersection exactly. Most of the software implemented through the BIM process have different processing style because of the computational differences occurred in many countries. In addition, the licensing fees of BIM software are quite expensive. Therefore, through the implementation of BIM process, conflicts may arise due to the local legislation. Therefore, in this study, it is aimed to develop a software that helps the BIM process, which calculates the concrete, formwork, formwork scaffolding and reinforcement quantities of a building by taking into account the semantic representation of the elements that make up the structure, and performs the 3D visualization of the structure, using the free and open source python programming language. In this context, a drawing interface is created and the geometric dimensions of the structure are defined by drawing with the mouse. In addition, by creating data entry boxes, the material information and mechanical properties of the building elements are defined. The developed software is tested on a 2-storey reinforced concrete building and the calculated quantity take-off values are checked manually. As a result of the experiment, it is determined that the amounts of concrete, formwork, formwork for the scaffolding and reinforcement are calculated exactly. The analysis results show that cost-effective BIM software that Turkish contractors can safely use through the management of the construction process can be developed if the capabilities of the software is improved.

Keywords: *building information modeling, quantity takeoff, python programming language, 3D visualization.*

Introduction

Project management of construction activities is tiresome because there are significantly many work items to control and manage. In addition to this, every quantity take-off tasks and construction scheduling have to be prepared from the beginning because construction projects and management of them are unique endeavors. BIM is a convenient tool for the construction

firms to execute the construction management related tasks such as quantity take-off and scheduling. BIM software can execute project management endeavors which were executed by much software in the past. Preparation of technical drawings, quantity take-off, and the schedule of the construction tasks can be given as examples that are performed by different software. Execution of project management tasks on sole software has important benefits for the contractors and the engineers as it reduces the risk of malfunctioning data extraction, incompatibilities caused by the version differences, and rework of the prepared documents.

BIM is a developing subject and in the literature there are important contributions to the BIM implementations. BIM is implemented by the academic and practical purposes as well as and certification intentions (Kalfa, 2018). Omaran et al. (2019) performed life cycle cost analysis of a building. The construction of the building is 4D simulated by a game engine. During the construction both the construction and operation costs of the constructed utility are simultaneously computed. Delgado et al. (2020) investigated the implementation of Augmented Reality (AR) and Virtual Reality (VR) by the Architecture, Engineering and Construction (AEC) sectors. Four discussion groups are formed and each group examined the benefits, complexities, difficulties, and the deficiencies of the state-of-the art AR and VR technology. The discussion groups revealed that the AR and VR technologies are not used effectively by the AEC participants. Ozcan-Deniz (2019) interviewed 18 construction firms to identify the possible applications of VR. Sarı and Pekeriçli (2020) investigated and compared the legal issues on the implementation of BIM in Turkey and in USA and UK. Temel and Başağa (2020) analyzed the code compliance checking from the data extracted from Industry Foundation Classes (IFC) file format. The study revealed that BIM models and software is appropriate for the detection of code violations without human endeavor.

Adobe Acrobat Reader version 9 or later enables visualization of 3D drawings. Nadeem et al. (2015) prepared 3D models on Autodesk 3DSMax and embedded them to Adobe Acrobat Reader pdf files. The mentioned file extraction allows rotation as well as zooming in and out on the 3D drawings of a building by Adobe Acrobat Reader software. As a result the 3D visualization of the building can be examined on site by tablets or mobile phones. Sacks and Barak (2007) states that 3D modeling decreases the design and drawing errors. Moreover, 3D drawings provide shorter delivery time, increase the efficiency and reduce the costs.

Millman and Aivazis (2011) state that Python programming language is an opportunity to write codes for the engineering applications. The ability of handling complex numbers, easiness of plotting and graphics are some of the advantages of the programming language. Quraishi and Dhapekar (2021) investigated the difficulty level of programming on Python and stated that instead of using spreadsheets for the necessary computations for the construction site management, the same computations can be programmed on Python language easily by the civil engineers. Sarvade and Pore (2019) developed reinforced concrete beam design software by Python. The study briefly utilizes the NumPy, SciPy, Pandas, and Matplotlib libraries of Pythons programming language.

Bettemir (2018) developed a procedure to decrease the difficulty and workload of quantity take-off computations of excavation, concreting, and formwork tasks. The developed algorithm is executed on spreadsheet. Khosakitchalert et al. (2019) implemented Dynamo software version 1.3.3.4111 to prepare quantity take-off of construction items such as walls and floor coverings. Lee et al. (2014) computed the QTO and construction cost of tiling construction item by automated inference process. Choi et al. (2015) developed a schematic QTO estimation process for the preliminary design stage of the buildings. The data is

extracted from IFC model to Open BIM software. Liu et al. (2016) implemented ontology-based semantic approach for QTO. Entity relationships among the construction items are formed and related materials and workmanship which constitutes the ontology is computed. In addition to geometric and topological relationships host relationships such as a wall can host a lintel or window is defined. Voids of quantity take-off are computed by database queries. The proposed system enabled faster and more accurate QTO.

Benefits of the utilization of BIM software is investigated by Olsen and Taylor (2017). The researchers conducted a survey and the respondents stated the advantages of BIM as fast QTO preparation, and more accurate QTO than manually prepared QTO. The disadvantages of implementation of BIM are stated as complexity of BIM software and possibility of entering outdated data.

Kim et al. (2019) investigated the inconsistencies of the computed QTO values caused by the definition of object models. Compositely modeled object and individually modeled object definitions are investigated and the study concludes that compositely modeled object definitions may cause up to 6% deviation from the exact QTO value. Individually modeled object definition contains more detail and thus provides better results.

Liu et al. (2022) developed a knowledge model based quantity take-off model in order to eliminate the inability of the state-of-the-art BIM software which does not enclose all the necessary data for precise automatic quantity take-off (QTO). The study suggests defining different types of slab-wall; slab-beam; slab-column and slab-wall joint connections. Consequently, better QTO estimations are obtained. Bettemir et al. (2021) prepared a quantity take-off estimation procedure for the volume of the excavation tasks. The literature review illustrates that the construction sector utilizes BIM mainly for the quantity take-off computations and visualization of the state of the construction. This situation motivated the authors to develop BIM software capable of executing the mentioned tasks. In the remaining part of the study, the methodology of quantity take off of concrete, formwork, and support for the scaffolding is described. In the fourth section a case study is performed to implement the developed software. In the final section the results and the findings are concluded.

Methodology

Exact quantity take-off algorithms of concrete, formwork, reinforcement, formwork scaffolding of a reinforced concrete structure is developed. In addition to this, 3D visualization of the 2D structural drawings are established. The developed algorithms are programmed on Python programming language, Sqlite3 database engine and Ursina game engine and software created. The software is tested on one story structure. An overview of the intended method framework is presented in Figure 1.

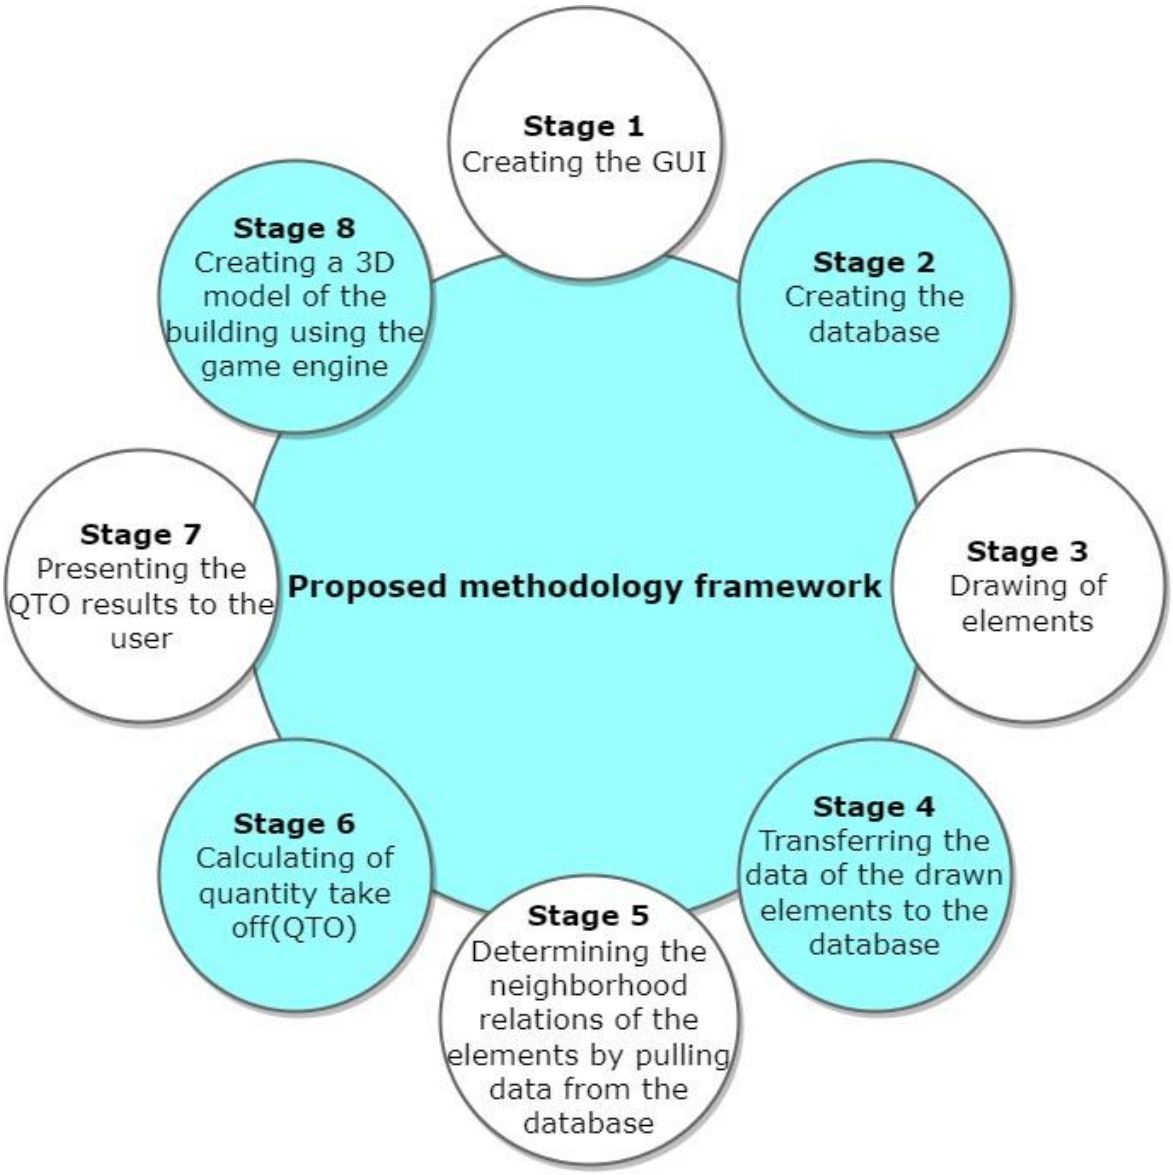

Figure 1: The framework of the developed quantity take-off and visualization software.

Creation of the Graphical User Interface

The Graphical User Interface (GKA) is built by Tkinter library which is the standard GUI development library developed for the python programming language. Using the Tk, Canvas, Frame, Button, Entry and Label classes in the Tkinter library, the GUI window, buttons, panels and drawing area in the window are created. By creating pop-up windows for column, beam and floor elements, the user is able to enter the geometric and material properties of the relevant element.

Creation of the Database

The execution of quantity take-off calculations and material as well as resource requirement computations require a database to manage and retrieve data about the drawn structure. SQLite database development library is used for the developed software. In addition to this,

job definitions of concrete, formwork, and support for the scaffolding are defined and stored in the database. The defined job definition tables are joined by the relevant construction activities for material and resource requirement computations.

Drawing the Structural Elements

Axes of x and y directions are defined in the drawing area to determine the nodal points of the elements as the first task of the drawing process. After this step, the required structural elements are created by pressing the "DRAW" button in the main window. The material and geometric properties of the elements are entered by the pop-up window. The user enters the mechanical and geometrical properties of the structural element by the pop-up window. The software starts the drawing process by mouse when the user completes the data entry process and approves the entered data. The structural elements are represented by two points which are located at the top left and bottom right corners. 2D model of the structural element is drawn by clicking on the aforementioned two nodes one after the other. The drawing of the structural elements completes the data entry process of the element. The drawing process is continued until all of the structural elements are drawn.

Creating the Database

All the features of the drawn elements must be stored permanently which enables editing, retrieving, deleting, and performing any kind of queries and analysis with the data. The entered data related with the structural elements are stored in data tables which includes the data about the unique id, position, dimensions, and properties of the elements. The data tables are formed by the Sqlite3 database engine. The created data tables are identical to each structural element type, because the data type and features are unique for each element type. For example, the data table containing the properties of the column elements is named column.db, while the data table containing the properties of the beam elements is named beam.db. The data stored in the database is used to construct the semantic relationships between the structural elements. The mentioned relationships will be used to calculate the quantity of contact in terms of length, area or volume. With the help of the database, the management of the data is realized in a more organized way. The database is created by the connect() method in the Sqlite3 library. Then, a cursor is created with the cursor() method to interact with the database. After the created cursor, adding, deleting operations or updating the data can be performed with the execute() method. The transaction in the database is committed with the commit() method and the database is closed with the close() method. In Figure 2, the code script of the function that deletes the data of a beam from the beam.db database is presented. By entering the number of the beam as the parameter of the function, the relevant beam is deleted from the database.

```
5  def delete_beam(kirisNo):
6      con_2 = sqlite3.connect("beam.db")
7      cur_2 = con_2.cursor()
8      cur_2.execute("DELETE FROM beam WHERE kirisNo ='" + kirisNo + "'")
9      con_2.commit()
10     con_2.close()
11
```

Figure 2: Execution of delete operation in the created database.

Determination of Semantic Relationships

Determination of the semantic relationships between the structural elements is extremely important to detect the topological relationships. These relationships are used to detect the contacts between the structural elements. The amount of contact in terms of length, area or volume is used to compute the amount of voids in the quantity take-off calculations. This ensures the prevention of repetitive calculation or omitting the quantity of the structural element. The neighborhood relationships of the elements is determined by the *find_overlapping()* method of the Canvas class. The coordinates of the region covering the element are determined by using the coordinate data of the element whose neighbors is to be determined. The mentioned parameters of the elements are entered as the parameter of the *find_overlapping()* method. Then, the neighboring elements are detected. The type of elements is determined by the tag parameter assigned while drawing the element. To illustrate, it is stated that the type of the relevant element is a column by stating "*tag = column"* in the tag of the command. Thus, the types of elements are easily determined while determining the neighborhood relations. Determining the neighborhood relations reduces the error rate, especially in the calculation of formwork quantity.

Quantity Take-off

The geometric properties, material properties and coordinate information of the structural elements are retrieved from the database before the quantity take-off calculations are made. The retrieved data is specific for each construction item whose quantity take-off is to be computed. To illustrate, the volume of the structural element is calculated to determine the amount of concrete necessary to construct the element. The intersection amounts between the columns and the slabs are detected. This data is used to compute and deduct the amount of voids. The unit of concrete is m^3.

The lateral areas of the structural elements are calculated in order to determine the amount of formwork. The obtained quantities are represented as gross area since some of the computed area contains the contact locations of the structural elements where formwork will not be applied. The detection of contact surface involves determination of neighboring beam-slab, column-slab, and beam-column neighborhoods. This task is achieved by logical queries among the structural elements. The contact area is computed by considering the positions and dimensions of the neighboring structural elements. Then, the amount of formwork is calculated by subtracting the lateral area of the surfaces in contact with the neighboring elements from the gross formwork amount.

The volume occupied by the structure is calculated to determine the amount of support for the scaffolding. The concrete quantity of the corresponding floor is subtracted from the volume of the floor. The unit of the support for the scaffolding is m^3.

The number of reinforcements for each structural item is calculated using the data related with the reinforcement quantity (reinforcement area, etc.) which is received from the user. The amount of reinforcement is computed by taking into account the restrictions on the number of reinforcements, reinforcement spacing and reinforcement ratio represented in TS500 and TBDY 2018. The spacing length is used to detect the number of reinforcement bars and

stirrups. The length of the reinforcement bar is computed by considering the neighboring structural elements. To illustrate the longitudinal reinforcement bar placed in a beam should elongate into the neighboring beams. The semantic relationships are used to detect the neighboring beams and their spans. After the detection of the length and the number of the reinforcement its quantity is computed in kg.

3D Visualization

In order to create a 3D model of the structural elements that constitute the building, the geometric properties and coordinate data of each element are retrieved from the database. The 3D model of the element is created using the *Entity()* class in the Ursina game engine. In the *Entity()* class, the position parameter is assigned as the coordinate information of the element, and the scale parameter is assigned as a tuple data type in the form of the element's width, height and height information (x, y, z). A sky object from the *Sky class* and a *camera object* from the *EditorCamera* class are added to the environment after the 3D model of the building is created. The 3D model of the structure can be scrolled, zoomed in and zoomed out, and the model can be viewed from the desired angle by the created sky object and the camera object. The mentioned utilities of the Ursina game engine provide important simplicity for 3D visualization. In addition, a first-person shooter can be created from the *FirstPersonController* class to navigate through the structure.

Case Study

Quantity take-off calculations of the formwork, concrete, reinforcement and support for the scaffolding as well as 3D visualization of a reinforced concrete structure are made in order to test the software's ability of quantity take-off computations. Moreover, construction of neighborhood relations, determination of contact areas and 3D visualization algorithms are also examined. The structural plan of the first floor is given in Figure 3. The formwork plan represented in Figure 3 is drawn by the developed software.

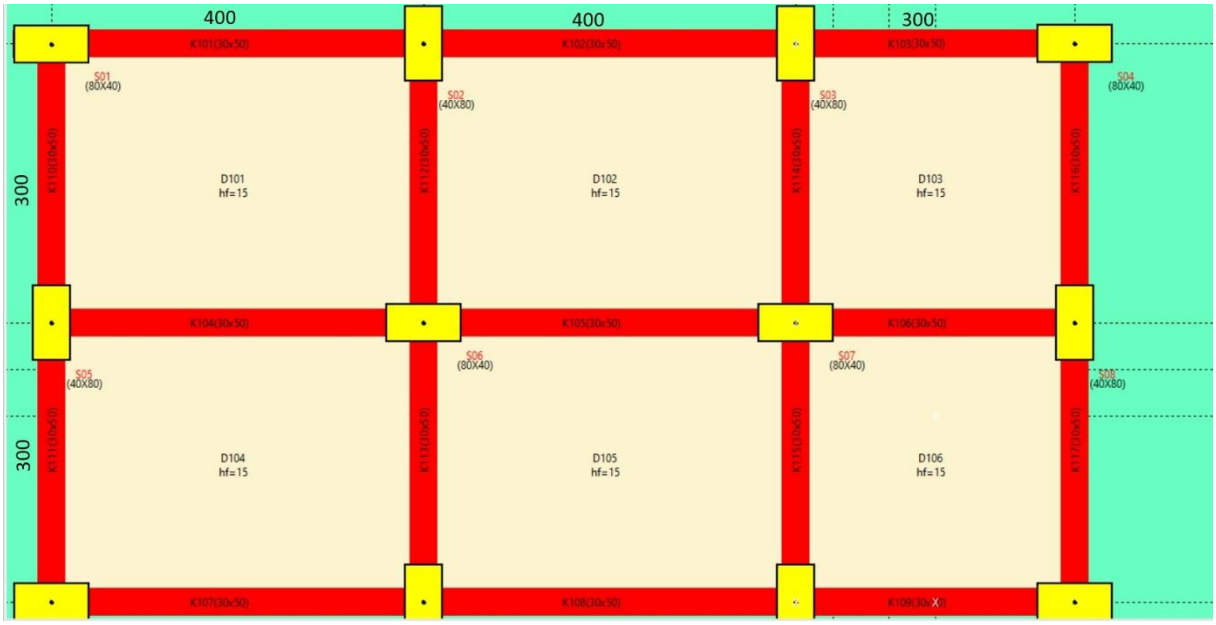

Figure 3: Structural elements of the case study problem which are drawn by the developed software.

Material information such as the concrete type of the structural elements, the yield strength of the steel and the maximum grain diameter of the concrete, as well as the number of floors and story heights are entered in a separate pop-up window opened by clicking the Building Information button. The geometric properties and other material properties such as the preferred rebar diameter are entered through element-specific pop-up windows before the drawing of the each element.

The coordinate data of the elements are detected according to the x and y pixel positions of the clicked points during the drawing process. All properties are transferred to data tables created for the each element type. The relevant quantity take-off algorithms are run and the quantity take-off results in .xls format are presented when the Beam Analysis, Column Analysis, Slab Analysis and Q.Takeoff buttons on the GUI are pressed. The results can be examined by opening the meter scales named .xls with the MS Excel program.

To illustrate the drawing process as shown in Figure 4, the "Beam" button is pressed to draw the beam element. Then, 3D drawn elements models are created automatically and displayed as in Figure 4 when the "3D" button on the GUI is pressed.

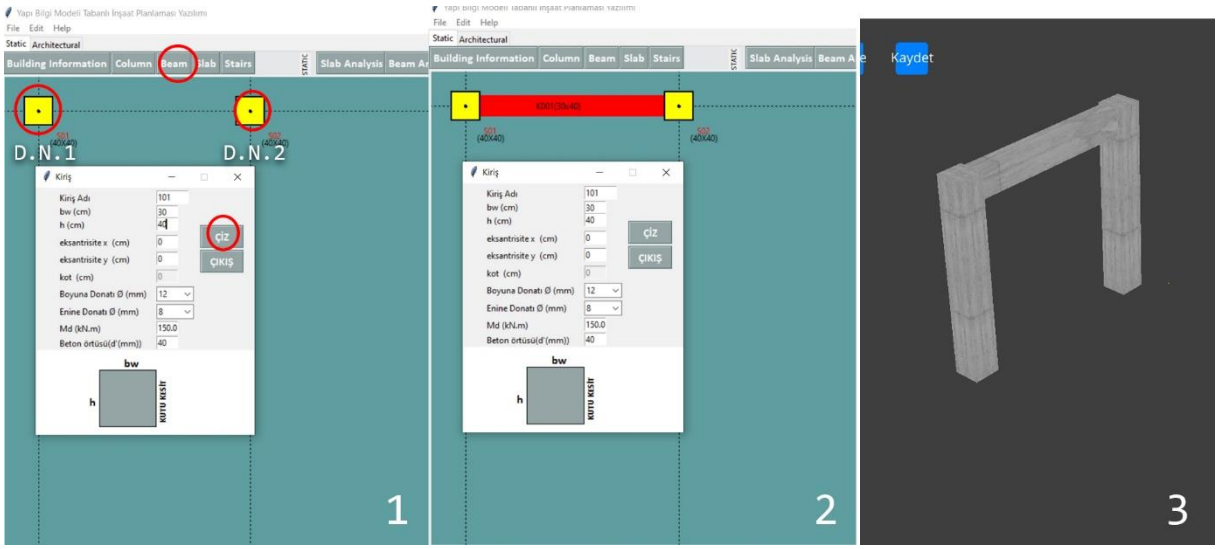

Figure 4: Representation of drawing and 3D visualization of column and beam structural elements.

By pressing the 3D button on the GUI, the 3D model of the structure is automatically created. The created 3D model can be examined and navigated by the user. The 3D model of the structure can be examined by scrolling, zooming in and out on the model in line with the capabilities of the Ursina game engine. The user can walk inside the building and navigate using the keyboard arrow keys and mouse. In Figure 5 and Figure 6, uncoated and concrete patterned 3D models of the structure are displayed. The figures are created after pressing the 3D button. Then the illustrated screenshots presented in Figures 5 and 6 are obtained.

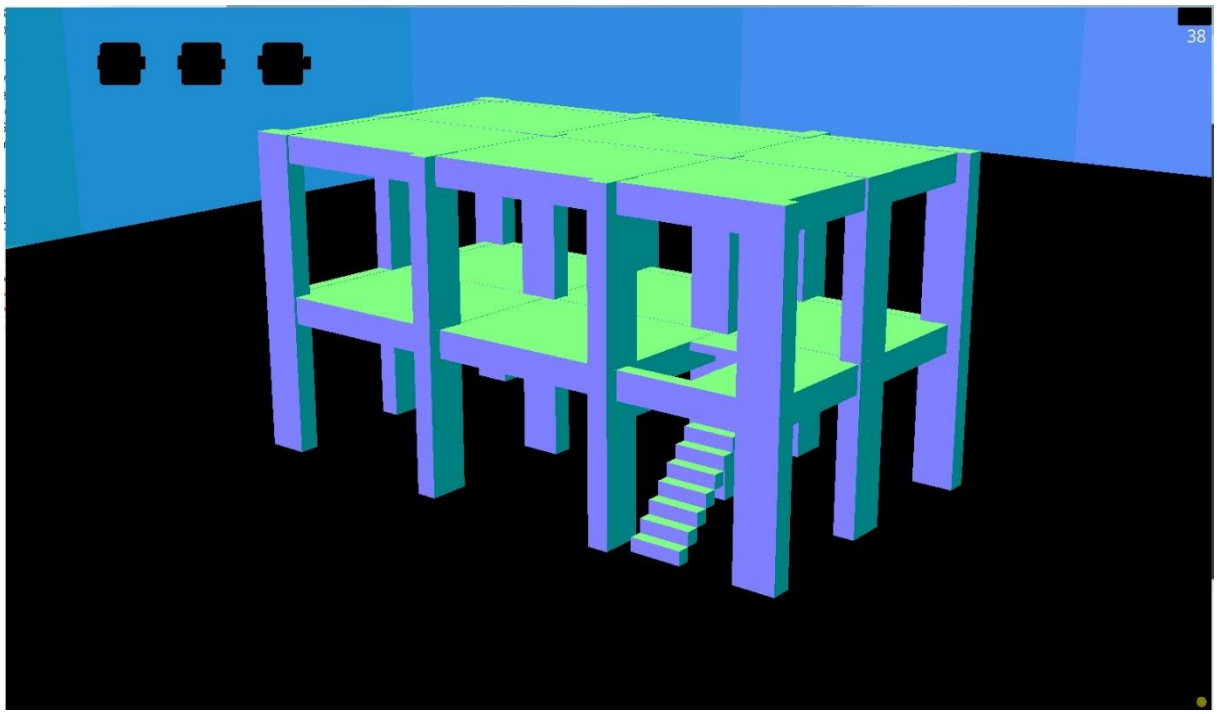

Figure 5: 3D visualization of the structure without concrete pattern.

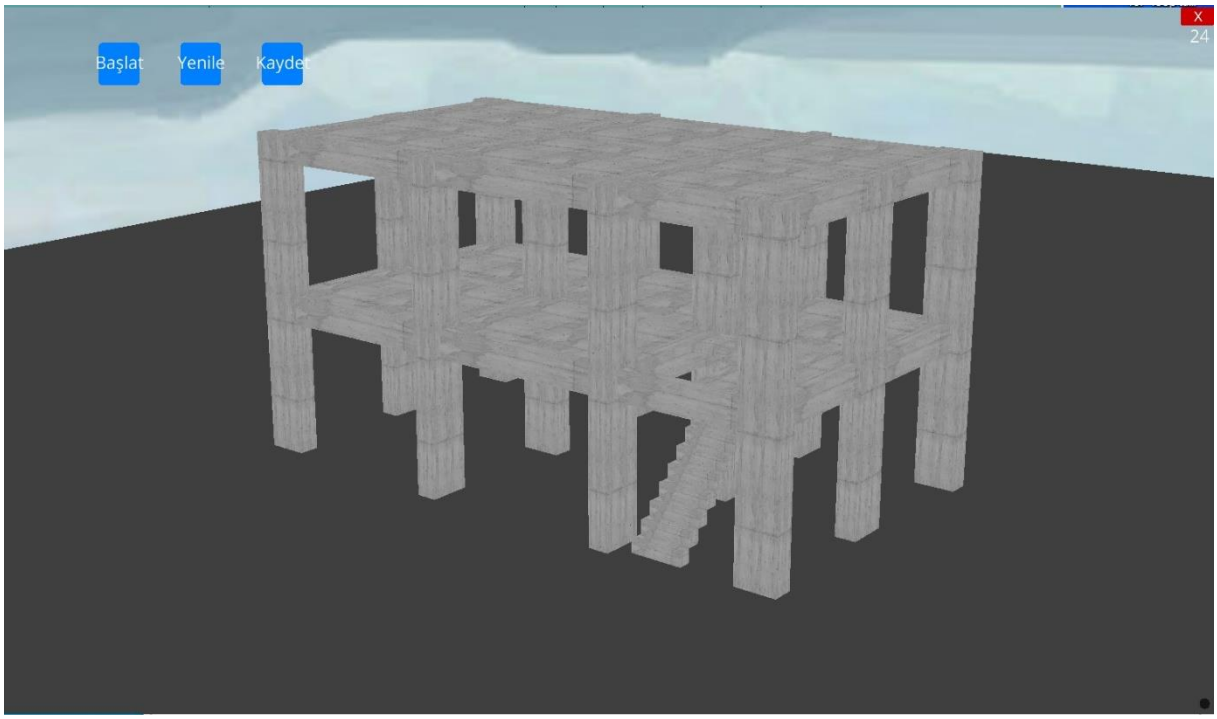

Figure 6: 3D Visualization of the structure with concrete pattern.

The developed software executes the quantity take-off algorithms and computes the quantity take-off of concrete, formwork and support for the scaffolding construction items. The results are presented in Figure 7 as the screenshot of the software. The represented data can also be extracted as excel file.

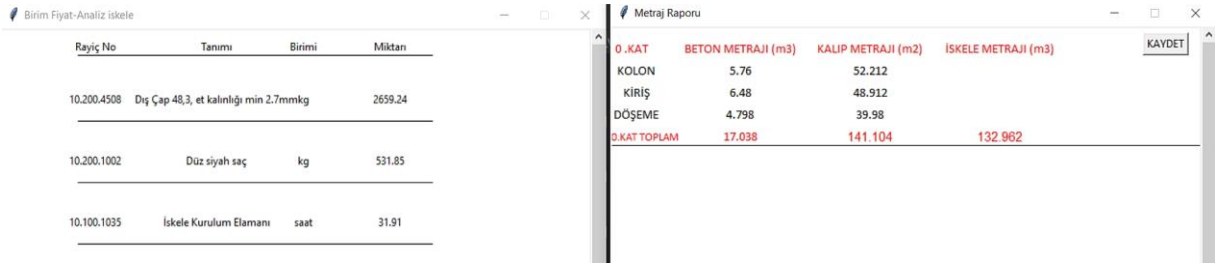

Figure 7: Results of quantity take-off computations and material requirements.

Conclusion

In this study quantity take-off software which can obtain the dimensions of the structural elements by drawing interface is developed. The software can accurately compute the quantity take-off of concrete, formwork, reinforcement and support for the scaffolding construction items. The quantity take-off results of the software is checked by manually computing the mentioned quantities and it is seen that the obtained results are exact. The developed software can perform 3D visualization of the drawn structural elements in 2D. The height or thickness data are adequate for the construction of the 3D model of the structural elements. The user can walk through inside the building by navigating the arrow buttons on the keyboard. The visualization and the quantity take-off computations should be extended to cover other construction items related with buildings as future study.

Abstract

Productivity stagnation and process inefficiency is a pervasive problem in the construction industry. Many processes are manual, resource-intensive and have a high potential for failure. At the same time, in the course of digitalization, new technologies were developed that can mitigate the existing problems.

The aim of the paper is to present a roadmap for the systematic implementation of Artificial Intelligence (AI) in a construction company. The roadmap considers implementation from a procedural, organizational and information technology perspective.

Based on literature research, the use of AI in other business sectors is shown. Additionally, existing approaches of the technologies in the construction industry are identified. The next step is to conduct expert interviews. Based on the interview results, the roadmap is derived. Furthermore, recommendations as minimum standards for the implementation of AI systems in the context of the use of the roadmap are defined.

The roadmap serves as a strategic framework for construction companies for a qualitative implementation of AI systems in the company structures.

The results of the article show the potential of AI in construction companies and the necessity of a uniform procedure plan to support the AI implementation, presented in a roadmap.

Keywords: *artificial intelligence, construction company, roadmap, strategic implementation.*

Introduction

In a direct comparison with other industrial sectors, the construction industry is characterized by poor productivity, inefficiency and a low level of digitalization. However, this dilemma has not just existed recently, but has been prevalent for several decades (Barbosa et al., 2017;

Adwan & Al-Soufi, 2016; Jäkel et al., 2022). In the course of Industry 4.0, artificial intelligence in particular is seen as playing a key role that can contribute to the further optimization and digitization of the global economy. These added values have already become noticeable in other sectors of the economy, for example in the service sector and manufacturing industry, through successful implementation of the technology (Buhgin et al., 2017; Abioye et al., 2021). Even in the conservative construction industry with its hands-on mentality, artificial intelligence has gained importance in recent years (Liu et al., 2019; Akinosho et al., 2020). Current research indicates that the use of AI technology is also constantly increasing in the complete construction industry and that there is a lot of potential (Darko et al., 2020; Pan & Zhang, 2021; Rampini et al., 2022; Sacks et al., 2020).

The potentials, areas of application and added value of AI are therefore known to the construction industry, but a uniform framework for the systematic implementation of AI technology for construction companies in their existing structures has been unavailable until now. This research paper closes precisely this research gap and develops a roadmap for AI implementation based on qualitative expert interviews and defines necessary minimum standards.

Related Works

The development of artificial intelligence has not gone unnoticed in the construction industry. Over the past year, several authors have examined the potential and opportunities that the implementation and use of various artificial intelligence techniques could bring to the construction value chain (Abioye et al., 2021; Hatami et al., 2022; Regona et al., 2022). These studies all come to the same conclusion that the construction industry should harness the benefits of artificial intelligence from the design phase throughout the construction phase till the operation of a structure. There is a wide range of artificial intelligence algorithms which can be categorized into seven subfields of artificial intelligence: Machine Learning (ML), Knowledge-based Systems (KBS), Computer Vision, Robotics, Natural Language Processing (NLP) Automated Planning and Scheduling and Optimization (Russell & Norvig, 2003). Recent literature shows, as Abioye et al. (2021) found, that especially Optimization attracted large interest among the scientific scene, followed by Machine Learning and Knowledge-based Systems. The research has condensed in the last decade, which shows the rapid growth of interest among researchers (Abioye et al., 2021). The adaption of the new technologies is confronted with a few challenges. Regona et. al. (2022) depict high initial costs for the implementation of artificial intelligence, security concerns, project uniqueness and the difficulties in information sharing, to name a few, as challenges inhibiting the industry wide introduction of artificial intelligence (Regona et al., 2022). Throughout the phases of construction projects, artificial intelligence can yield various improvements. In the following, exemplary AI applications are shown for each lifecycle phase of a building. In the planning phase, for example Artificial Neural networks or support vector machines can be used to accurately predict heating and cooling loads of planned buildings. Since the artificial intelligence algorithm only needs seconds for predictions, the energy planning could be implemented in real-time during the planning process, while established simulation tools use the finished design (Chou & Bui, 2014). Also, Artificial Neural Networks are used to increase the accuracy of cost estimations for engineering services of construction projects, which are often done by experts based on their experience (Matel et al., 2022). With the use of building information modeling, the planning data can be accessed in a more structured and uniform way. So, the review of the design in regard of clashes or compliance with regulations show potential

for integration of artificial intelligence (Hsu et al., 2020; Sacks et al., 2019). In addition, intelligent AI algorithms are also being used in construction to promote productivity and efficiency. Especially for safety aspects, artificial intelligence can create a healthier environment on construction sites. Computer Vision algorithms could be used to process data gathered by cameras and sensors which capture 2D and 3D images of a construction site. With the data an object detection and tracking algorithm could identify unsafe areas. (Lin et al., 2021; Oyedele et al., 2021; Seo et al., 2015) Further the use of robotics and automated systems on construction sites is fueled by the implementation of artificial intelligence. This is a huge opportunity to boost productivity of the construction industries. (Balaguer & Abderrahim, 2008; Davila Delgado et al., 2019) After completion and handover of the building, AI systems are used primarily for optimized management and maintenance of the building. Neural Networks can be used to improve decision making in facility management. Marzouk et. al. describes the use of artificial intelligence in facility management, which enables facility managers to maintain buildings in a more proactive manner. So expensive repairs or even sudden failure of the facility could be reduced (Marzouk & Zaher, 2020). Furthermore, Luo et al. (2019) propose a big data platform which uses artificial intelligence methods and sensor data to predict heating and cooling demands throughout a building. This information could then be used to run the building more efficiently.

As shown in the sections above, there is much potential through the use of artificial intelligence for the construction industry in different areas along the life cycle of a built structure. However, there is still no uniform framework for the implementation of AI systems in construction companies. The systematic application of the roadmap will facilitate access to the use of this key technology, minimize entry barriers and thereby enable AI systems to be implemented for all companies of different sizes. This strategic framework will be developed in this scientific article in the following subsections, hence closing the existing research gap.

Research Design

General Methodology

The scientific article consists of a total of three subsections - (i) state of the art, (ii) development of the roadmap, and (iii) derivation of company-wide minimum standards. In the first step, the general state of the art is determined by a literature analysis. This section was already described above. Based on this, the roadmap for the systematic implementation of artificial intelligence in construction companies is developed. The roadmap considers the implementation from a procedural, organizational and information technology perspective and also has a defined implementation timeframe. The basis for the roadmap development is the result of a preceding qualitative investigation in the form of expert interviews. Based on this, company-wide minimum standards for AI implementation are defined. The article ends with a discussion of the artifacts developed, a critical appraisal of the results and an outlook on the resulting research questions.

Structure of the Qualitative Study

To create a sound knowledge base for the development of the roadmap and to derive the minimum standards for the systematic implementation of AI in construction companies, a

qualitative study with semi-structured expert interviews was conducted. The interviews were systematically evaluated and generally valid statements for the roadmap were derived. As part of the semi-structured expert interviews, a total of thirteen experts were interviewed using a guide with semi-open-ended questions. The experts were selected from both academia and industry. The interviewees from industry were experts from the medium and senior management levels of construction companies. The representatives of science were specialists from the domain of computer science and artificial intelligence. This heterogeneous group of experts provides a holistic perspective on the subject matter and serves to generate knowledge at the process, organizational and information technology levels. The interviews were evaluated using content analysis according to Mayring and Fenzl (2019). The insights gained and generalized were used for roadmap development and the derivation of holistic, generally applicable minimum standards for implementation.

Development of the Roadmap

Fundamentals of Roadmap Creation

The development of a roadmap is understood as a creative analysis procedure used to forecast, analyze and visualize the basic steps of a development and implementation of technologies (e.g. products, services, etc.) and innovative methods. The roadmap aims to systematically implement corresponding products and technologies systematically in the future in a certain business area of a company. The basis of the roadmap development are the opinions of experts and involved persons with specific knowledge of the technologies or methods. The result is a future prognosis in which a path to systematic integration is presented in a visualized form. (Specht & Behrens, 2005). The roadmap is developed following the approach of Specht and Behrens (2005). It is defined as a mix model of a science and industry roadmap and comprises an ordinate (object axis) and abscissa (time axis) in the two-dimensional representation form. The ordinate contains a total of four object levels - processes, organization, data and application systems. On the one hand, this subdivision specifies the individual levels that need to be considered in the company, at the same time, clarifying their interdependencies for successful systematic implementation of the technology. The time axis (abscissa) reflects the defined period under consideration, which is derived on the basis of expert opinions. In addition, time dependencies are assigned to the individual object levels and subdevelopment steps. This strengthens the systematic character of a roadmap for its application in practice. The development of the actual roadmap is based on the results gained of the qualitative study, which will be explained in more detail in the next chapter (Zernial, 2008; Specht & Behrens, 2005).

Conducting and Evaluating of The Expert Interviews

The interview guide was differentiated according to the four object levels. These levels were considered individually while conducting in all interviews. A total of 13 experts with different expertise were interviewed. Seven interviewees worked for large construction companies, four for small and medium-sized enterprises, and two for public institutions. The areas of work of the experts interviewed were in the strategic area of the company (e.g., managing director or department head) or linked to the topics of digital transformation. Due to the fact that a presentation of all results of the thirteen interviews would require an excessive amount of space within the scope of the scientific article, a summarized presentation of all key statements per

object level is given below. The findings are determined from the interviews with the help of content analysis according to Mayring and Fenzl (2019) and after the generalization and consolidation, form the knowledge base for the further development of the roadmap. The first step is to describe the generalized core statements at the four object levels processes, organization, application systems and data. This core statements are shown in Table 1.

A general important finding from the expert interviews is the set time horizon for implementation projects. This time horizon should be four years for the first implementation and divided into annual stages. All levels have their own individual requirements, but there is still a direct dependency between all object levels. The core statements form the basis for a qualitative implementation of the AI system and the roadmap development.

Table 1. Core Statements of the expert interview.

Process Level
▪ Creation of a uniform understanding of all the main and secondary processes ▪ Identification of the automation potentials ▪ Creation of a high level of process standardization ▪ Perform a Make-or-buy analysis (Inhouse development or outsourcing)
Organization Level
▪ Creation of central responsibilities in the area of artificial intelligence ▪ Employment of IT experts and programmers with fundamental knowledge in the AI ▪ Knowledge sharing and training of own personal
Application System Level
▪ Creation of a central data base (Cloud system or own physical server) ▪ Establishment of a robust and stable IT infrastructure ▪ Creation of continuous interoperability between the application systems
Data Level
▪ Unified data standards and continuous data maintenance ▪ High level of data quality

Derivation of the Visualized Roadmap

Based on the results of the expert interviews, the roadmap is developed in the form of a two-dimensional reference frame. The roadmap can be categorized as a mix of a science and technology roadmap and has two axes (Kappel, 2001). The ordinate represents the object levels - processes, organization, data and application systems. The abscissa represents the time axis under consideration. The ordinate characterizes the main and sub-processes of the systematic implementation. The time horizon, in turn, considers a four-year time horizon for the implementation phase of an AI system. This duration for an implementation project was derived from the expert opinions and is further specified in sub-periods with a duration of one year in the roadmap. This subdivision allows a precise and systematic approach to be presented in each individual object level and cross-level dependencies in the individual implementation steps. The object levels are marked with different colors in the roadmap for better visualization. The following color scheme is chosen - processes (blue), organization (green), application systems (orange) and data (yellow). The individual implementation years are illustrated below, and the action steps are described.

In the first year, the principles for the complete four-year implementation period are set (see Figure 1). The object levels of the organization, application systems and data are important in this regard. The organizational level focuses on the establishment of a specialized work group and the recruiting and onboarding of suitable specialists. In the first year of implementation, the application systems level focuses on defining requirements for a central data room for the structured storage and management of all necessary data in the company. In addition, all existing interfaces between the AWS in the company are analyzed and measures for company-wide interoperability are defined. At the same time, all data in the company are analyzed and a uniform data quality standard for existing and future new data will be created.

In the second year of implementation (see Figure 2), the process level is also considered in addition to the object levels of the first year. The process-related measures focus on the identification and analysis of main and secondary processes in the company and their interdependencies. In addition, the processes are evaluated for existing automation potential through the use of AI systems and specific use cases are defined for initial pilot projects. In the organization, the knowledge about AI systems is continuously expanded in the working group and the first specialized IT project teams are established. This team subsequently prepares the measure of systematic implementation and development of AI systems. In addition, preparations are made for the data and IT infrastructure level.

Furthermore, the personnel requirements are defined and necessary training for additional employees in the company is planned. Moreover, a market screening of solutions already existing on the market or external service providers for the outsourcing of the development work is carried out. At the level of the application systems, the first implementation measures are taken on the basis of the defined requirements. In this context, the central database (company-owned server or cloud) is implemented, and the data storage structure and the extended infrastructure are developed. Within the context of the data, measures are implemented to maintain the inventory data to improve the quality. This data is then loaded into the company's previously newly established central data room. Another step in the second year of implementation is the selection of training and validation data sets for the AI system development process.

After the successful creation of the foundations on the four object levels, the third year focuses on the first development steps of the AI system for its one or more defined use cases (see Figure 3). At the process-oriented object level, a distinction is made between two possible approaches for the development and implementation step: in-house development or outsourcing. In the case of in-house development, a pretotype is developed in the first implementation stage. This serves as the first simplified version of the system and is used for initial analyses in the context of efficiency and further feasibility. This pretotype is considered a Minimum Viable Product (MVP) and has the minimum characteristics of the final product (Martins Pacheco et al., 2021). After successful creation of the pretotype, further development into a prototype takes place in the second implementation stage. The prototype is a functional but simplified system for its further training and validation in iterative cycles. (Martins Pacheco et al., 2021). Furthermore, the system is optimized until the defined goal of system efficiency is achieved. The outsourcing variant is carried out in cooperation with external companies or service providers. In this case, existing AI solutions are already purchased on the basis of the results of the market screening and further developed for the corresponding use in cooperation with the manufacturer. If no adequate solutions exist on the market yet and the personal resources for the development work are not sufficient, service providers can also be cooperated with for the complete system development if required. For example, this case can occur in small and medium-sized

enterprises, but it is not considered in the roadmap. In the context of the organizational level, a strong IT unit for the development, implementation and use of the AI systems is formed in the first two implementation years. In the third implementation year, the focus is on continuous knowledge transfer of the AI topic with other internal staff. This transfer will be accomplished by conducting internal employee training on how to use the future AI systems. If the development work is outsourced, the IT department with its AI knowledge serves as a coaching and control function for the company vis-à-vis external partners.

At the application system level, the permanent functionality of the IT infrastructure and the server play a central role. A frictionless infrastructure is the only way to ensure the quality of development and training of the system. Furthermore, the further identification and parallel development of additional API is required. On the object level "data", the corresponding inventory data is divided into a training data set and validation data set and used for prototyping and further development. Simultaneously, it requires compliance with enterprise-wide data management with constant monitoring of the defined data quality in the enterprise as well as the correct storage. In addition, company-wide data security standards and guidelines must be defined and established for the subsequent use of the AI system. If the company works with an external provider or service provider, it is essential to establish a contractual agreement for the AI development and use of sensitive company data. After completion of the third year of implementation, the first fully functional version of the AI system is available.

Following successful development in the third year, implementation in the existing process structures takes place at process level in the final year. This involves realigning the process structures and increasing the degree of automation. In addition, the focus is on evaluating the pilot project. Furthermore, the AI system will be continuously developed, and further AI projects will be planned and implemented in the company based on the experience gained from the systematic implementation. In the case of cooperation with third parties, it must be evaluated whether extreme services are still required for the follow-up projects or whether further development can be implemented independently. At the organizational level, an initial cost-benefit analysis of the AI development and the mid-term use of the system is performed. Furthermore, the experiences of the implementation project are processed and compiled in a company-wide lessons-learned documentation. This expands the company's knowledge base in the context of AI development and use. A further important aspect is the constant transfer of knowledge, the further training of employees in AI topics and the recruiting of suitable personnel for the subsequent projects. Depending on the planning of further developments of AI systems in the company, accurate planning of the expansion and scalability of the IT infrastructure is required. In the same way, the size of the data growth through the use of the AI system should be evaluated and, if necessary, the memory of the storage should be increased. Furthermore, the functionality under ongoing operation of the AI system should be evaluated and possible optimization measures implemented in the short term. In addition to the data room and the IT infrastructure, a demand-oriented and user-friendly control of the AI system for the employees must also be ensured. In addition, all interfaces along the process chain are constantly monitored during normal operation and optimized if necessary to ensure lasting interoperability between the various application systems. At the data level, continuous data maintenance, compliance with data protection, qualitative data management and structured data storage continue to play an important role under the aspect of the increasing number through the use of the AI system in daily operational business. In addition, the evaluation of the acquisition of additional metadata for the further optimization of the system is required. Furthermore, building on the standards set in the context of data management in the company, a uniform governance for dealing with artificial intelligence systems will be set up and

implemented in the company. This will ensure safe and responsible use of modern technologies in the long term.

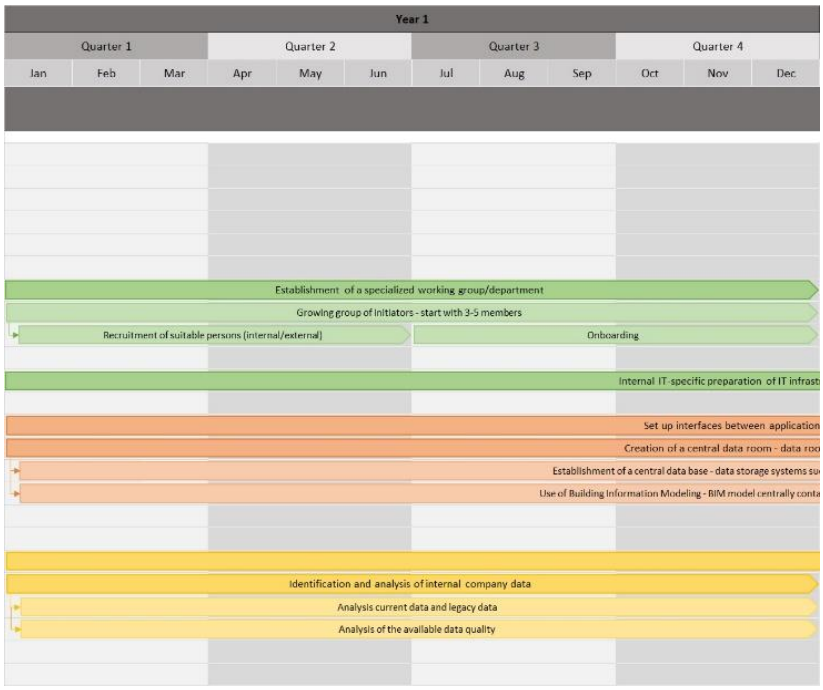

Figure 1: Roadmap in the 1st year of implementation.

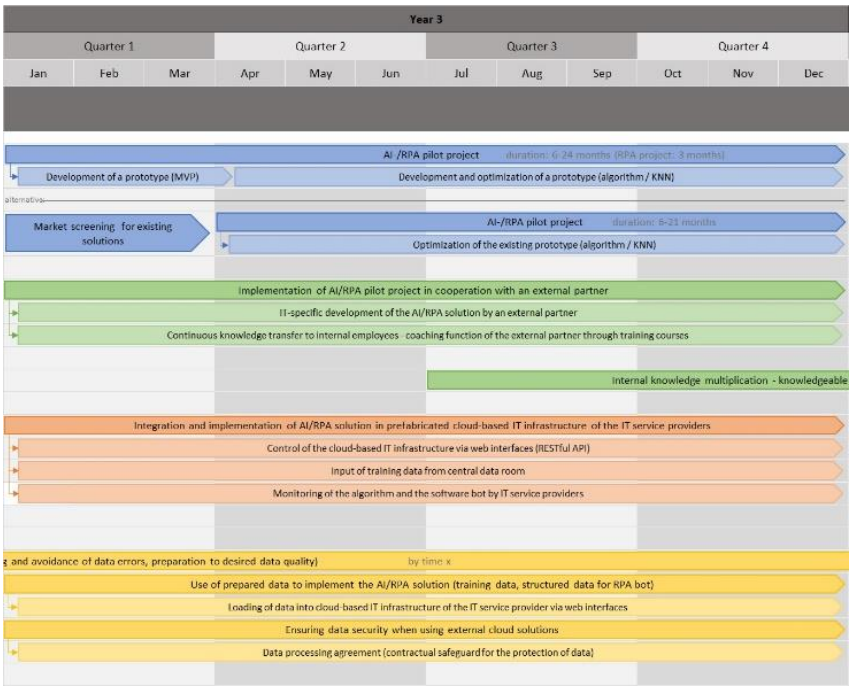

Figure 3: Roadmap in the 3rd year of implementation.

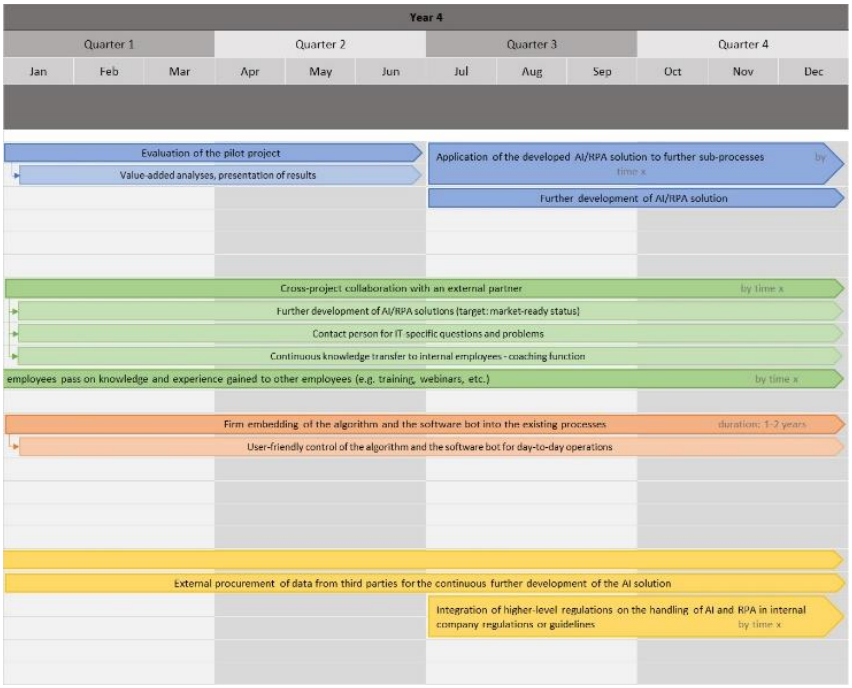

Figure 4: Roadmap in the 4th year of implementation.

Definition of company-wide minimum standards

Table 2. Minimum standards for AI implementation.

Minimum standards: Processes	**Minimum standards: Organization**
▪ Identification and recording of the overall business processes ▪ Standardization of business processes ▪ Identification of sub-processes ▪ Existence of continuous digital processes ▪ Identification of repetitive processes for pilot projects without risk	▪ Establishment of a specialized working group ▪ Involvement of an IT department or IT specialists (internal/external) ▪ Establishment of a central responsibility ▪ Cooperation of external specialists ▪ Build-up of know-how and continuous knowledge transfer ▪ Early recruiting of knowledgeable specialists (internal/external) ▪ Training of own employees ▪ Close cooperation with management ▪ Sensitization of internal employees to modern technologies
Minimum standards: Data	**Minimum standards: Application systems**
▪ Identification and knowledge of all existing data in the company ▪ Setting standards for internal data quality ▪ Creation of uniform data structures ▪ Continuous data maintenance ▪ Guidelines for data protection ▪ Overarching strategy for data governance and data management ▪ Training on secure data handling	▪ Creation and expansion of a high-performance infrastructure ▪ Ensuring a resilient and scalable IT infrastructure ▪ Interoperability between systems ▪ Interface integration ▪ Establishment of a central data room

After the development and description of the roadmap, generally applicable, company-wide minimum standards for the implementation of AI in construction companies are defined. The individual object levels of a company - processes, organization, data and application systems - are considered independently for this purpose. The content builds on the roadmap developed and is derived from the results of the expert interviews. The minimum standards are shown in Table 2.

Concluding, there is a connection and a direct dependence between the minimum standards of the individual object levels of the company. Hence, it is necessary to create the individual minimum standards in the company and to comply with them at the same time. Thus, the systematic implementation process of AI systems can be fully and qualitatively completed.
Non-compliance with the minimum standards at a single object level jeopardizes the qualitative implementation. This results from the level dependency and the chain of effects between the minimal standards. For this reason, the definition and specification of the minimum standards is essential when applying the roadmap for implementation projects.

Discussion

This article provides a roadmap for the systematic implementation of artificial intelligence in construction companies. A structured literature analysis of the current use of artificial intelligence along the life cycle in the construction industry and 13 expert interviews served as the basis for the roadmap development. The derived roadmap considers a time horizon for implementation of four years in total and differs between the four object levels - processes, organization, application systems and data. For a better utilization of the roadmap, company-wide minimum standards for the implementation and use of AI systems were additionally defined. The roadmap bridges an important research gap. It serves as a general framework for construction companies of any size and for any type of AI algorithm. Furthermore, it minimizes existing barriers to entry for future implementation projects and pilot projects with AI in the company, hence making widespread use possible. This increases the digitization of construction companies and consequently the entire construction industry in the medium and long term. In addition, the degree of automation of existing processes and their efficiency will be increased and, in the same way, productivity will be boosted. This creates a basis for the promotion of Construction Industry 4.0. Despite the conclusive development of the roadmap as a holistic and strategic framework for AI implementation, it is still necessary to consider limitations. So far, the knowledge base of the roadmap is an expert interview with 13 participants. Further specification requires the inclusion of additional experts with different expertise at the strategic, process and information technology levels. In addition, the roadmap has so far been a theoretical construct that should be tested for its accuracy and practicability through further validation steps, such as using the roadmap in a real case study in cooperation with an industry partner. Furthermore, the roadmap considers the technology of artificial intelligence very globally. In case of additional specification, it also requires the consideration of different AI models and training variants.

In future research activities, the developed research results, roadmap and minimum standards, will be further specified and validated with the involvement of further experts and practice partners. The specification will consider different implementation scenarios depending on the type of AI model, its characteristic intended use, and individual development and training. The validation of the artifact is aimed at using practical case studies.

Conclusion

The article centers on the development of a roadmap for the systematic implementation of artificial intelligence in construction companies and the definition of necessary minimum standards. In the first part, a literature analysis is conducted to identify existing AI use in the construction industry along the life cycle. Subsequently, thirteen qualitative expert interviews are realized and evaluated. The acquired findings serve as a foundation for the roadmap development in the next step. In addition, minimum standards for companies to implement and use the roadmap are derived. The roadmap and the minimum standards differentiate between the four object levels of a company: processes, organization, application systems and data. The roadmap serves as a generic model on a strategic level and describes relevant steps for a qualitative and successful development of AI systems and its implementation in existing structures of construction companies. Although the roadmap and minimum standards were developed based on a substantiated methodological approach, further research is needed by specifying and considering other aspects of managing AI in construction companies. In this way, the existing barriers to AI use will be further lowered and the attractiveness and

comprehensibility of the technology will be increased. As a result, in the medium and long-term horizon, the construction industry will experience an increase in the level of automation and digitization based on the successful development, implementation and use of AI.

WEB Based Waste Management System

Ö. H. Bettemir and A. Yıldız
Inonu University, Department of Civil Engineering, Malatya, Turkey
onder.bettemir@inonu.edu.tr, ahmetyildiz122@hotmail.com

Abstract

In Turkey, recycling process is executed by collecting different types of wastes in waste bins located mainly at the institutions, organizations and public corporations. The wastes are collected from the mentioned recycle bins and they are transported to a recycling center. The amount of waste collected from waste bins in many public areas is unknown since the amount of waste collected from the recycling bins is not measured. It is necessary to know the amount of collected waste in order to execute the recycling process effectively and efficiently. In this study, it is recommended to implement a web-based waste management system in order to solve the stated problems. In the specified system, first, distance measuring sensors is placed at all waste bins and the occupancy rate of the boxes and thus the amount of waste in the box will be measured by means of the placed sensors. The measured data are transferred to a web-based system. All the transferred is stored and monitored. Benefits of this system to institutions and organizations will be the possibility of determination of whether the size of the waste bin is sufficient or not. Moreover, how often the box should be emptied can be determined by analyzing the long-term measurements, and it will be ensured that recycling can be carried out efficiently with the ideal number of personnel. The system has potential of improvement with the use of artificial intelligence techniques. The developed system ensures effective and efficient recycling.

Keywords: *deneyap card, recycling, remote access, sustainability, waste management.*

Introduction

In the last century, the world population has tripled and there has been mass displacement from rural to urban areas. Approximately 50% of the world's population lives in cities and it is estimated that this figure will reach 70% by 2050 (Raina et al., 2017). The rapid growth of urbanization resulted in the production of large amounts of waste. Over the past decade, urban people consistently produced enormous amounts of waste that has a detrimental impact on human health and the environment. It is estimated that the world produces approximately 1.3 billion tons of solid waste per year and the amount of waste produced will increase to 2.2 billion tons per year by 2025. On average, each person produces about 0.11 to 4.54 kilograms of solid waste per day. It is estimated that 33% of solid wastes produced in cities are not managed in an environmentally friendly and safer way (Kaza et al., 2018; Bocquier, 2005). Improper management of wastes pollutes the oceans, spreads diseases and harms animals that eat waste unintentionally. Currently, recycling and waste management systems have become the focus of many cities and municipalities due to urbanization and climate problems. The

solid waste management system is the backbone of a smart and sustainable city and should include the functions of collecting, sorting and recycling the waste.

The basic processes of waste collection have remained the same for decades. Solid waste problems resulting from human activities have been tried to be solved by means of wild storage, landfill and incineration (Yılmaz & Bozkurt, 2010). Wild landfill is a method in which solid wastes are arbitrarily transferred and stored (Gökçe & Hasanoğlu, 2015). Landfill is a system in which garbage is disposed of by dumping the garbage into an area where the impermeability is provided and a drainage system to collect the leachate from the garbage is built, compacted every day and covered with soil (Aras et al., 2006). Incineration is carried out by burning the municipal solid waste directly without any pre-treatment in order to reduce the volume of the waste. This process is carried out to ensure the stabilization, sterilization of the wastes and to obtain energy from the waste (Aynur, 2011). Storing the wastes by burying or dumping, which is accepted as a wild storage method, increases the environmental problems caused by wastes and reveals the necessity of dealing with these problems in more than one dimension (Solak & Pekküçükşen, 2018).

The collection and storage of solid waste is under the responsibility of local governments, but due to financial and technical deficiencies, this task may not be effectively managed. The findings highlight the necessity of solid waste legislation and a compliant institutional structure. This is because an integrated solid waste management requires a significant financial resource which may be a bigger investment than a municipality can handle alone. The solid waste management policies and strategies are determined with political concerns rather than local needs. In addition to this the policies of the local governments is to prefer workarounds which causes the resources to be spend on waste management be shifted to other items even if there are sufficient resources (Solak & Pekküçükşen, 2018).

The amount of produced solid waste is very high and the management of solid wastes is very difficult. This fact led conducting studies on the recycling or reuse of solid wastes. For this reason, many public institutions, private institutions, and enterprises develop plans for the collection of solid wastes generated at homes and dormitories for recycling or reusing them. Many universities implement waste management actions to collect wastes which are produced inside the campus. On the other hand, managing the solid waste collected in large institutions requires a serious workload.

There are many recycling and waste bins especially in university campuses. Timely collection of wastes accumulated in the waste bins is an important problem for the university administrations. This is because the university administrations carry out the maintenance, cleaning and protection services of the university campus with a limited number of personnel. It is an important problem for university administrations to retain the waste bins, which are not filled in regular time intervals. In general, a single duty staff is appointed for a building and this staff is responsible for the cleaning of classrooms, academicians' rooms, toilets and the maintenance of the building's garden. For this reason, emptying and monitoring of waste bins has the last priority. When the waste bins are ignored, it cannot be noticed that they are full and cannot serve as represented in Figure 1. In this case, the recyclable wastes are thrown into the garbage bins, and both economic and environmental losses are experienced. In addition, wastes waiting for a long time in waste bins can cause hygiene problems. In order to prevent the mentioned problems, the amount of waste accumulated in the waste bins should be measured regularly and the last time the waste bins were emptied should be measured.

Figure 1: The handling difficulties of the recycle bins inside the campus.

Smart home technologies are an important source of inspiration for the automation of solid waste collection, which must be carried out with limited personnel and budget. Pavithra and Balakrishnan (2015) developed a system which carries out continuous monitoring of various household appliances with a smart phone in order to facilitate human life and prevent house fires. After connecting to a web server accessible from a smartphone, computer or tablet, home appliances can be remotely controlled and monitored. A light-dependent resistor (LDR) detects the fire and provides instant response to the fire by sending a message to the smart phone.

Al-Kuwari et al. (2018) developed IoT-based smart home automation detection and monitoring system to facilitate daily life. The system basically consists of sensors, processor, user interface, and data communication circuits. Data from all sensors is continuously uploaded and stored on the EmonCMS platform. EmonCMS is an IoT cloud server for logging data with an option to view it using dashboards. Finally, an automatic solar panel cleaning device is included to the developed system.

Measurement, data transfer and data processing techniques implemented in smart home systems can also be applied in the management of solid wastes collected inside the university campuses. With the help of IoT-based data transfer technologies, cameras and sensors, waste collection processes can be improved and modified.

In this study, a Web-based waste management system is created to prevent the difficulty of monitoring the collected waste and the hygiene problems that may be caused by the waste collection units. With the use of the developed system, efficiency of the waste management will increase, environmental pollution will be reduced, and the sustainability of the urban life will increase. Transparency and openness will be ensured by integrating the system into the blockchain in the future.

Abd Wahab et al. (2014) developed a web-based system for smart waste management. The weight of the waste accumulated in the boxes is automatically measured and the measured data is transferred to the web base. RFID system placed in the boxes tracks the collection of the accumulated waste by the authorized staff.

Ahmad et al. (2021) investigated the benefits of blockchain technology for the management of waste in cities. The utilization of blockchain technology can provide traceability, immutability, transparency and auditing features in a decentralized and reliable way. Real-time monitoring of waste, reliable sewage, compliance with waste treatment laws, efficient waste management, and preservation of waste management documentation are also discussed.

Kurre (2016) developed a system to detect overflow of dust bins with infrared distance measurement units. Rashinkar et al. (2017), Khedikar et al. (2017), Dhaya and Sujithra (2018) and Makde et al. (2019) developed a monitoring system for the waste collection which measures the occupancy ratio of the dust bin by ultrasonic sensors.

The properly management of waste and the efficient collection of waste in public institutions and organizations create a significant workload. Disruptions that may arise in waste management can lead to the neglecting the recycling of the potential wastes. Hygiene problems that may affect human, animal and environmental health, bad odor caused by the gases to be formed in the waste bins, pollution and throwing the wastes into the wrong bins due to the filling of the waste bins are examples of the possible adverse consequences. Data collection and data management has become significantly easier due to the reduced costs of sensors used in smart home technologies and the widespread use of internet of things applications. Consequently, a web-based waste management system that can instantly monitor the amount of solid waste thrown into the solid waste collection bins system is designed. The monitored recycling bins can collect many and different types of waste and the designed system can monitor when the solid waste bins are full, when they are emptied, and can estimate the amount of waste by processing the data collected over a long period of time.

Architecture of Waste Management System

It is aimed that the waste management system should have low initial investment and operating costs. Moreover data collection and data processing should be carried out in a way that requires minimal human intervention. The waste management system is based on the principle of measuring the amount of wastes in the recycling bin by placing an ultrasonic distance measurement sensor in a suitable location inside each recycling bin. Occupancy rate of the recycling bin will be computed by the measured distance data. The computed occupancy rate will be transferred to the central computer at regular time intervals. The flow chart of waste management is presented in Figure 2.

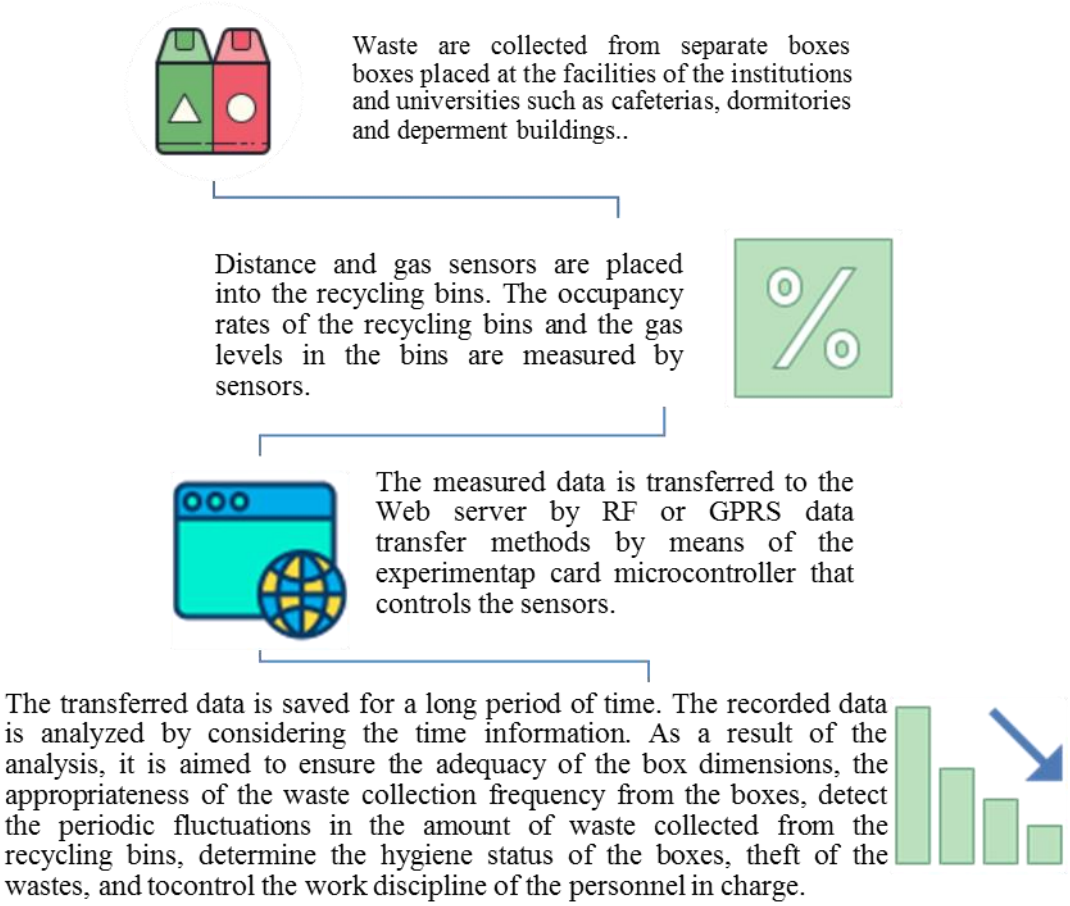

Figure 2: Flowchart of the web based waste management system.

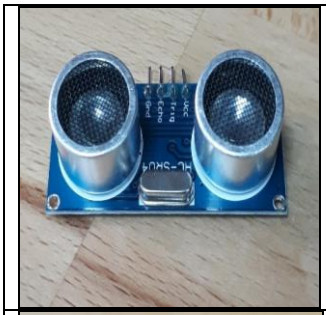
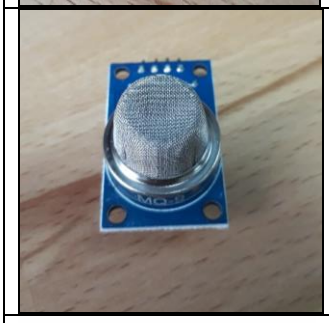
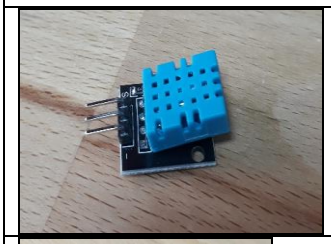
Waste is collected separately in recycling bins of certain dimensions. Waste collection boxes spread over a wide area within the university campus aiming to collect different type of wastes. Sensors are placed inside each waste bin to continuously measure the amount of waste in it. Weight sensors measure the weight of the waste inside the waste bins, but they are expensive. For this reason, monitoring the amount of waste by measuring the volume change inside the box is preferred. The volume measurement is carried out by measuring the distance with an ultrasonic sensor and determining the height of the waste. Since the ultrasonic sensor only measures one point, which may cause erroneous measurement, the ultrasonic sensor will be placed on a 40 cm long thin rod and a servo motor will be placed on the other end of the rod. When the servo motor rotates, the ultrasonic sensor will sweep and measure different positions inside the box. The height of the ultrasonic sensor will remain constant and will only sweep in the plane. The position of the ultrasonic sensor will be calculated by the trigonometric relationship between the position of the servo motor, the rotation angle and the fixed distance between the ultrasonic sensor and the servo motor. The height of the waste material is calculated by considering the location of the ultrasonic sensor and the distance between the ultrasonic sensor and the waste material. The amount of waste in the recycling bin is estimated from the height of the waste material measured from different locations. This process is performed every 1 minute.

Although recyclable wastes are expected to be disposed of in recycling bins, organic wastes can sometimes be thrown into recycling bins. This situation can lead to hygiene problems, especially in the summer season. For this reason, it is aimed to measure the concentrations of

CO_2 and methane gas in the recycling bins by placing a gas sensor inside them. Figure 3 shows the waste bins placed outside. Animals such as cats and birds can enter the boxes outside in search of food or water at night when there is no human activity. Such a situation may cause fatal consequences for animals that may enter the boxes where hazardous wastes such as waste batteries and fluorescents are collected. For this reason, LDR and PIR sensors will be placed inside the waste bins to detect motion.







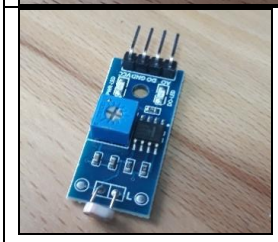


Figure 3: Recycling bins placed outside at the campus.

There are recycling bins in the campus to obtain compost from organic waste. The growth of bacteria accelerates especially with the warming of the air temperature. In order to determine the need for collection of the compost inside the bins, sensors measuring the temperature, humidity, CO_2 and methane density is placed in the bins, as well as measuring the fill rate. The decision to collect the compost material is taken according to the conditions of the environment where the compost material is located. Thus, the collection of compost waste, which is a laborious and costly work item, will be carried out in the most economical way.

When the responsible personnel for the maintenance of the recycling bins empties the bin, the staff will make the RFID reader read his card which is registered to him. The RFID card reader will be placed in a suitable place in the immediate vicinity of the recycling bins, and when the reading process takes place, the information that the waste bins have been collected will be recorded in the system. The collection information of the recycling bins will also be confirmed by comparing the occupancy rate of the waste bin, and the personnel in charge of the waste collection will be supervised.

In order to process the data obtained from the waste bins, the data must be transferred to the central computer in real time with access permission for the academic and administrative personnel responsible for the recycling bins when needed. For this reason, a web-based waste management system is developed, consisting of data collection, data transfer to the central computer, and data processing. During the data collection phase, the data to be collected from the recycling bins will be controlled by the Deneyap Card microcontroller and ultrasonic distance sensor, carbon monoxide and combustible gas sensor, temperature and humidity sensor, motion sensor, LDR sensor, and servo motor placed in each box. The sensors used in the system are explained in Figure 4.

	HC- SR04 Ultrasonic distance sensor measures the distance by sending sound waves from its trig pin in 40 kHz. The ECHO pin measures the received sound wave when the sound wave hits an object and returns. The sensor measures the travel time of the sound wave and computes the distance between the sensor and the object.
	MQ-5 and 9 sensors can measure the CO2 and flammable gases in the medium. The conductivity of the sensor increases as the gas concentration of the medium increases.
	HC-SR501 is an adjustable movement sensor. It detects the movements in the medium. The sensitivity of the sensor can be adjusted up to 5 meter distance.
	DHT11 temperature and humidity sensor contains 8 bit microprocessor and measures the temperatures between 0 and 50°C within 2°C error margin.
	LDR light sensor contains a light dependent resistance. At dark medium it outputs 0 V and outputs 5 V at bright medium.
	MG90S Rc Servo Motor is a small servo motor with 180 degree amplitude. The motor can be directly powered by the microcontroller.

	Deneyap Card contains ESP32-WROVER-E processing unit and internal Wi-Fi and Bluetooth data transfer modules.

Figure 4: Components of the developed system.

The main objectives of the developed system are low cost, flexibility and remote access. If the occupancy rate of the recycling bins is measured by the weight sensor, the cost of the system would increase considerably. For this reason, a weight sensor is not used for the occupancy rate measurement of the recycling bins.

The average of the occupancy rate data is used to increase the accuracy of the measurements. In order to filter out the outliers, the sensors inside the box will measure every second and record for one minute, and the average of 60 collected data will be sent to the central computer. In this way, measurements that may contain random errors caused by the sensor anomalies will be filtered as well as the size of the data to be transferred will be reduced.

Data transfer is carried out with the Deneyap card. Data transfer will be ensured by adding a module that transmits data via radio waves for recycling bins located outside. The data to be collected from the recycling bins to be placed inside the building is transferred to the central computer via the Wi-Fi network in the building. The data to be transferred is the code number and time of the relevant recycling bin unit, labeled occupancy rate, temperature, humidity values, and CO_2 and methane gas densities. When the PIR and LDR receivers placed in the box detect any motion in the box the sensors will output 1 and 0 vice versa. Each dataset will be sent in every 1 minute. In this way, the amount of data transfer will be limited to 150 bytes per minute. Since the data volume is low, it can be transferred by radio frequency data transfer modules. For this reason, it is aimed to send the data to the central computer in the campus with a radio receiver and transmitter with a booster antenna with a range of more than 300 meters in the open area. Different radio modules available to send data will be tried. In case the radio transmitter range is insufficient due to the surrounding trees and buildings, data transmission will be carried out with GPRS, which is a more expensive alternative.

The transmitted data will be stored by a web-based system and the data can be accessed by all authorized personnel. In this way, the occupancy rates of the recycling bins, their temperature, gas concentration and whether there is an entrance into the bin will be displayed on the web platform in near real time. Recycling bins that are full or nearly full will be reported specifically and brought to the attention of authorized personnel.

The purpose of the developed system is to measure the amount of collected material as well as to encourage the recycling. In order to carry out waste management effectively, the amount of collected waste should be measured and the data must be evaluated. Periodic fluctuations can be determined by analyzing the measured data within a certain time interval. The analysis will make it possible to determine whether the size of the waste bin is sufficient or not. In addition, to improve the efficiently of the personnel, the handling periods of the recycling bins will be analyzed and the optimum frequency of handling the recycling bins will be

determined. In addition, as a result of a possible negligence in waste collection, the wastes will be prevented from waiting for a long time in the recycling bins and the emergence of hygiene problems will be prevented.

The collected recycling material from department buildings, dormitories and cafeterias will be regularly measured. The collected material per person of each utility building will be determined. According to the amount of collected recycling material per person, a certificate of appreciation will be given to the administrative supervisor of the facility, and a thank you poster will be hung at the entrance of the building which achieves the highest amount of recycling. If the facility is very low in the ranking, trainings and meetings will be held to encourage recycling at that facility. In this way, the recycling culture and awareness will be spread throughout the campus.

Data collection process will continue for a long time and the data cloud of the collected recycle amounts will be modeled through time series analysis. Accordingly, future projections will be made and data will be provided for economic feasibility analyzes of waste collection and storage investments. In addition, periods during which periodic fluctuations may occur in the amount of collected recycling material will be determined and appropriate measures will be taken.

Conclusion

Many institutions have a duty to implement waste management and protect the environment. The management of solid wastes collected by recycling bins in university campuses which spreads over a wide area requires serious personnel resources. In this study utilization of an IoT supported web-based waste management system is proposed. The proposed system is cost-effective, is flexible and provides remote access, which will be a solution for the institutions having a campus settlement. The system consists of distance, gas, light and temperature sensors, a servo motor, data transfer module with radio frequency and Deneyap Card microprocessor. With the help of sensors, the amount of waste in the recycling bins will be measured, the occupancy rates will be displayed instantly, and the gas levels will be measured. By emptying the waste bins on time, hygiene problems will be prevented and human, animal and environmental health will be ensured. The data received from the sensors is stored on the web platform. The collected large data sets will be processed by time series analysis. The efficiency of the proposed system will increase with the accumulation of the data. In addition, data will be integrated with the blockchain to improve the system, ensuring transparency and openness. It is aimed to ensure a beneficial competition in the waste collection process by sharing the collected data with the people living inside the campus.

Measurement and Analysis of Haul Routes

Ö. H. Bettemir and A. Çırak
Inonu University, Department of Civil Engineering, Malatya, Turkey
onder.bettemir@inonu.edu.tr, alpercirak23@gmail.com

Abstract

Haul routes of a road or a dam construction where earthworks are intense affect the duration and cost of the earthwork to a great extent. Mapping and location applications such as Google Earth, provides location, height, distance and visual information. However most of the construction sites are settled in mountainous regions which are far from urban settlements. Satellite images and maps of these regions do not have enough resolution and accuracy. Therefore, the mentioned services cannot be implemented to determine the route of the haul roads used by the construction machines with reasonable accuracy. In order to help solve the stated problem a GPS measuring device consisting of NEO-6M GPS Module and Arduino Card is produced. The software for obtaining the GPS measurement data obtained by Absolute positioning method is coded by using C programming language. The device is mounted on a vehicle and haul route measurement is carried out with sufficient measurement accuracy and measurement frequency. The measurement data expressing the latitude, longitude and height are transferred to the computer in real time by the serial port. In this study the haul road of a mining facility is measured and recorded by the developed system. 3-dimensional measurement of the road is made by measuring at 640 points of the haul route. The system used in the measurements does not require an additional device other than Arduino card and GPS module. The specified devices can be obtained for approximately $20. Therefore, the designed system has a high price advantage compared to ready to use GPS positioning based devices available in the market. As a result the developed system will assist in the analysis process of determination of the most suitable haul truck which reduces the construction time and cost. The developed system can easily be assembled to a vehicle and can be used as vehicle tracking system.

Keywords: *earthwork, GPS, haul road.*

Introduction

Construction machineries are used to prepare the construction sites, as well as to perform the work items such as excavation, transportation, and compaction, leveling and demolition. Excavator, dump truck, backhoe loader, skid steer loader, bulldozer, scraper and motor grader are mainly used for the earthworks and site improvement tasks. Since the specified construction machines have high initial investment costs, it is very important to choose the right size as well as types and use them with high efficiency. Otherwise, the contractor may lose money or even forfeit the collateral. In order to prevent adverse consequence, the construction machines should be utilized with high efficiency which depends on many factors.

Loader and backhoe bucket volume, weight of the construction machines, engine power, swing angle, height of construction machine, transport distance of loader, soil and site conditions, operator's working efficiency and experience, environment and weather conditions, and haul route effects the job efficiency. Efficiency of the construction equipment affects cost of the earthwork. In order to keep the excavation cost low, construction equipment with appropriate production efficiency should be allocated. The amount of production per unit time that the construction machinery can perform significantly affects the unit cost of aggregate production.

For this reason, it is important to determine the production rate of the construction machines with high accuracy. Caterpillar (1979), Nunnally (2001) as well as Peurifoy and Schexnayder (2002) have published tables that determine how many cycles loaders and excavators can make in an hour, and the amount of soil which the bucket can be filled according to site, environment and job conditions. The table and charts are utilized manually, in order to automate the output estimation of the construction machines software based on regression models are developed. Edwards and Holt (2000) established a regression model using the cycle time of 35 hydraulic excavators and named the model ESTIVATE. The developed model estimates the cycle time of the construction machine based on its parameters. Edwards and Griffiths (2000) fed the artificial neural network with the data of 43 construction machines and established a prediction model according to the technical characteristics of the construction equipment. Edwards et al. (2001) presents a decision tool for selecting the optimum excavator type for job conditions and defined production scenarios by adding the linear programming algorithm to the realized forecasting model. Tam et al. (2002) aimed to increase the accuracy of the model by adding additional construction machines to the established model. Yang et al. (2003) estimated the production quantities of construction equipment with fuzzy logic. Vahdatikhaki and Hammad (2014) used location tracking techniques to simulate near real-time earthwork projects. It improved the simulation model parameters by measuring the differences between the simulation prediction and the actual situation.

Drygin et al. (2017) conducted a study to increase the unit time performance of construction equipment in Kuzbass open pit quarries and determined that reducing the idle times of the construction machines is the most efficiency increasing factor. Holt and Edwards (2015), Manyele (2017) and Balaraaman and Chandrasekaran (2021) examined the efficiency of construction machines in open pits and stated that the availability of maneuvering space of the excavators, the loading position, the size of the excavator, the compatibility of the truck and the excavator size had a great effect on the efficiency. Yoon et al. (2014) investigated the factors affecting the hourly excavation rate of the excavators and found that the truck height is not very important, but the distance between the excavator and the truck and the rotation angle are significant. Bettemir (2009) modeled the uncertainties and risks related to weather, ground conditions and operator productivity with Monte Carlo analysis and examined the effects of these factors on job completion time and equipment requirement. Sağlam and Bettemir (2018) developed software that estimates the excavation time and the number of required trucks by considering different ground and environmental conditions. Chan et al. (1989) developed a database system which focuses on selecting the most suitable construction machine for the earthwork project according to the technical data of the loader-excavators.

For many years, the European construction sector has been in a change process due to different effects such as globalization, legal changes and technical developments. The construction industry faces a challenging environment with very tight time and budget

constraints. At the same time, the lack of real-time information makes it impossible to control the construction projects effectively. Before the tender, accurate computation of the construction times and costs of the construction projects are very important. Tender files with incomplete or incorrect data contain significant risks. If the effects of the uncertainties in the aforementioned data on the construction time and cost are determined, the risk involved in the bid price and the construction time file will be determined more accurately.

The hauling route is one of the important factors affecting the production efficiency and cost of the earthworks. The soil type, road conditions, slope and total length of the route affect the production rate. With the real-time control of the haul routes and the combination of the right construction equipment, it is possible to determine the production rate, the volume of the transported soil and the consumed fuel before the commencement of the earthwork. There are location based applications, which presents the location, height, distance and visual information of the construction sites. However most of the heavy constructions in which the volume of the earthwork are intense, are far from the central settlements in mountainous regions. The visual information and the digital elevation model of the mentioned regions are obtained via satellite images which do not have high resolution and accuracy (Bettemir, 2011). Therefore, determination of the location of the haul routes through which the construction equipment passes with high spatial resolution will help the construction managers to determine the most suitable construction equipment to be used in the project, and to reduce the construction time and cost.

As a result there are important studies in the literature on the control and monitor of earthwork machines. Upon the widespread use of GPS systems and the improvement of positioning accuracy, many systems have been developed to monitor the movements of the construction machines and to monitor the construction quality and speed by placing precise GPS on the construction machine. Baertlein et al. (2000) developed a machine control system for the road construction that monitors the construction machine and directs it by achieving sub-centimeter precision with laser-guided dual-frequency real-time kinematic positioning method. Jonasson et al. (2002) and Lee and Han (2003) stated that the machine control systems created by using precise GPS receivers significantly increase the efficiency of the construction machines and significantly reduce the re-passes of dozers and graders that pass at the wrong height. Han et al. (2005) used Web CYCLONE software to simulate situations where earthworks are performed with and without a GPS-based machine control system. As a result of the simulation, it has been shown that the GPS-based system is 32.48% more efficient than the traditional system. The GPS-based system costs 22.88% less. Shengxiang et al. (2005) increased job tracking and quality control by placing sensitive GPS receivers on to the compactors in the earth fill dam construction. Rausch (2010) developed a system that increases the efficiency of the excavation and road construction by executing performance and cost analysis with the data obtained from GPS receivers placed on construction machines. The system records the position, time, coordinates of an excavator's bucket, and data sets consisting of directions and angles obtained from the GPS receiver. The specified GPS-based systems accurately measure the number of hourly cycles of the construction machines. But these sensors are sold at very high prices due to the use of very sensitive positioning devices and advanced artificial intelligence software. Because of their cost, CORS GPS-based systems are not in high demand in small and medium-sized open-pit mines.

In this study, a GPS measuring device consisting of NEO-6M GPS Module and Ardunio Card are assembled to obtain a cheap positioning device. The device is mounted on a vehicle in order to measure a real haul route cost-effectively with high accuracy and spatial resolution.

Design

Ardunio Card and NEO-6M GPS module are used to perform real-time observation and measurement of the excavation route. Arduino is a microcontroller platform with open source software and hardware. Arduino consists of both a physically programmable circuit board and a piece of software or IDE (Integrated Development Environment) that runs on computer, which is used to write and upload computer code to the physical board.

The Neo-6M module is a standalone GPS receiver module with high performance U-blox 6 chipset. It can monitor up to 22 satellites in 50 channels. It achieves the highest level of sensitivity among GPS modules. Unlike other GPS modules, it can update 5 locations per second with 2.5m horizontal location accuracy. The U-blox 6 positioning engine also offers a Time to First Fix (TTFF) of less than 1 second.

In order to realize a real and on-site application, the haul route of Çevkur mining firm of Zinc - Lead Open Mine located on the Malatya - Kayseri road is measured. The haul route is in the degraded form in which some portions are smooth and some portions are with bumps and pits.

In order to measure the haul route, NEO-6M GPS Module and Ardunio Card is mounted on a vehicle and the measurement of the haul roads is carried out with sufficient measurement accuracy and measurement frequency. The measurement data expressing the latitude, longitude and height of the road are transferred to the computer in real time by using the serial port over the Arduino Card with the software developed with the C programming language. The developed Arduino GPS receiver is shown in Figure 1.

Figure 1a: GPS device. Figure 1b: GPS device mounted on vehicle. Figure 1c: GPS transfer of measurement data.

Analysis of the haul route and the related calculations are carried out by transferring the latitude, longitude and altitude data to the Microsoft Excel software. Table 1 shows some portion of the data transferred to the Excel program.

Table 1. A portion of the measured spatial data.

Measurement	N (phi)	E (lam)	h
1	38.1681219	38.0796797	1173.2
2	38.1681220	38.0796797	1173.2
3	38.1681220	38.0796794	1173.1
4	38.1681208	38.0796769	1173.1
5	38.1681162	38.0796708	1173.1
6	38.1681068	38.0796654	1173.1
7	38.1680954	38.0796654	1173.1
8	38.1680849	38.0796723	1173.2
9	38.1680780	38.0796844	1173.3
10	38.1680763	38.0796979	1173.3
11	38.1680788	38.0797136	1173.3
12	38.1680855	38.0797302	1173.2
13	38.1680939	38.0797444	1173.2
14	38.1681030	38.0797567	1173.2
15	38.1681124	38.0797686	1173.0
16	38.1681214	38.0797791	1172.6
17	38.1681285	38.0797867	1172.5
18	38.1681367	38.0797929	1172.2
19	38.1681492	38.0797960	1171.9
20	38.1681653	38.0797912	1171.6

In order to compute the total length of the haul route, position data are obtained with respect to Earth Centered Earth Fixed (ECEF) Coordinates (Figure 2). The mentioned Earth-Centered Earth-Fixed (ECEF) coordinate system is also known as the "traditional terrestrial" coordinate system. It is a simple Cartesian coordinate system in which the center of the earth forms its origin. The +X axis passes through the intersection of the Equator and the Prime Meridian. ECEF coordinates are defined by the World Geodetic System 1984 (WGS84) standard.

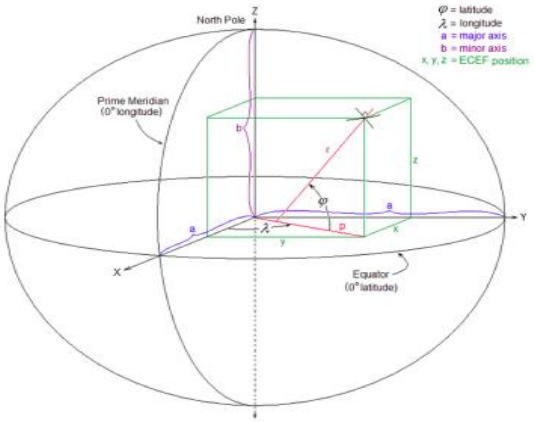

Figure 2: Definition of WGS84 (coordinate transformations by Dr. John Stryjewski).

The shape of the earth is defined by two parameters which are a, semi-major axis, and 1/f, the flattening parameter. The values of the semi-major axis and flattening parameters are a = 6,378,137 meters and 1/f = 298.257223563 (Torge, 2001).

The eccentricity and the normal distance are computed by Eqs. 1 and 2 respectively (Torge, 2001).

$$e = \sqrt{2f - f^2} \tag{1}$$

$$N(\varphi) = \frac{a}{\sqrt{1-(e \cdot \sin(\varphi))^2}} \tag{2}$$

Change in the horizontal coordinates of each point measured with the GPS receiver is determined by the formula presented in Equation 3 to find the total distance of the haul route. The given distance computation is based on the Euclidian distance.

$$\Delta D = \sqrt{(phi_{i+1} - phi_i)^2 + (lam_{i+1} - lam_i)^2} \times \frac{\pi}{180} \times N(\varphi) \tag{3}$$

The distance between the successive measurement points is found by multiplying the difference between the two points, by the normal distance. The total distance of the haul route is determined by adding the distance measurements of all points. In Table 2, a portion of the computed haul route distances by applying Equations 1 to 3 is given.

Table 2. Computed horizontal distance between the measurement points.

Measurement	**N(φ)**	**Δα**	**Distance**
1	6386305.535	0	0
2	6386305.535	0.011	0.011
3	6386305.535	0.033	0.105
4	6386305.535	0.309	0.309
5	6386305.533	0.852	0.852
6	6386305.530	1.208	1.208
7	6386305.525	1.271	1.271
8	6386305.522	1.400	1.404
9	6386305.519	1.553	1.556
10	6386305.518	1.517	1.517
11	6386305.519	1.772	1.772
12	6386305.522	1.995	1.998

20	6386305.551	1.873	1.896

The measurements conducted on the open mine haul route by the designed GPS receiver, contains measurements of 640 points. The latitude, longitude and height data are graphed as

cross section and longitudinal section. In Figure 3, horizontal graph of the haul road is created to analyze the latitude and longitude coordinate data of the haul route in the Microsoft Excel. The x-axis is the latitude and the y-axis is the longitude.

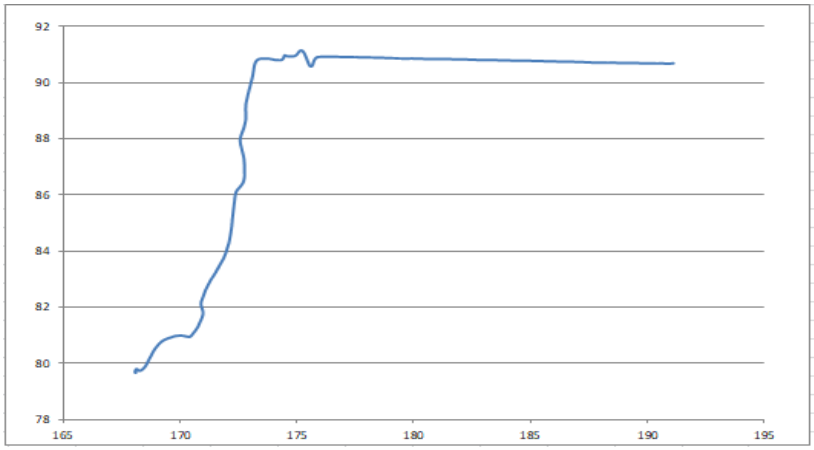

Figure 3. Horizontal graph of the haul route.

The vertical profile of the haul road created in Microsoft Excel is given in Figure 4. In the graph, the x-axis shows the total distance and the y-axis shows the elevation.

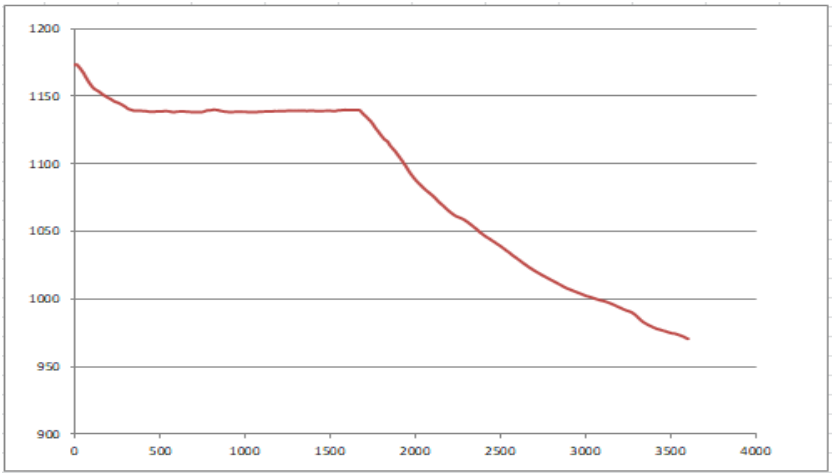

Figure 4. Vertical profile of the haul route.

The total distance of the haul route is calculated as 3602.28 meters based on the distance calculations executed on the position data collected by the GPS receiver. The highest point of the haul route is determined as 1173.2 m and the lowest point as 970.5 m. Thanks to the real-time coordinate measurement performed at the construction site, the haul route is determined with high resolution compared with the satellite image based location data services. In addition to this, the positioning accuracy of the GPS with absolute positioning is better than the free satellite image based location services. Because SRTM DEM is used to provide the elevation data which has lower accuracy than the GPS positioning with absolute positioning technique.

Discussion and Results

The utilized system during the measurements does not require an additional device other than Arduino card and GPS module. The specified devices are available for approximately $20 cost. Therefore, the designed system has a competitive price advantage compared to off-the-shelf GPS receivers. Moreover, the obtained coordinate data and the calculations and analyzes performed on the Microsoft Excel program can be easily stored because it occupies only 50 to 100 KB of storage space depending on the length of the haul route.

The developed system can be protected against falling, being affected by weather conditions and deterioration with a protecting case as future studies. The case can also protect the device from dusty environment. The effects of the construction machine selection, on the project cost and time can be investigated by recording the haul routes with different features such as GPS measurement system to the computer and comparing the different haul route alternatives. The velocities of the haul trucks can be monitored on the haul route by mounting the GPS measurement system and the condition of the haul route can be predicted.

A domestic system with sufficient positional accuracy that can be used instead of high-cost imported GPS measuring devices is developed. The low cost system can be used quickly and easily, and can be easily mounted on the vehicle, and provides real-time measurement. The engineers and contractors will have the opportunity to obtain data with satisfactory accuracy and resolution with reasonable cost. This benefit is important when the economic situation of our country is considered.

BIM Use in Retrofit Optimization for the Climate Change Mitigations and Adaptations Measures

H. Bıyık and A. M. Tanyer
Middle East Technical University, Department of Architecture, Ankara, Turkey
hbiyik@metu.edu.tr, tanyer@metu.edu.tr

Abstract

Sustainability and sustainable development are highly linked to climate change which has a growing interest in the literature. Climate change mitigation and adaptation measures are vital applications in the built environment to overcome the hazardous effects of climate change. However, the BIM integration with sustainability is still immature and rarely conducted. Besides, there is a need to link BIM and climate change in the scope of the climate change mitigation and adaptation measures. In this respect, this study aims to systematically investigate the distinguished studies about BIM use in retrofit optimization for climate change mitigation and adaptation measures. The Scopus and WoS database is used to search the published papers between 2012-2022 related to BIM and retrofit optimization from the climate change perspective. Most related papers to the topic are selected by reviewing their abstracts and chapters after omitting the duplications. As a result, selected papers are examined to identify and classify mitigation and adaptation measures in the scope of BIM use in retrofit optimizations. Niche themes, clusters, thematic evaluations, changes in concepts, the trend topics, applied methods and tools used in the studies are presented.

Keywords: *BIM, optimization, retrofit, climate change.*

Introduction

BIM (Building information modeling) enables the users to embed all information related to building parameters into the model. The information in the model can be used for different sustainable solutions, ranging from carbon emission calculations to energy performance simulations. In this respect, BIM integration with sustainability can be provided as a Green BIM concept (Khahro et al., 2021). However, its integration with sustainability is still immature and rarely conducted. Moreover, the increase in global temperatures (IPCC, n.d.-b) raises the climate change topic. Hence, various governments have set a target of a decrease in carbon emission levels within the scope of international agreements (IPCC, n.d.-a; IPCC WGI, n.d.; United Nations, 1998, 2015). Beyond the climate change mitigation measures to decrease carbon emission levels and energy consumption, climate change adaptation measures are also regarded (Díaz-López et al., 2022; Global ABC, n.d.; IPCC WG III, 2022). Different retrofits related to building components are made to improve building efficiency and decrease carbon emissions. Moreover, more comprehensive retrofits and refurbishments are also made to adapt various buildings to climate change in case of uncontrollable change. In addition, different retrofits as distinct scenarios are conducted to achieve the best results with optimized

building parameters and results (Lim et al., 2021; Seghier et al., 2022). However, BIM integration with even sustainability is considered immature (Khaddaj & Srour, 2016; Lim et al., 2021), whereas its integration with climate change seems challenging.

In this regard, this study aims to examine the studies related to BIM use in retrofit optimization for climate change mitigation and adaptation measures. The science citation indexed articles in Scopus and WoS are primarily used in the study.

Method

The related articles are detected through Scopus and Wos databases and clusters regarding their themes are created in the first step. The information from both databases is downloaded as BibTeX format to merge them in the R environment. 376 publications from Scopus and 134 publications from WoS are merged and detected five duplicates are removed.

The last merged BibTeX file without duplicates are converted to xlsx format to visualize the analysis results through biblioshiny (Biblioshiny, n.d.). The publication numbers, thematic evaluation, niche themes, clusters and most related publications for each cluster are detected through the bibliometric analysis. Niche themes and clusters by documents are overlapped to detect main clusters. Niche themes are generally related to energy efficiency, life cycle, optimization and architectural design with costs (Figure 1).

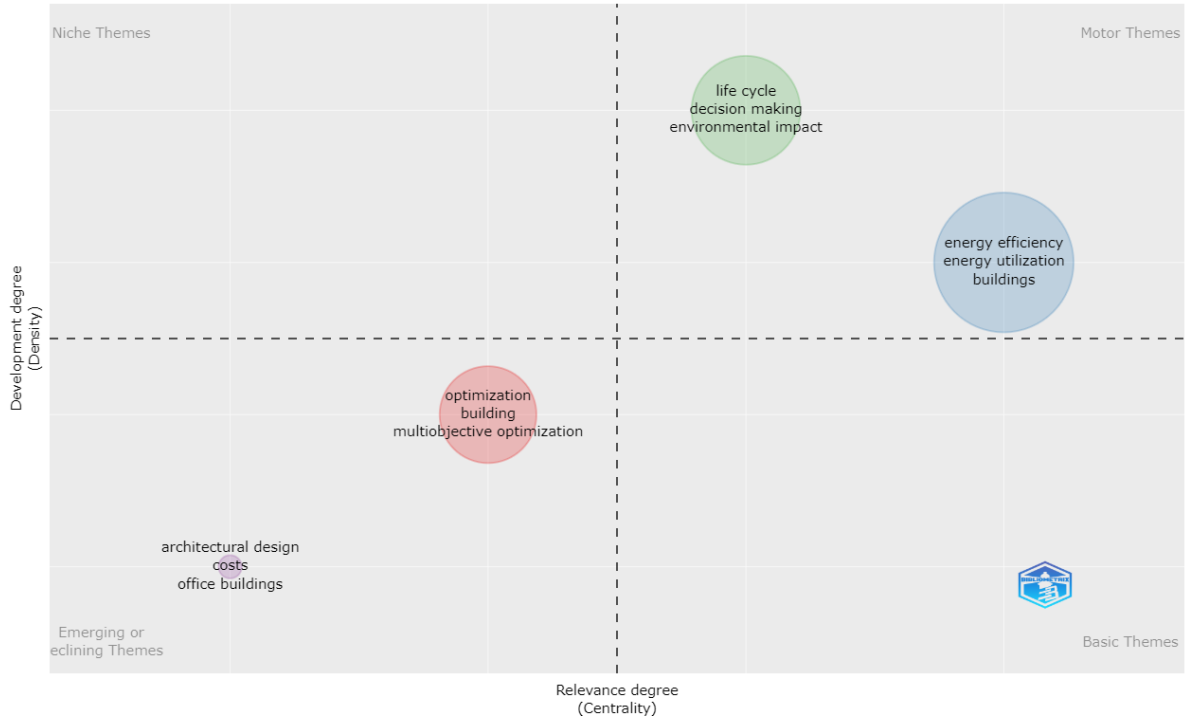

Figure 1: Niche themes.

On the other hand, the cluster about the life cycle, the cluster about energy efficiency and the cluster about optimization are highly studied with high frequencies regarding the clustering map (Figure 2).

label	group	freq	centrality	impact	color
All	All	All	All	All	All
energy efficiency - conf 25.2% buildings - conf 34.8% energy utilization - conf 28.4%	1	45	0.485141071367105	1	#E41A1C80
energy efficiency - conf 15.5% sustainable development - conf 19% retrofitting - conf 24.3%	2	32	0.369792046452276	1	#377EB880
life cycle - conf 53.8% environmental impact - conf 56.5% architectural design - conf 29.5%	3	60	0.393962759486854	1	#4DAF4A80

Figure 2: Clusters by document.

In this regard, overlapped three clusters in niche themes and clusters by documents are regarded as three main clusters in this study. These clusters are:

- Cluster 1 – life cycle
- Cluster 2 - energy efficiency
- Cluster 3- optimization / multioptimization

Subsequently, most related documents for each main cluster are detected through network data in coupling map clusters. Most related nine articles are selected to examine them in detail to find related retrofits, climate mitigation and adaptation measures and BIM use from climate change or at least a sustainable perspective. In the selection, documents except review papers are included to see the used methods and measures in the related studies. In the meantime, the publications in the most related and distinguished journals are generally regarded.

Analysis Results of the Studies

The bibliometric analysis of the studies shows that most of the total 505 documents are published after 2018. Therefore, this year can be considered a turning point for examining thematic evaluations (Figure 3).

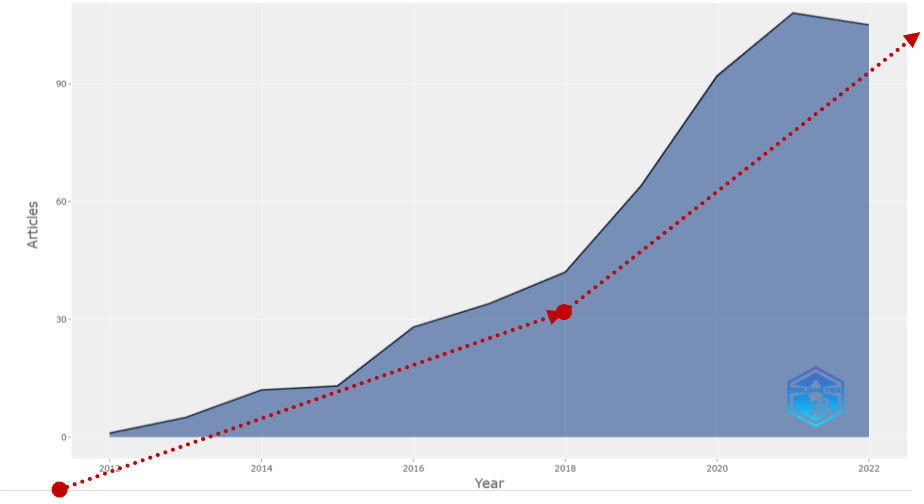

Figure 3: Annual scientific production.

Trend topics are examined regarding the turning point year – 2018. Buildings and optimization are highly examined after BIM and climate change topics in 2018. When energy efficiency was the following trend topic in 2020, sustainable development and decision-making were studied. In addition, it is notable that the life cycle is a trending topic in 2022, whereas carbon emissions after energy consumption are specifically conducted in 2022. Since this study is conducted before the mid of August, studies about carbon emissions might increase until the end of the year and be the top trend. In addition, it is vital that artificial intelligence is integrated into studies in 2022 (Figure 4).

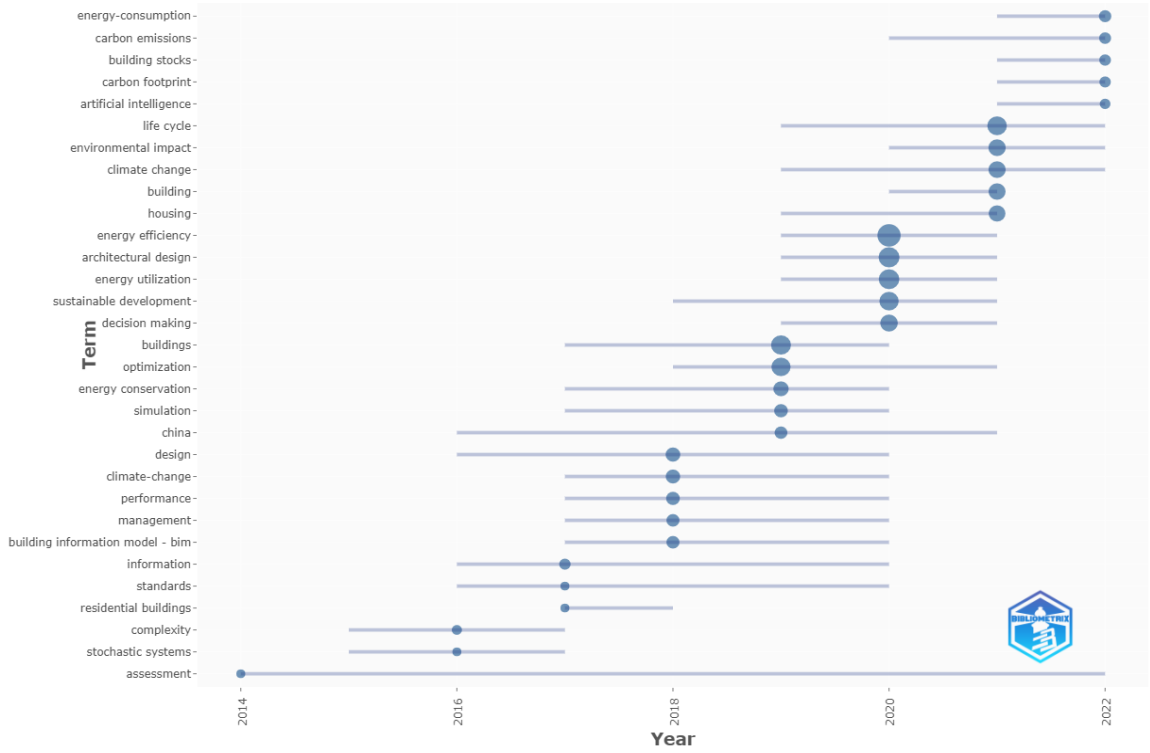

Figure 4: Trend topics.

Thematic evaluation after 2018 is examined regarding the author's keyword. It is clearly seen that multi-objective optimization beyond optimization dominates the field after LCA. On the other hand, climate change and sustainability are more discussed. Since the integration of BIM with LCA and sustainability has been highly discussed recently (Lim et al., 2021; Seghier et al., 2022), it seems logical that the BIM topic evolution to the LCA topic after 2018. It is notable that a literature review is more conducted after 2018. Since the integration of new terms such as climate change, optimization and artificial intelligence might be challenging for BIM, an increase in reviews seems logical. In order to provide more robust and valid integration frameworks and methods in the future, the backgrounds might be specifically examined (Figure 5).

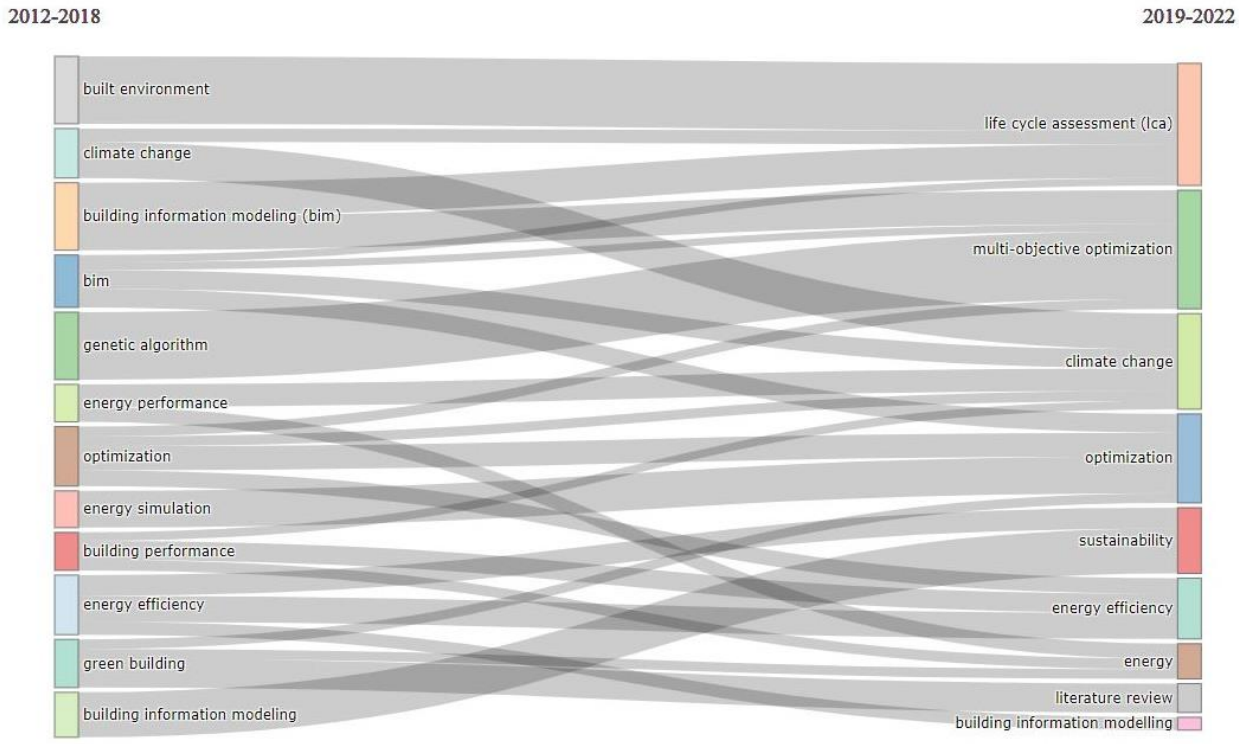

Figure 5: Thematic evolution.

Subsequently, the most related nine papers regarding their frequency in the network data are selected. Beyond the frequency, the publications in the most related sources are generally regarded. These articles are examined in detail to find out BIM use purpose in retrofits and their relations with climate change mitigation and adaptation measures. The information about articles and used tools with their purposes are tabularized. Residential and educational buildings worldwide are generally used in studies as case studies (Table 1). The BIM use in cluster 1 - life cycle is generally about integrating BIM with LCA (Motalebi et al., 2022; Rivera et al., 2021; Tushar et al., 2021). On the other hand, the studies in cluster 2 – energy efficiency integrates BIM with distinct energy tools such as "Autodesk Green Building Studio" (GBS) and "DesignBuilder." (He et al., 2019; Huskinson et al., 2021; Khahro et al., 2021) Moreover, BIM integration with ML methods and optimization tools such as Dynamo - Optimo is provided in the studies of cluster 3 – optimization (Chen et al., 2021; Chen et al., 2020; Ciacci et al., 2022).

Table 1. The information of the selected articles in detail.

Then, the type of retrofit measures is detected and their purposes as climate mitigation and/or adaptation are checked. The major retrofits are generally related to building envelopes and walls, roofs, windows and window-to-wall ratios (WWRs) are highly examined. Beyond that, renewable systems, appliances and rarely shadings are also integrated into the studies. The generation of future files is also investigated to see if there is a climate change perspective for future years or not. In this regard, it is detected that there is a need for climate change weather file integration into BIM (Table 2).

Table 2. Primary approaches and climate change measures in the studies.

Discussion and Conclusion

The BIM integration with sustainability is tried to advance; however, its integration with climate change, especially conducting future scenarios, is still rare. The LCA tools and energy tools are highly integrated with BIM. Beyond, the optimization tools and ML methods are combined with BIM to provide more comprehensive results or robust frameworks. Without integration of programming and ML methods, carbon emission and energy consumption calculation for optimization seem more challenging. Since different alternatives for each parameter are applied to scenarios for each possible result, various simulations are conducted after any change in a parameter. Hence, it turns into a time-consuming process that needs more effort. However, programming with correlation analysis and ML methods might be more effective in seeing results fast with limited data derived from simulations or real datasets. Therefore, cluster 3 – optimization studies provide comprehensive and less time-consuming approaches and predictions that require fewer input data. In addition, the studies generally include retrofits related to building envelopes such as walls, roofs, windows and window-to-wall ratios. Even if these measures are highly vital as climate change mitigation and adaptation measures, distinct measures should be integrated into retrofits, especially as cooling measures due to the increase in temperatures. Moreover, renewable systems and appliances are conducted in addition to the air leakages problem. However, passive measures should be more integrated since the increase in heat causes outages. Furthermore, only orientation as a building parameter from the general perspective is considered in the studies. Beyond the orientation, distinct general parameters related to buildings such as building form, compactness ratio and area and volume relationship (A/V) can be integrated into BIM-based

retrofits. Moreover, there is a need for climate change scenarios integration with BIM, including the mitigation adaptation retrofits, beyond its sustainability integration.

Exploring the Current Implementation Status of BIM, Lean Construction and Sustainability Concepts in Construction Industry

S. Hasan and Z. Isik
Yildiz Technical University, Department of Civil Engineering, İstanbul, Turkey
f9620005@std.yildiz.edu.tr, zeynep@yildiz.edu.tr

Abstract

With the AEC industry being one of the contributors to climate change, sustainability has become more than a trend in recent years. Building information model (BIM) offers engineers a genuine chance to help create a better world, So most researchers are focusing on building information modeling (BIM), sustainability(S), and lean (LC) fields. This paper aims to search for applying BIM, (S), and (LC) in construction and how those methods can affect the construction industry and enhance performance. The study explored the frameworks that integrate BIM with both LC and S. In especially, the study is expanded by highlighting the gaps. in the body of knowledge on BIM-LC and S in projects to help use lean techniques and BIM functions in sustainable public projects and megaprojects more effectively. It also summarizes what the researchers found of the critical success factors and constraints facing the achievement of the goal, which must be resolved, taking into account the research gaps. A systematic review methodology was employed. The result of a systematic review analysis helps in categorizing studies according to their content. The systematic review analysis showed that there are 11 journal papers only published between 2010 and 2022 (August). The current research also showed the scarcity of research on how it takes advantage of this inclusion in project performance as a real case study.

Keywords: *building information modelling (BIM), framework, lean construction, performance, sustainability*.

Introduction

Construction managers face constant challenges to solve problems within the construction industry, especially since it is the second-largest emitter of CO2 and accounts for one-third of all greenhouse gas (GHG) emissions (Al-Hamrani et al., 2021). In addition, the success of mega-engineering projects is affected by overcoming risks, including those associated with stakeholders (Aladağ & Işık, 2018). According to some experts, the main obstacle the construction sector faces is meeting its obligations and fulfilling its development role in the applications of the ideals of global sustainable development (Isik & Hasan, 2021). Sustainable development is defined as the provision of environmental, economic, and social services to all community members without damaging the durability of the built, natural, economic, and social systems at which the systems are dependent (WCED, 1987). As a sustainable construction, factors like energy efficiency, integrated design, indoor air quality, thermal

comfort, visual comfort, site suitability, acoustic comfort, spatial comfort, and building durability should be taken into account. (Nwokoro et al., 2011). The AEC sector regards as one of the least productive and technologically advanced sectors. So professionals must integrate manufacturing technologies with sustainability standards through all phases of the project's lifecycle like design and construction (Demirdöğen et al., 2021). BIM is a method based on intelligent 3D models that give professionals the tools they need to more effectively plan, design, build, and manage facilities. Additionally, enable more active decision-making (Azhar et al., 2012; Saieg et al., 2018). In contrast to tools or software, BIM is a process (Hardin et al., 2015, Eastman et al., 2011). If the construction processes have been integrated with BIM ideas, BIM technology would be effective in managing projects at any step of the project's lifetime. Implementing BIM technologies in project management might make the process better and unevenly cover all management facets. (Shaqour, 2022). Although the traditional engineering system focused on three-dimensional (3D) from various disciplines like architectural, structural, Mechanical and electrical power (MEP) engineers separately. BIM coordinates those models into one model and adds more "dimensions" of data to the information models, including time 4D, cost 5D, sustainability 6D, Operation & maintenance, Facility Management FM, 7D model (Porwal et al., 2013). After BIM was acknowledged the focus of studies on Lean Construction (LC) switched to an examination of the benefits of BIM usage in LC. LC consider one of the key techniques used to address issues in the AEC sector, where it improves project performance and reduces cost overruns (Demirdöğen et al., 2021). A theory known as "lean Construction" is based on the lean concepts Taiichi established in Toyota (Saieg et al., 2017). LC is a corporate approach whose main goal is to reduce waste (Saieg et al., 2017; Murata et al., 2018). The following five principles of lean theory can be summed up: (value, value stream, flow, pull, and perfection) (Womack et al., 2007). There are studies examining the twinning between BIM-LC, BIM-S, and LC-S in the area of performance enhancement in the design and construction sector, for example, according to Arayici et al. (2011), the application of BIM skills, including constructability analysis, energy, environmental analysis, and structural analysis, can improve project outcomes, particularly for projects striving to be lean and environmentally friendly. the study discovered parallels between green and LC performance metrics. However, according to Bostancı et al. (2022), there are extremely few studies that incorporate all three of these concepts together, Where the number of the results according to three concepts until May 2020 was 10 articles, almost started after 2017 (Mellado et al., 2020; Bostancı et al., 2022). By 2019, there was less interest in examining the relationship between BIM, LC, and S (Bostancı et al., 2022). LC implementation with BIM in the design process greatly improves project efficiency. Using BIM as a tool will assist in implementing LC principles by increasing owner value and eliminating waste (Eldeep et al., 2022). 56 connections were provided by (Sacks et al., 2010) as hypotheses of how lean and BIM interacted, taking into account the genuine difficulties that businesses have while implementing lean and BIM. Both the usage of BIM and LC have brought about significant developments that have led people to consider the sustainability of the world's future (Saieg et al., 2018). Additionally, BIM supports LC technology, where the majority of lean concepts utilized in the construction sector have components in common with BIM like visual analysis and data flows among stakeholders and the reduction of mistakes through guiding the management decision-making process (Saieg et al., 2018). Engineering-based information sharing issues are one of the main factors influencing diminishing construction project performance due to the creation of several types of conflicts (Tommelein et al., 2012). Making decisions during design and construction can result in the generation of a variety of waste (Sacks et al., 2010). As a result, sustainability is directly tied to BIM and LC. According to Lekan et al. (2018), combining LC-BIM ideas will produce a powerful framework that might help nurture characteristics that

support sustainable growth (Lekan et al., 2018). There are studies examining the twinning between BIM-LC, BIM-S, and LC-S in the area of performance enhancement in the design and construction sector. However, according to Bostancı et al. (2022), there are extremely few studies that incorporate all three of these concepts together, Where the number of the results according to three concepts until May 2020 was 10 articles, almost started after 2017 (Mellado et al., 2020; Bostancı et al., 2022). By 2019, there was less interest in examining the integration BIM, LC, and S (Bostancı et al., 2022). The study aims to discover the research gaps by knowing the current level of research on BIM, LC, and S simultaneously. Also, the study reveals if there is a framework that achieves an optimal synergy between BIM, LC, and S by full integration and if can it be applied to mega-projects to obtain maximum efficiency in certain aspects. The political objectives of diverse groups and local governments frequently have an impact on megaprojects (Jia et al., 2011). We hypothesize that the use of BIM, LC, and S must be combined, as it is in the Integrated Project Delivery (IPD) method, to fully realize the potential for the improvement of mega-projects. The following questions provide the main framework for the research:

Q1: What is the current level of research on BIM function with LC and S?
Q2: Is there a framework that integrates the three concepts in public or megaproject, can the framework be deduced through a literature review?
Q3: What is the current knowledge gap in academic research and/or practitioner concerns with the integration of lean construction; BIM technology and sustainability?

The following additional sub-questions were provided to guide the investigative process: What are crucial factors and challenges that will ensure the success of this integration in published research face? So, the research is not only seeking to show the current situation of the construction industry but also seeks the gaps to continue to be studied in future studies. To address the research issues that were presented. The article is divided into sections, and Figure 1 shows the overall review workflow. The findings of this study will further the current body of knowledge in the disciplines of BIM, LC, and S integration research. It reveals the importance and benefits of applying integration in projects and the tools to be used to reach integration in mega projects. It also reveals the main obstacles and challenges that stand on The road to the final adoption of BIM, LC, and S models in projects with a focus on critical success factors that lead to improved synergy and development of BIM, LC, and S goals. In addition, the study reveals the gaps that must be explored in the future to inform key stakeholders in the construction industry of possible solutions.

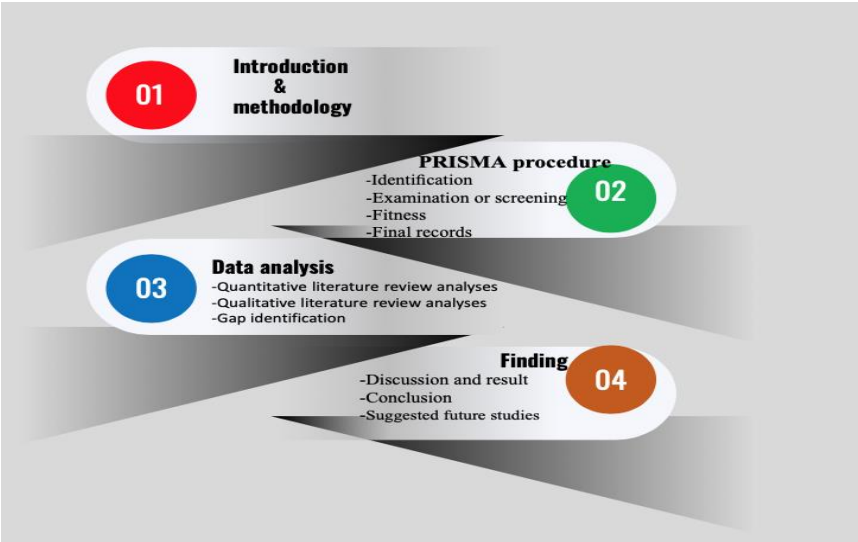

Figure 1: The overall review workflow.

Methodology

Systematic reviews serve as the reference standard for research evidence through assist in the creation of practice guidelines and providing information for decision-making (Moher et al., 2015). The study adopted a quantitative and qualitative research strategy. The systematic literature review (SLR) technique is explained in detail. The search results are discussed then the review of LC-BIM-S connections is provided. The research also proposes a methodology for developing a framework that demonstrates how to achieve the integration of BIM with LC to achieve megaproject sustainability. The study then identifies knowledge gaps to direct academics future research. The study's methodology guarantees an accurate description of the analytical strategy based on the protocols for systematic reviews and meta-analyses (PRISMA-P), following the procedure presented by Moher et al. and Okoli as shown (Moher et al., 2015; Okoli, 2015).

PRISMA Procedure

There are procedures used to gather, choose, and filter pertinent materials namely: Identification, Examination or screening, fitness or eligibility, and final records (Moher et al., 2015; Okoli, 2015; Qiao et al., 2021). It is presented in the diagram in Figure 2.

• Scoping :
The initial phase is scoping, during which research questions and queries are created. An extensive literature search was conducted based on: title, abstract, and keyword. The research was done by databases such as Clarivate analytics-Web of Science database to perform the scientometric analysis addressing BIM, lean, and sustainability. Journal papers in the following databases were screened during the identification phase: Elsevier (www.sciencedirect.com);Emerald(www.emeraldinsigh.com);Springer(https://www.springer.com/gp/);(https://link.springer.com);Taylor&Francis(www.taylorandfrancis.com);Wiley(https://onlinelibrary.wiley.com/action/showPublications ; ASCEE library (https://ascelibrary.org/); MIDPI open access journal (https://www.mdpi.com/) and Google Scholar database.
These databases were chosen because of their effective, simple, advanced search capabilities and their trustworthy and thorough academic content in the subject matter of this study. Mendeley, a reference manager that enables annotations, document-level searching, and simple duplication elimination, was utilized to consolidate, organize, and regulate the data acquired. Since the most relevant and trustworthy sources for literature reviews are peer-reviewed journals and conference proceedings, they were taken into consideration. (Saunders et al., 2012). Using inclusion and exclusion criteria, SLRs' fundamental properties are illustrated (Qiao et al., 2021). Thus, the requirements for inclusion in these SLRs are the Articles about BIM integration about sustainability and lean that were published in journals and conference proceedings articles were included over the previous 12 years (2010 - August 2022) since early studies were suggested using information technology in building. The study includes English-language articles and it was restricted to the following construction-related disciplines: decision sciences, engineering, business management, accounting, social sciences, economics, and finance.
• Identification:

According to Bostancı et al. (2022), the most relevant keywords in the integration of BIM with LC and S studies are (TITLE-ABC-KEY) - (“building information modeling" OR “building information modeling” OR "BIM") AND ("lean" OR “lean construction” OR “lean thinking”) AND ("sustainability" OR "sustainable" OR "green" OR "environmental"). The most popular keywords are “building information modeling, BIM capabilities, lean construction, “BIM” then comes “sustainability”, according to only Quantitative literature review analyses done by (Bostancı et al., 2022). After additional filtering based on the inclusion criteria, in total 12278 articles were found then eliminated the duplicates. After a total of 11009 items were removed, the remaining 1269 articles got further screening.

• Screening

Through title and abstract evaluations in this stage, 1269 articles among the databases were published between August 2010 and August 2022. Additionally, searches without specific keywords in the abstract were disregarded. 1192 items were left out.

• Fitness

The publications were examined to confirm their direct relation to integration between BIM, LC, and S with the effect of this integration on improving performance in the construction industry. According to the PRISMA-P standards, briefly reading an article's title, abstract, and entire text constitutes screening which may also be evaluated if there is a suspicion of ambiguity. So, some articles that focused on each concept separately were segregated. The literature review only covered 11 articles. Then, related articles were stored on a platform for managing references (Mendeley Desktop version).

• Inclusion or final records

The 11 selected research articles were subjected to a more thorough review and inspection. The research approach flowchart of (PRISMA) is shown in Figure 2, the results of the final approach show a large number of studies that were excluded from the analysis because they dealt with merging two concepts or of them. 11 papers were analyzed later to find the gaps as shown in Table1 which shows the phases of a literature review.

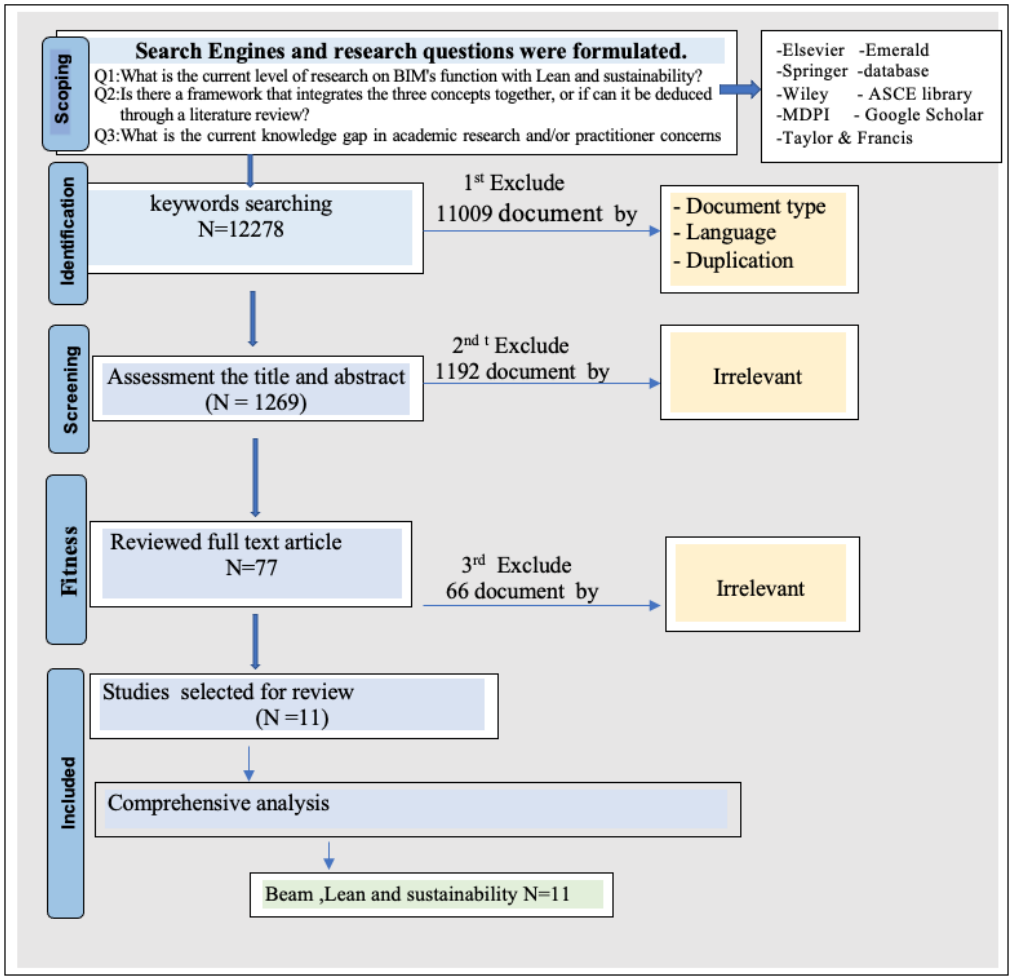

Figure 2: The research approach flowchart (PRISMA).

Table1: Phases of a literature review

Databases	Step review 1	1st Exclude	Step review 2	2nd Exclude	Step review 3	3rd Exclude	Final review
• Elsevier	548	365	183	139	47	44	3
• Emerald	448	424	24	23	1	0	1
• Springer	42	35	7	3	4	3	1
• Taylor & Francis	91	73	18	18	0	-	0

• Google Scholar database	10600	9604	996	985	11	7	4
Total	12278	11009	1269	1192	77	66	11

Data Analysis

To answer question 1 the study combined quantitative and qualitative research methods. Quantitative analysis is the process of combining quantitative data from numerous relevant studies in order to provide a thorough synthesis of empirical knowledge about a given topic (Bronson & Davis, 2011; Andjar-Montoya et al., 2018; Arayici et al., 2018). This technique has been applied in several studies that combine two ideas (BIM-L) or (BIM-S) (Saieg et al., 2018; Bryman,2017; Bryman, 2017). With the use of the research technique of qualitative analysis, data may be categorized to reveal trends (Reale, 2014).

Quantitative Analyses

The analysis concludes the largest number of publications was in 2018 as shown in Figure 3. It's interesting to note that 64% of the research on combining BIM with Lean and sustainability techniques has only recently been published (in the past five years), proving that this field of study is still in its infancy.

Figure 3: The distribution of articles by year.

Database of ScienceDirect and Google Scholar was the most published database for this topic, while publication was absent in each of "Taylor & Francis" and "Wiley" as shown in Figure 4. Through Table 2 and Figure 5. it could see that approximately 60% of articles were published in international journals with high cite score and the rest within scientific conferences. The highest-published journal in terms of cite Score is the "Journal of Cleaner Production" with a cite score of 15.8, then "Sustainable Cities and Society" and "Engineering Construction and Architectural Management" with a cite score of 14.4 and 5.7, 5.2 respectively. Finally, the Journal of "Sustainability" and Journal of "Theoretical and Applied Information Technology" with citing scores of 5 and 1.3 respectively. Table 3 shows Selected article information like authors, article title, citation, and keywords.

Qualitative Literature Review Analyses

The papers under analysis, which numbered 11 manuscripts, were comprehensively evaluated, including the following: Year; finding; limitation; gaps; research methods; suggested framework (FW); validation of suggested framework (VFW); Industry type; performance assets (PA) and whether the investigation identifies any potential integration or adoption restrictions or challenges. To respond to the following research issues, this review study critically analyzes the existing literature to answer the research questions. Table 4 shows the summary of selected articles.

Table 4. Summary of selected articles.

Ref. / year	Finding	Limitation & Gaps	Research methods.	F. W	V.F W.	Industr y type	PA.
Mellado et al (2020)	The research suggested a framework for integrating the three concepts, as it determined that the important factor for the interaction of BIM and Len is waste reduction, while BIM is positioned towards sustainability by promoting environmental aspects through waste reduction. it identified CSFs and showed that stakeholder integration is the most crucial factor.	It was advised to use it for a small-company strategy. - Lacks framework validation and there are yet no fully developed frameworks that might be compared. - CSF validation is still necessary. - There is no published study on how project performance might improve with integration but performance has been individually studied. - The findings indicated a lack of social integration.	Qualitative analysis 2001-2018	Yes	No.	Small sized construc tion project	No
Saieg et al.(2018)	The integration matrix for BIM, lean, and green was exhibited in the study. The advantages and disadvantages of BIM were merged, Study suggests doing a comprehensive evaluation of the literature pertaining to studies on synergies, BIM interactions, lean, and sustainability.	- On the selected databases, there is a restriction and a time limit. The range is 2006–2015. - It focused on peer-reviewed articles and conference proceedings in English, ignoring books or other - FW. has to be improved in order to seek real-world evidence and gradually verify it. -The paucity of studies that examine all three topics.	systematic reviews of the literature. A conceptual synthesis and quantitative results	No.	-	General	No
Ahuja et al. (2017)	The implementation of four BIM capabilities-MEP system modeling, energy and environmental analysis, constructability analysis, and structural analysis-can improve project outcomes, to be lean and green, according to a study that explored the causal relationships between different BIM capabilities. The research advises AEC businesses to explore implementing BIM on projects.	- A limited sample of architectural firms - LC and green's synergies and combined advantages still need to be better appreciated in practice. Few studies have examined the processes that enable simultaneous green and lean project improvements.	Qualitative comparative analysis by using crisp set qualitative comparative analysis (csQCA) method	No.	-	General sample from architect ural firms	Yes
Ahuja,et al. (2018)	The article has created a framework for organizational skills based on BIM that will enable the implementation of lean and green advantages. A road map for using BIM to provide a lean and green effect on building projects is presented.	It was found that in order to achieve the desired project outcomes, a company must adopt a fundamental BIM adoption culture throughout its project teams and the business as a whole.	Mixed-method by Semi-structured interviews, focus groups, and qualitative comparative analyses.	Yes	Yes	General construc tion	No
Bostancı et al.(2022)	The use of BIM and LC principles has increased the interest in this bilateral relationship since 2010. The analyses that are done show that a study's focus is on the chosen keywords. It aims to create a dynamic platform for further investigations.	-Using the Scopus database between 2011 and 2020 -Didn't demonstrate quantified benefits. There are extremely few studies that include all three of these terms. BIM, Lean, sustainability	The association between the phrases BIM, Lean, and Sustainability was examined using bibliometric analysis.	No.	-	General construc tion	No
Sepasgozar et al.(2020)	The study presented the most recent development tools BIM including LC principles. In order to use LC approaches more effectively. Results showed a significant synergy between LC & BIM in control interactions and a decrease in variability. The study provided a FW. that, together with the analysis, may be utilized as an illustration of the linkages between IT and production systems.	The articles relevant were from the Scopus database. There is a gap regarding the synergy of LC and the modeling of digital information and sensor-based technologies in particular construction domains, such as sustainable infrastructure projects, megaprojects, and stakeholders' involvement. The FW. needs to test empirical research. The paucity of research that examination of synergies.	A systematic review method 2000-2020	Yes	No.	General construc tion	No
Enache et al.(2010)	This study integrated green building practices, LC manufacturing techniques, and BIM to create an early conceptual model for the construction of healthcare facilities. The concept was developed with the early phases of planning and design for healthcare facilities in mind.	The concept was developed for healthcare facilities The use of only a few concepts that are appropriate for healthcare facilities, without a clear emphasis on the project's whole life cycle. Developed integrated model validation support is needed.	Multiple case study technique. Utilized were three case studies of healthcare facilities in the design stages.	Yes	Yes	healthca re projects	No
Koskela et al. (2010)	He examined the links between S, LC, and BIM. It was suggested that it is opportune to discuss action options of BIM, LC, and S coverage of requirements by the biggest construction client in each state. Mainly emphasized how methodologies might be used collaboratively; But other issues, for this integration, have not yet been resolved.	Their research is limited to the use of these concepts in collaborative settings; it has not yet addressed issues like a comprehensive framework for integration. FW. for integration, have not yet been addressed.	Examines the interactions between three present drivers.	No	-	General construc tion	No
Rahman, et. Al.(2013)	The research developed a proposed conceptual framework, to reveal the maximum "sustainable value. It studied a conceptually-level integrated approach that links BIM and LC to promote sustainable principles across a project's whole life cycle in the AEC sector.	It is essential to examine the various facets of this integrated strategy through collaboration between academia and industry.	Review to develop framework	Yes	No.	General construc tion	No
LEKAN et al. (2018)	highlighted the obstacles to LC, BIM, and S with The crucial components of Lean-BIM integration for sustainable construction. The research presented the benefits of applying BIM and LC in the various construction stages, which were obtained through a field survey of two hospital projects. The research also presented the sequence of these benefits in terms of importance, which was also obtained from the field questionnaire. The index of relative agreement with BIM principles was determined	The framework has to be verified by applying to a project's life cycle process and carrying it through each stage.	Data from the sample population was gathered using questionnaires to document the opinion of the workforce about the viability of integrating lean construction and BIM for sustainable building on a Likert scale of 1 to 5.	Yes	yes	Hospital s	No
Ahuja, et al.(2014)	An assessment performance framework for BIM was created as a prototype using the GRIHA evaluation process. The findings suggest that BIM-enabled projects may more successfully integrate lean and green practices and provide value. By citing 8 lean principles and 15 specific Green Rating Integrated Habitat Assessment (GRIHA) criteria.	The proposed framework addresses only the environmental linkages to sustainability. The proposed framework needs to be refined by additional research	It includes conceptualizing a BIM-based framework, feedback from business leaders, revising the framework in light of the feedback, and testing the framework on 3 case studies.	Yes	Yes.	General construc tion	Yes

Selected Studies

The beginning of the emergence of a study of the framework that combines the three concepts of BIM, LC, and S was in the year 2010 when the study demonstrated the possibility of integrating three ideas and introducing a BIM-LC-S strategy in the AEC sector. Enache et al. (2010) illustrated the relation using a conceptual construction delivery model. During the programming and preliminary design phases of healthcare facilities, Figure 6 shows a representation of the factors investigated in this study, along with an early conceptual model.

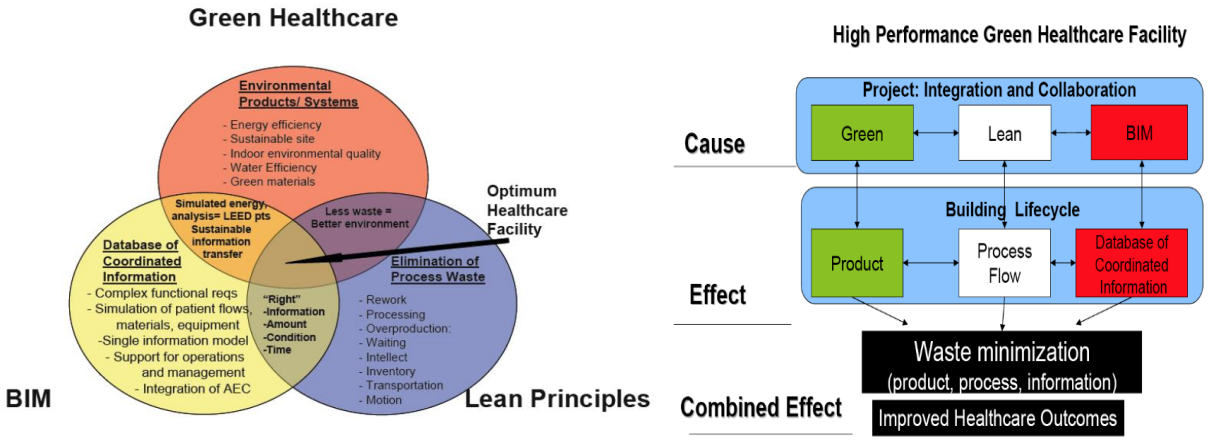

Figure 6: Early adoption of BIM, LC, and green initiatives (Enache et al., 2010).

Koskela et al. (2010) explored how BIM, LC, and S are related. Their study mainly emphasizes how methodologies might be used collaboratively; But other issues, such as a fundamental structure for this integration, have not yet been resolved.

According to Rahman, et al. (2013), BIM and LC that complement sustainable principles are the main goals of this integration. these construction concepts are illustrated through decreased material waste, computer-controlled production, and reduced variability. The supporting connection is represented by the color coding as in Figure 7 & Figure 8.

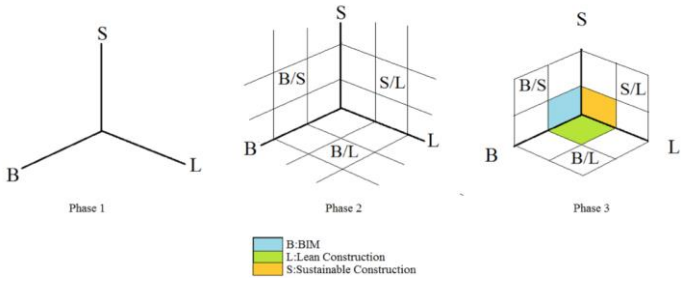

Figure 7: Integrated BIM, LC and, S Framework (Rahman et al., 2013).

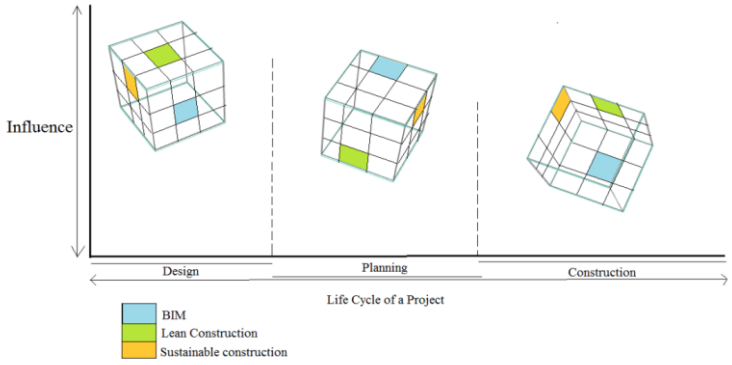

Figure 8: Implementing BIM, LC, and S at various project phases (Rahman et al., 2013).

Ahuja, et al. (2014) created a theoretical assessment framework for BIM as a prototype using Green Rating Integrated Habitat Assessment (GRIHA), an environmental assessment schemes system for directing and measuring performance. They suggested that BIM can integrate LC

and green practices more successfully and provide value by identifying 8 LC principles and 15 chosen (GRIHA) criteria. Study interlinkages LC and green driven by BIM were captured as shown in Figure 9.

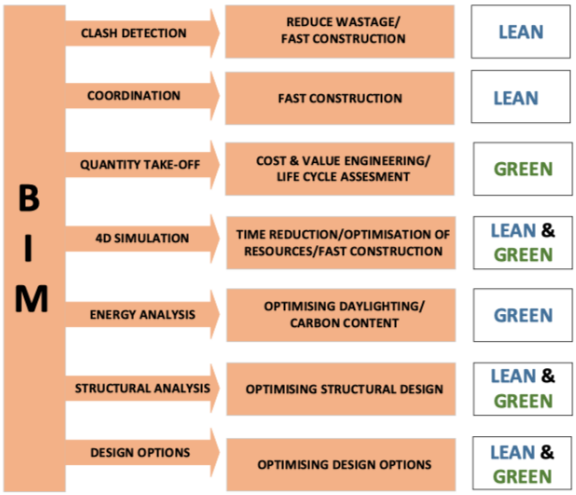

Figure 9: Different BIM components that contribute to lean and green (Ahuja et al., 2014).

In addition, Ahuja et al. (2017) analyzed 16 projects in architectural firms. Three BIM capability sets that result in lean and green outcomes were discovered through analysis. According to their research, "independent BIM capabilities of Energy and environment analysis (E&EA), structural analysis (SA), MEP system modeling (MEP), and constructability analysis (CA)" are the four main BIM capabilities that a design organization has to focus on. They found the effect of LC and BIM implementation on economic, social, and environmental performance. Further, Ahuja, et al. (2018) created a framework for organizational capabilities based on the previous BIM framework.

Saieg et al. (2018) considered three ideas (S/green, lean, and BIM). A systematic review was utilized. The study developed BIM, LC, and Green integration matrix depending on the perception by Sacks et al. (2010) that identified BIM function and LC principles as shown in Table (4-5). According to Figure 10, cells with numbers reflect positive interactions (green), while cells with parentheses and orange reflect negative interactions. LEKAN et al. (2018) highlighted the obstacles to LC, BIM, and S with The crucial components of Lean-BIM integration for sustainable construction. The research presented the benefits of applying BIM and LC in the various construction stages, which were obtained through a field survey of two hospital projects they were: "Improves safety & environmental issues, improves time, cost, and quality, helps to identify constraints within the construction, focuses on value than cost; optimizes resource delivery schedules; aids reduction in on-site transportation, results in standardization of work practices". The research also presented the sequence of these benefits in terms of importance, which was also obtained from the field questionnaire. In addition, the index of relative agreement with BIM principles was determined through a questionnaire.

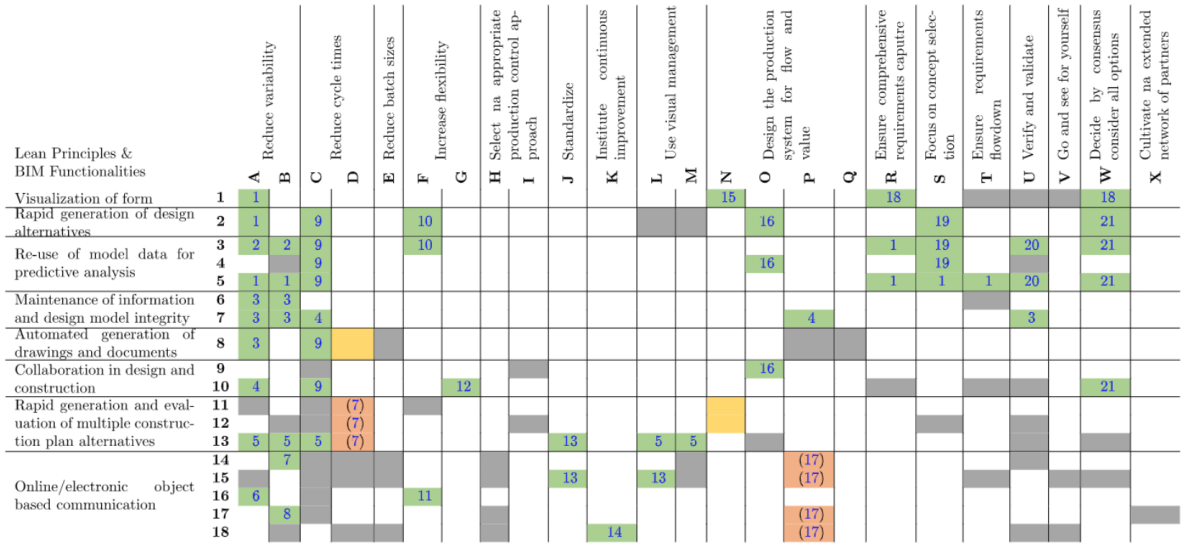

Figure 10: BIM, lean and green integration matrix (Saieg et al.,2018).

Mellado et al. (2020) recommended a framework for connecting the three ideas since it found that waste reduction is crucial for the integration between BIM and LC towards sustainability by encouraging environmental considerations. It identified crucial success elements. Stakeholder integration is one of the most crucial factors to take into account. The findings demonstrated a deficiency in social integration, one of the three elements of sustainability. Figure 11 shows the theoretical framework and its components.

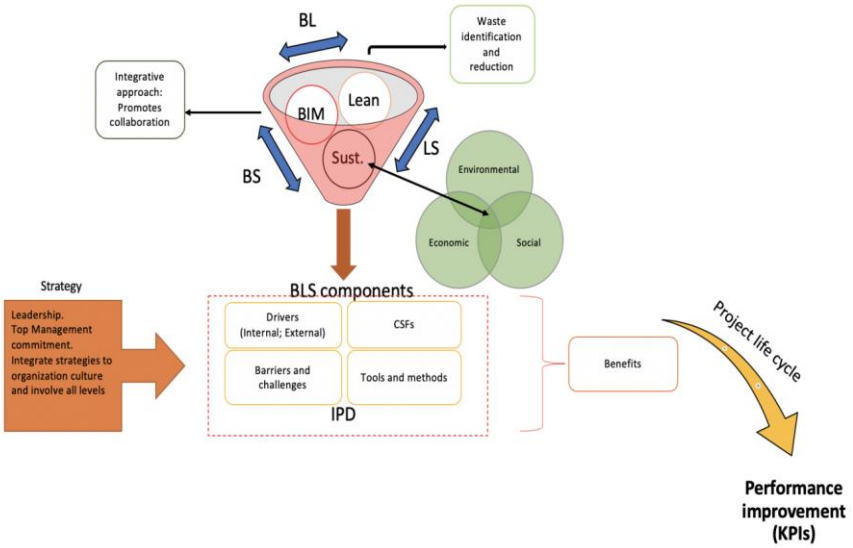

Figure 11: Theoretical framework and its components (Mellado & Lou, 2020).

Sepasgozar et al. (2020) presented the most recent development of digital tools (BIM) including LC principles, like:

-Structural Building Information Modeling (S-BIM) with Set-based Design (SBD), where SBD is a lean approach which increases efficiency throughout all stages of a project by sharing information and working with relevant sectors to eliminate waste components.

-Using KanBIM idea that is "a lean construction production management system that uses BIM." This system offers site-specific interfaces to address the resource management constraints of the construction project. The study concludes that there is significant synergy between LC-BIM in design-related and construction-related activities. That enables time and overall cost optimization while raising project quality reducing waste and non-value-added activities, optimizing processes, enhancing oversight, and enabling digitization so that the project can be seen. Finally, in 2022 a bibliometric study was conducted to look at how the phrases BIM, LC, and S relate to one another, a study's focus is on the chosen keywords, and aims to create a dynamic platform for further investigations. They conclude that there are extremely few studies that include all three of these terms. BIM, Lean, sustainability. (Bostancı et al., 2022).

Results and Discussion

By reviewing selected articles, the first proposed framework was for a big project for the healthcare facilities sector (hospitals) in America by Enache et al. (2010). He outlines the integration of BIM, LC, and S through a conceptual build delivery strategy during the early programming and design stages through a case study of three projects. For the same sector, For the same sector, CSFs for sustainable construction in hospitals were highlighted through a field survey and case study of two hospitals by Lekan et al. (2018), where the most important CSFs were: Regular training in Management commitment, Great work environment, collaboration between partners, and communication. Also, the main obstacles were: Fragmented nature of the industry, the extended implementation duration, and the Lack of adequate skills. As a result, the authors believe that it is possible to apply the proposed framework while overcoming obstacles and tracking the CSFs for the integration of LC-BIM for sustainable construction in hospitals projects, which were presented in these two articles,

with the possibility of expanding the examination scope of the proposed model further and a case study of more projects according to the geographical area because the conditions of the place govern the extent of success and the applicability of this framework. On the other side, another developed framework for linking the three ideas in small and middle organizations was found. This article mentions that waste minimization is critical for the incorporation of BIM and LC towards sustainability by encouraging environmental considerations and stakeholder integration is one of the most crucial factors to take into account (Melado et al., 2020). However, this framework needs to be implemented in practice to prove it. Most authors examined how the integration of BIM, LC, and S be in the project. This enables eliminating waste and non-value-added tasks, enhancing project quality, strengthening supervision, and enabling digitalization so that the project can be observed while also decreasing overall time and cost (Sepasgozar et al., 2020). But, the authors believe that the Green integration matrix developed by Saieg et al. (2018) is more mature to demonstrate the integration aspects (S/green, lean, and BIM) because it is based in detail on BIM function and LC principles defined by Sacks et al. in 2010. In addition, the advantages and disadvantages of BIM were merged into the matrix. The review introduced also a simple framework for integration that showed that sustainability is the main goal of this integration, mainly emphasizing how methodologies might be used collaboratively; other issues, such as a fundamental structure for this integration, have not yet been resolved (Rahman et al., 2013; Koskela et al., 2010).

According to several sequential studies conducted by Ahuja et al. (2014, 2017, 2018), starting with the identification of 8 LC principles and 15 criteria for the selected Scheme Environmental Assessment (GRIHA) scheme, then he analyzed 16 projects in architecture firms. Three groups of BIM capabilities that result in lean and green outcomes were identified through analysis. They found that a design organization should prioritize independent BIM capabilities for energy and environmental analysis (E&EA), structural analysis (SA), mechanical, electrical, and plumbing systems Modeling (MEP), and construction analysis (CA). They found the impact of LC and BIM implementation on economic, social, and environmental performance. Then in 2018, he created a framework for organizational capabilities based on the previous BIM framework. The author believes that these studies are very important because they took into account the capabilities of BIM that lead to simple and green results. Three paths that lead to resilience and sustainability in projects were identified as follows:
Path1: BIM-based MEP system modelling with energy and environment analysis (E&EA) at the design stage and performing structural analysis (SA).
Path2: BIM-(MEP) with use of energy and environment analysis (E&EA) at the design stage and absence of constructability analysis (ca).
Path3: BIM-(MEP) with absence of use of energy and environment analysis (e&ea) and having a clear understanding of constructability analysis (CA).

Figure 11 shows a suggested diagram prepared by the authors depending on Ahuja et al. (2017). We suggest by tracing the same paths on megaprojects, it is possible to evaluate the optimal path that can be taken according to the type of project, to reach benefit. The search has produced a set of the gap that can be summarized in the Table 5. Which opens the path towards completing their search in them.

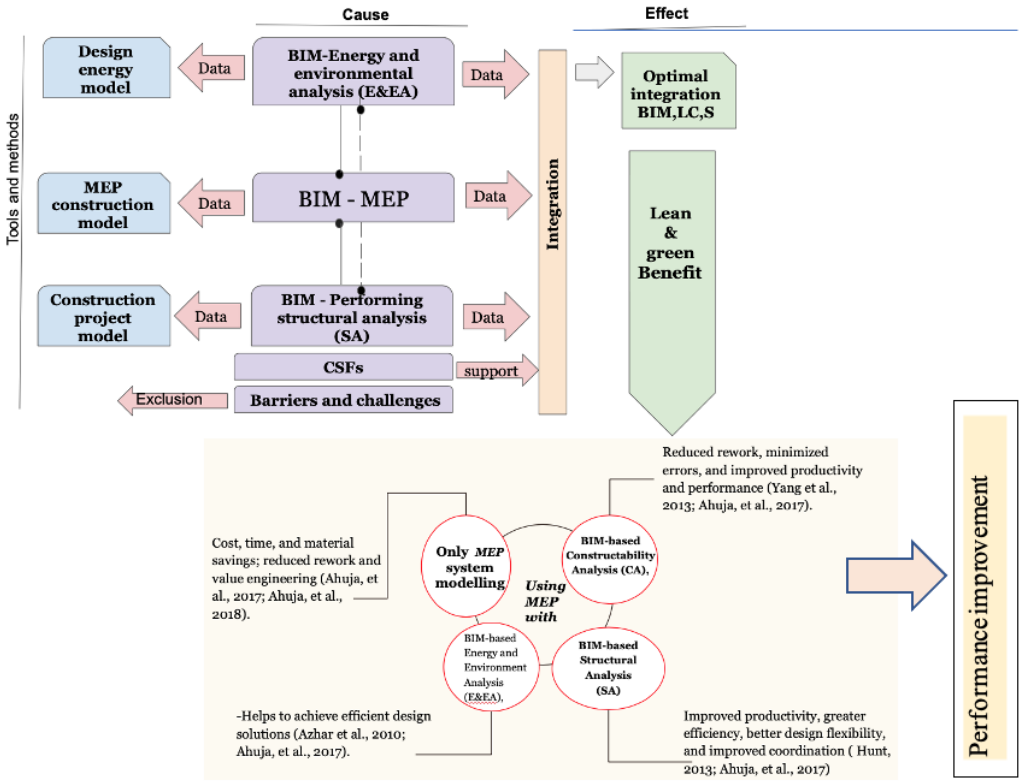

Figure 11: Graphical representation of proposed model.

Table 5. The gaps in selected articles.

Ref.	Gaps
(Mellado et al., 2020; Bostancı et al., 2022; Koskela et al., 2010)	There are extremely few studies that include all three of these terms. BIM, LC, and S
(Mellado et al., 2020)	CSF validation is still necessary.
(Mellado et al., 2020; Ahuja et al., 2017; Rahman et al., 2013)	There is a dearth of studies on how integration would improve project performance, and each performance factor has been examined in each concept separately.
(Mellado et al., 2020; Saieg et al., 2018; Ahuja et al., 2014)	There is no enough models and thorough frameworks to be compared with suggested BLS framework.
(Mellado et al., 2020)	Results indicated that social integration, a component of sustainability, was lacking.
(Saieg et al., 2018; Arayici et al., 2017; Sepasgozar et al., 2020; Enache et al., 2010)	Seek and gradually verify real-world evidence for the purpose of improving the framework and exploring it in depth.
(Sepasgozar et al., 2020; Mellado et al., 2020)	In some areas of construction, such as sustainable infrastructure projects, megaprojects, and SMEs' capabilities, there is a glaring knowledge gap regarding the synergistic interactions of LC principles and the modelling.
(Lekan et al., 2018)	Most studies were without a clear emphasis on the project's whole life cycle.

Performing

The similarities between LC and green outcomes as performance measures when applying BIM on they were: reduced rework, lower costs, reduced waste, a safe workplace, value engineering, quicker construction, shorter lead times, increased trust, resource optimization, and material conservation (Ahuja et al., 2017). According to previous studies, the use of BIM in conjunction with LC and green efforts on construction projects enhanced project results (Yang et al., 2013; Azhar et al., 2010; Ahuja et al., 2017; Ahuja et al., 2018; Hunt, 2013) as shown in Figure 11.

Barriers & (CSFs)

A crucial component of the framework is defining key success factors (CSFs) (Lou & Alshawi, 2009). Several studies have looked into the obstacles, difficulties, (CSFs) of BIM adopted and their effects on the execution of construction projects. (Olawumi & Chan, 2019; Dave et al., 2013; Ghaffarianhoseini et al., 2017; Chan, 2014; Azhar et al., 2012; Sacks et al., 2010; Chan et al., 2019; Sacks et al., 2018). But Evans et al. (2021) investigated how BIM and LC worked together in construction mega projects in the MENA region. Additionally, it looked into difficulties, crucial success factors (CSFs), and crucial failure factors, but the researchers did not consider the interaction of sustainability with BIM and LC in their study of megaprojects. Through a review of the research covered in this study, the critical success factors and barriers to achieving integration in BIM, LC, and S have been identified as follows:

a. Critical success factor

Management commitment, a beneficial work environment, coordination, teamwork, training, early involvement, dedication, qualified people, and culture of praise, customer service, and integration, system and procedure change management, routine workforce training, proper planning, team integration, integration of the whole supply chain, promotion of a culture of continuous improvement, benchmarking of suppliers, coordination and communication between stakeholders,, the using MEP system modeling, energy, and environmental analysis, constructability analysis, and structural analysis (Lekan et al., 2018; Mellado & Lou, 2020; Azhar et al., 2008).

b. Barriers

Lacking managerial commitment, a long implementation duration, improper training, insufficient knowledge and skills, a failure to use core strategies, standards and methodology gaps, the industry's fragmented nature, cultural obstacles, a lack of application of concepts and understanding, objection to change, government inefficiency and instability, a protracted supply chain, a lack of confidence, and other elements (Lekan et al., 2018; Mellado & Lou, 2020; Sepasgozar et al., 2020). Organizations, nations, and regions differ in their willingness to use BIM technology (Azhar et al., 2012). In addition, researchers did not consider the interaction of BIM with LC and S in their study of megaprojects and obstacles that prevent their implementation. Therefore, away from previous studies, Evans et al. (2021) investigated how BIM and LC collaborated on Mega projects, but without sustainability content. Further, they looked at significant obstacles that important construction players had while attempting to integrate BIM-LC into megaprojects in the MENA region only. They only looked at CSFs that enhance BIM and LC integration for mega projects in the MENA area (Evans et al., 2020a,b).

Conclusion

There are frameworks mentioned in the previous studies to study the possibility of applying the BIM, LC, and S concepts in the project. It can be concluded we need to study the functions of BIM that serve the principles of LC and achieve sustainability in accordance with the objectives (environmentally -economically-socially). It can be done by following the success factors and overcoming obstacles, thus achieving this mission.

Mega projects are big, complicated projects, that have a lot of uncertainty which can result in weak performance (Flyvbjerg et al., 2017; Bruzelius et al., 2002; Priemus et al. 2008; Liu et al., 2014). Through chosen prior studies, the foundational knowledge and structure for the integration of BIM, L, and S were discussed. However, no prior study has done a thorough assessment of how BIM, L, and S are applied in megaprojects. Therefore, including the usage of BIM, L, and S in the management of megaprojects call for a pretty robust methodology.

The PRISMA approach was used. Scholarly publications were chosen and subjected to a qualitative study. It is discovered that after 2010 the documentation of the BIM, LC, and S interrelation began, while there are several papers linked to every two concepts. There are only 11 publications specifically addressing how LC, BIM, and S practices interact, while nine pieces had more than 366 citations. The results revealed the existence of frameworks linking the three concepts, but the majority of the frameworks that were seen either explain some general concepts only or are formulated according to the circumstances of the study area or it is only a theoretical study that needs proof of the validity in a realistic study. In addition, only two researchers identified BIM functions and capabilities that support LC concepts toward sustainable buildings by identifying three possible paths through collecting data from realistic projects. The results suggested one framework that used some paths to integrate BIM, LC, and S on megaprojects then we can evaluate each path to find the most beneficial one. The search has produced a set of gaps that are summarized in table 5 which opens the path toward completing the investigation in them. Moreover, there is a big and obvious gap in the availability of an integrated framework for sustainable infrastructure projects. That means the majority of organizations are still at the beginning of the learning curve in this regard. The results also indicated that social integration, an element of sustainability, was missing.

Future Study

In order to fill these gaps, we propose these research subjects and areas.

1- Identification of the CSFs for the integration of BIM, L, and S of infrastructure projects.
2- Studying the obstacles to achieving the integration of BIM, L, and S of infrastructure projects.
3- Applying the proposed path to infrastructure projects, finding the optimal path, and making the necessary corrections to update the framework.

The study's overall conclusion is regarded as providing both researchers and practitioners with important advice to successfully plan and execute BIM, LC, and S. It is important to identify the targeted interest to accumulate experience and develop gradually to take more advantageous linkages between them.

Abstract

The seek for global solutions and applications is ongoing as the relevance of the struggle against the climate problem grows by the day. One of the most crucial strategies for resolving the climate crisis is the Circular Economy, which has gained prominence in recent years. Circular Economy is a sustainability strategy that combines zero waste, lean production, and life cycle thinking, aids in the fight against the climate crisis in many different fields. Considered of construction industry is responsible for more than 90% of water use and biodiversity loss and only 12% of the materials used in the construction industry are circular, these conditions practically force the industry to expand itself to meet the Sustainable Development Goals. On the other hand, with the use of digital technology, it may be possible to estimate demand, manage inventory, reduce waste by evaluating the best methods for recycling and remanufacturing, and improve sustainable operations. However, technology adaption is still at low levels in construction industry when compared to other sectors. In this context, this study aims to create a foundation for the circular economy models by identifying the digital tools that might contribute the circular economy in the construction industry with the help of a comprehensive literature review. The tools employed in the literature were explored for this purpose, and the findings were compiled in a frequency analysis table. Results show that the contribution of building information modelling, artificial intelligence, robotic and additive manufacturing technologies, which are frequently used in Construction 4.0, also play a major role for the circular economy. Furthermore, it has been recognized that inter-sectoral cooperation, governmental regulations, and incentives are necessary for a circular construction economy in addition to the development of most new technologies and their proper application through integration.

Keywords: *Circular Economy, Digitalization, Construction Industry.*

Introduction

At the Royal Meteorological Society of London in 1938, engineer Guy Stewart Callendar gave a speech on climate change in which he quantitatively demonstrated that the world is warming and claimed that human-created industries are to blame (Weart, 2015). At the UN Conference on the Human Environment (Stockholm Conference), held in Stockholm in 1972,

many countries with different socio-economic structures and development levels came together for the first time on the subject of "environment". Since then, many regulations have been made on climate change and the environment. However, the European Green Consensus, which enabled the most important process in recent years to be taken on behalf of the climate crisis, has very serious goals. This agreement is a new growth strategy that aims to transform prosperous society with a modern, resource-efficient, and competitive economy without net greenhouse gas emissions where economic growth is decoupled from resource use by 2050. The agreement is built on basic principles such as the transition to a clean and circular economy, the efficient use of resources, the protection of biodiversity and the reduction of pollution. After the announcement of the European Green Deal which aims to boost the efficient use of resources by moving to a clean, circular economy and stop climate change, revert biodiversity loss and cut pollution, companies start to seek sustainable business models to ensure an inclusive transition. To achieve this transition, countries and companies need to internalize the circular economy model in many sectors (Smol et al., 2020). In circular economy, all the benefits that may occur from the raw material choice to the end of the process where the product turns into waste from an economic and environmental perspective get into focus whereas the linear economy focus on the buy-build-use-dispose process.

Various disciplines have developed ideas related to the circular economy over many years, such as natural capitalism, regenerative design, cradle-to-cradle concepts, biomimicry, blue economy, industrial symbiosis, and industrial metabolism. A foundational principle of Circular Economy (CE) has been established by all these fields and concepts (Haas et al., 2020). The CE concept and border is still not clarified and there are no standards to contribution for sustainable construction (Kristensen & Mosgaard, 2020). But there is a vast scale of research that mainly focus on study below related to the circular economy.

In recent years investigators have created some index-based methodologies to measure the performance of CE (Kalmykova et al., 2018; Parchomenko et al., 2019; Mhatre et al., 2021). Kirchherr et al., (2017) mentioned that there are 114 definitions of circular economy in the literature and analyzed these definitions. As emphasized at the end of the study, it is important to draw the boundaries and define the words for their permanence and correct use. Lacy et al., (2016) mentioned resource use, which is about the world resource consumes more than 1.5 times its natural resource capacity. Studies conducted on a global scale show that while the circularity rate was 9.1% in 2018, it decreased to 8.6% in 2020, that is, a gap that needs to be closed is opening more and more as time goes on (Circularity Gap Reporting Initiative, 2020). Wilson & Velis, (2015) emphasized that generally datas on the life cycle of solid wastes recorded in high-income countries and also C&D waste is the most important type of waste with a rate of 36%. Terra dos Santos et al. (2022) investigates the relationship between circular economy and sustainability. Study mainly focusses on the social dimension, which is the absence part of CE. They created a model for this and after analyzing they could not conclude that circularity alone guarantees sustainability. Geissdoerfer et al., (2017) revealed that the circular economy is seen as a condition for sustainability, a beneficial relationship or an exchange. Stahel, (2010) says that the connection between the Circular Economy and emerging concepts such as the Performance Economy, the Sharing Economy, and new business forms such as benefit companies can be explored. Bocken et al., (2016) stated in his study that the circular economy will contribute to "strong sustainability" and slower consumption patterns, that is, to close resource cycles as well as to slow them down. Dantas et al., (2021) conducted a systematic literature review to determine how the "CE-I4.0"

connection, which is a combination of circular economy practices and Industry 4.0 technologies, can contribute to the achievement of Sustainable Development goals. The objectives related to the application of circular economy practices and Industry 4.0 technologies are explained.

When circularity is mentioned in the construction industry, studies on waste & demolition management come predominantly. However, in the report announced by Green Deal, it is emphasized that buildings consume 40% of the total amount of energy consumed. Despite this, the building stock renewal rate is in the range of 0.4%-1.2%. Although the EU's climate targets aim to double these rates in terms of energy efficiency, this situation shows the importance of circularity for us Facility Management. Some academic studies in the construction industry are as follows: Kristoffersen et al. (2020) has established a detailed framework for the use of digital technologies in the manufacturing sector for the circular economy. Bocken et al. (2016) explained the terminology of slowing down, closing and narrowing resource cycles and created a list of product design strategies and business model strategies for key decision makers in businesses to facilitate the transition to a circular economy. López Ruiz et al., (2020) presented a theoretical framework in which they identified the factors that may affect the concept of the circular economy in the construction and demolition sector. Hossain et al. (2020) aimed to identify the impacts, assessments, contributions, and challenges of CE in the construction industry. Emphasis on design, material selection, supply chain, business model, uncertainty and risk, collaborations between actions, knowledge of understanding, relevant policy, integration of urban metabolism, and challenges for CE. Ghaffar et al. (2020), explored current applications of construction & demolition waste (C&DW) management and awareness of the concept of circular construction (materials reuse, recycling, and recovery) in the UK. As a result of the research, he mentioned that the legislation to be created by the state can significantly affect the circularity. He says the focus should be on smart dismantling or demolition of buildings and ways to optimize cost-effective processes. Foster G. (2020) has studied the circular economy that can reduce environmental impacts in cultural heritage buildings and proposed a comprehensive circular economy framework for adaptive reuse. Balbay et al. (2021) conducted a circular economy SWOT and Pest analysis of Turkey. The high rate of waste imports, the lack of incentives and inspections, and the development of new job opportunities by the circular economy despite high inflation rates are just a few of the key results from the PEST analysis. The lack of knowledge about investigations conducted to ascertain the waste analysis or the sort and quantity distribution of the wastes is one of the SWOT analysis's results. It is vital to recognize the potential for manufacturing that complies with European market criteria inside the Green Deal framework.

Many studies have created a model for the circular economy by using digital technologies or have obtained results with some analysis. However, the number of studies on which digital technologies will be used extensively to achieve the Circular Economy in the construction industry is few. As a result of the literature review conducted in this study, with the use of digital technologies, prediction of demand and manage inventory, thereby minimizing waste by assessing the best practices for remanufacturing and recycling and enhancing sustainable operations may arise. With the Construction 4.0 revolution, sustainable buildings and smart green cities can be built. In structures where digital twins can be created, cost-effective operating modes can be used with new cyber-controlled HVAC systems. At the same time,

the building's dynamic response to changes in energy supply is analyzed to show the building's need for maintenance or renovation. By using real-time data with IOT, accurate data can be accessed quickly without going to the construction site. It enables tracking of construction materials, vehicles, and equipment, and instantly detects the need for repair and repair of the machine. Thanks to devices with internet connection, carbon emissions can be measured during and after the construction process, and economic and environmental effects can be minimized by optimizing the data correctly. One may argue that digitization is what has changed the construction industry the most. It may be claimed that the circular economy strategy will be significantly impacted by digitization. Investigating how and how frequently these technologies are employed for the circular economy is crucial in this regard. Circular economy models vary according to sectors and policies of countries. It is classified according to strategies ranging from R0 to R9 in circular economy approaches, which include what will be done from the production stage to the life cycle (Khaw-Ngern et al., 2021). In each model used, the circular economy approach differs according to each strategy or country, as well as the digital tools used. Finding the digitalization tools used in the circular economy approach and how often they are used will shed light on researchers who will make a comprehensive circular economy model in the construction industry.

Research Methodology

There are over 16000 documents on the "circular economy" in the Scopus database. 9000 of these studies are published since 2020. Especially after the European Green Deal held in 2019, it is seen that the work of the academy in this field has increased. Because of this reason this study mainly focusses on last 4 years. In this study, articles that contribute to the circular economy with digital technologies are filtered. For this, 3550 documents were reached by using “("built environment" OR "building" OR "construction") AND ("digit*" OR "digital technology" OR "industry 4.0") AND "circular economy" AND (LIMIT-TO (OA , "all"))” filters in the Scopus database. Among these articles, 15 articles related to the research topic were examined. The main topics covered in 15 articles are briefly as follows:

- According to Cetin et al. (2022), the Dutch government applies circular principles in construction, renovation, maintenance and demolition projects. A case study was conducted in social housing institutions. He said that artificial intelligence, digital twins, and scanning technologies are beneficial to circularity, and 12 challenges were identified for digital technology adoption. He emphasized that material passports are unfortunately only implemented in pilot projects, while artificial intelligence and digital twin are only used in resource optimization and data-driven maintenance operations. They say that these technologies need to be developed and their interoperability increased. Baduge et al. (2022) study is about machines and deep learning methods and applications in Construction 4.0. They benefit from artificial intelligence for the circular economy, especially for the production process efficiency. They also highlight the importance of strategies for the challenges of developing models on data collection, storage and deletion with intelligent vision and sensors.
- Elghaish et al. (2022), conducted a comprehensive and critical overview scientometric study on 115 papers in the circular supply chain in the construction industry. Lack of capital required for CE adaptation and regulatory shortcomings and complexity of

estimating the salvage value of building materials that will motivate the construction industry for CE adoption. It is said that the most important in this field is the integration of the CE concept into new smart cities. However, for this, researchers on behalf of existing buildings/cities need to be increased. In addition, the authors aimed to contribute to the operation stage by analyzing existing solutions in order to apply them on behalf of CE in the construction industry, producing a conceptual model integrated with blockchain and IoT.

- Kromoser et al. (2022) outlined the importance of circular structures. Their research on walls with additive manufacturing on fully recyclable wood to produce circular economic structures. In the model developed on the 3DP Biowall concept, the advantages and disadvantages of construction strategies are discussed.
- Maiurova et al. (2022) conducted a case study that shows how an integrated waste management with digitalization which controls municipal solid waste generation in Berlin could be applied in Moscow. Thanks to digitalization in recycling in Moscow, it has improved local waste management practices during the Covid-19 process and created 5000 new jobs and reduced operating costs by 75%. In addition, the robot arms used with AI and ML reduced the volume of non-recycled waste by 20%.
- Elghaish et al. (2022) conducted a systematic review of 115 papers, interrelationship between different technologies of Industry 4.0 investigated to encourage the implantation of circular economy in the construction industry. It has created a conceptual model for the optimized circular economy by using different technologies for reuse to improve building performance.
- Colorado et al. (2022) revealed an econometric analysis as a result of their research on construction and demolition wastes in Colombia. Experimental characterization and analysis of the C&D waste type was carried out with X-ray diffraction and scanning electron microscopy for infrastructure projects.
- Charef (2022a) research suggests that there is a lot of interest for the circular economy, but organizational tools for the construction industry's CE transition are dramatically lacking. For this, they have created a BIM-based trans-scalar theoretical framework. This framework detailed the use of BIM throughout the building lifecycle and visualized interactions between phases and relevant stakeholders in the UK context.
- Caldas et al. (2022) classified the 30 papers reviewed in total as slowing loops, closing loops, and narrowing loops. In terms of CE strategies and climate change mitigation, closed loops constitute the majority. They mainly relate to recycling and end-of-life reuse and use of recycled materials. As a result of the study, it has been determined that LCA and BIM are the most useful tools in terms of the conventional building design process or in the disassembly project.
- Charef (2022b) highlighted doubts about the use of BIM in end-of-life (EOL) activities. It also states that BIM's adoption of the Circular economy is still in its infancy. The study aims to improve their understanding and application of the CE approach with a trans scalar theoretical framework in BIM contexts.
- Çetin et al. (2021) investigates which digital technologies potentially enable the circular built environment and in what ways it can be achieved is the subject of research. He classified circular economy strategies according to the core principles of regenerate, narrow, slow, close, and collaboration. As a result of the framework

created and the workshops conducted, it is important to note that interactions between Digital Technologies demonstrate leveraged capabilities towards achieving CE goals.

- Lekan et al. (2021) conducted research aimed at providing a pathway to sustainable innovations through technological and infrastructure developments. The data obtained as a result of the survey conducted on 150 construction companies were analyzed. He proposed a technical, circularity and innovative system that would correctly adapt the I4.0 tools to the C4.0.
- Kovacic et al. (2020) It assesses the extent to which digital technologies are used and for what purpose and identifies their potential and challenges for achieving CE targets. It also proposes a framework for a Digital Platform for Circular Economy (DEEP). This framework mentioned to BIM specifications that public policies, manufacturers' environmental product declaration, and eco-repository data should be integrated throughout the lifecycle of control.
- Khadim et al. (2022) He says that there is no consensus about opinion and practice in the name of circular economy in the building and construction industry. For this, building circularity indicators have been proposed and a comprehensive systematic literature review has been carried out. He emphasized that innovative technical solutions on behalf of adaptability and disassembly are effective in measuring the circular potential of structures.
- Yu et al. (2022) stated that the efficiency and challenges of implementation of information communication technologies have not yet been determined. In this direction, it is aimed to develop decision support tools based on IT technologies to apply the circular economy in the construction sector.

The summary on the use of digitalization tools in construction industry towards CE was also presented as a frequency analysis table (Table 1) below.

Table 1. Frequency of digitalization tools uses across the construction industry towards Circular Economy.

Digitalization Tools	Çetin et al. (2022)	Baduge et al. (2022)	Elghaish et al. (2022)	Kromoser et al. (2022)	Maiurova et al. (2022)	Maiurova et al. (2022)	Colorado et al. BIM: Building information modelling, VR: Virtual reality, AR: Augmented reality, MR: Mixed reality, AI: Artificial intelligence, DT: Digital twin, DP: Digital platforms, Scan Tech: Scanning technologies, IoT: Internet of things, ML: Machine learning, DL: Deep learning, RM & AM: Robotic and additive manufacturing, LCA: Life cycle assessment, WMP: Waste management plan BMP: Building material passports, GIS: Geographic information system.

The study's findings show that BIM, AI, RM, and AM technologies are referenced more frequently than others.

Discussion & Conclusion

The global warming-related climate catastrophe is largely attributable to the linear understanding in the production and consumption sectors. In a linear economy, value is determined by the quantity produced, and the cycle of "buy-build-use-demolish" is maintained. The circular economy includes the concepts of zero waste, lean production and life cycle. Not only is it process-oriented, but it also offers the chance to assess all potential advantages of the choice of raw materials through the point at which the product becomes wasted from an economic and environmental standpoint. Even if there are several research on sustainable building practices and the use of digital technologies in these studies, there should be more applications and studies on the circular economy. The decisions made with Greendeal (2019) have led to more people becoming interested in the circular economy theory. Knowing how and when to take use of Construction 4.0 technology is crucial to maintaining this growing interest. In this study, it has been identified which technological instruments the circular economy may benefit from by looking at the useful items. The construction industry's circular economy studies were researched in this literature between 2018 and the present, and it defined the technological tools that were used and their frequency.

The results obtained from the technologies used in 15 articles with the aim of circular economy in the construction industry show that Building Information Modeling, Artificial Intelligence, RM, and AM technologies are used more frequently than other technologies. In the world today, managing a construction firm is impossible without keeping information about the construction process. When it concerns time, money, quality, or anything else, a company should gather and evaluate this data. The BIM is the modeling method for accomplishing this since it allows for merge collaboration and interoperability. Additionally, BIM level changes to 6D and 7D BIM for digital tools that are used for sustainability and facilities management. This circumstance led us to predict that BIM would be one of the most popular techniques in literature, and our findings corroborated this expectation.

You cannot handle all the analyse findings manually if your organization has data from sensors or other technology tools to manage better and obtain effective solutions, such as cost or time management. At this stage, AI aids in coordination and supervision of both the construction process and the facility management part, such as HVAC and lighting controls. Additionally, thanks to AI, trash management for the demolition project may be made simpler and more effective by employing digital twins and material passports. The circular economy includes nine strategies, and when we compare digital tools to those strategies, RM and AM really fulfil most of them. Because of this, as well as the rising need for this form of manufacturing, these tools are among the most often used ones in our study findings.

However, although this shows that these technologies are more inevitable to achieve a circular approach than others, we must emphasize that these technologies are also extremely important. As an example, we can say that the number of mentions of blockchain technology in articles is low compared to other technologies. However, the opportunities created by this technology will reduce the amount of paperwork's by shortening the paperwork processes, prevent time losses in the production process, and thus reduce the carbon footprint and environmental impacts that will occur indirectly with the reduced project duration. In addition, it can contribute to resource management thanks to the life cycle and raw material verification method, in the management of tracking and monitoring of wastes, in energy management to obtain a smart grid.

Findings show that Circular Economy goals may be achieved with the proper adaptation of the technologies used for Construction 4.0 and the integration of digital technology in the built environment. Instead of developing or discovering new technologies, employing existing technologies wisely and focusing on circularity methods offers suitable answers in our circular economic existence. Therefore, this study serves as a starting point for identifying the theoretical and practical gaps in literature. The proposed table of technologies is not sufficient to develop a model for circular economy, despite the fact that this research examined important published studies on the use of digital technologies to achieve circular economy in the construction sector. It must be created with additional technological applications and with information on how to utilize it during the construction phases in order to support further research. Among the studies analysed, Çetin et al. (2022) and Yu et al. (2022) will be helpful to researchers working in this field by outlining at what stage of construction and for what purpose technologies that can utilize circular economy may be used, as well as by providing a lot of digital technology in detail.

Organizational Resilience and Agility: The Impact of COVID-19 Pandemic on the Construction Industry

A. Şanlı and E. F. Taş
Istanbul Technical University, Department of Architecture, Istanbul, Turkey
sanlial@itu.edu.tr, tase@itu.edu.tr

Abstract

With the World Health Organization (WHO) announcing the coronavirus 2019 (COVID-19) outbreak as a pandemic, many organizations faced uncertainty. This pandemic process has had both positive and negative effects on organizations. Many organizations, with the desire to adapt to change and survive, have determined and implemented new strategies by making use of technological resources. Construction organizations, which take slower steps in adopting and applying technology compared to other organizations, have also become open to change with the pandemic. The positive and negative developments experienced during the COVID-19 pandemic process have revealed that organizations should be prepared for all kinds of changes. Therefore, in the post-pandemic "new normal" period, it is important for construction organizations to adapt quickly to change and develop survival strategies. Resilience and agility are key factors in adapting to and coping with change and fostering future success. Resilience is the ability to bounce back and adapt in the face of difficulties. Agility is the ability to adapt to change and react quickly. Therefore, this research which is an evaluation of the literature examines the effects of the pandemic on construction organizations and encourages organizations to adopt advanced technologies and build resilience and agility against future unexpected events.

Keywords: *construction organizations, COVID-19 pandemic, organizational agility, organizational resilience, technology.*

Introduction

Organizations often face unexpected events in highly volatile and uncertain times. The importance and magnitude of the effects of these unexpected events, which are also expressed with concepts such as rare events, surprises, disasters, and crises, on organizations can be surprising (Duchek, 2020). For example; Unexpected events such as severe flooding in the Netherlands in 1953, a severe earthquake in Turkey in 1999, the extreme tsunami in Indonesia in 2004, a severe earthquake in Pakistan in 2005, and Hurricane Harvey in 2017 affected the economy and organizations in these countries and threatened business continuity (Iqbal et al., 2021). Today, the unexpected event that the whole world is facing is the COVID-19 pandemic. Covid-19, first identified in Wuhan, China in December 2019, has become a global pandemic at the end of March 2020. Due to the spread of this virus, which was not seen in humans before, both by air and through direct and indirect contact, life has practically come to a halt in many countries. To date (28 June 2022), there have been approximately 542 million

COVID-19 confirmed cases, and 6.3 million deaths due to COVID-19 (World Health Organization, 2020).

The construction industry is one of the industries most affected by the coronavirus. The construction sector is an important driving force of the economy of countries, as it forms the organizational backbone of the economy. The construction sector accounts for around 13% of the gross domestic product (GDP) of many countries and is important for sustainable development worldwide (Chih et al., 2022). This sector has a wide range of stakeholders and is, therefore, a complex sector of the economy as it is directly and indirectly linked to other sectors of activity such as production and energy use, finance, materials, equipment, and labor. The chain reaction of negativities in this sector may adversely affect the economy (Ogunnusi et al., 2021). With the emergence of this pandemic, construction organizations have been faced with negative effects such as closures, restrictions, low cash flow, procurement, occupational health and safety, work from home, workforce, and contract problems (Ogunnusi et al., 2021; Assaad & El-adaway, 2021). Despite the negative effects of the pandemic, it has affected construction organizations in a positive way, such as technology adoption, acceleration of technology, expansion of prefabricated construction, and implementation of industry 4.0 technologies.

Organizations must be prepared and continually adapt to change to gain a competitive advantage and survive in uncertain environments (Burnard & Bhamra, 2011). Construction organizations must deal with unexpected events, adapt, and act quickly (Padalkar et al., 2016). Organizations need resilience capacities to cope with, adapt to, and recover from the COVID-19 pandemic (Nah & Siau, 2020). Agility triggers construction organizations to adapt and react quickly to uncertainty and change (Chen & Siau, 2020). Besides, important to follow technological developments to adapt to change. Technology enables flexibility and agility (Nah & Siau, 2020). Therefore, in these uncertain times, it is important for construction organizations to develop resilience and agility and adopt new technologies to support organizational adaptation to change and uncertainty.

In this study, based on the example of COVID-19, inferences will be made by evaluating the literature for the construction organizations to adopt new behavioral models, application steps, and technologies by adapting to sudden and new strategies in the face of unexpected sudden events. In this context, this study aims to contribute to the future direction of construction organizations in the post-COVID-19 period by focusing on the effects of the COVID-19 pandemic on construction organizations. The research aims to (1) determine the positive and negative effects of the COVID-19 pandemic on construction organizations; (2) present the role of advanced technologies in the construction industry, and (3) emphasize the importance of resilience and agility in organizations.

Methodology

The aim of this research is to present the importance of the construction organizations to adopt advanced technologies and develop resilience and agility against unexpected situations such as pandemics. For this purpose, the method of this research consists of two steps. First, the words "pandemic" and "construction organizations" were scanned together and the research made between 2020 and 2022 was examined in the literature. Research related to this method has been reached and the negative and positive effects of the pandemic process, which are scattered in the literature, are grouped. Then, the words of "construction organizations",

"organizational resilience", "organizational agility", and "technology" were scanned together. The studies reached by this method were examined and the benefits that construction organizations can apply to be prepared for unexpected situations in the future are presented.

The Impact of COVID-19 Pandemic on the Construction Organizations

According to the literature research, one of the organizations most affected by the COVID-19 pandemic is construction organizations. These effects are both positive and negative. In this section, the negative and positive effects of the COVID-19 pandemic on construction organizations are presented.

Negative Effects

Construction organizations faced many challenges due to the measures taken to prevent the spread of the rapidly spreading COVID-19. These downsides need to be understood before suggesting strategies to counter the adverse effects caused by the unprecedented COVID-19 pandemic (Assaad & El-adaway, 2021). This research presents the negative effects of the pandemic on construction organizations, which is scattered in the literature review, by gathering them under the following headings.

Closures and restrictions. The world has come to a standstill with the outbreak of the COVID-19 pandemic. Social distancing and quarantines necessary to support people's health and safety have halted most activities (Assaad & El-adaway, 2021). The normal functioning of construction activities was also hindered (Spieske & Birkel, 2021). Construction organizations have been forced to close or operate with restrictions on their national or international sites (Chih et al., 2022). Due to these restrictions and closures, construction organizations have moved towards collapse (Ogunnusi et al., 2020). Planned projects were canceled, and existing projects were suspended or postponed (Assaad & El-adaway, 2021).

Cash flow. Maintaining cash flow is one of the main challenges faced during the COVID-19 pandemic (Sierra, 2021). Construction organizations have been adversely affected by the complexity and uncertainty in estimating cash flow during the pandemic era (Ayat & Kang, 2021). The reduction of construction work resulted in lower-income. With the cessation of construction sites, customers that supported the continuation of the projects suspended their financial flow. Construction materials cost increased due to delays. The fact that the stakeholders had to cut their financial support had negative effects (Ogunnusi et al., 2021). For construction organizations that rely heavily on cash flow, these cuts have created significant financial stress (Chih et al., 2022). According to Ogunnusi et al. (2020), critical challenges that construction organizations face with cash flow include: "poor capital input; low/no income generation; poor business sustainability; revenue loss; increase in cost; lack of fund; client paused funds; financial impact and disruptions; extra budget; delayed project financial commitment".

Delay. Delays are one of the biggest setbacks that construction organizations have to deal with. These delay challenges have become more complex with the pandemic (Ogunnusi et al., 2020). Construction projects have been adversely affected by many delays due to measures taken for health and safety reasons, reduction in the number of workers, lack of craftsmen, the inability to obtain necessary permits due to the closure of establishments, difficulties in

supplying materials and equipment, and discontinuation of work due to health concerns (Ogunnusi et al., 2021; Assaad & El-adaway, 2021). Delays in ongoing projects, payments, deliverables, planning, and more due to closures and restrictions have had a negative impact. Delays in making decisions by customers resulted in wasted time and late payments (Ogunnusi et al., 2021). COVID-19 disrupted the project schedules, extended the total duration of the project, and an average of 20% reduction in onsite production due to these sudden slowdowns (Sierra, 2021). These delays have reduced construction productivity during the pandemic (Ogunnusi et al., 2021).

Health and safety. Another challenge faced by organizations during the pandemic period is occupational health and safety (Lingard et al., 2021). Workers and professionals in construction organizations are at high risk of infection (Ayat & Kang, 2021). Therefore, with the emergence of the COVID-19 pandemic, health and safety in construction organizations has become even more important. The World Health Organization has presented procedures such as paying attention to the social distance that must be followed at active construction sites, paying attention to hygiene, and working remotely if there is someone in the employee's family with COVID-19 to prevent the spread of the pandemic (Spieske & Birkel, 2021). These procedures have negatively affected construction organizations in many ways (Wang et al., 2021). Health and safety rules, which must be strictly enforced, have caused extra costs and it has been stated that establishments that do not comply with these rules will have to close. These procedures have caused delays in the supply chain and in the work of contractors (Sierra, 2021). It has changed the way of doing business as employees in the workplace have to comply with social distance (Wang et al., 2021). In addition, communication problems and sharing of resources caused problems in business processes (Ayat & Kang, 2021).

Supply chain. Changes made to slow the COVID-19 pandemic have disrupted the supply chain of construction projects (Iqbal et al., 2021). The quarantine, which started with the emergence of the virus in China, started to have an impact on construction materials in early 2020. With the spread of the virus all over the world in March, all stakeholders involved in the supply chain, such as raw material suppliers, manufacturers, or shippers, faced obstacles (Sierra, 2021). Many international suppliers and logistics organizations stopped operations to contain the epidemic. Almost 50% of organizations have experienced COVID-19-related delays in receiving supplies and products from suppliers (Assaad & El-adaway, 2021). Organizations faced significant disruptions in their supply chains, such as labor, materials, and equipment (Chih et al., 2022). The problems, which first started with the shortage of material supply, deteriorated to a great extent, affecting construction organizations (Gamil & Alhagar, 2020). This showed how vulnerable construction organizations are to suppliers (Assaad & El-adaway, 2021). Disruptions in the supply chain caused financial shocks, delays, and disruption of the normal functioning of construction activities (Ogunnusi et al., 2021). For this reason, construction organizations have faced many difficulties due to supply chain disruptions and logistics bottlenecks during the pandemic period.

Remote-working. Professionals, managers, workers, and many employees of construction organizations have switched to remote work to reduce the number of people in the working environment and to comply with social distance rules (Lingard et al., 2021). Remote working has created many challenges and reduced productivity in construction organizations (Ogunnusi et al., 2020). Construction organizations differ from other organizations in that they require the participation of all employees to monitor whether activities are carried out correctly. Insufficient information transfer, and inability to follow up and control work hindered construction activities (Gamil & Alhagar, 2020). The training of workers was

difficult due to the fact that the training, which should be given practically at the construction site, was conducted online (Assaad & El-adaway, 2021). In addition, employees were negatively affected by the way of working remotely due to factors such as difficulty in focusing, increased workload, inability to provide a suitable workspace, feeling of loneliness, work burnout, disorders in work-life balance, and mental health disorders (Ogunnusi et al., 2021; Assaad & El-adaway, 2021; Lingard et al., 2021).

Workforce-related. Construction organizations faced many labor problems such as lack of labor force, protection of workers, sheltering workers, and taking health and safety precautions during the pandemic era (Assaad & El-adaway, 2021). The construction program was re-planned in such a way that the contractors did not overlap, ensuring a limited number of employees in the field. This caused the work to be prolonged and the days of filling the construction site with workers to get the job done quickly are over (Sierra, 2021). Construction organizations have had difficulties in housing the workforce. While many people were living in the same room in the pre-pandemic era, this is no longer possible due to the rules introduced during the pandemic period. It was very difficult to find shelters that comply with the hygiene rules required for the workers to stay (Assaad & El-adaway, 2021). Cash flow problems of construction organizations were first reflected in the workers (Ayat & Kang, 2021). Workers or professionals who contract COVID-19 are required to undergo a 14-day quarantine, which further delays field operations (Assaad & El-adaway, 2021). It led to a shortage of manpower due to illness and quarantine of employees (Sierra, 2021). Due to the social distancing rules, the work done by less than necessary people caused the workers to work long hours (Assaad & El-adaway, 2021). The unemployment problem has emerged due to closures and restrictions (Ogunnusi et al., 2020). About 40% of organizations have had to lay off workers (Assaad & El-adaway, 2021). Many temporary workers fell below the poverty line due to unemployment (Spieske & Birkel, 2021). Additionally, the pandemic has had negative effects on construction workers, such as the risk of getting sick, the absence of worker protections such as sick leave and paid leave, job loss and salary cuts, late payments, inability to find new jobs, and housing (Gamil & Alhagar, 2020; Ogunnusi et al., 2021; Assaad & El-adaway, 2021; Sierra, 2021; Ayat & Kang, 2021).

Contract. There are concerns that construction organizations will engage in costly and protracted disputes due to the impact of the pandemic. Legal disputes cause expensive disruptions due to both time and cost (Sierra, 2021). COVID-19 pandemic negatively impacted contract disputes (Ayat & Kang, 2021). These effects on contracts varied from contract to contract, from nation to nation (Ogunnusi et al., 2020). Since the pandemic is an unexpected event, the contracts did not specify what to do in the face of this situation (Ogunnusi et al., 2021). The possibility of construction organizations encountering such a deadlock was not foreseen during the tender and contract (Ogunnusi et al., 2020). Delays, time and cost overruns, and barriers to field operations have disrupted contract flow (Gamil & Alhagar, 2020). Organizations face potential contract penalties and cancellation of contracts due to project delays (Assaad & El-adaway, 2021). Problems arising from this unexpected situation can be accepted as force majeure. Counting the pandemic as force majeure ensures that the delay period is extended and no compensation is paid for the cost. However, the legal definition of force majeure depends on the contract text and most definitions do not include the word pandemic. Therefore, this situation creates a gray area and is left to the interpretation of the parties. Therefore, lengthy and costly legal problems have arisen, which has made the situation worse (Sierra, 2021).

Positive Effects

The literature review mentions that besides the negative effects of the COVID-19 pandemic on construction organizations, many positive effects have also occurred. Construction organizations faced some improvements and changes in this process. This research presents the positive effects of the pandemic on construction organizations, which is scattered in the literature review, by gathering them under the following headings.

Adoption of technology. The COVID-19 pandemic highlights the importance of using technologies for organizations to survive and move forward in development (Nah & Siau, 2020). The fact that COVID-19 is forcing organizations to rapidly transform the way they do business using digital technologies provides organizations with an opportunity to participate in innovation and transformation (Lingard et al., 2021). Construction organizations, slower than other organizations in adopting advanced digital technologies due to factors such as high implementation and investment costs, insufficient information, resistance to change, hesitation in the security of data, and reluctance (Spieske & Birkel, 2021), have made great strides towards implementing advanced digital technologies such as cyber-physical systems, big data, blockchain, digital twin, augmented reality, robots, three-dimensional printing, among others since the outbreak of the pandemic (Wang et al., 2021). Adoption of technology by construction organizations reduces the spread of COVID-19, as well as reduces cost and time wastage, improves quality and efficiency, improves processes, and increases occupational safety (Spieske & Birkel, 2021).

Remote working environment. Many construction organizations to contain the spread of the pandemic, have had to work remotely in face-to-face formats due to restrictions. It was discovered that construction organizations are not office-based and can be run remotely (Ogunnusi et al., 2020). By working from home, the time spent in traffic decreased, so employees continued their work in a more motivated way by spending more time on their personal life and their work efficiency increased. Travel costs, general costs such as water and electricity in the office, and the costs used in face-to-face working such as printing and stationery have decreased (Ogunnusi et al., 2021). The use of advanced technologies in construction organizations has increased (Biorck et al., 2020). The fact that the training to be given to the employees had to be given remotely created an opportunity for the adoption of technology-based training methods such as virtual and mixed reality (Assaad & El-adaway, 2021). Technology had to be used compulsorily to meet operational needs such as face-to-face meetings and seminars. This situation has revealed more flexible and new working models that are not normally tried, providing more online communication and the opportunity to develop virtual alternatives (Ogunnusi et al., 2021). Some job interviews were conducted using digital technologies through Virtual recruitment. It has been proven that communication can be made with web-based technologies such as zoom meetings, micro team meetings, and video calls over the internet (Spieske & Birkel, 2021). Construction organizations have adapted to different ways of working and it is expected that their way of working in the virtual environment will be integrated into construction activities in the post-pandemic period (Goodman, 2020).

Interactive collaboration. Collaboration and accurate information flow were ensured with the use of advanced technologies during the pandemic period. "Digitization and virtualization" technologies were used to run works remotely with collaboration (Spieske & Birkel, 2021). With the use of BIM, designers and engineers work collaboratively and confidently (Wang et al., 2021). Work plans were prepared with 4D and 5D simulations. Materials, resources,

workforce, employee welfare, and cash flow were managed with the help of online channels (Biorck et al., 2020). Before the pandemic period, construction organizations that only exchanged information on paper and by communicating face to face, benefited from cloud-based solutions to cope with the changing ways of doing business due to the rules brought by the pandemic, to provide accurate information flow, and observe the construction process. With cloud-based solutions, workforce monitoring is done via smartphones, tablets, iPads, or other devices, data such as field reports are accessed accurately and quickly, and project tracking is provided (Remkes, 2020). With these technologies, construction organizations realized that it would be possible to work collaboratively during the time of the pandemic.

Health and safety. The pandemic has encouraged construction organizations to improve occupational health and safety measures (Ogunnusi et al., 2021). Workers worked in suitable housing conditions in accordance with social distance and hygiene rules (Ayat & Kang, 2021). Industry 4.0 technologies were used to increase security measures and the tendency toward technology increased (Spieske & Birkel, 2021). For example, a construction organization took precautions against the possible risk of COVID-19 by enabling workers to fill out health forms through a special technology platform (Assaad & El-adaway, 2021). Construction organizations can monitor security measures such as face masks, social distance rules, real-time employee health, COVID-19 symptoms, construction processes, and disinfection of tools and equipment, through advanced technologies such as automation, robotics, 3D printing, and cloud-based applications (Assaad & El-adaway, 2021). Cloud-time monitoring applications were used to protect the health of field workers and to monitor their compliance with social distance rules and their entry and exit. These applications are agile applications that can be changed quickly and easily (Remkes, 2020). Besides, wearable IoT devices can be used to monitor people's compliance with social distancing rules to control the spread of COVID-19 and with IoT systems capable of detecting temperature ranges, it can monitor the movement of employees with high temperatures and inform those concerned (Nah & Siau, 2020). The measures taken during the COVID-19 process have encouraged construction organizations to increase future health and safety measures and to anticipate, plan, take precautions, implement and maintain potential risks (Lingard et al., 2021).

Productivity increase. During the pandemic era, the use of digital tools that increase efficiencies such as real-time job tracking, digital workflow management, simulation, and advanced software has become stronger (Biorck et al., 2020). Mobile technologies such as photos and videos were used to reach and manage the data in the field as quickly as possible. Thus, teams and resources were executed more efficiently (Remkes, 2020). Besides, during the pandemic era, construction organizations have adopted BIM technology to increase construction efficiency. In the city of Wuhan, China, two hospital projects were designed, built, and opened for use in a short time, 9 and 12 days, respectively, with extraordinary efficiency, by utilizing BIM technology. BIM technology facilitated the collaboration of project participants and enabled high-quality projects to be completed in a short time (Wang et al., 2021).

Off-site construction. Construction organizations had the opportunity to improve their off-site work to minimize employee interaction during the pandemic period (Iqbal et al., 2021). For instance, although many projects were stopped during the pandemic period, some projects such as hospital projects continued, one of these projects was built as modular structures using high technologies, and the project costs decreased and the construction speed increased (Chen et al., 2021). Construction organizations became more motivated and willing to make off-site construction or use precast elements (Goodman, 2020).

Workforce. Countries have had to close their doors to different countries due to COVID-19. This situation encouraged the involvement of local workforce in construction activities (Ayat & Kang, 2021). The lack of sufficient number of workers in the field due to social distancing rules also encouraged the use of advanced digital technologies. Construction organizations have tended to use technologies such as artificial intelligence, robots, and cloud systems to compensate for the absence of workers (Spieske & Birkel, 2021).

Sustainability. COVID-19 proved to be an opportunity to achieve sustainability goals (Ogunnusi et al., 2021). The remote working imperatives brought about by COVID-19 have resulted in less carbon footprints at the project site. The reduction of time spent in traffic and food and plastic waste due to remote working reduced carbon emissions (Ogunnusi et al., 2021). Besides, off-site production can contribute to sustainable goals by reducing noise and air dust in the construction site environment (Biorck et al., 2020).

Rethinking project management. The pandemic had positive effects that broadened the management perspective of construction organizations and opened their horizons (Ogunnusi et al., 2020). These positive effects can be listed as; new strategies emerging through the use of technological tools, lessons learned, virtual management, predicting future planning, minimizing losses, improving job performances, adopting safety practices, assessing risks, off-site management, appropriate planning and coordination of construction activities, accepting changes, and greater awareness of force majeure (Ogunnusi et al., 2021; Iqbal et al., 2021). The fact that the pandemic restrictions caused the projects to be managed remotely had positive effects that highlight the role of technology in project management. Software was used to manage teams and resources remotely without field visits. The management process was followed by the mobile forms filled by the workers in real time. In case of possible unexpected events, construction organizations realized the importance of data collection obtained during the pandemic period for future management (Remkes, 2020). Construction organizations have benefited from BIM technology to manage projects during the pandemic era (Wang et al., 2021). Artificial intelligence encourages more informed decision making against unexpected situations like COVID-19. COVID-19 has drawn attention to blockchain applications in cost, procurement and contract management in construction projects (Spieske & Birkel, 2021).

The Future Direction of the Construction Organizations

Understanding the negative and positive effects of the sudden outbreak of the COVID-19 pandemic on construction organizations supports preparation for unexpected events in the post-pandemic period. Construction organizations can cope with the negative effects of the pandemic, survive and turn these effects into positive effects, by developing the organization's resilience and agility capabilities and adopting advanced technologies.

Organizational Resilience

Organizational resilience is the organization's capacity to anticipate possibilities, identify risks, develop situation-specific responses, cope positively with unexpected complexities, constantly innovate, adapt quickly to changes, act proactively, and take transformative actions to take advantage of unexpected events that threaten the organization's survival (Burnard &

Bhamra, 2011; Annarelli & Nonino, 2016; Nah & Siau, 2020; Duchek, 2020). Organizations are systems that operate in a dynamic, uncertain, and changing environment (Goodman, 2020). In highly volatile and uncertain times, organizational resilience enables organizations to deal effectively with unexpected events, bounce back from crises, foster future success, gain strategic awareness, and gain competitive advantage (Duchek, 2020). This resilience capability is an important success factor in mitigating any threats that organizations face, being prepared to reach a new desired state, maximizing recovery speed, and managing unexpected situations (Annarelli & Nonino, 2016). In a pandemic like the COVID-19 pandemic, organizations need resilience capacities to cope, adapt, and recover from the pandemic (Nah & Siau, 2020). Therefore, organizations need to consciously develop their flexibility capacity. Resilient organizations can learn and develop appropriate capabilities that improve future preparedness. With the ability to adapt and change as an aspect of resilience, organizations can turn threats into opportunities, develop new capabilities, and achieve breakthrough growth when change becomes the new normal (Burnard & Bhamra, 2011). Therefore, beyond surviving the pandemic, construction organizations need to engage in transformative activities, act proactively, adapt, and be prepared for the future to maintain their competitive advantage and improve their resilience. The adoption of technology by construction organizations forms the basis of a roadmap that will enable the organization to transform, be prepared for unexpected situations, and improve their resilience (Syed et al., 2020).

Organizational Agility

The origin of the word "agile" comes from the Latin word "agere" which means going forward, changing direction quickly and easily (Online Etymology Dictionary, 2022). Agility represents the speed aspect of resilience (Chen & Siau, 2020). Agility is the ability to spot opportunities quickly, change direction, and avoid collisions (Duchek, 2020). This ability enables detect opportunities and threats and responds quickly by anticipating possible scenarios in an unstable and rapidly changing environment (Chen & Siau, 2020). Agility has its origins in lean manufacturing and is rooted in the manufacturing industry. In the early 1990s, organizations started implementing agile approaches to adapt to changes (Harraf et al., 2015). These agile approaches have started to be implemented primarily in the software industry to respond quickly to changes, uncertainties, and risks. The fact that these applications in the software sector increase productivity have been a driving force for other sectors to use agile approaches (Cobb, 2015). Organizational agility is a competence that makes it possible to be aware of the nature of the changes occurring within and around the organization, to think strategically, adopt an innovative mindset, manage change successfully, adapt to changes and turn them into opportunities, and to be proactive. Implementing agility involves the organization's perception, foresight, entrepreneurial vigilance, and proactivity (Harraf et al., 2015). This competence is related to the ability to innovate quickly, accurately, and efficiently in all processes of the organization. An agile organization has the capabilities to quickly detect and respond to opportunities and threats (Chen & Siau, 2020). Agility is an important pillar for development and keeping competitive power (Chih et al., 2022). Speed and responsiveness, the two main components of agility, are critical to organizational success in today's competitive environment (Harraf et al., 2015). Organizational agility improves the organization's ability to provide high-quality products and services and increases the competitiveness of the organization by enabling the organization to integrate with new and advanced technology (Crocitto & Youssef, 2003). Besides, in a dynamic, challenging, and often unpredictable environment of change, organizational agility bridges the relative inertia

gap between the pace of organizational learning and the pace of environmental change and enables the organization to gain a competitive advantage by adding proactivity, adaptability, flexibility, speed, and learning and innovation skills to the organization (Appelbaum et al., 2017). Organizational agility allows organizations to sense the changes caused by the current COVID-19 pandemic and quickly anticipate what needs to be done (Al-Omoush et al., 2020). Therefore, it is important for construction organizations to adopt agile organizational competence against the uncertainties, difficulties, and changes they face due to these unexpected events such as pandemics, to be prepared for unexpected events, to survive, to gain competitive advantage, to react quickly, to adapt, and to adopt new technologies.

Conclusion

In conclusion, in this research conducted with the aim of encouraging construction organizations to develop their organizational resilience and agility skills against unexpected events such as COVID-19 and to adopt advanced technologies; identified the positive and negative effects of the COVID-19 pandemic on construction organizations; presented that the COVID-19 pandemic is a driving force for construction organizations to adopt technology, and encouraged construction organizations to adopt advanced technologies and develop their resilience and agility capabilities in the post-pandemic era.

The COVID-19 pandemic has had both positive and negative effects on construction organizations. In this research, the negative effects are presented under eight titles as closures and restrictions, cash flow, delay, health and safety, supply chain, remote-working, workforce-related, and contract challenges, and the positive effects are presented under nine titles, as adoption of technology, remote working environment, interactive collaboration, health and safety, productivity increase, off-site construction, workforce, sustainability, and rethinking project management. By investigating these effects, construction organizations can be prepared for the 'new normal' situation after the pandemic and unexpected events that may occur in the future. Construction organizations must combat the negative effects of the COVID-19 pandemic and turn the positive effects into opportunities. The COVID-19 pandemic has forced organizations to adapt their business processes and operational practices, rethink traditional methods to survive, and highlighted the importance of using technologies for organizations to build resilience and move forward in development. The adoption of new technologies increases the resilience and agility of organizations. Resilient and agile organizations can learn and develop appropriate capabilities that improve future preparedness. Organizational resilience triggers organizations to deal effectively with unexpected events, support future success, and gain competitive advantage. Organizational agility enables construction organizations to react and adapt quickly to uncertainty and change. Developing organizational resilience and agility capabilities and adopting advanced technologies can effectively help construction organizations to be prepared for unexpected events such as COVID-19 that they may encounter in the future, to cope with, adapt to change, and turn these events into opportunities. Therefore, this research which is an evaluation of the literature encourages construction organizations to develop resilience and agility skills and adopt advanced technologies.

Risk Assessment in Construction Projects: A Case of Housing Project

A. Kazaz and G. Arslan
Akdeniz University, Department of Civil Engineering, Antalya, Turkey
akazaz@akdeniz.edu.tr, gokcenarslan@ akdeniz.edu.tr

Abstract

Development of technology and rapid change in customer needs; increase the competition in the construction sector and decrease the profit share of the projects. This situation makes it mandatory for companies to minimize the deviations that may occur in the project's time, quality, and cost objectives. Studies show that risk management will contribute positively to achieving these objectives successfully. Risk management is a cycle consisting of the stages of identifying and evaluating risks, taking counter-strategies and monitoring risks. In line with the studies carried out, it has been revealed that the realistic identification and evaluation of risks is inevitable for a successful risk management. In this study, it is aimed to determine and evaluate the risks frequently encountered in construction projects. A housing project was taken as a case study and risks were identified and evaluated as a result of expert opinions and literature review. According to the results obtained, the three risk groups with the highest impact for construction projects are organizational risks, financial risks and construction risks.

Keywords: *construction risks, construction sector, Monte Carlo simulation, risk analysis, risk management.*

Introduction

In the business world, risk is an inevitable factor for all sectors, and risks that cannot be managed effectively hinder the successful of the projects. However, the one-off, complex structure of construction projects requiring a combination of different expertise makes the construction industry more risk-prone compared to other sectors.

Risk management has many features that can provide many advantages for the construction sector, which is the locomotive of the economy, especially in developing countries (Birgönül & Dikmen, 1996). Due to the fact that each construction project is unique and dynamic, the construction operation involves numerous uncertainties, multiple intricacies, varies techniques, and divergent environments. Therefore, identifying and managing the potential risk factors, which can significantly vary from project to project depending on several conditions, plays a crucial role in enhancing the performance and accomplishing the successful delivery of the enterprise (Jarkas & Haupt, 2015).

This study aims to identify and prioritize the risks frequently encountered in construction projects. Within the scope of the study, initially, the risks that may be encountered in

construction projects were determined and classified in line with the literature research and expert opinion. In the continuation of the study, the risks were prioritized by considering the probability of occurrence of each risk factor, the degree of impact on the time and cost objectives. Subsequently, a risk analysis based on simulation was carried out on the project selected as a case study.

Risk Management in Construction Sector

The construction industry plays a significant role in the development of every nation's economy through value creation, employment and contribution to Gross Domestic Product (GDP) (Schoonwinkel & Fourie, 2016; Owoo et al., 2018; Urbański et al., 2019; Boateng et al., 2020).

Risk is an inevitable factor for all sectors in the business world and causes the project to fail when it is not managed effectively. As a result of its unique structure, the construction industry is exposed to greater risks in comparison with other industries. It has unique features as:

- Projects taken long periods, with processes that are complicated
- Financial intensity
- Dynamic organization structures (Taylan et al., 2014).

In construction projects, the target is generally determined as function, cost, time, and quality limits. For this reason, the most important risks encountered in constructions are exposure to these limits. The result of this situation is described as a failure (Baloi & Price, 2003). Arıkan (2005) stated that construction projects contain many uncertainties arising from the project, country, and market, making it difficult to implement risk management in construction projects. He also emphasized that in order to carry out the projects systematically, risk management systems that cover topics such as measuring project performance under varying scenarios and using past project experiences for new projects should be developed and used.

According to a study by Bowers and Khorakian (2014), it is stated that successful implementation of risk management systems is very rare in most construction companies in the developing countries of the world (Bahamid & Doh, 2017).

Currently the practice of risk management is reactive, semi-permanent, casual and unstructured within the construction industry, resulting in a lack of capacity to manage risks appropriately. The main barriers that were found for the implementation of an effective risk management system are the lack of formality of the system and the lack of integrative mechanisms of risk management among the parties involved in the project (Choudhry & Iqbal, 2013)

In addition to the above-mentioned features of the construction industry; the fact that globalization and technological developments have accelerated the competition in the construction sector both increase and diversify the risks related to the sector. These risks, which are numerous and diverse, constitute an obstacle in achieving the basic objectives such as completing the project in the planned period, not exceeding the foreseen costs, and achieving the targeted quality. This situation makes it imperative to analyze the risks in detail in all projects aimed at success and to determine and apply the necessary methods to minimize the possible negative effects. The need to analyze the risks and demonstrate the necessary attitude towards the risks makes effective and successful risk management inevitable.

Methodology

The aim of this study is to identify and prioritize the risks frequently encountered in construction projects and to examine the effects of risks on the time and cost performance of the projects. In line with the purpose of the study, first of all, construction project risks were determined and classified based on expert opinion and literature review. Then, a risk analysis of the project selected as a case study was conducted to investigate the effects of identified risks on the time and cost performance of construction projects. The project, which is considered as a case study, is a 4-block superstructure project for residential and office use in Turkey. The total area of the project is 89,065 m^2 and unit price contract type was used in the project. The site plan of the exemplary project is shown in Figure 1.

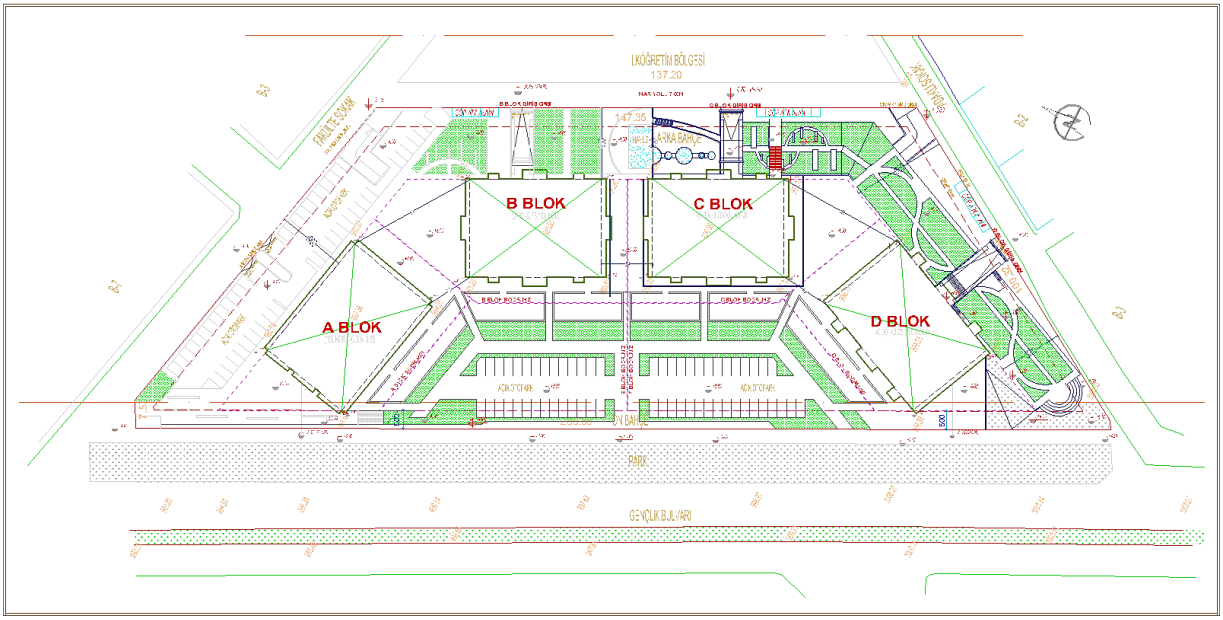

Figure 1: Layout plan of the project.

After the risks were determined, the project, which was taken as a case study, was planned with Primavera Risk Analysis (PRA) software and the risk analysis of the project was carried out with the help of Monte Carlo Simulation technique under the determined risks. In line with the results obtained, the effects of risks on the time and cost performance of the project were determined and revealed.

Monte Carlo method, one of the simulation techniques, is a system based on probability theory. It was created based on statistical and mathematical techniques. In this way, an experiment or a physical event that needs to be solved is animated and solved by using random numbers repeatedly in the computer environment. It facilitates the understanding of the behavior of highly complex systems whose analytical results are not easily accessible (Yıldız, 2011; Kaplan, 2014).

Findings and Discussion

In the first part of the study, the risks that can be encountered frequently in construction projects were determined and classified based on expert opinion and literature review. Within the scope

of the research, 63 risk factors were identified and classified under 8 main risk groups: design, contract, political, financial, managerial, organizational, construction and environmental. For the case study, the risk score for each risk determined within the scope of the research was determined by evaluating the risk probabilities and the effects of the risk on time and cost. While evaluating the possibility of risk and the effect of risk on time and cost; very low (VL), low (L), medium (M), high (H) and very high (VH) levels were used as ratings. The probability and impact assessments of the identified risks are given in Table 1.

Table 1. Identified risks and risk scores.

Risk Group	Risk Explanation	Prob.	Time Effect	Cost Effect	Risk Score
Design	Incompatibility between design projects	VH	M	L	15
	Change of design standards	L	L	L	4
	Faulty design	VL	M	VL	2
	Low performance of the design team	VL	VL	VL	1
	Adaptation problem of designers to the standards of different countries	N	N	N	0

	Epidemic disease	VL	VL	VL	1

The ranking of the main risk groups according to the risk scores for the selected project is shown in Figure 2. Considering the risk scores of the risks affecting the project, it is seen that the risk group with the highest impact is organizational risks with a rate of 30%. Organizational risks are followed by financial risks with 21% and construction risks with 15%. Construction risks are followed by design risks (13%), management risks (9%), contract risks (5%), political risks (4%) and environmental risks (3%).

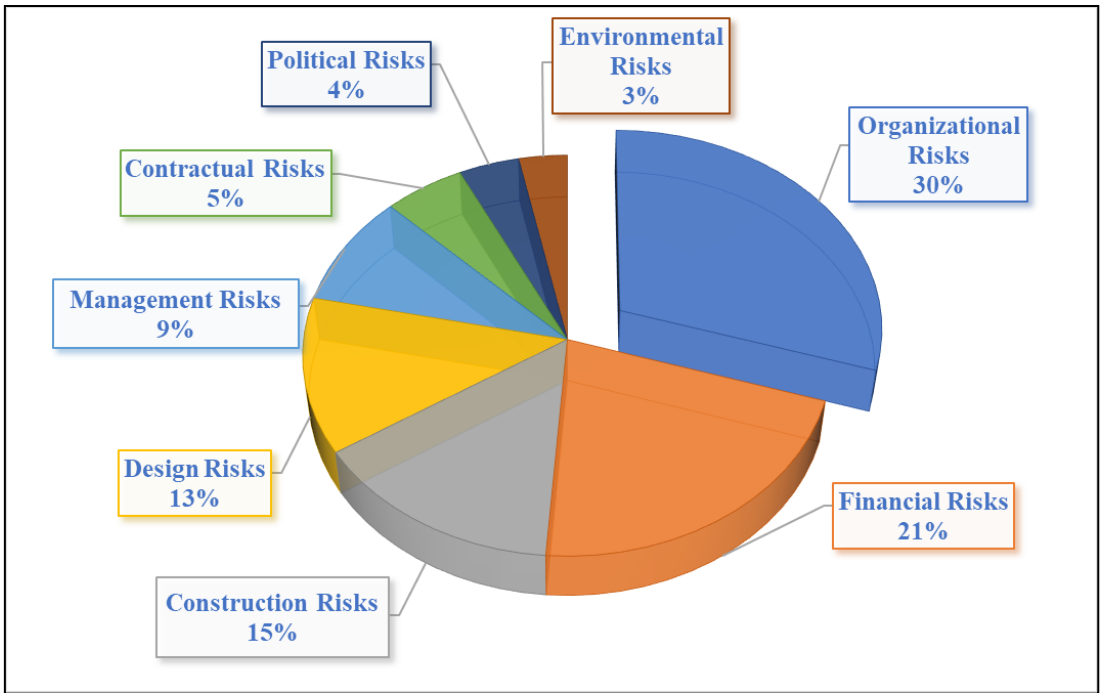

Figure 2: Ranking of risk groups according to risk scores.

The ranking of risk factors belonging to organizational risks, which are in the first place according to risk scores, is given in Figure 3. In the ranking made on the basis of risk scores, it has been revealed that the risk factor with the highest impact among organizational risks is the risk of faulty and or inadequate planning.

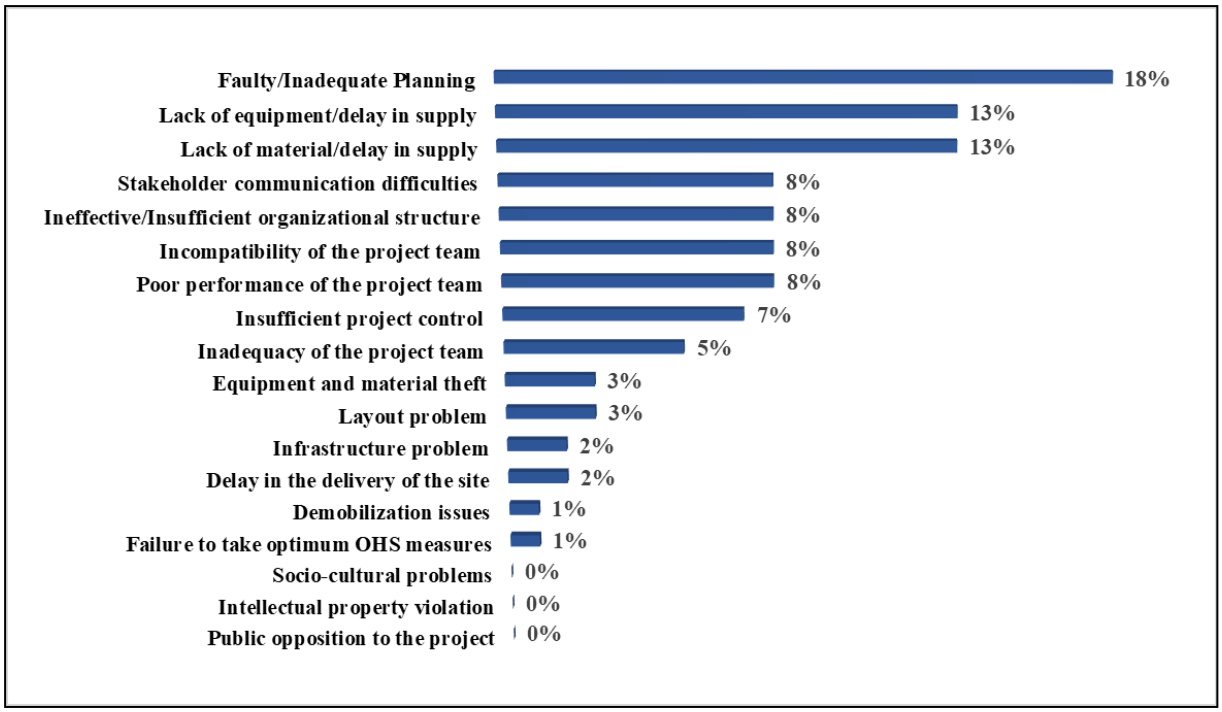

Figure 3: Ranking of organizational risks according to risk scores.

The highest risk factors within the financial risk group are the risks of increase in material prices and incorrect cost estimation with a rate of 25%. In the financial risk group, the third and fourth rank is the risk of experiencing an economic crisis and an increase in labor costs with a rate of 19%. Cash flow shortage ranks last among financial risk factors with 13% (Figure 4).

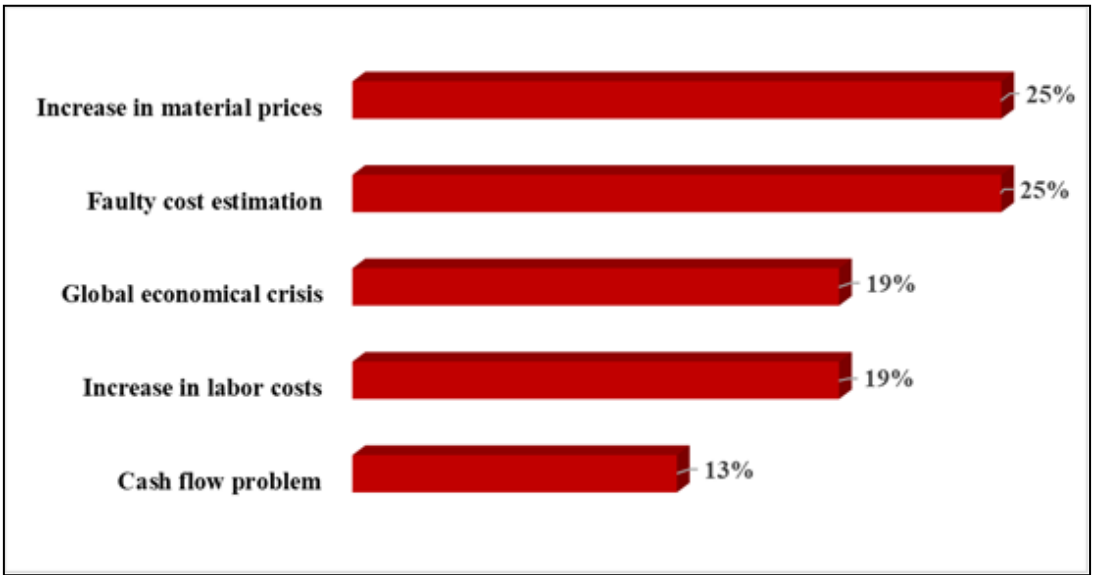

Figure 4: Ranking of financial risks according to risk scores.

In terms of risk scores, construction risks are the most effective risk group after organizational and financial risk groups. Among the risk factors constituting construction risks, occupational accidents resulting in death or serious injury and faulty construction practices were determined as the most effective construction risks with a rate of 22%. In the third and fourth rank, there

are the risks of occupational accidents resulting in moderate and mild injuries and problems in final admission (Figure 5).

Figure 5: Ranking of construction risks according to risk scores.

The project was planned with the help of PRA software and the basic processes of the project were determined as design, contract, site delivery, rough construction works, finishing works, mechanical works, electrical works, landscape works and control/delivery process. If the risks are not taken into account as a result of the planning, it is foreseen that the project will be completed in 904 days and with a cost of 107,197,703 TL. The durations, costs and planned start and end dates of these processes are listed in Table 2.

Table 2. The durations, costs and planned start and finish dates of the processes.

Project Main Processes	**Activity Duration (Day)**	**Planned Start Date**	**Planned Finish Date**	**Activity Cost (TL)**
Design	97	16.01.2017	22.04.2017	₺2,015,000
Contract	25	24.03.2017	17.04.2017	₺20,00
Site Delivery	50	18.04.2017	6.06.2017	₺90,00
Rough Construction	509	7.06.2017	28.10.2018	₺31,632,194
Finishing Works	833	16.01.2017	28.04.2019	₺32,232,337
Mechanical Works	510	2.09.2017	24.01.2019	₺11,776,523
Electrical Works	596	6.09.2017	24.04.2019	₺14,608,349
Landscape Works	110	28.01.2019	17.05.2019	₺3,100,000
Project Control and Delivery	70	29.04.2019	7.07.2019	₺80,00
General Expenses				₺11,643,300
Total	**904**	**16.01.2017**	**7.07.2019**	**₺107,197,703**

The risks were defined to the relevant project activities in the case study and simulation analysis was carried out with the help of PRA software. The changes that may occur in the project duration as a result of the simulation analysis for the case where the risks are included in the calculation, but no risk measures are taken are shown in Figure 6.

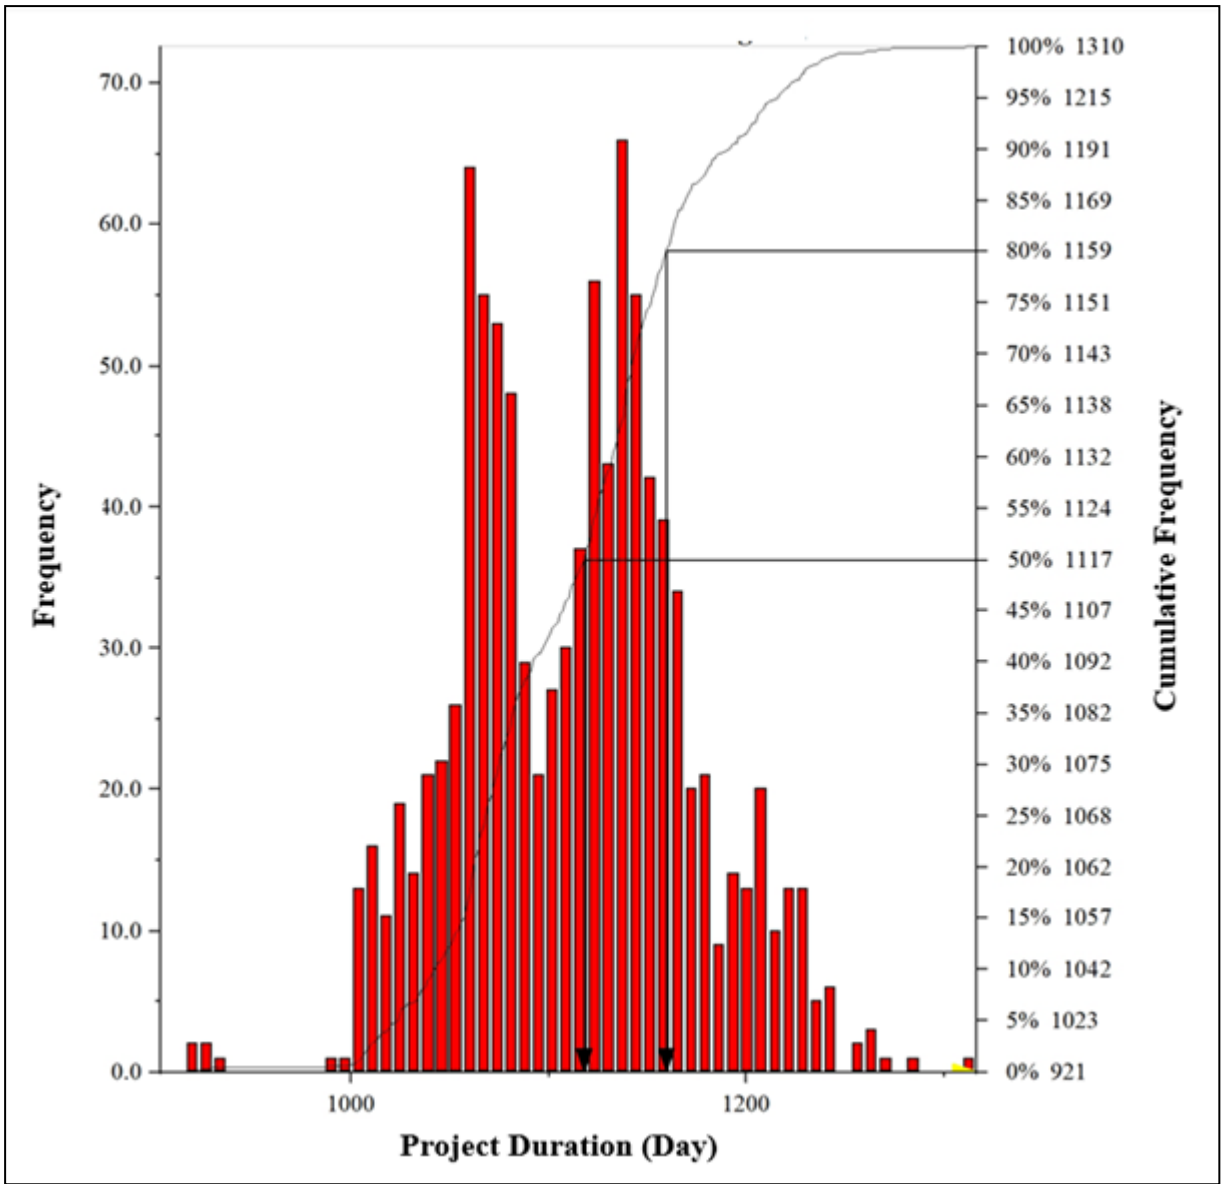

Figure 6: Project duration frequency distribution.

It is seen from the frequency distribution of the duration given in Figure 6 that the probability of completion of the project within the predicted 904 days after the simulation analysis with 1000 iterations under the determined risk effects is less than 1%. Considering the risks, it is predicted that the project can be completed in 1159 days with 80% probability. After the risk assessment, it was determined that the project could be completed in 1310 days at the latest.

As a result of the impact of the risks foreseen for the case study on the relevant activities of the project, it was observed as a result of the simulation analysis that the project cost could vary from 114,194,086 TL to 183,102,029 TL. The cost-frequency distribution obtained as a result of the analysis for the situation where the risks are taken into consideration is shown in Figure 7.

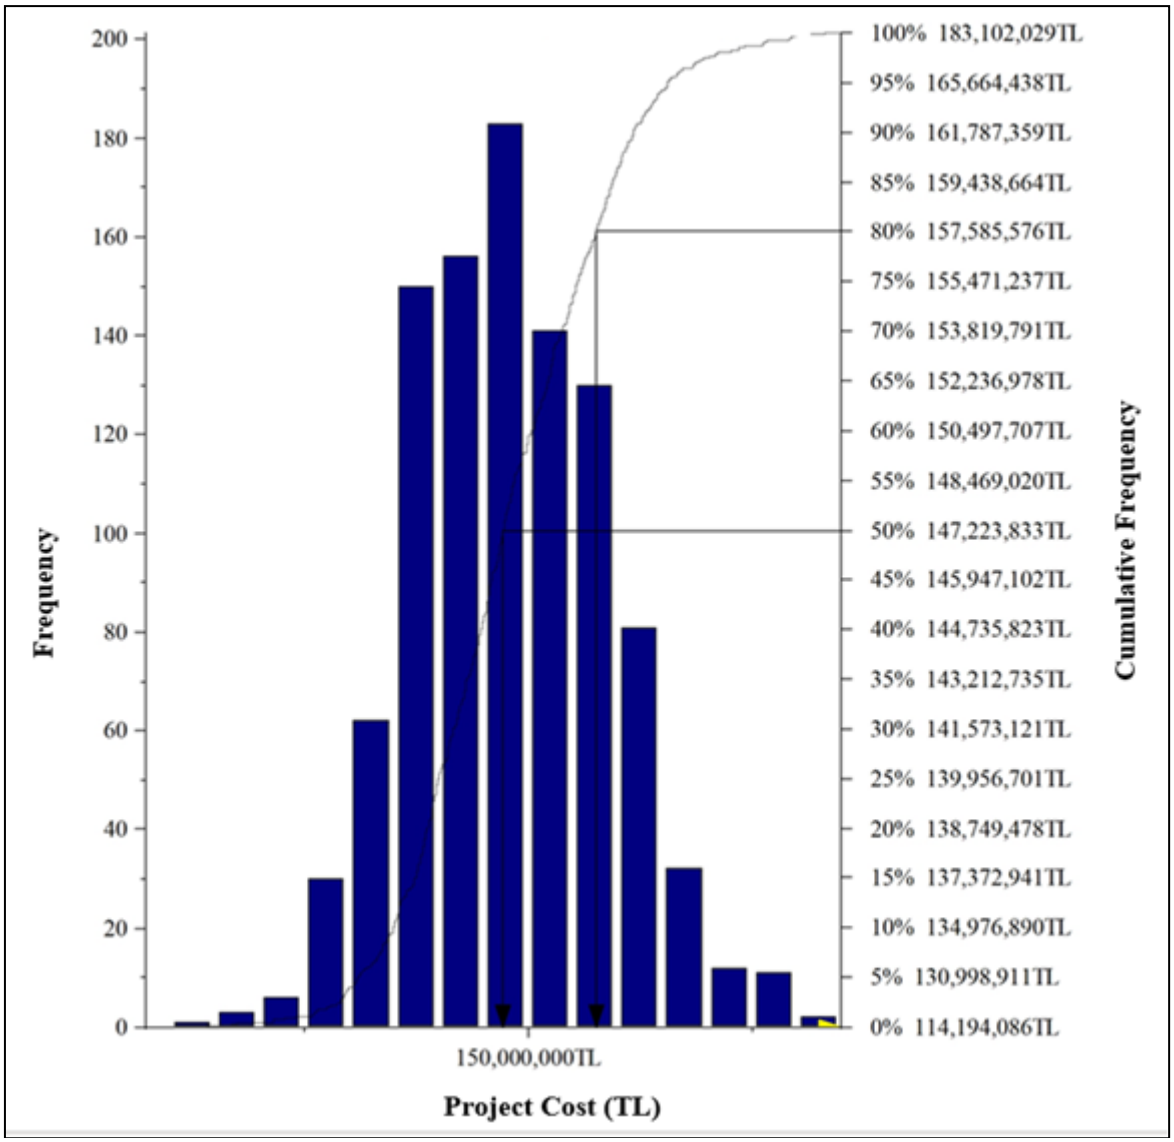

Figure 7: Project cost frequency distribution.

As a result of the analysis made for the scenario where risks are included in the calculation, but no measures are taken against any risk, it is predicted that the project will be completed with a probability of 80% with a cost of 157,585,576 TL. The probability of realization of the cost target of 107,197,703 TL determined for the project during the planning phase is less than 1%, as is the time target. The fact that the probability of reaching the values determined for the time and cost targets is less than 1% indicates that a realistic and accurate planning has not been made for the project.

As a result of the analysis of the project, which was taken as a case study, it was determined that the risks would increase the duration of the project by 28% and the cost by 47% when the projected values for the duration and budget of the project were examined, in the case where the risks were taken into account, but no risk response was given.

Kazaz et al. (2012) stated that the first three factors that affect time and cost overruns in construction projects are financial factors, government effects and labor-related factors, respectively. In 2015, Eker stated that among the internal risks in the construction industry, the

first three risk factors that highly affect the cost are designs that require advanced technology, insufficient information about the place where the project will be built, and faulty construction practices. Among the internal risk factors, it has been revealed that the risk factors that affect the project duration the most are stopping all or part of the work, faulty budget and time planning, and faulty construction practices. It is stated that war, inflation and fluctuations in the exchange rate difference are the external risk factors that affect the cost the most while the risks of war, natural disaster and prolongation of bureaucratic procedures are the first three risk factors that affect the duration the most.

İncir (2003) stated in his study that the most effective risks for the construction sector are economic and financial risks, and as a result of the simulation analysis he made on a case study, the project cost increased by approximately 22%. In the study carried out by Uzuntaş in 2010, a retrofitting project was taken as a case study and simulation analysis was made. As a result of the analysis, it has been revealed that risks can increase the cost of the project by approximately 92%. In a similar study, in which the Marmaray project was considered as a sample project, Abdollahi (2010) stated that as a result of the simulation analysis carried out, the risks could cause a 177% deviation in the project duration and a 50% increase in the project cost. In 2015, Türker conducted a study to investigate the effects of risks on the time and cost of a 13-floor housing project. At the end of the study, it was estimated that risks could increase the duration of the project by 34% and the cost of the project by 12%.

As the common point of different studies, it is seen that the most effective risk factors in the time and cost performance of projects are financial risks. The results of the study also show that the risks cause the construction projects to exceed the time and cost targets at a high rate. Considering this situation, it is understood that an effective risk management is inevitable for the successful conclusion of construction projects.

Results

The aim of this study is to determine the most effective risks for construction projects and to investigate their effect on time and cost targets. For this purpose, a risk analysis of a housing project, which was taken as a case study, was made and the results were examined. The findings revealed that the most influential risk factors for construction projects are financial, organizational and construction risks. Considering only the time and cost target in the risk analysis constitutes the limitation of this study.

It is thought that the numerical data obtained from this study will shed light on risk management for project owners and managers, especially in small-scale construction projects. In addition, it is thought that future studies with different types and sizes of construction projects will reveal the relationships between the main factors affecting risk management in construction projects and contribute to the development of risk management practices in construction projects.

Abstract

Technological developments, the increase in the world population and the rapid change in customer needs have increased the competitive environment in the construction sector. The highly competitive environment makes risk management mandatory for construction companies. Construction projects are exposed to many risks due to their unique structure. A successful risk management requires a realistic assessment of these many risks and the determination and implementation of appropriate strategies. Within the scope of the study, firstly, the risks that may be encountered in construction projects were determined and grouped through expert opinions and literature review. AHP method, one of the multi-criteria decision-making techniques, was used to prioritize risks. The strategies that can be taken against the identified risks were determined in line with the expert opinions and the TOPSIS technique was used to choose between the strategies that could be applied. It is thought that the obtained model will contribute to decision makers in risk management in construction projects.

Keywords: *AHP, construction Risks, construction Sector, MCDM, risk management, TOPSIS.*

Introduction

In today's rapidly changing, developing, and globalizing world; technological, economic and political changes cause to increasing of uncertainties. In an environment of increasing uncertainty, companies need to understand and successfully implement the risk management system in order to determine their future strategies and achieve their goals and missions. Construction projects are exposed to lots of various risks, from the design stage to the tender process, from construction to delivery, and even to operation processes. These risks cause the construction projects not to be completed in the desired time, at the desired quality and at the determined cost. These risks, which arise in different processes of the project, adversely affect one or more of the project stakeholders if they are not managed effectively. Construction projects that have various risks according to the project structure, size, complexity and construction type; are among the priority project types that risk management should be applied. The aim of this study is to generate a decision support model for the prioritization of the risks frequently encountered in construction projects and the risk strategies that can be applied. For this purpose, initially, based on literature review and expert opinions, construction project risks and measures that can be taken against these risks have been determined. Considering the main objectives of the projects, the ranking of the project risks was carried out through the AHP (Analytical Hierarchy Process) technique. Fuzzy-TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) technique was used to select among the risk measures that can be

applied for prioritized risks. It is thought that the findings can guide risk management practices in the construction industry and foreseen that the developed model can be improved by restructuring for different construction projects in future studies and contribute to the literature.

Risk Management in Construction Projects

Compared to other sectors in the construction sector; scope, quality, time, and cost deviations are observed more frequently. The long-term and complex stages of construction projects, the fact that each project has different characteristics, being under the influence of external factors, it's high cost, diversity of techniques used in construction and dynamic organizational structure cause this situation (Flanagan & Norman, 2003; Akintoye & Macleod, 1997; Smith et al., 2006). Construction projects are carried out with the participation of many stakeholders such as employers, designers, contractors, subcontractors, suppliers. The risks that may affect these participants at different processes and levels, and the effective analysis and management of these risks pose a major challenge for practitioners in the industry (Chatterjee et al., 2018).

Al-Bahar and Crandall (1990) define the risk management process for contractors as follows: Risk management is a set of processes consisting of systematically identifying risks, analyzing identified risks, and developing strategies against risks in order to eliminate, reduce or control risks. Risk management is the systematic application of management policies, procedures and practices, communication, consulting, context and identifying, analyzing, evaluating, processing, monitoring and reviewing risks. The main purpose of risk management is to identify, evaluate and control risks for project success (Hey, 2017; Süllüoğlu, 2019).

When the studies conducted by different researchers on the classification of construction project risks are examined, it is observed that financial, construction, political, design and managerial risks take place in the common denominator. Numerous studies have also been conducted on prioritization of construction project risks. For example, Befrouei and Taghipour (2015) stated in their study that the factors that most affect cost risk are tight programming schedule, increase in material prices and disagreement between stakeholders. In the same study, it was revealed that the factors affecting the time risk the most were the tight programming schedule, design revisions and prolongation of bureaucratic procedures. It has been revealed that tight programming schedule, problem of communication between stakeholders and lack of skilled workforce have a high impact on the quality risk and; is also stated that tight schedule, noise pollution from the construction and the lack of information about the construction site have the highest impact on environmental risks. It has been also stated that the factors that affect the occupational health and safety risk the most are tight work schedule, insufficient security measures and ineffective subcontractor management. In the study conducted by Lin and Chen (2021), the researchers stated that the risk groups that affect the project objectives the most are the contractor, subcontractor and design risks, and the external risks do not have much effect on the project objectives. Insufficient site control, faulty construction, insufficient training to the operators, and lack of knowledge and experience of the design team were the risk factors that most negatively affected the project objectives. On the identification and assessment of sustainable construction project risks, El-Sayegh et al. (2021), 30 risks were classified under management, technical, green team, green material, and economic risk groups. The top 5 risk factors with the highest impact were employer's financing shortage, faulty sustainable design, design changes, tight schedule and faulty scope definition. In another research, a risk analysis was carried out for a construction project in Vietnam, which will be carried out with the design-build delivery method chosen as a case study. Within the scope of the study, a total of 28 risks

were determined and these risks were divided into 5 different groups as political and legal, economic and financial, construction, design, contract and tender risks. As a result of the risk analysis, it has been stated that the top 3 risk factors are delay in project approval, inflation and faulty design-design change factors (Nguyen & Nguyen, 2020).

Ahmadi et al. (2017) developed a decision support model for the selection of risk responses with the help of multi-criteria decision-making techniques, in which they identified risk and risk responses specific to road projects. As a result of the study, the first five risk events that are most effective in the highway project were insufficient budget allocation, delay in payments, increase in tar prices, contractor's equity shortage and sudden price increase in other materials other than tar. For the risk of increase in tar prices; four risk responses have been identified: Allocating an additional budget, developing a new design using compressed concrete instead of tar, accepting price increases, and pre-procurement and storage of tar. As a result of the analysis made by using multi-criteria decision-making techniques among the identified risk responses, it was revealed that the most effective risk response would be a design change.

In their study, Beltrão and Carvalho (2019) developed a decision support model based on the Fuzzy AHP technique in order to create a risk breakdown structure for public construction projects in Brazil and to prioritize construction risks. Within the scope of their studies, they identified 54 risks under 8 main risk groups. From 8 main risk groups, including social, project, construction, financial, economic, political, environmental, and managerial risks; it has been revealed that the most effective risk group were project and political risks. The most effective project risks were identified as bid package and contract deficiencies, cost underestimation or overestimation and design errors. It was stated that the risks of corruption, bureaucracy and political interference were the risks with the highest impact within the political risk group. Based on risk factor, it was stated that the three most effective risks were, respectively, difficulty in environmental licensing, design revision request during construction and corruption risk.

Methodology

Due to the characteristics of construction projects, the importance of risk management practices in construction projects is increasing day by day. The stages of identifying and analyzing risks, developing strategies against risks and monitoring risks constitute the risk management process. As in all sectors, it is critical to identify risks and create response strategies for risk management in construction projects. Within the scope of this study, a hybrid decision support model based on the AHP-Fuzzy TOPSIS technique has been developed in order to identify and prioritize risks and risk responses. In the first part of the study, risk and risk strategies were determined in line with expert opinion and literature review. The identified risks have been weighted with the help of the AHP technique, taking into account the cost, duration, quality, sustainability and occupational health and safety criteria determined as the main objectives of the construction projects. After the weighting of the project risks, the Fuzzy-TOPSIS technique was used for the selection of the determined risk measures. The flow chart of the study methodology is given in Figure 1.

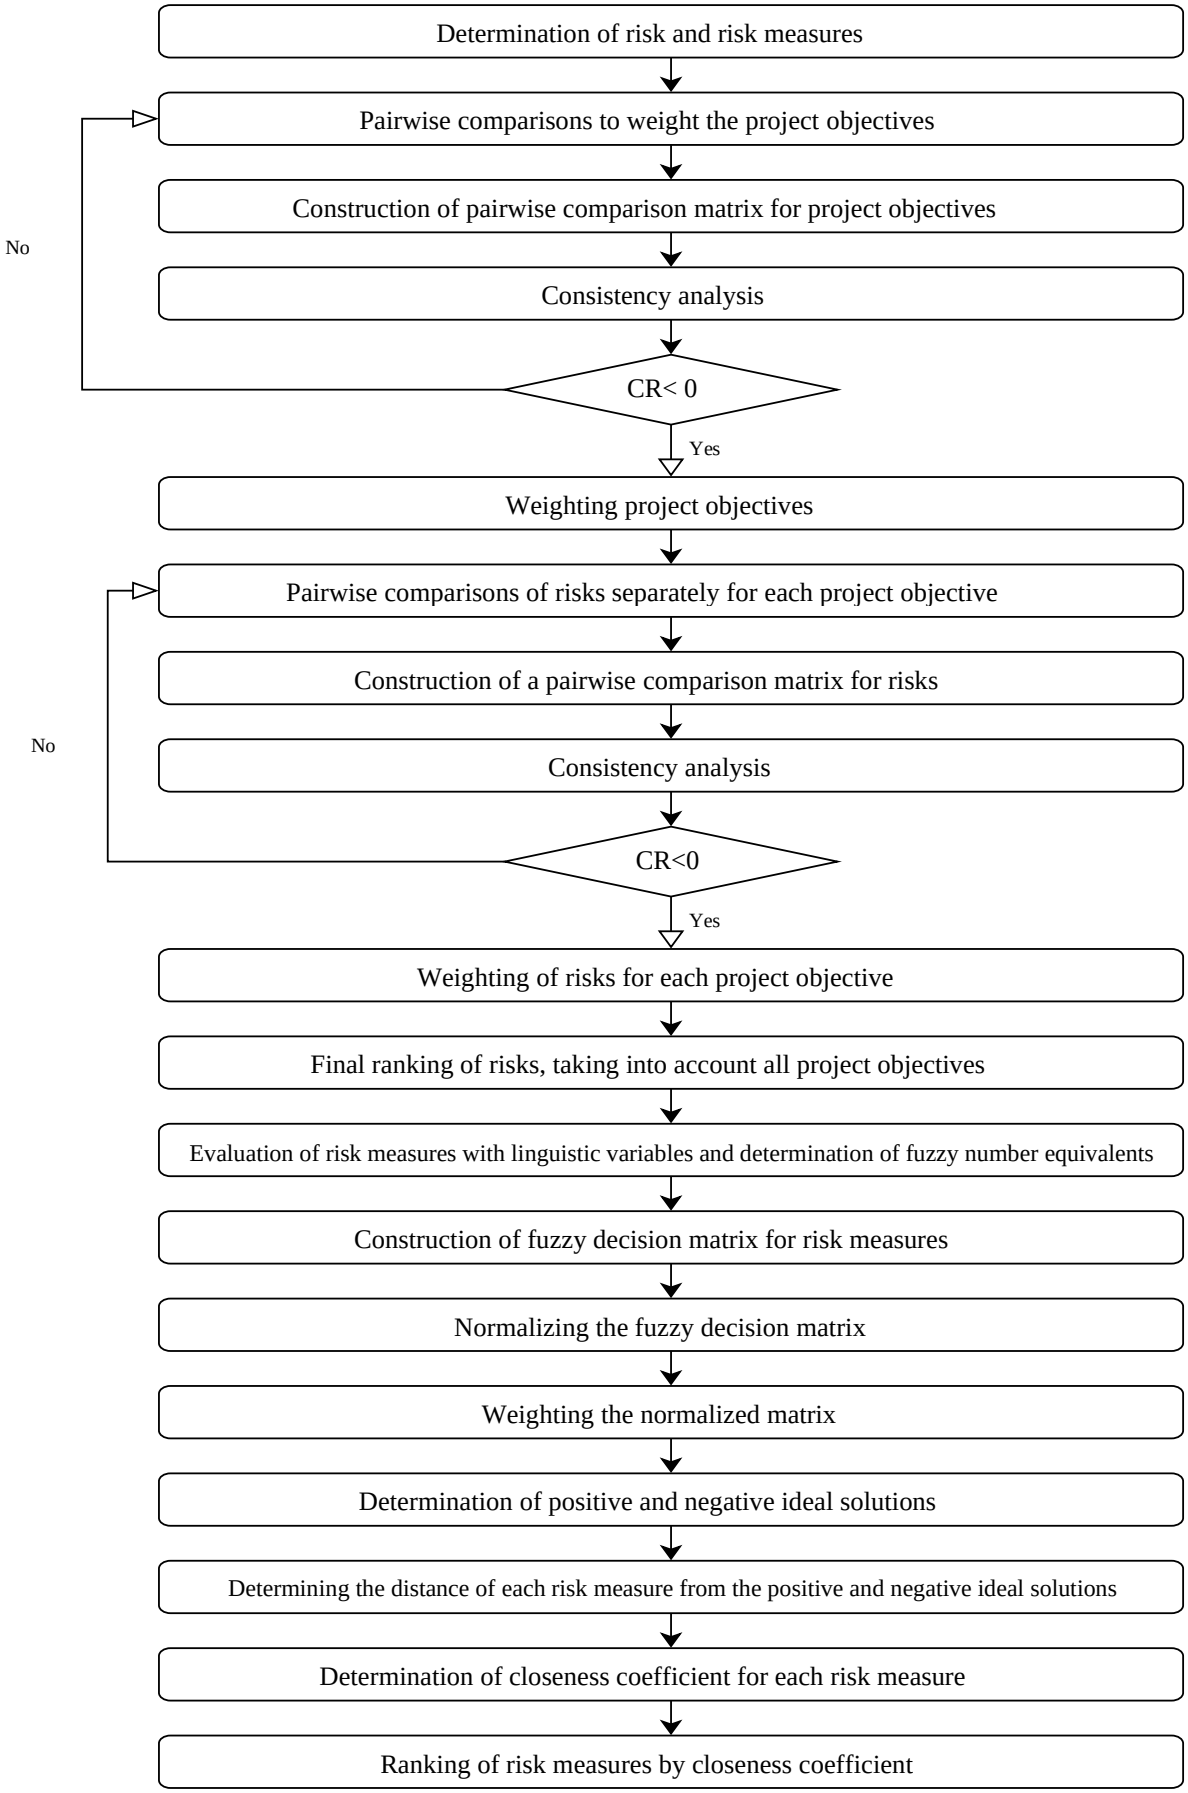

Figure 1: Framework for risk and risk measure prioritization by the proposed model.

Findings and Discussion

In the light of the results of the literature research on the determination and classification of risks in construction projects and the expert opinions; 7 main risk groups were determined as design risks, contractual risks, political risks, financial risks, management and organizational risks, construction risks and environmental risks (Table 1). As shown in Table 3, 20 risk measures that can be taken against the risks determined for construction projects have been determined in line with previous studies and expert opinion.

Table 1. Risk classification and explanations.

Risk Code	Risk Classification	Risk Explanations
CR01	Design Risks	Incompatibility between design projects, incorrect design, low performance of the design team, design revision demand
CR02	Contractual Risks	Lack of contract documents, Uncertainty in contract clauses, Unbalanced responsibility (risk) distribution, Unclear project scope
CR03	Political Risks	Business interruption due to security problems such as War, coup, terrorism, etc., Prolongation of bureaucratic procedures, Embargo and quota applications, Nationwide strike
CR04	Financial Risks	Cash flow shortage, incorrect cost estimation, increase in materials and labor prices, economic crisis
CR05	Management and Organization Risks	Delayed management decisions/approvals, Wrong selection of contractor/subcontractor/consultant firm, Wrong supplier selection, Selection of contract type that is not suitable for the project, Low performance of the project team, Ineffective/Insufficient organizational structure, Stakeholder communication problem, Layout plan problem, Incorrect/insufficient planning
CR06	Construction Risks	Faulty construction practices, Poor quality of material/equipment , Incorrect construction technique / method, Geological problems, Low labor force performance, Occupational accident, Insufficient material/equipment
CR07	Environmental Risks	Adverse weather conditions, Natural disasters (earthquake, flood, erosion, fire, etc.), Ecological damage potential, Epidemics

Table 2. Measures against risks.

Risk Measure Code	Risk Measures
RM1	Artificial Intelligence Based Decision Support Systems
RM2	Detailed examination of contract clauses/ consultancy for the preparation of contracts
RM3	Checking on -site feasibility
RM4	Keeping good relations with bureaucratic structures
RM5	Detailed preparation of insurance policies
RM6	Effective market analysis and good feasibility study

RM10	Including the escalation condition in the contract
RM11	Performing Life Cycle Analysis
RM12	Influencing risk premiums on business items
RM13	Adopting the lean management understanding
RM14	Effective procurement and resource planning
RM15	Organizing events to increase productivity
RM16	Ensuring regular and effective construction site/project control
RM17	Providing regular and effective trainings to employees

RM18	Accurate information of employees on OHS and taking optimum OHS measures
RM19	Clear Determination of the Scope of the Project
RM20	Defining force majeure clearly and accurately in contracts, adding clauses about cost increase and delays caused by natural disasters

The main targets set for the successful conclusion of construction projects generally consist of cost, time, quality and safety criteria. Considering the energy crisis, which the critical importance of it continues to increase in recent years, it is clearly seen that it would be more beneficial to include the sustainability criterion among the success targets of construction projects. Within the scope of this study, cost, time, quality, occupational health and safety and sustainability criteria for construction projects have been determined as criteria to be considered for a successful project. Within the scope of the study, initially, the weights of these criteria were tried to be determined. In the weighting of the criteria, AHP technique was used in line with the expert opinion.

AHP was developed by Thomas L. Saaty in 1977 and provides a structured approach to the determination of multiple criteria and importance levels. AHP is mainly based on pairwise comparisons of criteria. In this study, project risks were accepted as criteria, and measures that could be taken against risks were accepted as alternatives. AHP technique was used to prioritize risks (criteria) and, Fuzzy-TOPSIS technique was used in the selection of risk measures (alternative). The pairwise comparison scale used to prioritize risks according to project objectives is given in Table 3.

Table 3. Pairwise comparison scale (Saaty, 1990).

Importance level	**Value Definitions**	**Description**
1	Equality	Each activity contributes equally.
3	Less important	As a result of experience and evaluations, an activity is a little more preferred than the other.
5	Quite important	As a result of experience and evaluations, one activity is much more preferred than the other.
7	Very important	An activity is preferred very strongly compared to the other.
9	Highly important	An activity is preferred as the highest possible degree compared to the other.
2,4,6,8	Intermediate values	If words are insufficient to make an assessment, a value in the middle of numerical values is given.

The comparison matrix used for the weighting of the project objectives, the normalized matrix and the weights of the project objectives are shown in Table 4 and Table 5.

Table 4. The comparison matrix of the priority of the project objectives.

	Cost	**Time**	**Quality**	**Sustainability**	**Safety**
Cost	**1.00**	3.00	7.00	8.00	4.00
Time	0.33	**1.00**	5.00	8.00	3.00
Quality	0.14	0.20	**1.00**	4.00	0.33
Sustainability	0.13	0.13	0.25	**1.00**	0.25
Safety	0.25	0.33	3.00	4.00	**1.00**

Table 5. Normalized comparison matrix and criterion weights of project objectives.

	Cost	Time	Quality	Sustainability	Safety	Weight	Ranking
Cost	0.54	0.64	0.43	0.32	0.47	0.48	1
Time	0.18	0.21	0.31	0.32	0.35	0.27	2
Quality	0.08	0.04	0.06	0.16	0.04	0.08	4
Sustainability	0.07	0.03	0.02	0.04	0.03	0.04	5
Safety	0.14	0.07	0.18	0.16	0.12	0.13	3

In order to evaluate the consistency of pairwise comparisons in the AHP technique, the consistency index (CI) should be determined, and the consistency ratio (CR) should be below 0,10. The equations given below are used to calculate the consistency index and consistency ratio (Yıldırım & Önder, 2014).

$$CI = \frac{\lambda_{max} - n}{n-1} \quad (1)$$

$$CR = \frac{CI}{RI} \quad (2)$$

λmax, which will be used in the calculation of the consistency index and consistency ratio, indicates the largest eigenvalue of the matrix, n indicates the number of criteria, and RI indicates the random index. The consistency ratio (CI) in ranking the project objectives was found to be 0.070 and it was accepted because it was less than 0.10. It has been determined that the most important criterion among the project objectives was the cost and, the cost criterion is followed by time, OHS, quality and sustainability factors, respectively. The processes followed in the sequence of the project target criteria were also applied in the prioritization of the risks for each project target separately. The risk rankings obtained as a result of considering each project objective separately are given in Table 6.

Table 6. Ranking of construction project risks in line with the project objectives.

Project Target	Risk Code	Project Risks	Weight	Ranking	Consistency Rate
Cost	CR04	Financial Risks	0.41	1	**0.062 < 0,10**
	CR05	Man. and Org. Risks	0.24	2	
	CR06	Construction Risks	0.14	3	
	CR01	Design Risks	0.08	4	
	CR03	Political Risks	0.07	5	
	CR07	Environmental Risks	0.04	6	
	CR02	Contractual Risks	0.02	7	
Time	CR05	Man. and Org. Risks	0.37	1	**0.040 < 0.10**
	CR04	Financial Risks	0.30	2	
	CR06	Construction Risks	0.14	3	
	CR01	Design Risks	0.08	4	
	CR02	Contractual Risks	0.04	5	
	CR07	Environmental Risks	0.03	6	
	CR03	Political Risks	0.03	7	
Quality	CR06	Construction Risks	0.36	1	**0.042 < 0.10**
	CR05	Man. and Org. Risks	0.25	2	
	CR04	Financial Risks	0.19	3	
	CR01	Design Risks	0.09	4	
	CR02	Contractual Risks	0.05	5	
	CR07	Environmental Risks	0.03	6	
	CR03	Political Risks	0.02	7	

Sustainability	CR07	Environmental Risks	0.33	1	**0.095 < 0.10**
	CR01	Design Risks	0.22	2	
	CR04	Financial Risks	0.19	3	
	CR05	Man. and Org. Risks	0.12	4	
	CR06	Construction Risks	0.08	5	
	CR02	Contractual Risks	0.03	6	
	CR03	Political Risks	0.02	7	
Safety	CR06	Construction Risks	0.39	1	**0.091 < 0.10**
	CR05	Man. and Org. Risks	0.25	2	
	CR07	Environmental Risks	0.15	3	
	CR01	Design Risks	0.10	4	
	CR04	Financial Risks	0.05	5	
	CR02	Contractual Risks	0.04	6	
	CR03	Political Risks	0.02	7	

Consistency ratios for the pairwise comparisons of risks, which were made by considering each project objective, were calculated as less than 0.10 and the ranking of the risks was carried out. In the continuation of the study, a final ranking was made for the risks by using the project target weights for the case where all the project objectives are considered together. As shown in Table 7, in the risk ranking made for the situation where all of the cost, time, quality, OHS and sustainability targets are included; It is seen that financial, management and organization and construction risks have critical importance and taking precautions against these risks will contribute to the successful conclusion of the projects. It is also thought that financial risks may have a much more critical importance for construction projects, especially for developing countries whose economic stability has not been ensured. It is estimated that financial difficulties have the highest impact among the identified risks as they can cause both managerial problems and poor construction quality. Management and organizational risks, on the other hand, were thought to be caused by the traditional management approach away from the use of information technologies, inadequate decision mechanisms and the lack of competent personnel. It is assumed that the first two risk groups will seriously affect the construction risks. It is believed that unstable cash flow, poor site order and inadequate site control will adversely affect construction quality, especially material and equipment quality. In addition, it is thought that the irregular site environment and the lack of OHS, and technical knowledge will increase the probability of occupational accidents, and this could have a negative effect on the construction process.

Table 7. Final risk ranking.

Risk Code	Risk	Weight	Ranking
CR04	Financial Risks	0.31	1
CR05	Man. and Org. Risks	0.27	2
CR06	Construction Risks	0.19	3
CR01	Design Risks	0.09	4
CR07	Environmental Risks	0.06	5
CR03	Political Risks	0.04	6
CR02	Contractual Risks	0.03	7

For a successful risk management determining the measures to be taken against the risks and monitoring the risks are inevitable as identifying and classifying risks. In this part of the study, it is aimed to determine the most appropriate risk measures for the prioritized risks. For this purpose, risk measures were accepted as an alternative and Fuzzy TOPSIS technique was used for the most ideal alternative selection. As the first step in the evaluation of alternatives; expert opinion was sought on how effective the risk measures were for the identified risks through the

linguistic variables shown in Table 8. A fuzzy decision matrix was created in line with the views received using triangular fuzzy numbers.

Table 8. Linguistic variables and triangular fuzzy number equivalents in alternative evaluation (Chen, 2000).

Linguistic Variables	**Triangle Fuzzy Numbers**
Very Good (VG)	(9,10,10)
Good (G)	(7,9,10)
Medium Good (MG)	(5,7,9)
Fair (F)	(3,5,7)
Medium Poor (MP)	(1,3,5)
Poor (P)	(0,1,3)
Very Poor (VP)	(0,0,1)

By using the fuzzy decision matrix, a normalized fuzzy decision matrix is obtained, and the matrix is denoted by "*R*" and expressed by $R = [r_{ij}]_{mxn}$. The equation shown in (3) and (4) was used for the normalization process of fuzzy decision matrix (Türkben, 2022).

$R = [r_{ij}]_{mxn}$ i =1, 2, …. m; j = 1,2, …. n ;

$$r_{ij} = \left(\frac{a_{ij}}{c_j^*}\ \frac{b_{ij}}{c_j^*}, \frac{c_{ij}}{c_j^*}\right) \quad c_j^* = max_i c_{ij} \tag{3}$$

$$r_{ij} = \left(\frac{a_j^-}{c_{ij}}\ \frac{a_j^-}{b_{ij}}, \frac{a_j^-}{a_{ij}}\right) \quad a_j^* = min_i a_{ij} \tag{4}$$

Weighted normalized decision matrix is created, since each existing criterion has different degrees of importance. The equation shown in (5) was used to determine the elements of this matrix (Türkben, 2022).

$$V = \left[v_{ij}\right]_{mxn} \quad v_{ij} = r_{ij}\ x\ w_j \tag{5}$$

The values of FPIS (A^*), which is the fuzzy positive ideal solution, and FNIS (A^-), which is the fuzzy negative ideal solution, are shown in (6) (Chen, 2000).

$$A^* = (v_1^*, v_2^*, \ldots, v_n^*)\ v_j^* = (1,1,1)\ v_j^- = (0,0,0) \tag{6}$$

For each of the alternatives, their distances from the fuzzy positive ideal solution and the fuzzy negative ideal solution are determined. The distance to FPIS (A^*) and FNIS (A^-) is given in (7).

$$d_i^* = \sum_{j=1}^{n} d\left(v_{ij}, v_j^*\right) \qquad d_i^- = \sum_{j=1}^{n} d\left(v_{ij}, v_j^-\right) \tag{7}$$

Closeness coefficients are used to rank the alternatives whose results are obtained. For each alternative, the closeness coefficients CC_i are determined by using the formula in (8) separately.

$$CC_i = \frac{d_i^-}{d_i^* + d_i^-} \tag{8}$$

Finally, the alternative selection process was completed by sorting all the alternatives from the largest to the smallest according to their closeness coefficients. Weighted normalized fuzzy decision matrix, FPIS (A^*), FNIS (A^-), and closeness coefficient (CC_i) are shown in Table 9.

Table 9. Weighted normalized fuzzy matrix and closeness coefficients.

Risk Measures	CR01 (%9)	CR02 (%3)	CR03 (%4)	CR04 (%31)	CR05 (%27)	CR06 (%19)	CR07 (%6)	FPIS (A^*)	FNIS (A-)	CC_i

Table 10. Final ranking on risk measures.

Code	Risk Measures	Ranking
RM8	BIM -based project management	1
RM1	Use of artificial intelligence-based decision support systems	2
RM7	Effective and realistic planning/work program	3
RM14	Proper procurement and resource planning	4
RM13	Adopting the Lean Management Understanding	5
RM16	Ensuring regular and effective construction site/project control	6
RM15	Organizing events to increase productivity	7
RM12	Influencing risk premiums on business items	8
RM19	Defining the project scope clearly	9
RM20	Defining force majeure clearly and accurately in contracts, adding articles about cost increase and delays caused by natural disasters	10
RM10	Including the escalation condition in the contract	11
RM5	Detailed preparation of insurance policies	12
RM2	Detailed examination of contract articles / consulting for the preparation of contracts	13
RM3	Checking the applicability/feasibility on site	14
RM6	Effective market analysis and proper feasibility study	15
RM9	Ensuring the reliability of credit institutions	16
RM11	Performing Life Cycle Analysis	17
RM18	Accurate information of employees on OHS and taking optimum OHS measures	18
RM17	Providing regular and effective trainings to employees	19
RM4	Keeping good relations with bureaucratic structures	20

When the final ranking of risk measures is examined, it is seen that the first five risks that can be most effective against risks are: BIM-based project management, use of artificial intelligence-based decision support systems, effective and realistic work schedule, effective procurement and resource planning and lean management approach (Table 10). In the light of the findings, it was concluded that the rapid change of technology and globalization can increase the risks of construction projects. However, these rapid changes can also provide

facilitating access to information, achieving a systematic and effective decision-making and management environment with the help of technologies such as artificial intelligence, virtual reality, cloud systems, etc. Considering these benefits; it is thought that the increase in the pace of globalization and technological development can be used as a powerful tool for measures to be taken against risks and more successful construction projects can be realized.

Results

This research aimed to develop an AHP-Fuzzy TOPSIS-based decision support model to identify and prioritize general risks related to construction projects and to choose between the measures that can be taken against these risks. Within the scope of this study, all project objectives were considered as a whole in the prioritization of risk and risk measures. A holistic approach has been tried to be achieved by including sustainability and safety objectives in addition to the basic project objectives such as cost, time, and quality in the developed model. The results of the study revealed that the risk group with the highest impact for construction projects is financial risks, while managerial and construction risks follow financial risks. The study also demonstrated that; BIM supported project management, the use of artificial intelligence-based decision support systems, realistic and effective work schedule, solid procurement and resource planning and the adoption of lean management approach are the most effective measures that can be taken against risks.

It is foreseen that the model developed within the scope of this study and the information obtained can guide the sector on risk management practices and contribute to the literature. Addressing construction project risks at a general level, failure to evaluate risk impact and probability levels separately, not considering sub-risk factors in the risk breakdown structure; constitutes the limitations of this study. In future studies, it is predicted that these limitations can be eliminated, and the model can be applied for specific construction projects by supporting artificial intelligence technologies.

Stress-Performance Relationship in Architectural Offices: The Effect of Covid-19 Pandemic

M. Karabaş and A. Köksal
Yildiz Technical University, Department of Architecture, İstanbul, Turkey
miraykarabas@gmail.com, almula@yildiz.edu.tr

Abstract

Construction industry is among the sectors with high organizational stress levels due to its structure. High stress levels affect not only work performance but also the success of the projects. In addition, the Covid-19 pandemic, which emerged in China in December 2019 and spread rapidly all over the world, has greatly affected the lives of employees. The purpose of this study is to investigate the effect of the Covid-19 pandemic on the stress-performance relationship of architectural office employees. The survey was conducted to 55 architects in Turkey and the outcome was analyzed in SPSS. In the relevant literature, the stress-performance relationship has been discussed with four different models: positive relationship, negative relationship, inverted U-shaped relationship and non-relationship models. As expected, the stress-performance relationship was positive in the pre-Covid-19 (ß=.52, p<.01) but interestingly it reversed in the Covid-19 period (ß=-.45, p<.01). Research outcome indicates that with the Covid-19 pandemic, the stress (t_{54}=9.88, p<.05) and performance (t_{54}=2.87, p<.05) levels of employees decreased compared to pre-Covid-19 period. Even though they both decreased, they did not decrease at the same magnitude. It is expected that the outcome of this study will contribute to develop strategies to increase the performance of employees.

Keywords: *Architectural offices, Covid-19 pandemic, organizational stress, job performance.*

Introduction

Stress has originated from the Latin Word "estrictia". Starting from the 17th century, it was used in the sense of disaster, trouble, grief and then power and pressure (Güçlü, 2001). With its meaning in psychology, the concept was first discussed in 1936 by Hans Selye, who was called the father of stress (Senaratne & Rasagopalasingam, 2017). Selye (1976) defines stress as the body's response to a demand directed at the person. However, he states that it does not matter whether this demand arises from positive or negative conditions.

Today, workplaces where people spend most of their time have turned into uncertain environments with intense competition for employees (Güçlü, 2001). Uncertainty in organizations causes stress in employees (Şimşek et al., 2001). Organizational stress can occur as a situation that excites, disturbs, or puts pressure on the person (Saikala & Selvarani, 2015). Organizational stress which is among the most common work-related health problems

in Europe, has become an important issue for many industries in recent years (Leung et al., 2015).

Construction industry is among the high-stress industries due to task complexity, multi-stakeholder structure, communication problems between stakeholders and various business processes (Enshassi & Al-Swaity, 2015). In addition, tight deadlines, limited resources, and long working hours also play an important role in increasing the stress levels of the employees (Bowen et al., 2014). According to the research conducted by Great Place to Work (2020), which includes various sectors from 13 countries including Austria, Denmark, France, Greece, Germany, Italy, Norway, Sweden, Spain, Switzerland, Netherlands, Turkey and England, construction industry is the sector with the highest stress level. In addition, pressure in tight project delivery deadlines and long working hours are the most important factors causing work-related stress.

Regardless of the positions in the organizations, certain amount of stress is expected in construction industry (Soni, 2014). Architectural offices, one of the main stakeholders of the sector, are also involved in all stages of projects from the initiation stage and have high work-related stress for their employees.

Covid-19 disease, which emerged in Wuhan, China in December 2019 and spread all over the World, was defined as a pandemic by the World Health Organization (WHO) on March 11, 2020, (Hamouche, 2020). With the Covid-19 pandemic, working conditions of many businesses changed, and employees experienced remote working (Bouziri et al., 2020). This change has greatly affected the social and professional lives of people (Tekin, 2020). According to a study conducted by Akça and Tepe Küçükoğlu (2020), the remote working model causes people to spend a lot of time in the same environment, restricting their social lives and increasing their stress levels. An increase in the stress level can result in a decrease in employee performance (Serinikli, 2021).

In this context, the aim of this study is to examine the effect of Covid-19 pandemic on the organizational stress-job performance relationship of architectural office workers. The study targets the construction industry as a sector and architectural offices in particular. The population in this study are architects working in architectural offices operating in Turkey. A survey was conducted to 55 architects to measure organizational stress and job performance. The outcomes were analyzed with SPSS.

It is anticipated that this study will raise awareness about the effect of Covid-19 on the relationship between organizational stress and job performance in architectural office managers and office owners. With this awareness, managers are expected to develop strategies to increase employee performance and to create a win-win situation in the manager-employee relationship. This improvement which will take place at the office level, will also contribute to the construction industry.

Organizational Stress and Job Performance Relationship

Stress, which is among the concepts adopted by industrialized societies, is the effort of a person by pushing her/his physical and psychological limits due to unsuitable conditions (Cüceloğlu, 2002). The employee tends to experience stress when the employee's competence does not match the expectations and the requirements of the job (Colligan & Higgins, 2006).

Organizational stress has great importance as a factor that affects the behavior of individuals, relationships with people and productivity (Korkut, 2014).

Although it is generally believed that there is a negative relationship between organizational stress and job performance, this relationship is much more complex (Riggio, 2014). In the relevant literature, the stress-performance relationship is explained with four different assumptions: positive, negative, inverted U-shaped relationship and non-relationship models. According to the positive relationship model, there is a positive linear relationship between stress and performance. Low stress level cannot activate the person, it will result in low performance, while the person's performance will increase with high stress level. In the negative relationship model, there is a negative linear relationship between stress and performance. Accordingly, as the stress level increases, a decrease in the performance is expected. In the inverted U-shaped relationship model (Figure 1), it is assumed that low-level stress will not activate the person and causes low performance in addition to this, excess of stress also causes low performance, because the person will spend all time to cope with stress. In this model, the optimum level of stress is needed for high performance. Finally, in the non-relationship model, it is assumed that there is no significant relationship between stress and performance (Sullivan & Bhagat, 1992). Among these models, in the relevant literature there is a consensus in inverted U-shaped relationship model (Cohen, 1980).

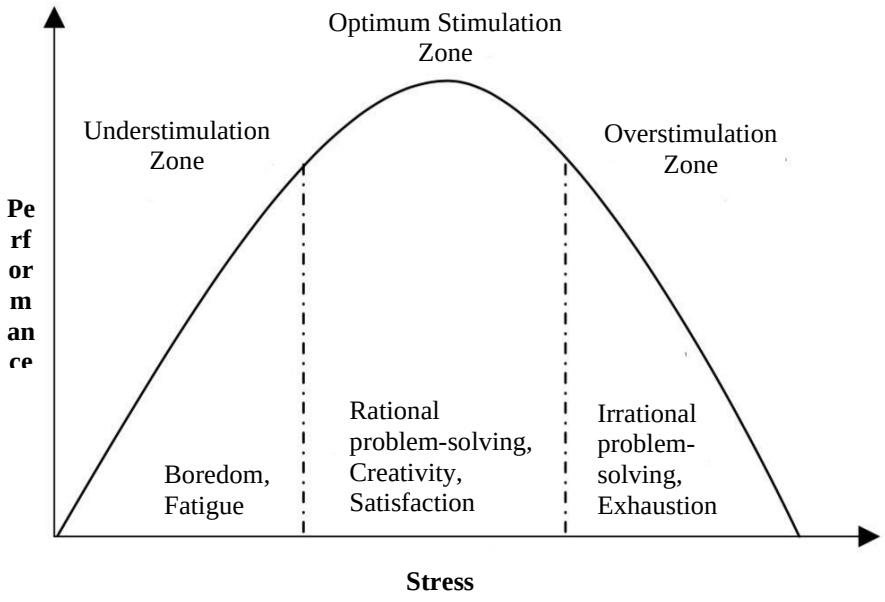

Figure 1: Inverted U-shaped relationship between stress and performance (Leung et al., 2015).

The negative effects of stress have a wave effect, starting from individuals, spreading to family, social environment and then society (Bowen et al., 2014).

Methodology

In this research, a demographic form and three different scales were used to collect data from architects. The *organizational stress scale*, developed by Theorell et al. (1988) and adapted to Turkish by Yıldırım et al. (2011), measures the organizational stress level of architects. The Cronbach Alpha value of this scale was determined as 0.80. The scale consists of 14 items in

a 5-point Likert scale (1=Never and 5=Always). The scale consists of four sub-dimensions: *social support*, *workload*, *skill use* and *decision making*. High scores obtained from the overall scale indicate high stress and low scores indicate low stress. Two negative sub-dimensions on this scale are reverse scored: Social support and decision making. For these two sub-dimensions, high scores indicate low and low scores indicate high social support and decision-making. Ergun's (2008) *job performance scale* was used to measure the job performance levels of architects. The Cronbach Alpha value of the scale was determined as 0.83. The scale consists of 9 items in a 5-point Likert scale (1=Too much and 5=Too few). This scale consists of two sub-dimensions: *job success* and *job satisfaction*. High scores obtained from the overall scale indicate high performance, while low scores mean low performance. Finally, Paşa's (2007) *performance appraisal scale* was used to measure the factors affecting the job performance of the employees. The Cronbach Alpha value of this scale was determined as 0.90. Similar to the first scale, it consists of 14 items in a 5-point Likert scale (1= Strongly disagree and 5=Strongly agree). Considering the Covid-19 pandemic, pre-Covid-19 and Covid-19 period options were added for all the items in the scales, and the participants were asked to make their evaluations for the pre-Covid-19 and Covid-19 period.

Among the three different scales used in this study, Yıldırım et al. (2011)'s organizational stress scale and Ergun (2008)'s job performance scale were associated with the aim of examining the relationship between organizational stress and job performance. In addition, Paşa (2007)'s performance appraisal scale was included in the study to examine the other factors affecting job performance in more detail.

An online survey was conducted to architects working in architectural offices in Turkey in a four-month period between June 2, 2021, and October 2, 2021. A total of 123 questionnaires were responded, 8 of them were left out due to incomplete response. Of the remaining 115 questionnaires, 60 were left out of the scope of this study because the respondents changed their workplace, and the change of stress level could not be measured due to the environment change. Therefore, 55 respondents were included in this study.

While the effect of the Covid-19 pandemic on organizational stress and job performance was examined with two dependent samples t-test, the bilateral relationship between organizational stress and job performance was examined by using correlation analysis. In addition, the factors affecting the performance of the employees were also analyzed with frequency analysis. Statistical analysis was evaluated using the 'SPSS 26.0 for Mac' software program. Demographic characteristics of the participants are given in Table 1.

Table 1. Frequency analysis of demographic profile of participants.

Demographic Variables	**Frequency (f)**	**Percentage (%)**	**SD**
Age			
<30 years	43	78.2	0.52
31-40 years	10	18.2	
41-50 years	2	3.6	
Gender			
Female	41	74.5	0.44
Male	14	25.5	
Education			
Bachelor	37	67.3	0.69

Master's degree (Student)	12	21.8	
Master's degree	6	10.9	
Income Status			
<3000 Tl	3	5.5	0.85
3001-5000 Tl	26	47.3	
5001-7000 Tl	16	29.1	
>7001 Tl	10	18.2	
Total	55	100.0	

The frequency analysis of the participants' working conditions in the pre-Covid-19 and Covid-19 period is given in Table 2. This analysis shows that remote working increased in the Covid-19 period either partially or completely.

Table 2. Frequency analysis of participants' working conditions in the pre-Covid-19 and Covid-19 period.

Working Conditions	**Pre-Covid-19**			**Covid-19 Period**		
	Frequency(f)	**Percentage(%)**	**SD**	**Frequency(f)**	**Percentage(%)**	**SD**
Working in the office every day	51	92.7	0.42	28	50.9	0.84
Working remotely on certain days	2	3.6		13	23.6	
Working remotely every day	2	3.6		14	25.5	

Findings

Organizational Stress Levels in the Pre-Covid 19 and Covid-19 Period

Yıldırım et al.'s organizational stress scale (2008) was used to measure the organizational stress level of the participants. The scale addresses organizational stress with four sub-dimensions: workload, skill use, decision making, and social support. The workload sub-dimension consists of 3 items, including the example statement "Do you have to work too fast?". The skill use sub-dimension consists of 3 items, including the example statement "Does your job require high-level skills and expertise?". Decision-making sub-dimension consists of 2 items, including the example statement "Can you decide on your own how to work in your job?". Finally, the social support sub-dimension consists of 6 items, including the example statement "I get along well with other employees at my workplace". High scores on workload and skill use increase the stress level, while high scores on decision making and social support decrease.

Two dependent sample t-test analysis were applied to measure the organizational stress levels in the pre-Covid-19 and Covid-19 period (Table 3). The analysis indicates that the change in organizational stress level is statistically significant between pre-Covid-19 and Covid-19 period (t_{54}= 9.88 and $p<0.05$). In the Covid-19 period, stress levels of employees decreased. In the sub-dimensions, the workload and skill use levels of the employees decreased, and the social support and decision-making (reverse scoring) levels increased in the Covid-19 period.

Analysis also shows that all sub-dimensions have statistically significant effect on the change in organizational stress, but the effect of social support is the most (t_{54}=11.69 and $p<0.05$).

Table 3. Two dependent sample t-test analysis of organizational stress level in the pre-Covid-19 and Covid-19 period.

Variable		**Mean ($\bar{X}$)**	**SD**	**df**	**t**	**p**
Organizational Stress	Pre-Covid-19	3.77	0.49	54	9.88	0.00
	Covid-19 Period	2.81	0.37			
Sub-Dimensions		**Mean ($\bar{X}$)**	**SD**	**df**	**t**	**p**
Workload	Pre-Covid-19	3.98	0.66	54	3.11	0.00
	Covid-19 Period	3.85	0.73			
Skill Use	Pre-Covid-19	3.76	0.78	54	4.82	0.00
	Covid-19 Period	3.29	0.48			
Decision Making	Pre-Covid-19	3.18	1.06	54	2.09	0.04
	Covid-19 Period	2.63	0.96			
Social Support	Pre-Covid-19	3.87	0.60	54	11.69	0.00
	Covid-19 Period	2.11	0.56			

Job Performance Levels in the Pre-Covid 19 and Covid-19 Period

Ergun (2008)'s job performance scale was used to measure participants' job performance. The scale addresses job performance with two sub-dimensions: job success and job satisfaction. The business success sub-dimension consists of 4 items, including the example statement "Sometimes I make mistakes at work.". The job satisfaction sub-dimension consists of 5 items, including the example statement " Sometimes I am reluctant to go to work.". High scores on job success and job satisfaction increase the job performance.

Two dependent sample t-test analysis were applied to measure the job performance level in the pre-Covid-19 and Covid-19 period (Table 4). The analysis indicates that the change in job performance level is statistically significant between pre-Covid-19 and Covid-19 period (t_{54}= 2.87 and $p<0.05$). Even though, job performance levels of employees decreased in the Covid-19 period, this decrease is not as much as in the organizational stress variable. Analysis also shows that job satisfaction sub-dimension has statistically significant effect on the change in job performance, but job success sub-dimension has no significant effect (t_{54}=1.67 and $p>0.05$).

Table 4. Two dependent sample t-test analysis of job performance level in the pre-Covid-19 and Covid-19 period.

Variables		**Mean ($\bar{X}$)**	**SD**	**df**	**t**	**p**
Job Performance	Pre-Covid-19	3.71	0.75	54	2.87	0.01
	Covid-19 Period	3.53	0.81			
Sub-Dimensions		**Mean ($\bar{X}$)**	**SD**	**df**	**t**	**p**
Job Success	Pre-Covid-19	3.73	0.79	54	1.67	0.10
	Covid-19 Period	3.63	0.80			
Job Satisfaction	Pre-Covid-19	3.69	0.84	54	2.83	0.00
	Covid-19 Period	3.45	0.98			

Organizational Stress and Job Performance Relationship in the Pre-Covid-19 and Covid-19 Period

To examine the relationship between the organizational stress levels of the participants and their job performance, Yıldırım et al. (2011)'s organizational stress scale and Ergun (2008)'s job performance scale were associated. The evaluation of this bilateral relationship was carried out by accepting the inverted u-shaped relationship model, which there is a consensus about in the relevant literature.

The relationship between organizational stress and job performance of the participants in pre-Covid-19 and Covid-19 period was examined by correlation analysis and the results are given in Table 5. If the correlation coefficient is $r<0.2$, as very weak correlation or no correlation, if it is between 0.2-0.4, as a weak correlation, if it is between 0.4-0.6, as a moderate correlation, if it is between 0.6-0.8, as a high correlation and if it is $r>0.8$, it is interpreted as a very high correlation (Prapanjaroensin, 2017).

According to the findings, there is a significant, moderate level and positive relationship between stress and job performance in pre-Covid-19 ($r(55) = -0.52$ and $p<0.01$). In the Covid-19 period, there is a significant, moderate level and negative relationship between stress and job performance ($r(55) = -0.45$ and $p<0.01$). In other words, in this study conducted with the same sample group, while the relationship between organizational stress and job performance was positive in the pre-Covid-19, this relationship was reversed in the Covid-19 period. Outcome of the analysis are not supported by the inverted u-shaped relationship model.

Table 6. Correlation analysis of the relationship between organizational stress and job performance in pre-Covid-19 and Covid-19 period.

Variables		**Mean ($\bar{X}$)**	**SD**	**1**	**2**
Pre-Covid-19	1. Organizational Stress	3.77	0.49	-	0.52**
	2. Job Performance	3.71	0.75	0.52**	-
Covid-19 Period	1. Organizational Stress	2.81	0.37	-	-0.45**
	2. Job Performance	3.53	0.81	-0.45**	-

* $p<0.05$, ** $p<0.01$

Factors Affecting Job Performance

Pasha's (2007) performance appraisal scale was used to examine job performance in more detail. The scale consists of 14 items, including the example statement "Safety of my job affects my performance" and aiming to find the factors that affect the job performance of the participants.

The frequency analysis results of the factors affecting the work performance of the employees in the pre-Covid-19 and Covid-19 period are presented in Table 5. Among the factors affecting the performance of 55 employees in both periods, while item 5 The fairness and respect of my supervisors affect my performance' has the highest average (4.87/4.82), item 13 Competitive opportunity in the workplace affects my performance' has the lowest average (3.55/3.16). However, analysis results show that both in the pre-Covid-19 and Covid-19 period, the greater part of the items in the scale have high degree of impact on job performance.

Table 5. Frequency analysis of factors affecting job performance in pre-Covid-19 and Covid-19 period.

Factors Affecting Job Performance		**Mean ($\bar{X}$)**	**SD**
1. The assurance of my job affects my performance.	Pre-Covid-19	4.35	0.70
	Covid-19 Period	4.29	0.83
2. The salary amount and promotions affect my performance.	Pre-Covid-19	4.55	0.72
	Covid-19 Period	4.56	0.74
3. Personal and professional development opportunities affect my performance.	Pre-Covid-19	4.55	0.72
	Covid-19 Period	4.56	0.76
4. My co-workers affect my performance.	Pre-Covid-19	4.64	0.70
	Covid-19 Period	4.51	0.84
5. The fairness and respect of my supervisors affect my performance.	Pre-Covid-19	**4.87**	0.39
	Covid-19 Period	**4.82**	0.64
6. Being appreciated affects my performance.	Pre-Covid-19	4.69	0.60
	Covid-19 Period	4.56	0.90
7. The opportunity to socialize with my co-workers affects my performance.	Pre-Covid-19	4.15	1.01
	Covid-19 Period	3.95	1.11

	Covid-19 Period	4.49	0.74

Conclusion

In this study, the effect of the Covid-19 pandemic on the organizational stress and job performance levels of architects working in architectural offices and the correlation between these variables are examined. In addition, the factors affecting the performance of employees in pre-Covid-19 and Covid-19 period are also analyzed. The outcome of the analysis indicate that social support, which has the greatest effect on reducing the stress levels of employees increased in the Covid-19 period. This is an interesting result and requires further analysis to be supported because in the relevant literature, it is expected that social support will decrease in the remote working model in the Covid-19 period. The fact that the increase in social support reduces the stress level is coherent with the relevant literature. In addition, the decrease in skill use of people may have reduced their job satisfaction, which is the most important reason for the decrease observed in job performance. The change in the organizational stress - job performance relationship during the Covid-19 process may have resulted from the excessive decrease in the stress level. It was also observed that the Covid-19

pandemic did not influence the factors affecting job performance. As a result of these findings, this study provides an insight into how the stress and performance of employees will be affected in potential future remote working situations. This study is limited to 55 architects working in architectural offices in Turkey. It is expected that this study will be supported by future analyzes. As a result, the performance of the employees will be increased with various strategies to be developed and this improvement at the office level will also have a positive impact on the construction industry as well.

A Bibliometric Analysis of Covid-19 Research in Built Environment Literature

E. Ülkeryıldız
Akdeniz University, Department of Architecture, Antalya, Turkey
evrenulkeryildiz@akdeniz.edu.tr

Abstract

The disaster of "Covid-19 pandemic" which has been introducing various radical changes on the life style of people such as (1) the usage of urban spaces, (2) spatial problems, (3) the transformation of shared spaces and (4) working practices. These radical changes have been receiving an overwhelming interest from scholars from various disciplines since SARS-CoV-2 corona (i.e., Covid 19) virus set a global pandemic. As a result of this overwhelming interest, a rich but a fragment literature prevails on the radical changes caused by Covid 19 pandemic in built environment studies. The research presented herein explores this rich but fragmented literature on the effects of Covid-19 pandemic by adopting a systematic research design strategy namely bibliometric analysis. Bibliometric analysis is a research approach which enables to scholars to map the evolution of a concept, a research theme, a research stream or domain. It uses scholarly data to identify the publication patterns based on authors, research subjects, keywords, geographic locations, and time and source type. A bibliometric analysis of the concept of Covid-19 pandemic presented herein is a timely response to the maturity level the research on the radical changes caused by Covid 19 evolved. The research presented herein offers bibliometric analysis of built environment studies on the disaster of Covid-19 based on 843 scholarly papers published between years 2020 and 2022. The research results reveal that the most commonly used research keywords or subject terms used in these scholarly published scholarly papers include epidemiology, risk assessment, aesthetic values, human activity, and construction projects. It is also observed that research studies predominantly driven by two countries namely US and China. The results of bibliometric analysis also reveal that the main theme of the radical changes caused by Covid-19 pandemic includes housing, spatial, reorganization, neighborhood issues, city planning, and sustainable development and working practices. It is also discovered that the spatial reorganization response of countries to Covid 19 pandemic to varies from country to country mainly due to the regional characteristics of the countries.

Keywords: *bibliometric analysis, Covid-19, pandemic, spatial reorganization, working conditions.*

Introduction

The rapid spread of the Covid-19 pandemic in 2020 has interrupted and transformed our daily life routines and in turn it has profound impact on the built environment. Covid-19 pandemic has unpredictably changed not only the built environment but also our practices and activities

to conceptualize, design and construct it. A wide range of our daily practices has been sharply interrupted, constrained or/and transformed beyond our imaginations. The interruptions, restrictions and transformations observed in our daily practices obviously captured the central agenda of the built environment researchers, like any other researchers. The term "built environment" is a broad concept and in turn a difficult concept to define. It refers "to human-made structures (e.g., urban and rural design characteristics, recreational structures) that may facilitate or impede an individual's ability to be physically active access to the existing built environment has been taken under control all over the world, and measures have been taken for social and economic life by transforming the built environment with short-term solutions" (Gray et al. 2012). It is clear that from this definition that the boundaries of research in "the built environment" is difficult to define. Yet the complex interplay of activities and entities expressed in this definition should be holistically understood and analyze. Failing to appreciate the subtle interplay of these activities and entities can significant slows down scientific progress in the built environment research with respect to the Covid-19 spread.

Wolf (2016) argues that infectious diseases are not the main reason why we are constrained and/or forces to transform our daily life in context the built environment but it is the subtle operation of social and spatial inequalities in access to housing, health, education, economic and other resources. A brief review of the current state of the built environment research reveals that spatial, social and economic inequalities, transformation of values with regarding the built environment, nature of human activity become more visible especially during major pandemics. With a similar foresight, Corburn (2004) points out that there is a clear link between built environment and public health issues and points out that this relationship becomes more evident under conditions of the major pandemics. However, the link between the built environment and major infectious diseases such Covid - 19 has rarely been studied before Covid-19 pandemic (e.g., Alirol et al., 2011; Matthew & McDonald, 2006). But following the Covid - 19 pandemic, analysing and identifying the relationship between the built environment and the Covid - 19 outbreak have become a worldwide research priority (e.g., Amerio et al., 2020; Frumkin, 2021; Megahed & Ghoneim, 2020; Pinheiro & Luís, 2020; Rojas-Rueda & Morales-Zamora, 2021).

Pinheiro and Luís (2020) argue that there has been an increase in the number of publications related to Covid-19 on Web of Science (WoS), and so many references can be found on Science Direct, but less than 1% of them relate to the built environment in 2020. The primary objective of the analyzed research studies in past appears to be on the examination of spatial-temporal variations of Covid-19 in different contexts (Liu et al., 2021). The research studies reports the association between the built environment and Covid-19 pandemic based on variables such as population density (Carozzi et al., 2020; Hamidi et al., 2020), housing (Amerio et al., 2020; Rogers & Power, 2020), social and economic issues (Andersen et al., 2021).

Previous research studies on Covid-19 based on spatial analysis are precious for public health measures. Additionally some researches indicate that social isolation and distancing are important for community responses which provides people to have safe access and secure housing (Rogers & Power, 2020). Furthermore, it reveals the necessity of comprehensive transformations that will ensure spatial justice for all users rather than temporary solutions in the design of the post-pandemic built-environment. For this reason, each situation should be considered, from subjective/local suggestions to spatial problems arising from the pandemic, to consequences that are likely to bring a more inclusive and holistic approach to the built environment from an objective/global perspective. However, this requires a detailed analysis

of every issue discussed in the relevant literature on the Covid -19 pandemic related to the built environment.

The worldwide spread of Covid-19 has resulted in numerous research studies which focus on the identifying the impact of Covid-19 pandemic on the built environment. It is clear that built environment does not have a universal practices, organizations, forms or structures. Therefore, the impact the Covid-19 pandemic and action plans to mitigate its negative outcomes have not been purely identical or generic on contrary they should be context dependent. Various analytical lenses should be used to explore the built environments because the built environments are produced and shaped at different social, political, biological, economic domains and scales. The challenges presented pandemics life Covid-19 can only be address by adopting multiple and different frameworks (Wolf, 2016). Furthermore, the built environment in different parts of the world is affected differently by climatic conditions, life expectancies, water infrastructures, legal regimes, transnational mobility, financial resources, population density, health beliefs and practices, development plans and governance structures (Wolf, 2016).

A critical analysis of the Covid-19 pandemic and built environment research can provide important insights on how the built environment research is positioning itself and developmental trajectory, in particular, sensitivity to local context and the presence of pluralist approach, how the diverse research perspective of the built environment responding to the multiple, complex and highly localized nature of Covid-19.

Analyzing Covid-19 research studies related to the built environment requires an analytical method that fits its purposes. In this study, bibliometric analysis method has been used to examine built environment factors related with the pandemic. Bibliometric analysis is a research approach which enables to scholars to map the evolution of a concept, a research theme, a research stream, or domain. It uses scholarly data to identify the publication patterns based on authors, research subjects, keywords, geographic locations, time, and source type (Ellegaard & Wallin, 2015).

Research Methodology

The objective research presented herein is to conduct a bibliometric analysis on the Covid 19 pandemic in the built environment. The search for the relevant articles was performed at the Scopus database. The search yielded 843 articles published between 2020 and 2022. The search results were analyzed by using bibliometric analysis software (VOSviewer). The research presented herein uses descriptive and quantitative approach to explore the response of built environment research to Covid 19 pandemic and trace the trajectory of emerging research field. It adopts bibliometric analysis method based on articles indexed at Scopus database. The bibliometric analysis method used in the research presented herein was designed in the light of guidelines recommended by Prado et al. (2016). The research design adopted herein includes five main stages: (1) research operation, (2) search procedures, (3) selection procedures, (4) data adequacy and (5) scientific production analysis (Figure 1). The scientific production analysis, Stage 5, is the core bibliometric analysis and yields results in two categories: (1) performance analysis and (2) scientific trajectory mapping. The performance analysis in bibliometric analysis explores the *contributions* of research constituents, whereas scientific trajectory mapping focuses on the *relationships* between research constituents (Donthu et al., 2021). The Boolean operators “AND” and “OR” were

used to identify the relevant articles (Figure 2). The search in the Scopus database was performed through topics including title, keywords and abstract. The topics used in this search process includes: Covid-19, construction industry, architectural and design. Four search filters were also applied: (1) the search will be limited to articles, only; (2) the search time will comprise all the years; (3) the search will be performed in only engineering, social, business, energy, arts, economy and health subject areas; and (4) the search will be conducted in English. The search on Scopus database was performed in July 2022.

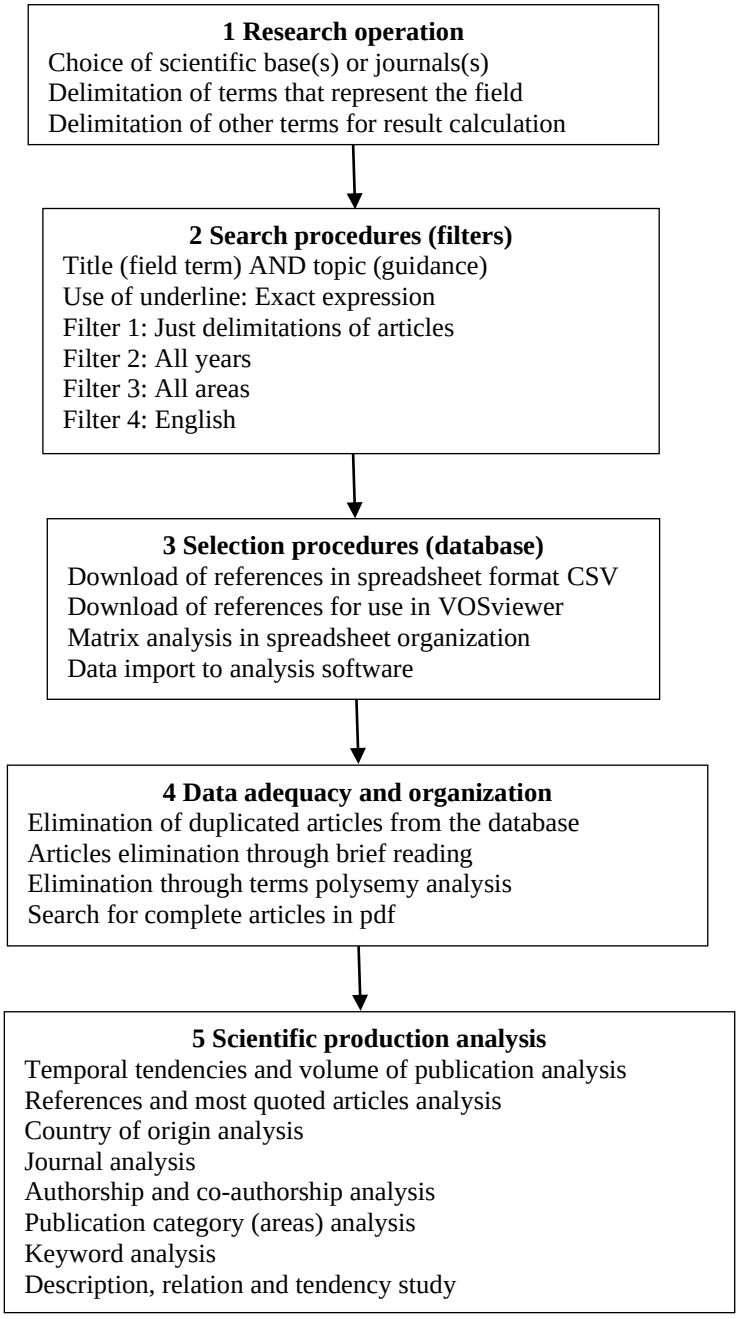

Figure 1: The research design (adapted from Donthu et al., 2021; Prado et al., 2016).

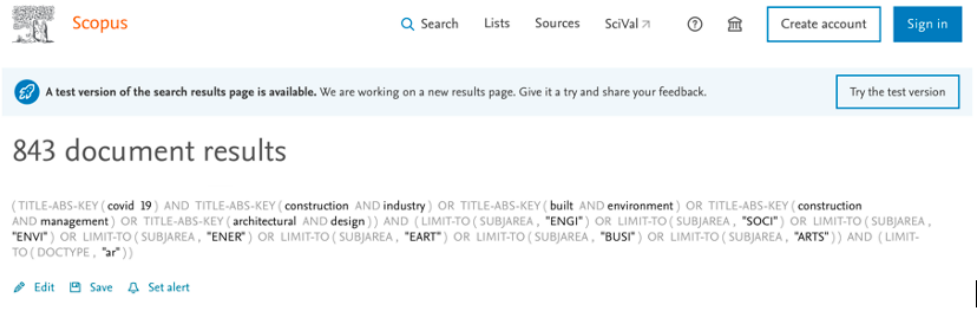

Figure 2: Search criteria for bibliometric analysis

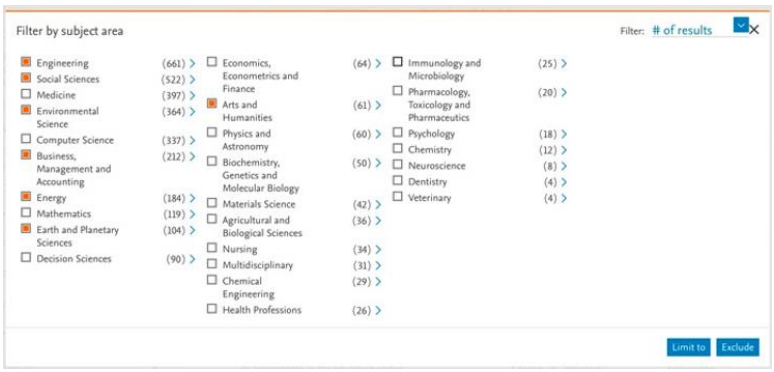

Figure 3: Subject areas filters used for bibliometric analysis.

Research Findings and Discussion

The main search yielded to 843 articles between 2019 and 2022. These articles were used as the basis for the bibliometric analysis presented herein. Table 1 presents the 10 highly cited articles among the 843 articles analyzed. The number of citations for articles is based on Scopus database.

Table 1. The most highly cited articles (top ten).

Li et al. (2020) analyze the air quality changes during the Covid-19 pandemic in a selected region and use an empirical model investigate impact of decreased human activities on air quality changes. Zhou et al. (2020) proposes a decision support model based on geographical information system to address the challenges presented by Covid-19 pandemic. Venter et al. (2020) explores the influence of Covid 19 pandemic on mobility patterns, recreational activity, ecosystem service, aesthetic values, spatial analysis and issues regarding the environmental green justice. Megahed and Gohneim (2020) propose a road map for construct "the antivirus-built environment" based on lessons learned from Covid- 19 pandemic. Amerio et al. (2020) explore the psychological effects of Covid-19 pandemic. They report that housing plays a major role in influencing people mental health and wellbeing during Covid-19 pandemic and suggest that strengthened multi-interdisciplinary approach involving urban planning, public mental health, environmental health, epidemiology, and sociology, is needed to inform the planning implementation and monitoring of housing policies centered on population health.

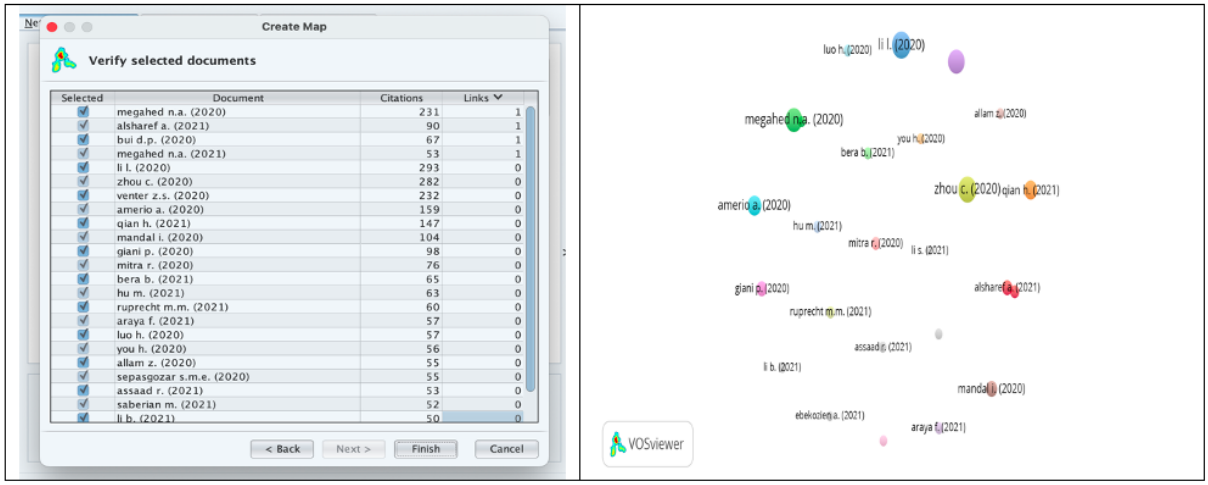

Figure 4: The ranking of articles based on number of citations and links.

A succinct review of top ten highly cited articles reveals that they adopt pluralist approach to address the multidimensional challenges presented by Covid 19 pandemic in the built environment (See Figure 4). The link between and among the highly cited articles appear to be very weak (i.e., the link strength =1). The observed very weak strength link can be attributed to the fragmented and nature of the built environment literature.

Two of out of ten highly cited articles (Li et al., 2020; Mandal & Pal, 2020) are published by "Science of the Total Environment" journal. Furthermore "Science of the Total Environment" journal has highest citations based on the search criteria used in this study (Total Number of Citations = 449). It is also becomes evident that "Sustainable Cities" journal (Total Number of Citations = 420) and "International Environment Research and Public Health" journal (Total Number of Citations =305) and are ranked 2nd and 3rd in the number of citations, respectively.

Figure 5: The ranking of journals based on the number of citations and total link strength.

Top three countries based the number of citations are China (6 articles and 885 citations), United States of America (8 articles and 646 citations) and Malaysia Australia (2 articles and 333 citations) (See Figure 6).

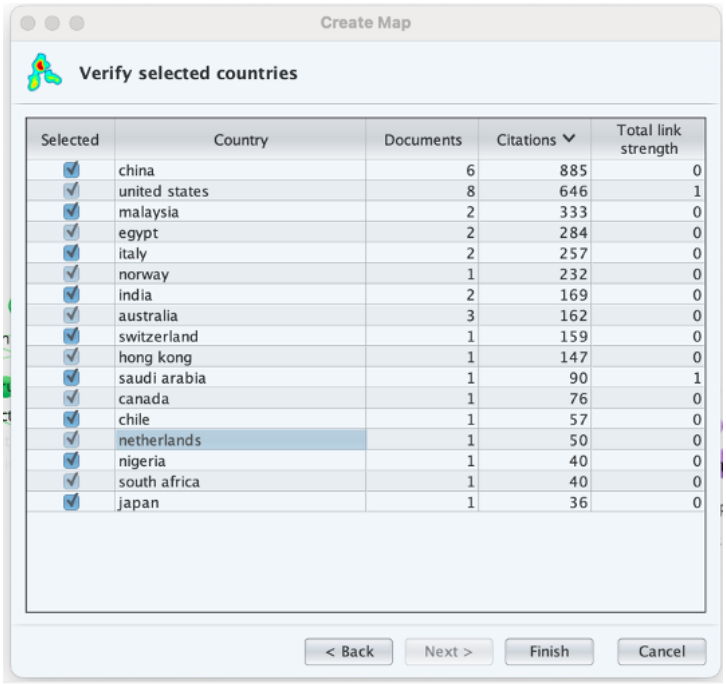

Figure 6: The ranking of countries based on the number citations.

The analysis of keyword co-occurrences yields Cluster ten clusters (See Figure 7). Cluster 1 is centered on nodes of pandemic and Covid-19. Cluster 2 is located at the periphery of the nodes of construction, construction projects and construction sectors. Cluster 3 is centered on the nodes urban planning, human activity, viral disease, aesthetic value cities. The remaining clusters are located on various nodes such as research methods, country, space design, social issues, and health issues.

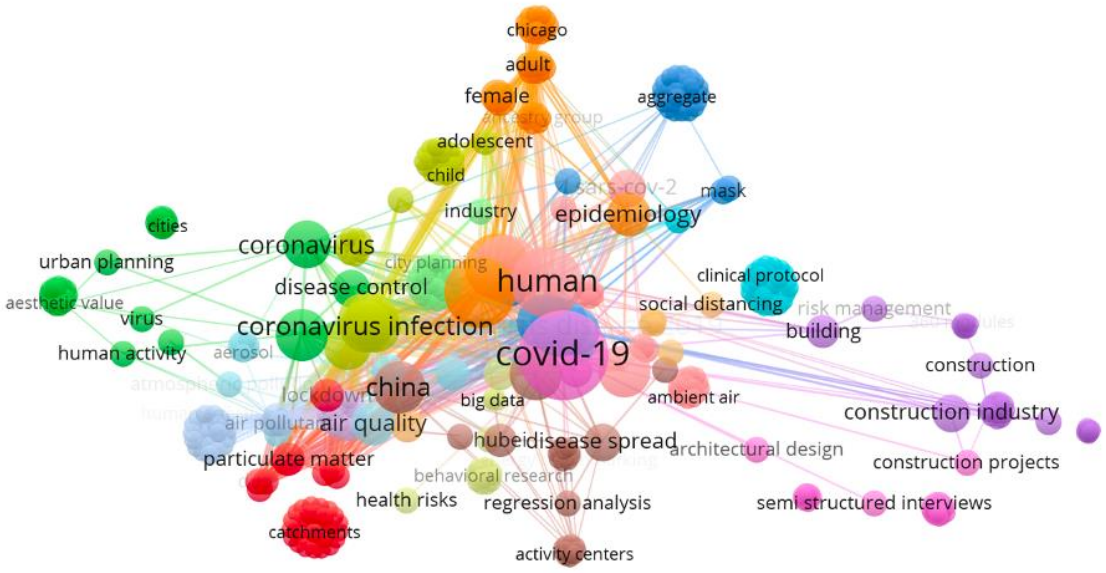

Figure 7: Keyword co-occurrence analysis map.

Conclusion

In this study, a bibliometric analysis of Covid-19 pandemic in the built environment literature is presented. The main research finding is that built environment has a rich but fragmented nature. As a direct result of its nature, the strength between and among research studies in the build environment appear to be very weak. The weak strength link while promotes diversity in turn fuels pluralist approach. Yet it prevents the cross fertilization of outputs of sub-research streams.

The theoretical frameworks and/or concepts that are expected to play a role in the shaping of the built environment literature after the Covid -19 pandemic, especially by analyzing the research findings obtained can have fruitful outcomes for future studies. The integration of competing or even conflicting theoretical frameworks and/or concepts and their reflections in the built environment literature can shed some light on the direction in which the built environment research studies will evolve in the years to come.

The research presented herein has a number of limitations. Firstly, the bibliometric data used in this study has a limited capacity to represent all of the scholarly research on Covid -19. Secondly, the actual reason for an article's citation cannot be easily inferred by performing bibliometric analysis. Thirdly, a highly cited article implies that it is influential in the literature. Yet an article citation count does not mean that the article provides a major scientific breakthrough or not. Fourthly, articles in non-English language were excluded in this research. Fifthly, articles published in scholarly journal were only included in this study. Sixthly, the time span of the (the window of analysis) bibliometric analysis presented herein is relatively short.

Abstract

The COVID-19 pandemic brought unprecedented challenges to the U.S. construction industry, which vary across different geographic regions due to variations in local government policies and regional economies. To effectively handle similar challenges, it is critical to understand the magnitude of regional impacts. This research aimed to assess the negative effects of COVID-19 on the construction industry across six U.S. regions as classified by the U.S. Census Bureau. The research methodology included a literature review, followed by data collection through survey questionnaire responses from construction professionals. The following negative impacts of COVID-19 were evaluated in this study: canceled projects, forced layoffs, delayed schedules, and reduced productivity. A mean ranking analysis on 211 survey responses indicated regional differences in perceived negative impact scores. The most significant impact due to canceled projects was reported in the Northeast. The Pacific West reported the highest impact score on construction layoffs and productivity reductions. And the Pacific West and Northeast reported the highest impact to delays in project schedules. Overall, the Pacific West and Northeast regions reported the highest negative impact scores, potentially due to state shutdowns and quarantine policies. The findings will help policymakers and construction firms develop strategies relevant to regional needs and circumstances caused by future outbreaks.

Keywords: *construction industry, construction layoff, COVID-19, COVID-19 impacts on construction, pandemic, productivity, canceled construction projects, construction delays.*

Introduction and Purpose

The coronavirus, commonly referred to as COVID-19 or 'the pandemic,' has severely impacted public health since its outbreak in early 2020 (Dryhurst et al., 2020). In addition to a large-scale health crisis, the pandemic resulted in global social and economic issues ranging from public education disruptions to supply chain delays. Given the worldwide implications of the pandemic and the socio-economic sectors affected, it is important to study its short-term impacts and projected long-term consequences in different contexts.

As a driving force in the global economy, the construction industry has faced multiple challenges due to the pandemic. National lockdowns have resulted in temporary stops to construction projects and supply chain issues. As a result, project schedules experienced significant delays. Furthermore, quarantine measures and social distancing requirements negatively impacted construction productivity and increased demands on the construction workforce. Since telecommuting is not an option for construction field work, the quarantine measures resulted in difficulties in ensuring safety and productivity while meeting the deadlines of the construction projects (Daniels et al., 2020).

The impacts of the pandemic have been evaluated in numerous academic studies focusing on different industries from varying social, economic, and environmental perspectives (Weir et al., 2021; Chowdhury et al., 2020; Maneenop et al., 2020; Uğur et al., 2020). Research investigating the pandemic and the construction industry has addressed implications from several perspectives, including workers' health and safety, supply chain issues and material price instabilities, project delays, and contractual and legal issues (Jeon et al., 2022; Alsharef et al., 2021; Assaad & El-adaway, 2021). While the macro-level effects of the pandemic are important to understand, there is also a need to focus on identifying regional impacts as various countries and geographic regions exhibit social, economic, governmental, and cultural differences in their own unique ways.

This study aims to investigate the preliminary impacts of COVID-19 in the U.S. construction industry across six U.S. regions classified according to the U.S. census bureau (Pacific West, Mountain West, Mid-West, Southwest, Southeast, and Northeast), as shown in Figure 1. A literature review provided four main categories of impact on the construction industry: canceled projects, forced layoffs, delayed schedules, and reduced productivity. In light of the literature review, an online survey was conducted with the members of a nationally recognized construction association to understand pandemic-specific impacts on construction firms. The preliminary results of this study indicate that every region was negatively impacted by the pandemic, which opens the door to future studies that could investigate the relations of these impacts to each region's geographical, political, and cultural characteristics. The findings of this study will help policymakers and construction firms develop strategies relevant to regional needs and circumstances caused by future outbreaks.

Background

COVID-19 has affected every aspect of the worldwide economy – including the construction industry – and despite its short history, numerous academic studies on the pandemic have been conducted. This background section will focus on research relating to COVID-19 and construction organizations which primarily focus on risk management and mitigation strategies.

Almost 10% of the U.S. workforce works in a construction-related occupation, and workforce health and safety is a principal objective for most construction organizations. Pamidimukkala et al. (2021) identified virus exposure as the most significant concern for construction field workers and, as expected, that social distancing measures lessened the risk of virus exposure. Additionally, remote workers at construction organizations identified isolation and the work environment as their most pressing concerns. The same study revealed strategies to cope with these challenges. These included redefining job site safety with physical distancing measures, regular temperature checks, flexible work schedules, implementing technology for meetings, and frequent interaction with other workers (Pamidimukkala et al., 2021).

Another study (Raoufi & Fayek, 2021) identified 177 actions to control and mitigate the effects of COVID-19 in construction organizations. These actions were then categorized into the following categories: health and public health directives, safety, workforce, workflow and productivity, communication, suppliers and subcontractors, economics and cost/budget issues, logistics and support, technology, regulations, disputes/claims, and contractual issues, insurance and bonds, suspension of work/project, restart/relaunch of work/project, new normal, and concerns about the welfare of employees. Routine health monitoring, workforce support, flexible communication and coordination among stakeholders, risk assessment of the supply chain, and resource issues were examples of the recommendations to mitigate the possible risks of the pandemic (Raoufi & Fayek, 2021).

Guidelines for responding to the pandemic with best practices were presented in Assaad and El-adaway (2021)'s study within four categories 1) workforce-related issues, 2) project and workplace considerations, 3) procurement and supply chain implications, and 4) contractual, legal, and insurance issues. Jeon et al. (2021) identified the relationships between the pandemic and the Purdue Index for Construction (Pi-C), which measures the health status of the construction industry in five dimensions: economy, stability, social, development, and quality. The impacts of the pandemic were most significant on the stability dimension of the Pi-C (Jeon et al., 2021). Alsharef et al. (2021)'s study revealed risk and safety management measures such as forming a task force to review the pandemic's impacts, additional organizational training, managing delays, and benefiting government relief programs.

Considering the ongoing impacts of the pandemic, it is clear that researchers will continue to focus on different aspects and measures of the pandemic on the construction industry. As one of the world's largest and most populous countries, the U.S. has several social, economic, and cultural variations across geographic regions. Therefore, the primary focus of this study is to identify regionally specific impacts of COVID-19 on the construction industry.

Methodology

Data for this study were collected through a Qualtrics survey distributed by a nonprofit national organization focused on serving and educating construction financial professionals. Prior to general distribution, a pilot survey was developed and distributed to 12 participants, and pilot survey feedback was incorporated into the final survey. Final surveys were distributed to general and associate members through the national organization list serve email. After the initial survey request, weekly reminders were sent to potential survey respondents, and regular reminders were posted on the national organization's web-based discussion forum that engages members on various construction related topics. Additionally, it was requested that survey recipients share the survey link with colleagues. The survey was available for 60 days between Sep 25, 2020, and Nov 25, 2020.

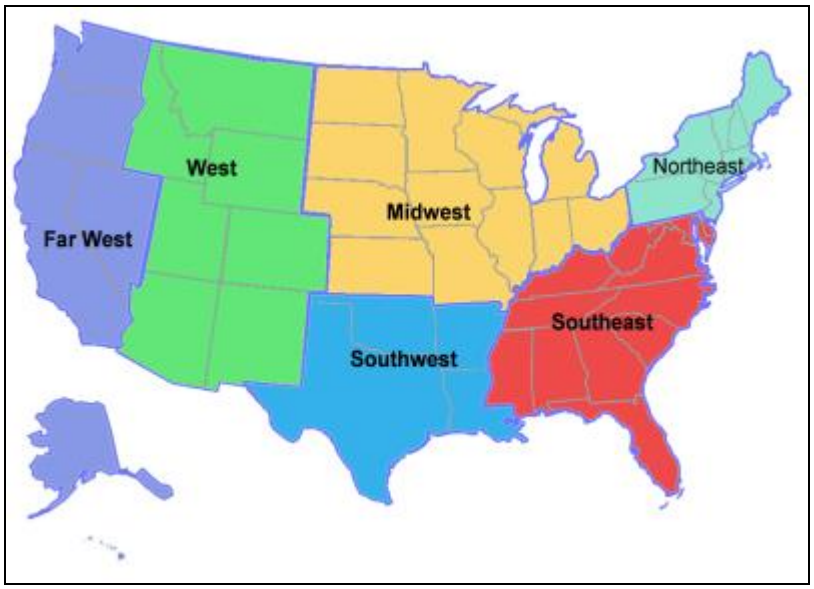

Figure 1: U.S. Regional classification of survey participants.

The survey measured the negative impacts of COVID-19 in four risk categories: 1) canceled projects, 2) forced layoffs, 3) delayed schedules, and 4) reduced productivity. Participants were given a sliding 100-point scale for rating the negative impact of COVID-19 (0-20 minimally impactful, 20-40 somewhat impactful, 40-60 moderately impactful, 60-80 significantly impactful, 80-100 substantially impactful). A 100-point scale was utilized to provide a high level of sensitivity in analysis.

Study participants were delimited to professionals that reported working for the following types of construction firms: 1) *General/Prime Contractors* (more than 20% of construction work self-performed) (n = 96) and 2) S*ubcontractors* (50% or more of construction work performed for another contractor) (n = 115). Participants reported annual revenues ranging from less than $36MM to more than $500MM. Participants reported the geographic region where their organization was headquartered as classified by the U.S. Census Bureau.

After the survey was closed, responses were grouped by firm type and geographic region, and mean scores were calculated. A total of 211 responses were evaluated for this study.

Results

Canceled or Delayed Projects

Figure 2 reports the average regional impact score for *Canceled or Delayed Projects* for general contractors (n = 87) and subcontractors (n = 115). On average, general contractors (M = 46) reported slightly higher impact scores than subcontractors (M = 43). Regionally, the general contractors in the Southwest reported the lowest impact scores (M = 29), while the Northeast (M = 54) and Southeast (M = 51) reported the highest impact scores. Regional impact scores for subcontractors varied less than for general contractors. Subcontractors in the West reported the lowest impact scores (M = 35), and participants in the Far West reported the highest (M = 47). Except for the Southwest, subcontractors in all regions reported lower impact scores than general contractors.

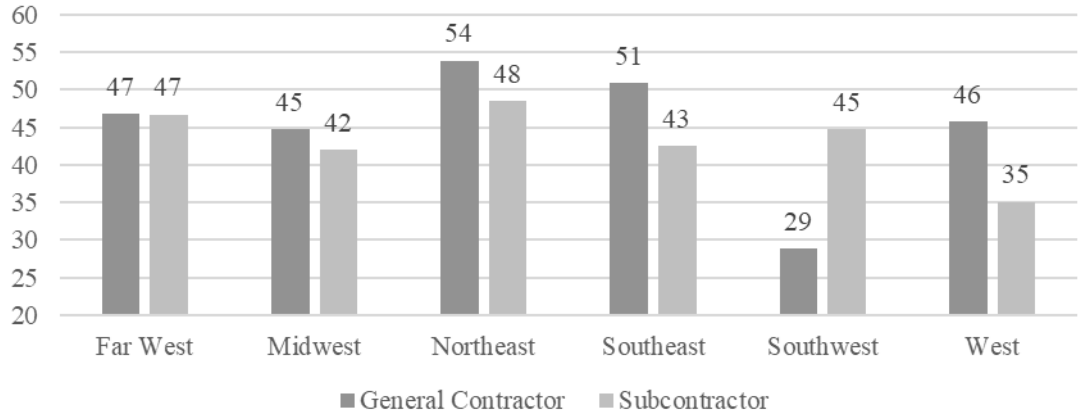

Figure : Impact of COVID-19 relating to cancelled or delayed projects.

Forced Layoffs

The average regional impact scores for *Forced Layoffs* for general contractors (n = 63) and subcontractors (n = 84) are reported in Figure 3. On average, general contractors (M = 24) reported lower mean impact scores than subcontractors (M = 27). General contractors in the Southwest reported an average impact score of only 5, while all other regions reported impact scores between 21 and 30. For subcontractors, regional impact scores ranged between 21 and 28 for five of the six regions. Subcontractors in the Far West reported the highest impact score at 38.

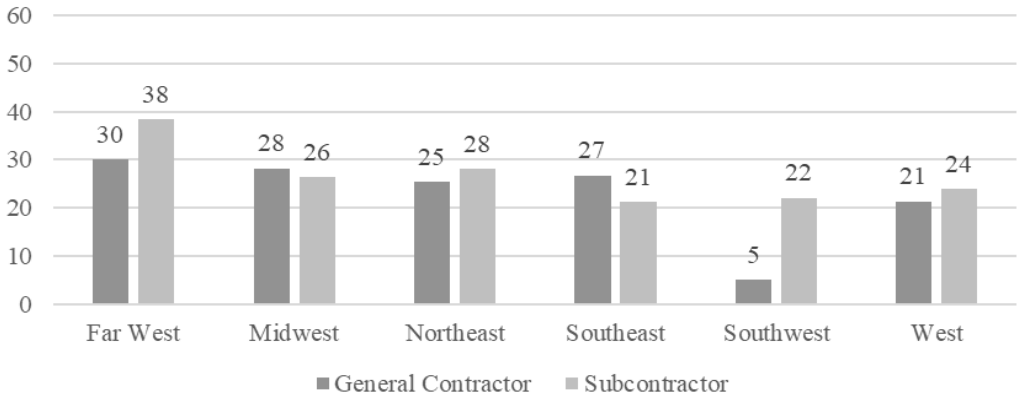

Figure 3: Impact of COVID-19 relating to forced layoffs.

Project Schedules

Figure 4 reports average impact scores for *Project Schedules* for general contractors (n = 83) and subcontractors (n = 113) by region. On average, general contractors (M = 43) reported ostensibly higher impact scores than subcontractors (M = 41). General contractors in the Northeast (M = 50) and Far West (M = 49) reported the highest impact scores, while their Southwest counterparts reported the lowest (M = 29). Similarly, subcontractors in the Northeast and Far West reported the highest mean impact scores at 50 and 46, respectively, with subcontractors in the West reporting the lowest at M = 32. Subcontractors and general contractors for all regions reported impact scores within 11 points.

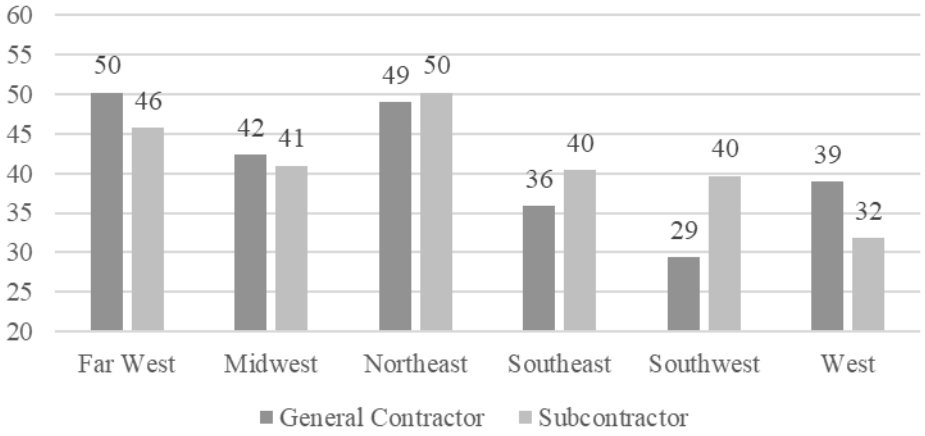

Figure 4: Impact of COVID-19 relating to project schedules.

Reduced Productivity

Regional impact scores relating to *Reduced Productivity* for general contractors (n = 89) and subcontractors (n = 110) are found in Figure 5. Overall, general contractors (M = 37) reported slightly lower impact scores than subcontractors (M = 40). General contractors in the Far West reported the highest impact scores (M = 50). Subcontractors in the Southeast (M = 48)

and Northeast (M = 47) reported the highest impact scores, while counterparts in the West (M = 36) reported the lowest.

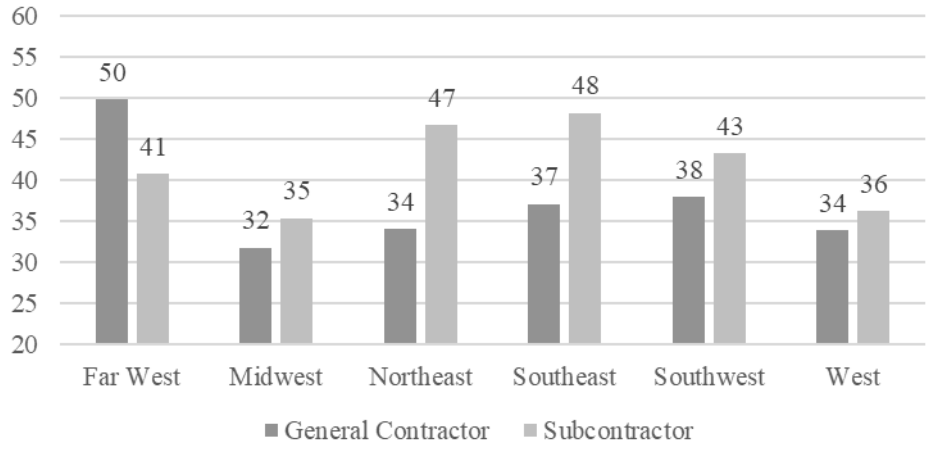

Figure 5: Impact of COVID-19 relating to reduced productivity.

Discussions and Future Research

While negative impact scores were reported in all four risk categories, disparities in impact scores across categories and geographic regions merit further discussion. For example, the impact scores of forced layoffs were notably smaller than those of the other risk categories in all six geographic regions. While beyond the scope of this study, future studies exploring the reasons for these impact scores are merited. Future research could focus on the correlation between an already tight construction labor market and low layoff impact scores. Additionally, potential studies could evaluate the effects of construction firms' financial health on forced layoffs and if construction firms perceived less risk (i.e., felt a greater sense of control) relating to internal layoffs compared to governmental quarantine mandates and owner-prescribed delays and cancelations (Franzese, 2020).

Regional differences in impact scores are also worth mentioning. Notably, general contractors and subcontractors in the Far West and Northeast regions reported higher than average impact scores in almost all categories. Conversely, general contractors and subcontractors in the West and Southwest reported lower than average impact scores in nearly all categories. These results suggest that regionally specific factors affected risk perceptions and therefore merit further exploration. Future studies exploring regional differences in governmental regulation along with regional social, economic, and cultural variations may shed light on the causes of disparate regional impact scores (Franzese, 2020).

Limitations and Conclusion

Evaluation of study results should take into account limitations and constraints. For example, study participants were solicited through –a national association that primarily serves construction finance professionals. While these professionals are likely involved in strategic decision-making and planning for construction firms, their perceptions of risk – particularly related to productivity and project delays – may differ from project-level professionals such as

project managers and superintendents. It should also be noted that this study only evaluated a small timeframe in a rapidly changing business and regulatory climate.

This study explored the negative impacts of the COVID-19 pandemic on construction firms as reported by construction finance professionals across six geographical regions of the U.S. General contracting and subcontracting professionals reported pandemic-specific impacts to 1) project cancelations and delays, 2) forced layoffs, 3) project schedules, and 4) reduced productivity. Across all four risk categories evaluated, general contractors and subcontractors reported pandemic-specific negative impacts with regional differences in the magnitude of these impacts. The results of this study are beneficial in understanding risks associated with future pandemics or other global economic disruptions and how the extent of these perceived risks differ across regions in the U.S.

Abstract

Risk, complexity, and uncertainty are inherent components of mega construction projects due to their characteristic features. A failure to synthesize these concepts within a structured approach leads to unrealistic risk assessments, ineffective management strategies, and poor project performance. The Integrated Risk Assessment Process (IRAP) could assist practitioners in identifying and quantifying the risks in their projects more realistically. This research, therefore, aims to demonstrate the practical benefits of IRAP. For this purpose, a case study was conducted with the retrospective analysis of a mega pipeline project in Turkey. IRAP was employed at the beginning, middle, and end of the project by analyzing the complexity and uncertainty factors, as well as strategies implemented to manage them. In order to clarify the role of management strategies, risks at the planning stage of the project were also assessed without considering the strategies. With the rating exercise, variations in the complexity, uncertainty, and risk levels at different project stages were observed. The findings from the demonstrative case study revealed the potential contributions of IRAP to risk management and monitoring in mega construction projects.

Keywords: *complexity, management strategies, mega construction projects, risk, uncertainty.*

Introduction

Risk assessment constitutes a critical phase of project risk management. It enables project managers to set project performance targets more realistically and allocate resources more effectively. For instance, risk assessment can be utilized during the bidding stage of a project to determine an appropriate contingency budget (Dikmen et al., 2022). It can also help monitor the risk levels during the execution of the project and learn from actual risks as a part of the post-project evaluation. However, in order to take full advantage of risk assessment, it is necessary to comprehend all factors that may affect project risks. Traditional risk assessment

methods, such as probability and impact rating, mainly focus on treating uncertainties in the project. Although widely used in practice, they usually fail to account for the interdependencies between different risk sources. Since they are not capable of reflecting the true nature of risks, especially under high complexity, new approaches are needed to assess complexity-induced risks (Taroun, 2014). This is particularly important for mega construction projects as they are characterized by risk, complexity, and uncertainty (Boateng et al., 2015; Erol et al., 2018; Hu et al., 2015). A failure to synthesize these concepts within a structured approach leads to unrealistic risk assessments, ineffective management strategies, and poor project performance. Hence, the success of a megaproject largely depends on how well risk-related concepts are addressed (Dimitriou et al., 2013; Giezen, 2013; Kardes et al., 2013).

With the increasing criticism of fragmented risk management approaches recently, new research efforts have emerged to incorporate complexity into risk management (Erol, 2020; Jensen & Aven, 2018; Thomé et al., 2016). Some risk models have also been developed specifically for this purpose (Qazi et al., 2016; Dikmen et al., 2021). However, the project management literature lacks studies reporting the practical benefits of implementing complexity-based thinking in risk management through real cases. From this point of view, this paper aims to demonstrate how an integrated risk assessment approach developed by the authors (Erol et al., 2020; Erol et al., 2022) can assist practitioners in identifying and quantifying the risks in their projects more realistically. For this purpose, a case study was conducted with the retrospective analysis of a mega pipeline project in Turkey.

The remainder of the paper is organized as follows. The next section gives some background information on the integrated risk assessment approach utilized in this study. Then, details are provided about the implementation of the risk assessment process in the demonstrative case study. Finally, the benefits of the proposed approach and possible future studies are discussed.

Integrated Risk Assessment Process (IRAP)

The Integrated Risk Assessment Process (IRAP) was developed as a result of an exploratory study involving interviews with 18 managers from 11 mega construction projects. Based on these interviews, the interrelations between risk-related concepts were identified, and a conceptual model linking the themes of risk, complexity, uncertainty, and management strategies was proposed. More information about this model, which forms the basis of IRAP, can be found in Erol et al. (2020).

IRAP is composed of four main steps. It starts with identifying the risk sources (complexity and uncertainty) of the project. Some complexity factors can be specified at the beginning of the project by analyzing features, such as size, number of stakeholders, and technical difficulty. These factors constitute the "static complexity" of the project. Similarly, some uncertainty factors can be identified at the front end of the project with the existing knowledge and experience of the project management team. The second step of IRAP is formulating management strategies for the identified risk sources. The purpose of these strategies is both to facilitate the management of complexity and uncertainty factors and reduce their magnitude in the project. However, strategies formulated to deal with the existing factors may trigger the emergence of new risk sources that leads to secondary risks. For this reason, there is an iterative process between the first two steps of IRAP. This iterative process is expected to result in a network in the third step, linking the risks to complexity and uncertainty factors, together with the strategies formulated to manage them. The last step of IRAP is analyzing the resulting risk

network. The network analysis is a crucial step of IRAP since it enables project managers to rate the risk sources by considering the interdependencies between various factors. Since the measures taken based on the network analysis may introduce new risk sources, there is a feedback loop to repeat the previous steps before the finalization of IRAP. In addition to "static complexity," "dynamic complexity" may arise as the project progresses due to the changes in the existing factors or the involvement of new ones. Similarly, initially identified uncertainties may decrease, or new factors may emerge. Furthermore, the dynamic nature of the projects may require updating the existing management strategies or formulating new plans. Therefore, IRAP should be repeated periodically throughout the project.

Although IRAP can be operationalized with different analytical techniques based on network analysis, the risk assessment of the case project was performed with the ANP model developed by Erol et al. (2022). According to this model, the overall risk of a mega construction project is calculated with eight risk factors. These risk factors are connected to three main clusters: complexity, uncertainty, and management strategies. The complexity cluster is composed of 17 factors under the technical, organizational, and environmental complexity categories. The uncertainty cluster contains two main categories, comprising uncertainty about the future and vagueness about the project. Management strategies cluster, on the other hand, include flexibility and control strategies, which are also linked to other clusters. Consequently, the overall risk of a mega construction project can be calculated using the parameters at the lowest level of the hierarchy. These parameters, consisting of 17 complexity factors and two uncertainty categories, are the risk sources of the project. The weights of the risk sources in the model were determined by the domain experts through a two-round Delphi study. For more detailed information about the ANP model, interested readers may consult Erol et al. (2022).

Implementation of IRAP to a Mega Pipeline Project

In order to exemplify the implementation of IRAP, a demonstrative case study was conducted with the retrospective analysis of a mega pipeline project (the name is withheld due to confidentiality concerns). As a transnational natural gas pipeline project, it has significant strategic importance for the countries involved due to its potential to improve their competitiveness in global energy markets. In Turkey, the project was divided into several lots. The construction works of each lot were awarded to different contractors as sub-projects. In this paper, IRAP has been applied to one of these projects. The investigated project has a total length of more than 400 kilometers. It was a design-bid-build project with a lump-sum contract. While the contract price was more than $400 million, the total project duration was approximately three years. The project's contractor was a joint venture of one international and two Turkish construction companies. The project was completed without any significant cost overrun or delay. Since the project has all the characteristic features of a mega construction project, it was an appropriate case example for demonstrating the assessment of risk-related factors through IRAP. The information used in the case analysis was provided by the planning and contracts manager of the project, who has 15 years of experience in large-scale construction projects. Due to the broad authority and responsibility he owned in the project, all managerial and technical issues could be elucidated.

During the case analysis, IRAP was applied to three project stages. In this respect, complexity and uncertainty factors, as well as strategies implemented to manage them, were analyzed at the beginning, middle, and end of the project. These stages correspond to the progress rates of approximately 10%, 50%, and 90%. Then, the ANP model was employed to calculate the risk

scores of the project at these three stages using the identified complexity and uncertainty factors. Furthermore, to clarify the role of management strategies in the assessment process, risks at the planning stage of the project were calculated without considering the strategies implemented for complexity and uncertainty factors. With the rating exercise, variations in the complexity, uncertainty, and risk levels were observed for different project stages. Consequently, the potential contributions of IRAP to risk management and monitoring in mega construction projects were evaluated with a real application. The following subsections elaborate on the implementation of IRAP in the case project.

Identification of the Risk Sources and Management Strategies

The risk assessment procedure started with the identification of the risk sources in the project. Since the weights of the ANP model were available for 17 complexity factors and two uncertainty categories (Erol et al., 2022), the risk sources in the case project were identified through these parameters. However, under each uncertainty category, three uncertainty factors were defined to analyze the risk sources of the project in more detail. Corresponding category weights of the ANP model were distributed to these factors equally. Thus, 17 complexity factors under the technical, organizational, and environmental categories, as well as six uncertainty factors that belong to the categories of the uncertainty about the future and vagueness about the project, were analyzed for the risk assessment of the project. Table 1 lists these risk sources.

Table 1. Risk sources assessed in the case project.

ID	Risk Source	Category
C1	Size of the Project	Organizational Complexity
C2	Strategic Importance of the Project	Environmental Complexity
C3	Political or Macroeconomic Instability	Environmental Complexity
C4	Variety of Financial Institutions or Sponsors	Organizational Complexity
C5	Interactions between the Stakeholders	Environmental Complexity
C6	Inadequacy of the Contract	Organizational Complexity
C7	Lack of Technical Experience	Technical Complexity
C8	Changes in the Project Scope	Technical Complexity
C9	Unrealistic Project Targets	Technical Complexity
C10	Unavailability of Resources	Organizational Complexity
C11	Interactions between the Project Disciplines	Organizational Complexity
C12	Cultural Diversity	Organizational Complexity
C13	Multiple Critical Paths (Parallel Activities)	Technical Complexity
C14	Staff and Equipment Mobility	Organizational Complexity
C15	Physical and Logistic Constraints	Environmental Complexity
C16	Technological Novelty of the Project	Technical Complexity
C17	Originality of the Project Design	Technical Complexity
U1.1	Weather Conditions	Uncertainty about the future
U1.2	Rental Cost of the Equipment	Uncertainty about the future
U1.3	Force Majeure Events	Uncertainty about the future
U2.1	Quality Performance of the Project	Vagueness about the project
U2.2	Health and Safety Performance of the Project	Vagueness about the project
U2.3	Public Opposition	Vagueness about the project

Each factor in Table 1 was evaluated with the project manager to draw a comprehensive picture of the risk sources in the project. Table 2 exemplifies how "Physical and Logistic Constraints" led to risk events at different project stages.

Table 2. Evaluation of a risk source.

Risk Source	General Evaluation
C15: Physical and Logistic Constraints	The project involved geographically dispersed construction areas where different physical constraints exist. Since each region has unique conditions, the project teams had to deal with various physical obstacles. In particular, problems were encountered due to the weather conditions of the high-altitude points. On the other hand, there were also logistic constraints as the construction was performed in a wide area. For example, although the pipes were supplied by the owner, transporting them to different construction locations was the responsibility of the contractor. The pipes procured from Chinese and Turkish suppliers required specific logistic arrangements. In the middle of the project, the pipes shipping from China landed at a different port, a far distance from the original port stated in the contract. For this reason, additional logistics difficulties arose in the project. Furthermore, the distance between the main camps and construction locations was increasing with the progress of the project. In later stages, it started to take a longer time to arrive at the construction area, which caused a reduction in effective working time. Thus, the contractor had to take different measures to cope with logistic problems throughout the project.

IRAP also requires determining strategies to manage identified risk sources. For instance, Table 3 tabulates the strategies implemented for the "Physical and Logistic Constraints" at three different project stages. Since a strategy implemented to manage a specific risk source may have a positive or negative impact on other sources, affected factors were also listed in the table. While some of these management strategies directly change the level of complexity or uncertainty in the project, others influence the manageability of the risk sources.

Table 3. Management strategies implemented for a risk source.

Project Stage	Implemented Strategy	Other Factors Affected by the Strategy
Beginning (≈ 10%)	In order to avoid physical constraints, seasonal conditions were considered when planning the works. Accordingly, the construction activities at high-altitude points were scheduled to be performed between April and September. On the other hand, in order to minimize logistical problems, the fly camps were utilized in addition to the main and intermediate camps. Furthermore, since each pipe at the stockyard had to be positioned in a specific location, their GPS coordinates were monitored through pipe tracking software.	Consideration of the seasonal conditions in the construction plan facilitated the management of U1.1 (weather conditions). On the other hand, precautions related to the logistic constraints facilitated the management of C14 (staff and equipment mobility).
Middle (≈ 50%)	The contractor had the right to request a change order in case the pipes landed at a different port. Accordingly, additional transportation expenses were covered with the change order issued by the owner.	Discussions for the issuance of the change order in the project have increased the complexity in C5 (interactions between the stakeholders).
End (≈ 90%)	In one of the construction locations, when the distance became too far from the main camp, the related teams were moved to a hotel in a nearby town. In order to get the approval of the owner, the contractor took additional safety precautions in the hotel. As a result, the time spent to arrive at the construction area was reduced considerably with this arrangement.	Moving the teams to a hotel made the management of U2.2 (health and safety performance of the project) more difficult. Moreover, the inspections made by the owner to ensure the hotel is suitable in terms of physical space and fire systems further increased the complexity in C5 (interactions between the stakeholders).

Rating the Risk Sources

Following the identification of the risk sources and strategies developed to manage them, a rating exercise was conducted for different project stages. There were three main issues required to be considered by the project manager while scoring a factor. First of all, its magnitude in the project during the stage of assessment should be determined. Second, the direct impact of the strategy implemented for this factor should be reflected in the rating. Third, the indirect impact of the other strategies affecting this factor should also be taken into account. For instance, while rating C5, strategies developed for C15 were also considered since they influenced this factor (see Table 3). Thus, instead of an isolated analysis, IRAP ensured the assessment of complexity and uncertainty factors within a network setting. Based on this procedure, all risk sources were rated on a five-point scale by considering their level at the beginning, middle, and end of the project. Besides these three stages, another rating was provided for the planning stage of the

project without considering any strategy. Table 4 presents the complexity and uncertainty scores assigned for these stages.

Table 4. Scores of the risk sources for different project stages

Risk Source	Planning (No Strategy)	Beginning (≈ 10%)	Middle (≈ 50%)	End (≈ 90%)
C1	5	5	5	5
C2	2	2	1	1
C3	4	3	1	1
C4	2	1	1	1
C5	5	3	4	4
C6	4	4	4	3
C7	2	1	1	1

Calculation of the Risk Assessment Scores

In order to calculate the risk assessment scores, the ratings given in Table 4 were multiplied by the corresponding weights of the ANP model (Erol et al., 2022). According to the ANP model, the score of each risk factor is estimated via three complexity and two uncertainty categories. Therefore, the first step was determining the category scores through corresponding complexity and uncertainty factors. To illustrate this operation, Figure 1 demonstrates the calculation of the "Environmental Complexity" at the beginning of the project using the scores of the related complexity factors and their weights. In Figure 1, scores that belong to C2, C3, C5, and C15 were multiplied by the weights written on the arrows. Then, the results obtained were summed up to determine the total category score (2.89). The same operation was repeated for other complexity and uncertainty categories to calculate their scores as well.

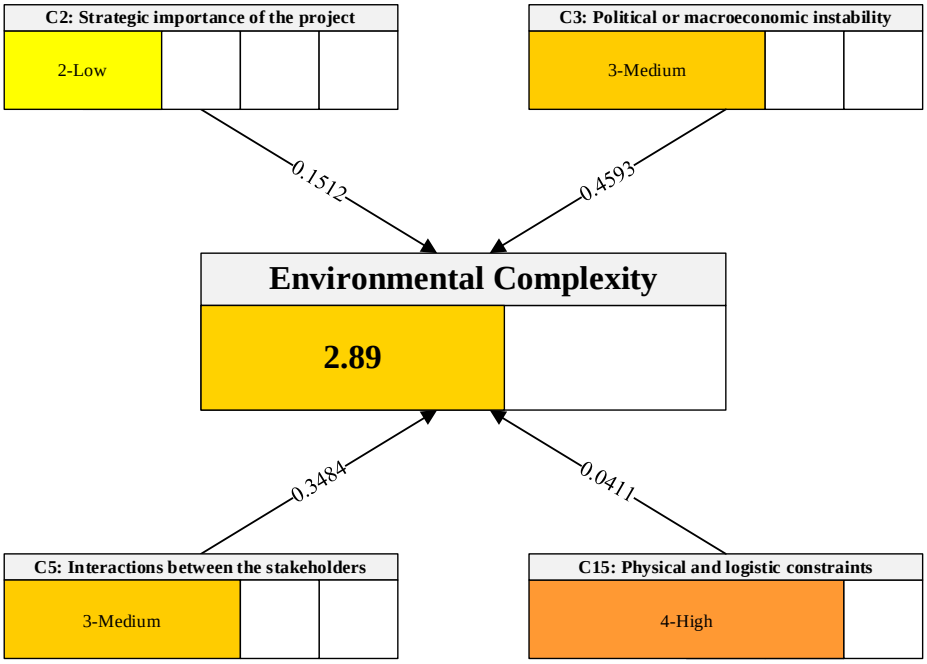

Figure 1: Calculation of a category score.

The next step was determining the scores of each risk factor via the five categories. In this respect, Figure 2 exemplifies the calculation of the "Contractual Risks" at the beginning of the project. In Figure 2, scores determined for three complexity and two uncertainty categories were multiplied by their total weights written on the arrows to calculate the total risk score (3.01). The same category scores were also multiplied by the weights of other risk factors so that all risk scores could be determined.

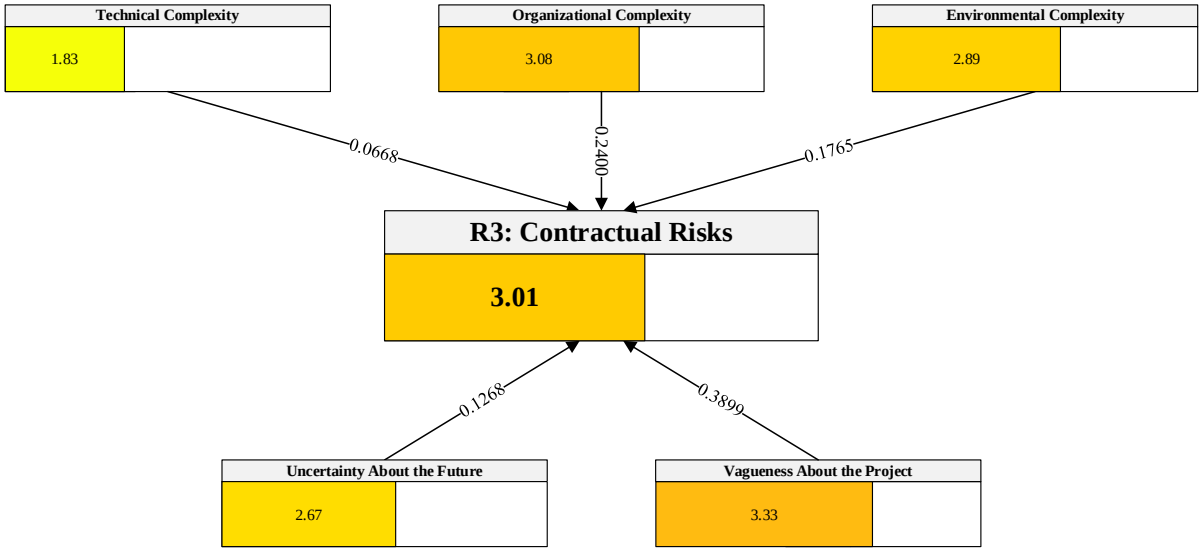

Figure 2: Calculation of a risk score.

The final step of the calculations was determining the overall risk of the project. For this purpose, the score of each risk factor was multiplied by the corresponding weights, and the results were summed up. Figure 3 illustrates the calculation of the overall risk score (2.86) at the beginning of the project.

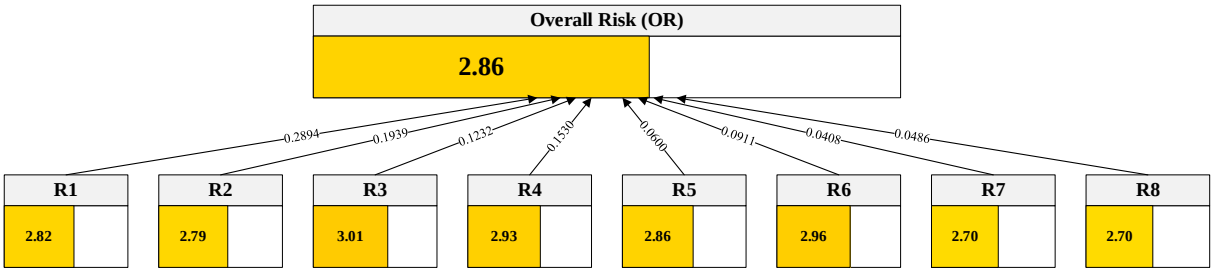

Figure 3: Calculation of the overall risk score.

Based on the calculation procedure explained above, the risk assessment scores of all factors were determined for four project stages. Table 5 presents the risk assessment scores calculated using the ratings given in Table 4. According to the results, R3 was the most significant risk factor during the planning stage of the project. Similarly, due to the unfavorable contract clauses, R3 was anticipated as the most crucial risk factor by the project manager at the beginning of the project. Hence, the result calculated by the model aligned with the perception of the manager. R6 was determined as the second-highest risk factor, followed closely by R4 and R1. These findings were also considered reliable. According to the project manager, the governance and coordination of the geographically dispersed project teams was the most challenging part of the project. Similarly, the owner was evaluated as an important risk factor because of not only the strict contractual obligations but also the extremely high standards set in the project. Furthermore, the volatile environment caused by the coup attempt at the beginning of the project has increased R1. Even though R3 has been among the top three risk factors throughout the project, its impact was mitigated after the contractual amendment made during the project. Therefore, R6 became the most significant risk factor after the middle of the project since the coordination issues continued to be a challenge over the course of the project. On the other hand, R7 and R8 were the least significant risk factors for most of the stages. According to the project manager, the project was not very challenging in terms of construction operations since the same activity types were repeated at different locations. Similarly, except for the changes in the alignment sheets at the beginning of the project, design-related issues were not considered a critical risk factor. Hence, the calculations of the model reflected the thoughts of the project manager. Apart from these two factors, R1 became the least significant risk factor at the last stage as the impact of the country-related problems has reduced towards the completion of the project.

Table 5. Risk assessment scores for different project stages.

Risk Factor	Planning (No Strategy)	Beginning (≈ 10%)	Middle (≈ 50%)	End (≈ 90%)
R1: Country-related Political and Economic	3.47	2.82	2.22	1.72
R2: Financial	3.35	2.79	2.26	1.80
R3: Contractual	3.63	3.01	2.42	1.96
R4: Owner-related	3.48	2.93	2.40	1.97
R5: Procurement	3.43	2.86	2.30	1.86
R6: Project Management and Organization	3.49	2.96	2.45	2.02
R7: Construction-related / Technological	3.26	2.70	2.15	1.77
R8: Design	3.27	2.70	2.14	1.76
OR: Overall Risk	3.45	2.86	2.30	1.84

The risk assessment scores in Table 5 demonstrate that all risk factors, as well as the overall risk, have decreased throughout the project. The results also revealed the critical role of management strategies in reducing project risks. For instance, strategies implemented at the beginning of the project enabled more than a 17% reduction in the overall risk. Nonetheless, the changes in the risk scores also depend on the factors affecting the magnitude of the source parameters. Figure 4 visualizes the changes in the scores calculated for three complexity and two uncertainty categories together with overall risk at different project stages. Accordingly, categories displayed different behaviors in terms of variations in the scores. Despite the existence of management strategies, organizational complexity continued to increase throughout the project. However, the results should not imply that the management strategies used in the project were ineffective. On the contrary, they helped keep the high organizational complexity of the project at an acceptable level. In contrast to organizational complexity, environmental complexity showed a declining trend over time. In terms of technical complexity, variations were inconsistent. Although there was a slight decrease until the middle of the project, it started to climb thereafter. On the other hand, the level of uncertainty declined continuously over the project duration. The decrease in vagueness about the project might be achieved by closing the information gap over time. Similarly, the impact of uncertainty about the future can be expected to decrease as the project progresses. For example, an increase in the rental cost of the equipment at the end of the project could be less significant as compared to the initial stages. Furthermore, management strategies contributed to decreasing the level of uncertainty in the project for both categories. As a result, the risk reduction in the case project was more closely associated with lowering the uncertainty level.

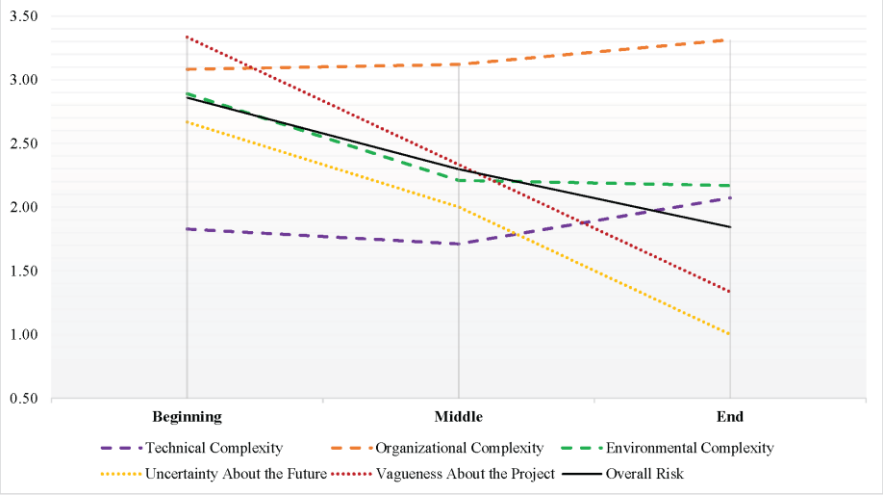

Figure 4: Changes in the category and overall risk scores.

It should be noted that despite the decreasing trend in the risk level of the case project, other projects may not show the same behavior. The emergence of a critical risk source during the project may cause sudden increases in the risk level. Similarly, a strategy developed for a risk factor may increase the risk level in other factors. For instance, hiring a subcontractor to reduce the technical risks in the project may amplify the coordination-related risks. Therefore, both the risk sources and the impact of management strategies should be assessed periodically, as promoted by IRAP.

Summary and Conclusions

In this paper, the implementation of an integrated risk assessment approach was demonstrated in a mega pipeline project. After a detailed analysis of complexity and uncertainty factors, risks of the project were calculated at different stages, and variations were observed. According to the findings from the demonstrative case study, the performance of the proposed risk assessment approach is promising in terms of unveiling the risk sources in the project and reflecting the risk perception of the project manager. Thus, IRAP has the potential to improve the risk management performance of mega construction projects. The following are the main takeaways from the demonstrative case study:

- The main benefit of the proposed risk assessment approach is that it integrates complexity-based thinking into risk management. While the traditional risk assessment techniques are based on estimating the probability and impact of unknowns, IRAP promotes analyzing the static and dynamic complexity factors, together with the uncertainty factors, as potential risk sources of the project. It facilitates the exploration of all possible risk causes in the assessment process.
- Another important aspect of IRAP is that management strategies are engaged in the risk assessment process. In traditional approaches, identification, analysis, and response are the successive phases of risk management. However, IRAP integrates the response strategies into both the identification and analysis of the risk sources. During the identification phase, they provide a feedback loop to uncover new risk sources resulting from their impact on the project. They are also taken into account during the analysis phase as their effects are reflected while rating the magnitude of the identified risk factors. Thus, management strategies constitute the cornerstone of the network-based approach in IRAP.
- IRAP also provides a practical risk monitoring approach for ongoing projects. It facilitates the assessment of the risk levels throughout different project stages and the evaluation of the fluctuations in the risk factors over the source parameters. Thus, the reasons for the increase in the risk level during a specific period of the project could be identified using IRAP.
- Although IRAP principally serves for risk assessment during the project lifecycle, it may also be used for other purposes. For example, as it can simulate the impact of different strategies on risk levels, scenario analysis may be performed with IRAP to select the most appropriate risk management strategies. Moreover, within a database setting, it may help record the lessons learned for the forthcoming projects.

Despite the reported benefits, it is evident that further studies are needed to test the validity of IRAP both in risk assessment and other applications. The risk sources and weights used in this paper have been based on the authors' previous studies. They can be customized for different projects to assess their unique conditions more realistically. Although IRAP was developed for mega construction projects, it can be applied to other project types for comparative purposes. It is also possible to compare IRAP with different risk assessment approaches to evaluate the performance or applicability. Moreover, other network-based quantitative methods, such as Bayesian networks, network theory, and system dynamics, can be utilized to operationalize IRAP. The advantages and disadvantages of these methods over ANP can be reported in future studies. On the other hand, the findings of the demonstrative case study were based on retrospective analysis and reflected the subjective views of the project manager. Longitudinal case studies that include more participants may better explain the sequence of risk events and their interactions with the complexity and uncertainty factors. They can also serve to test other potential benefits of IRAP, such as analyzing alternative risk scenarios for different

management strategies and recording the lessons learned for new projects. Finally, decision-support tools can be developed to facilitate the implementation of IRAP.

Management of Risks Influenced by Information Asymmetry During Construction: Framework for Research

A. Cerić and I. Ivić
University of Zagreb, Faculty of Civil Engineering, Department for Organization, Technology and Management, Zagreb, Croatia
anita@grad.hr, iivic@grad.hr

Abstract

In construction projects a large part of the costs associated with risks fall on communication risks. Communication risks can occur at any time during the life of construction projects and can affect the activation of other risks. They are influenced by information asymmetry among project participants. Information asymmetry is a situation in which participants in the same project, although having the same goals, sometimes do not share information with other parties involved in the project because of self-interest. This is a typical principal-agent problem. Effective management of risks influenced by information asymmetry during the construction phase remains a challenge for project participants. The focus of this paper is on the risk management in construction projects to gain perspective on possible tools and methods for risk identification, analysis, and risk response. Also, basic concept of principal - agent theory and types of information asymmetries are introduced. Finally, the framework for research is proposed as a guidance for future work on the development of a comprehensive system for management of risks influenced by information asymmetry in construction projects.

Keywords: *communication, construction projects, information asymmetry, risk management.*

Introduction

The construction sector is of great importance for the world economy and the progress of society. Global construction output in 2020 was US$10.7 trillion and is expected to grow by 42% between 2020 and 2030 to reach US$15.2 trillion (Robinson et al., 2021). According to Robinson et al. (2021), "the global construction industry is set to be a global engine for economic growth and recovery from COVID-19". Investments in some large and complex projects, the so-called mega projects, with long duration and social importance, exceed as much as a billion dollars (Flyvbjerg, 2014). However, projects often face difficulties in terms of meeting deadlines, planned budget and quality. As a result, the entire construction sector has a bad reputation for being inflexible and unable to cope with the changes that occur during project implementation. A possible reason is the fact that risks and uncertainties are present in the construction sector much more than in other industries (Flanagan & Norman, 1993).

Throughout the process of conceptualizing, planning, designing, constructing, and commissioning buildings, it is easy to expect a large number of unforeseen or uncertain

events. The main sources of uncertainty and risk in projects include their uniqueness, complexity, large number of assumptions made during the planning process, limitations, large number of participants involved, and changes during implementation that are difficult to predict at the beginning of the project (Hillson, 2009). Also, there are external factors that include market, competing companies, changes in organizational, political, economic, technological, legal, international, environmental, and demographic factors (Hillson, 2009). It is impossible to expect a risk-free project, so managing risks is necessary for the successful implementation of projects.

Most common risks in construction projects are communication risks. The Project Management Institute (PMI, 2013) states that communication risks account for 56% of the total risk costs in projects. Communication risks can occur at any time during the life of the project. Their most important consequence is failure in meeting project objectives (Assaf et al., 2018; Choudhry et al., 2018; Berard & Karlshoej, 2012; Couto, 2012; Mephyans-Robinson, 2010; Schwalbe, 2010). According to Cerić and Ivić (2021) and Cerić (2014), communication risks are influenced by information asymmetry among project participants. Information asymmetry is grounded in principal-agent theory, defining a situation between two parties in which one is better informed than the other, and they do not share common interests (Jensen, 2000).

Effective communication risks management during the construction phase remains a challenge for project participants, mainly because of non-existing measurement tools. Therefore, a framework for research on management of risks influenced by information asymmetry during construction is presented in this paper. First, some basic terms of risk management process in construction projects are described in order to investigate possible tools and methods for risk analysis. Then, the implications of information asymmetry are explored, and risks influenced by information asymmetry are identified. The paper closes with the proposed framework for future research on risks influenced by information asymmetry during construction.

Risk Management

The purpose of risk management is to increase the likelihood that project objectives will be achieved through the management of threats, and by taking advantage of opportunities that may arise (Adelsberger, 2015). Therefore, the risk management process is one of the most important processes in project management. For many years, before the emergence of the risk management, construction projects ended with serious consequences on deadlines, budget, quality, and relationships among participants. Although participants were aware of the risks, they did not quantify them. Today, risk management is defined as "a system which aims to identify and quantify all risks to which the business or project is exposed so that a conscious decision can be taken on how to manage the risks" (Flanagan & Norman, 1993, p. 45). Risk management was enriched in the 1980s and 1990s by scientific publications related to the construction industry (Flanagan & Norman, 1993; Carter et al., 1994), various guidelines (CIRIA, 1996; APM, 1997; ICE & FIA, 1998), and also practically. Over the years, the process has evolved, and many models and methods have been developed designed to improve the decision-making process in an environment of uncertainty and risk.

In addition to scientific publications, international standards and norms are the broadest and most influential source of information on the risk management process, and the most famous

of them is the standard ISO 31000: 2018, Risk management – Guidelines. The International Standard Organization has issued another publication, which specifically explains the terminology related to risks (ISO 31073:2022, Risk management - Vocabulary), and another that discusses risk assessment techniques in more detail (IEC 31010: 2019, Risk management - Risk assessment techniques).

Different interpretations of risk-related concepts are available from different sources, and even the concept of risk itself has different interpretations, some of which are described below.

Sometimes the terms *uncertainty* and *risk* are equated and are often mentioned only in a negative context. However, they need to be distinguished. When we talk about uncertainty, it represents any event for which the outcome is unknown, and the outcome can be either positive or negative. On the other hand, according to Hillson (2009, pp. 6-7), risk is "uncertainty that matters", "risk is a type of uncertainty, but not every uncertainty is a risk". Risk is more specific than uncertainty and has a dual nature. It includes an *uncertainty* to which a certain number is assigned (in English language there are several terms for that number: likelihood, chance, probability, possibility), and *consequences* for something of importance. For example, a lottery game is an uncertain event because its outcome is unknown, and it can be either positive (cash gain) or negative (loss of money we paid for the ticket). On the other hand, that game does not pose a risk to us if we have not paid the ticket. The moment we decide how much we want to pay for a ticket, the event is assigned a probability of winning (it is higher if we pay more and less if we pay less). So, in order for that uncertainty to become a risk, the outcome of that event must have consequences for our goal to make money, and we must assign a number to that uncertainty. After drawing lottery numbers, this risky event will have either a positive (*opportunity*) or negative (*threat*) effect for us.

Numerous papers have tried to define risk. In one group of definitions, risk is presented as an event: "risk is an uncertain event or condition that, if it occurs, has a positive or negative effect on one or more project objectives" (PMI, 2017, p. 397); "risk is a situation or event where something of human value (including humans themselves) has been put at stake and where the outcome is uncertain" (Rosa, 1998, p. 28). In the second group, the risk is a consequence or effect: "risk is an uncertain consequence of an event or an activity with respect to something that humans value" (IRGC, 2005, p. 19); "risk is the effect of uncertainty on objectives" (ISO, 2018, p. 1). In the third group of definitions, risk is presented as a probability or chance: "risk is the chance of an adverse event, and it depends on circumstances" (CIRIA, 1996, p. 9); "risk is the probability of an adverse outcome" (Graham & Weiner, 1995, p. 30). Finally, the fourth group of authors argues that for a complete definition of risk it is necessary to take into account its dual nature, and define it not only as an event, consequence or probability, but comprehensively: "risk refers to uncertainty about and severity of the events and consequences (or outcomes) of an activity with respect to something that humans value" (Aven & Renn, 2009, p. 6); "risk refers to uncertainty of outcome, whether positive opportunity or negative threat, of actions and events. It is the combination of likelihood and impact, including perceived importance" (Cabinet Office, 2002, p. 7); "risk is a two-dimensional combination of events/consequences and associated uncertainties" (Aven, 2010, p. 624).

Many scientific publications have described the risk management process. The basic three steps of this process have remained the same for many years: risk identification, risk analysis, risk response (Flanagan et al. 1987; Crispin, 2020).

Risk Identification

Risk identification is a first step in every risk management process. It involves identifying any risks that could affect the project objectives. Identification includes naming and describing risks.

Important terms used to describe risk include *risk source*, *event*, *consequences*, and *likelihood*. Here we provide definitions from (ISO, 2018), which are internationally accepted and used. Risk source is defined as "element which alone or in combination has the potential to give rise to risk". It can be tangible or intangible. Event is an "occurrence or change of a particular set of circumstances". An event can have one or more occurrences, multiple causes, and multiple consequences. An event can also be something that is expected and does not happen, or something that is not expected and does happen. Therefore, the source of risk is a broader concept than the event. An event can be a source of risk, but the source of risk does not have to be an event. Consequence is defined as the "outcome of an event affecting objectives". The consequence can be certain or uncertain and can have a positive or negative direct or indirect effect on the goals. The consequences can be expressed qualitatively or quantitatively. Likelihood represents a "the chance of something happening, whether defined, measured or determined objectively or subjectively, qualitatively or quantitatively, and described using general terms or mathematically (such as a probability or a frequency)". It should be differed from mathematical term *probability* that has a narrower meaning.

Other terms that often appear in risk identification process include *vulnerability*, *exposure*, and *hazard*. These terms describe the source of risk in more detail and do not have to be used in every context. Hazard is a "source of potential harm" (ISO, 2022). It is always associated with negative effects on goals. The hazard may be a substance (for example, oil), a site (for example, an oil refinery) or a situation (for example, an oil spill from an offshore plant). Vulnerability is "the property of something resulting in susceptibility to a risk source that can lead to an event with a consequence" (ISO, 2022). Exposure is defined as an extent to which an organization and/or stakeholder is subject to an event (Aven, 2011).

Methods that can be used to identify risks include expert opinions, participation in project meetings, surveys or interviews with relevant participants, brainstorming, the development of checklist, and SWOT analysis. Also, cause-and-effect diagrams can be formed, which graphically show risk factors and their possible causes, as well as other similar methods. Regardless of the chosen method, the correct identification of the risk requires the expertise of the participants in the process.

Depending on the nature of the risk, we distinguish two different types: *risks arising from an event* and *risks not preceded by any specific event*. The risks associated with the event are easier to identify. Their identification is based on the identification of the source of the risk, the event and its effect (Flanagan & Norman, 1993). Thus, one risk event can have several different sources, but also several different effects or consequences. The occurrence of some risky events can be influenced (such as the risk that two engineers will not coordinate

properly when working on a project), while the occurrence of some cannot be influenced (such as weather risks).

Risks that are not preceded by any specific event have in many cases not even been identified, and their importance has been particularly pronounced recently. There are two types of such risks, and these are variability and ambiguity risks (PMI, 2017, p. 398). *Variability risks* are related to the uncertainty that exists about some key characteristics of a planned event or activity or decision. Examples of such risks include: productivity may be above or below target, the number of errors found during testing may be higher or lower than expected, or unseasonal weather conditions may occur during the construction phase. *Ambiguity risks* are related to the uncertainty that exists about what might happen in the future. Some of the project areas where imperfect knowledge could have implications for project objectives include: elements of the requirement or technical solution, future developments in regulatory frameworks, or inherent systemic complexity in the project.

Thorough risk identification is the most important step in the entire risk management process. The result of the identification is the risk register, which is constantly updated during other phases of the risk management process, but also throughout the project, in order to provide the most accurate information about the risks at a given time.

Risk Analysis

Risk analysis is performed in order to describe the impact of identified risks, in as much detail as possible. Not all identified risks will be equally important, so the aim of the analysis is to prioritize them and obtain data with which to decide in the next step which risks need to be minimized and in what way. This is done by assessing the likelihood of occurrence of the risk and the strength of its consequences, which together represent its impact on the objectives.

The detail of the analysis and the methods used in this step depend on the purpose of the analysis, the availability of the information, and the resources available. The methods used can be divided into qualitative and quantitative, and a combination of them can be used. Qualitative methods are usually always applied, while quantitative methods are used only when greater detail is needed. The choice of the best method depends on various factors such as the availability of data and resources, the knowledge and skills of the analyst, and the required representation of the results. A qualitative approach to determining the list of priorities in risk management is applied when an appropriate database is not available (Cerić & Marić, 2011).

Risk matrices, influence diagrams and *event trees* are most often used to present the results of qualitative analysis. These tools use non-numerical data in describing risks, so called linguistic variables: weak, medium, strong (consequence or likelihood). To prioritize risks, multicriteria methods are also used, which use the ordinal scale to rank risks by impact*: multi-attribute utility theory* and *analytic hierarchy process* (Cerić, 2003). Research in construction (Marčić et al., 2013; Cerić & Marić, 2011) has shown that the most complete and adaptable method for qualitative risk analysis is the analytical hierarchical process because it can be used to determine solutions to otherwise complex problems using simple expert judgment. In cases where there is an interconnection of variables, instead of a hierarchical one, an *analytical network process* is used, which has also found application in construction (Cerić et al., 2013).

Risk Response

After conducting a risk analysis, experts have enough data to help them evaluate the risk and decide on mitigation measures. Risk evaluation involves making informed decisions about which risks need more attention and over which no action needs to be taken. In this step, it is necessary to pay attention to individual risks, but also to their interaction and the broader context of risk. Following the evaluation, the risk register is updated with information on the risks for which responses need to be planned.

General rules for designing risk mitigation strategies, according to the literature (CIRIA, 1996; Flanagan & Norman, 1993), include: risk avoidance, mitigation, absorption, and transfer. Combinations of these measures may also include risk sharing, which includes partial absorption, and partial risk transfer (Thakur et al., 2016).

If the risk is marked as unacceptable in the registry, the response may be risk avoidance or transfer. If undesirable, the response may be any of the above. If the risk is marked as acceptable, it can be absorbed with regular monitoring. If it is negligible, no risk response is required at that point.

Framework for Research

In the previous section some basic terms of risk management are defined. This enabled the classification of key processes, methods, and elements that need to be clarified in the case of risks influenced by information asymmetry. In order to apply the comprehensive management of risks influenced by information asymmetry in construction projects, new framework for research is developed in this paper.

From the field of behavioral economics, principal–agent theory can be applied to explain communication risks in construction projects. Principal-agent theory describes the relationship in which one party, designated as the principal, engages another party, designated as the agent, to perform a task on their behalf (Cerić, 2021). According to Liu and Ma (2020), there are information asymmetries and goal conflicts in the agency relationship. Information asymmetry considers that an agent possesses more or better information regarding the details of individual tasks assigned to him, his own actions, abilities, and preferences (see Akerlof, 1970). Goal conflicts refer to conditions in which the desires and interests of the principal and the agent are in conflict with each other (Kivisto, 2008). Information asymmetry and goal conflicts lead to opportunistic behaviors by participants and increasing agency costs (Kivisto, 2008).

According to Turner and Müller (2004), the project owner and contractor form the key relationship in construction projects. In extended principal-agent framework, the project owner is the overall principal and all the other participants (such as designer, project managers, supervisors) are agents directly or indirectly employed by the project owner. However, between some of the participants (for example, contractor’s and owner’s project managers) there is no direct contract. At best, their relationship is based on the guidelines provided by professional organizations concerned with project management and related field, but it remains non-contractual and difficult to control. According to the principal-agent theory, all the participants are guided by self-interest, as illustrated in Figure 1.

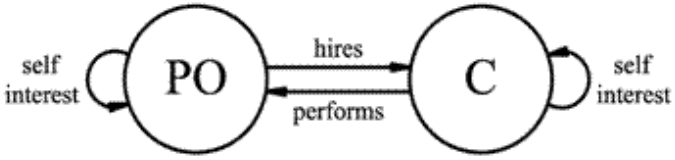

Figure 1: Basic principal–agent theory framework for construction projects (PO: Project owner, C: Contractor) (Cerić, 2016).

The principal hires an agent when he does not have the necessary knowledge and skills or the job is too complex and he lacks the knowledge to carry out certain phases of the job, and/or there is not enough available time. The reward to the agent is agreed in advance and the principal is obliged to pay it. The amount of agent's fee usually depends on the interest that the principal has in the realization of the set task. Thus, it can be said that the principal (project owner) depends on the agent (contractor) to undertake a task on the principal's behalf (Müller & Turner, 2005). In order to realize the interest of the principal, agent is ought to perform the task optimally. Nevertheless, the goals of the principal and the agent differ as each will seek to maximize its usefulness. The selfish action of the agent is consistent with the assumption that all individuals seek to maximize their own benefit, even when it may involve significant damage to the client (Schieg, 2008). Opportunistic behavior is possible because principal cannot (without compensation) supervise the agent. The greater the information asymmetry, the greater the likelihood of opportunistic agent behavior.

Due to characteristics of the principal-agent relationship and information asymmetry between the construction project participants, three types of risks arise: *adverse selection*, *moral hazard*, and *hold-up* (Schieg, 2008; Forsythe et al., 2015). *Adverse selection* occurs when the principal is not aware of the exact qualifications of the agent before the contract is signed. The agent hides its true characteristics in order to trick the principal and gain a contract. This is a situation where the agent has an advantage over the principal due to possessing and hiding relevant information that the principal cannot access on his own. In the case of *moral hazard*, the agent delivers below the quality specified by the contractual relationship. The principal cannot be sure whether the agent is doing his best because he sees only the result, while only the agent knows how much effort he has put in. *Hold-up* also occurs after the contract is signed. In this case the principal has already invested some resources in the belief that the agent will behave appropriately, but the agent acts opportunistically.

There are several possibilities for the mitigation of risks influenced by information asymmetry. Principal can apply *screening* of agent characteristics before contract is signed. During the tendering process, the principal can create multiple contracts and the agent should, by his choice of contract, reveal information about himself and how much effort he is willing to invest. On the other hand, agents can signal its true characteristics with their behavior on the market. Reputation also provides valuable information before signing the contract. After the contract is signed, in general, the relationship between project participants is controlled by means of contractual control (Bower & Skountzos, 2003). The contract expresses the intentions of the two parties, and so the roles and responsibilities of both sides are evident in the case any dispute arises (Simister & Turner, 2003). However, since multiple non-contractual relationships exist in every construction project, other means, such as relational control (trust) should be employed (Li et al., 2021; Marinho et al., 2021).

Considering all the acquired definitions in this paper, risk must include: (1) *Activity of importance* (construction of a building), (2) *Objectives at stake* (completion of a project within a defined deadline, budget or quality), (3) *Uncertainties about the outcome of that activity*. Adverse selection, moral hazard and hold-up all provide a threat to construction project objectives, but their emergence is very ambiguous. Investigation of these risks involves different areas of human sociology, psychology, and economy, therefore being a challenge to carry out. Qualitative methodology is selected as the most appropriate in this case, since risks influenced by information asymmetry cannot be quantitatively determined or measured. Framework for research shown in Figure 2. puts together two research areas – risk management and information asymmetry, in order to provide guidance in developing a management system for communication risks caused by information asymmetry in construction projects.

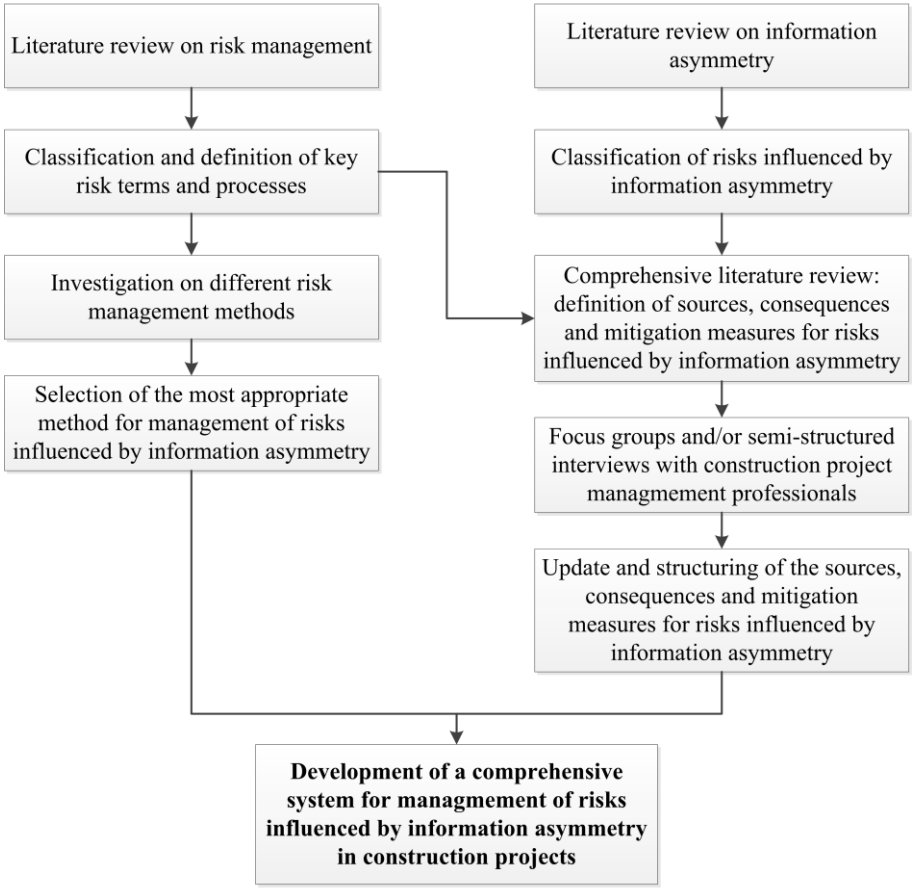

Figure 2: Framework for research on risks influenced by information asymmetry in construction projects.

The results of the first four steps of the proposed framework are presented in this paper. They include *literature review* in two areas (risk management and information asymmetry), *classification and definition of key risk terms and processes*, as well as the *classification of risks influenced by information asymmetry*. The following step will include a *comprehensive literature review* of key construction project management literature. The goal will be defining a list of *sources*, *consequences* and *mitigation measures* for risks influenced by information asymmetry.

To properly assess all the aspects of these risks in construction project environment, expert opinion of construction project professionals will be of great importance. Focus groups and/or semi-structured interviews will be carried out to evaluate, structure and update the list of risk sources, consequences and mitigation measures. The final steps will include an *investigation on available methods for risk management* and the *selection of the most appropriate method* to analyze risks influenced by information asymmetry. The research will result in the *development of comprehensive system for management of risks influenced by information asymmetry*. This will enable timely and precise identification, analysis and response on construction project risks influenced by information asymmetry between the main participants.

Conclusions

Risks influenced by information asymmetry are present in every phase of the construction project, before and after signing a contract between project participants. This paper provides a framework for research on management of risks influenced by information asymmetry in construction projects. A brief introduction into the concepts of risk management and information asymmetry is given, to provide an understanding of the main aspects that need to be studied. Framework presented in this paper shows the use of different qualitative methods with the goal of putting together two research areas – risk management and information asymmetry and providing guidance in developing a management system for communication risks in construction projects. The ambiguous nature of risks in questions requires exploration of different areas of human sociology, psychology, and economy. Expert opinions must be in focus to properly evaluate all the aspects of such risks. That type of research provides its challenges, but also offers a potential for comprehensively capture new ideas and possibilities for delivering successful and resilient construction projects.

Framework for research presented in this paper will provide the necessary guidance in developing the comprehensive system for management of risks influenced by information asymmetry in construction projects, which will be of great value for construction management professionals as well as for future researchers in the field.

Abstract

Tanzania's residential construction has been facing the most rapid and challenging growth in the construction industry. In global residential construction, many firms have tried to address challenges by introducing new methods of construction. However, most developing countries like Tanzania pose to be reluctant to the developing methods of construction due to a lack of knowledge and skills. Prefabricated construction (PFC) is one of these methods used around the world with a significant impact on the housing industry. Considering the growing risks in Tanzania's traditional method of construction (TMC), this research aims to provide knowledge on the prefabricated construction application. In this study, a comparative risk assessment between PFC and TMC is conducted by using Analytic Hierarchy Process (AHP). The findings showed that owner, economic and political related risks are the most significant factors for the PFC, whereas owner and nature-related risks are the most critical factors for the TMC in Tanzania. This study provides insight to the public, construction industry, and investors on the deployment of PFC in Tanzania's residential construction. These findings have important implications for understanding and enforcing PFC in Tanzania's residential construction industry.

Keywords: *Analytical Hierarchy Process, prefabricated construction, risk assessment, traditional method of construction.*

Introduction

The construction industry has been playing a significant role in determining the development and progress of a nation. The sector accounts for about 5% of total GDP in developed countries, while it tends to account for more than 8% of GDP in developing countries. Additionally, 100 million people are employed today in the construction sector worldwide (Global Construction Perspectives & Oxford Economics, 2013). In the industry, residential housing constitutes 38% of global construction volume; transport, energy, and water infrastructure 32%; institutional buildings 6%; commercial buildings 12%; and industrial sites 13% (World Economic Forum, 2016). However, the building and construction industry causes some challenges due to its high consumption of energy, water, and raw materials (Shan et al., 2017). As the European Union stated, the building sector is responsible for approximately 40% of primary energy use, 50% of all extracted materials, and 30% of carbon emissions; thus, adopting long-term efforts toward enforcing energy reduction is highly expected (Tsimplokoukou et al., 2014). According to the result of Jaillon and colleagues' study (2009),

the average construction waste can be reduced by 52% by using prefabrication rather than conventional construction methods. Moreover, the use of modern construction methods has a significant economic effect by reducing production hours by 31% (Nahmens & Ikuma, 2011). Besides, not only does the modern construction method such as prefabrication benefit the environment, but it also demonstrates significant advantages, such as improved quality control, reduction of construction time (20%), construction waste (56%), dust and noise on-site, and labor requirement on-site (9.5%) (Jaillon & Poon, 2008). However, most developing countries, including Tanzania, are reluctant to develop construction methods due to a lack of knowledge and skills.

Most of the innovation practices in Africa have been sluggish since not enough emphasis is implemented on the innovation practice. Narrowing down the construction industry to East Africa, Tanzania being precise, the construction industry accounted for 5% of the nation's GDP (Jason, 2008), which rose to 8.3% of the nation's GDP in 2013 (National Bureau of Statistics – NBS; Ministry of Works). In 2015, the Tanzania National Bureau of Statistics (NBS) enlisted the growth of the Tanzanian construction sector as 17.6%, followed by a decline in the growth to 6.9% in 2016 due to reduced investments in construction activities. This reduction in investment has led to the struggle of Tanzania's residential construction units in the industry. According to 2001 housing figures published by the Tanzanian Ministry of Lands and Habitat Development, there is a demand for 600,000 housing units in the major urban areas (Mehta & Bridwell, 2005). Since then, the country's population has risen from 35 million to 56.8 million (United Nations estimate July 1st, 2017), increasing the demand for housing units. Thus, innovations such as prefabrication in the construction sector contributed to the industrial practices in developing countries like Tanzania. However, the issues of such countries, including poor infrastructure, have resulted in a significant increase in the risks in the construction sector, and risks are different for every construction project depending on its size and nature (Subramanyan et al., 2012). Therefore, this study aims to evaluate the main risk factors of TMC and PFC in Tanzania's current construction era. Despite both methods being used globally, PFC has brought a substantial change in the worldwide development of construction industries over the last few decades (Wong et al., 2003).

Research Background

TMC dates to before 12000 BC. Since then, there have been various changes in both the construction materials and its methods of execution. As a result, the construction industry experienced many innovations in terms of materials and processes. Apart from the techniques and machinery innovation in the TMC, the PFC has also been developed. However, compared to other industries such as chemicals, electronics, and automobiles, the construction industry is the sector with the less innovation slope (Kulatilake, 2016).

PFC is one of the modern construction methods, and the UK government defines PFC as "the innovations in house-building from the construction site to the factory" (Pan et al., 2007). The Construction Industry Institute from the USA defined prefabrication "as a manufacturing process that takes place at a particular facility." Prefabrication is a manufacturing process in a specialized facility in which different materials are combined to establish a component of the final installation (Gibb, 1999). The prefab industry is the backbone for developing new ideas in the construction business (Dineshkumar & Kathirvel, 2015). In the construction field, prefabrication is regarded as the first level of industrialization, followed by mechanization, automation, robotics, and reproduction (Richard, 2005). The adoption of PFC was analyzed in

different literature on its benefits. Tam et al. (2007) define the seven benefits of PFC: (i) frozen design at the initial, (ii) enhanced controlling of quality improvement, (iii) construction cost reduction, (iv) less construction time, (v) incremental of environmental performance, (vi) integrity on the building design and finally (vii) construction, and artistic issues on the building. Similarly, Goodier and Gibb (2007) remarked on the benefits of PFC and highlighted its flexibility and sustainability. Moreover, Li et al. (2014) revealed how developed countries (e.g., USA, Sweden, and Australia) are the main contributors, whereas the contribution of developing countries (Turkey and China) is anticipated to increase (Li et al., 2014). However, both methods include some particular risks because of the difference between the approaches. For example, TMC involves construction on site, and PFC involves construction in a controlled environment. Therefore, to conduct proper risk management for PFC, the primary risk sources need to be identified and distinguished from the difference with TMC. Because the literature lacks a study that compares the risk sources in TMC and PFC in developing countries, this study aims to evaluate related in the Tanzanian construction industry to lead a better innovation development.

Methodology

This study aims to evaluate the risk factors of TMC and PFC in Tanzania's current construction era and provide insight to the parties in the construction sector and the public. After conducting a literature review to identify risk factors, an Analytical Hierarchy Process was performed using the data collected from experts to obtain the importance of each factor.

Selecting Critical Risk Factors

This research identified risk factors related to TMC and PFC through a detailed literature review. After eliminating studies, 23 peer-reviewed articles were selected. These studies are not limited to a particular country or region. Nineteen are related to the onsite construction, and four are on the offsite construction. Initially, the risk factors from all the selected studies are listed. Because different studies tend to have similar risks, a frequency column is formed to attain the similarity between the selected studies. The risk factors with a frequency of more than four are then separated, and groups are established to fit the relevant risks. As a result, a total of 32 risk factors exist in at least four academic papers. Finally, these risk factors are used to further evaluate to obtain the ranking of the very significant risk factors for the TCM and PFC.

Analytical Hierarchy Process (AHP)

AHP is a multi-criteria decision method introduced by Thomas Saaty in 1980. Saaty defined AHP as "a decision-making model that aids us in making decisions in our complex world" (Saaty, 1988). As the name states, it involves a hierarchy of the goal to the alternatives linking them. Fundamentally the AHP works by establishing priorities for alternatives and criteria used to judge the alternatives (Saaty, 2001). The AHP has various uses for the decision-maker (Saaty, 1988): (1) to assist in designing a form that represents a complex problem, (2) to measure priorities and choose among alternatives, (3) to measure consistency, (4) to predict a cost analysis, (5) to formulate a cost analysis, (6) to design forwards, and backward planning, (7) to analyze conflict resolution and (8) develop resource allocation.

The AHP arranges the selected factors in a hierarchy structure and first undergoes priority derivation for the performance of the alternatives. The priorities are then derived based on pairwise assessments using judgment. Finally, a weighting and adding process is used to attain the overall priority for the alternatives to the goal (Saaty, 2001). The pairwise assessments are normally conducted with the aid of a matrix. The matrix setup will contain a diagonal of 1's since when comparing similar criteria, so they will have the same importance. Since Saaty stated that AHP aids us in making decisions in our complex world, determining the weights is significant. The higher the criteria weight, the more important the criteria are considered to be. These criteria weights are calculated by the mean of the normalized criteria comparison matrix.

Shortly, the AHP generally has a trend in its procedure, starting with constructing a hierarchy of criteria from the available information and then integrating the information by normalization to obtain the relative rankings. Data from the qualitative and quantitative sections are then compared, and weights, in other words, priorities are acquired. In this method, the groups are considered independent of each other, as the factors in a single group are not to be thought to have any inter-relationship with another group. The goal node is only affected by the 2nd level of the hierarchy, whereas this level is only affected by the 3rd level, and subsequently, the alternatives are affected by the 3rd level (Vayvay et al., 2012). Thomas Saaty's team developed a software package called SUPERDECISION to conduct the ranking.

Data Collection

This study aims to evaluate the risk factors of TMC and PFC in Tanzania's current construction era. Since PFC is an unfamiliar technique in Tanzania, experts from the Turkish Prefabricated industry with international construction experiences in Africa, including Tanzania, are selected, while the TMC experts are from Tanzania. Table 1 and Table 2 show the experts' current position and their number of years of experience. Most professionals work in the production, planning, sales, and management sectors since these sectors are the crucial and most important ones in prefabricated construction. The prefabrication construction professionals were selected from four different privately-owned companies in Turkey. The traditional method of construction professionals has an average of 19 years of experience, most of whom are civil engineers in various companies. Similarly, the professionals also work in privately-owned construction companies in Tanzania.

The participants were asked to fill in pairwise comparison tables to rank sub-criteria and the alternatives. As Saaty (1977) suggested, a 1 to 9 Likert scale was used for the comparison. After modeling the hierarchical structure, the data is analyzed in SUPERDECISION software.

Table 1. Experts' information from PFC.

Professional	Position	Years of Experience
1	General Manager	18
2	General Manager	20
3	Factory Director	18
4	Production Manager	18
5	Project Manager	11
6	Planning Director	11
7	Civil Engineer	7
8	Senior Corporate Sales Manager	19
9	Corporate sales Manager	7
10	Sales Manager	3

Table 2. Experts' information from TMC.

Professional	Position	Years of Experience
1	Chief Engineer (Civil Eng.)	39
2	Managing Director (Architect)	35
3	Managing Director (Civil Eng.)	28
4	Managing Director (Civil Eng.)	33
5	Architect	20
6	Civil Engineer	20
7	Civil Engineer	20
8	Civil Engineer	6
9	Project Supervisor	4
10	Site Engineer	3

Findings

As a result of the AHP analysis, the importance of each risk factor is revealed. Table 3 and Table 4 show the ranking of factors for both TMC and PFC. The risk factors with the highest mean overall normalized weight in the external PFC are *sudden bankruptcy/ availability of finance* (0.0796) and *instability of political condition and war threat* (0.0759). These risk factors are from economic and political sub-categories. Further analysis is made for standard deviation, coefficient of variation, and variation degree.

The risk factor with the highest mean overall normalized weight in the internal PFC is *change or variation of orders* (0.0840) from the owner category, similar to the results obtained from the internal PFC risk factors. These levels of risk factors are grouped according to the mean overall normalized weights. The risk factors with normalized mean weight above 0.05 are considered Highly Significant (HS), mean weight between 0.03 and 0.05 are considered Moderately Significant (MS), mean weight between 0.01 and 0.03 are considered Somewhat Significant (SS), and below 0.01 are considered Not so Significant (NS).

Table 3. Importance weights of internal risk factors.

Category	**Internal Risk Factors**	**For TMC**		**For PFC**	
		Mean Overall Normalized weights	**RANK (Category)**	**Mean Overall Normalized weights**	**RANK (Category)**
Owner	Delayed payment	0.0470	4 (MS)	0.1187	1 (HS)
	Change or variation of orders	0.0840	1 (HS)	0.0749	4 (HS)
Designer	Changes in plan/design	0.0259	19 (SS)	0.0068	32 (LS)

Discussion and Conclusion

This study focuses on revealing the significant risk factors of the PFC and TMC. Therefore, this study evaluates 32 risk factors under nine categories and compares their significance in terms of TMC and PFC methods. The study results showed that in terms of internal risks, Change or variation of orders (0.0840), Acts of God (0.0555), and Weather/climate conditions (0.0517) are the three most important factors for TMC; while Delayed payment, Sudden bankruptcy/ availability of Finance, and Instability of political condition and War threat are the most significant ones for PFC. Considering that most of the critical risk factors are government-related, this makes it more manageable by close participation between the government with the investing companies in the PFC. Previous studies have also found similar TMC risks in developing countries such as Kenya and Tanzania. For instance, the study conducted in Uganda resulted in similar significant risks, including lack of training/skills and defective/poor design (Muhwezi et al., 2014).

Similarly, an investigation of factors causing construction project delays in Kenya was conducted, resulting in identical significant risks such as delayed payment, defective design, and management problems (Talukhaba, 1999). The East African countries are developing countries and highly need investors to steepen the growth slope. Considering the high population growth in (East African Community Facts and Figures – 2016 Report) Burundi (3%), Tanzania (2.7%), Uganda (3%), Kenya (1.3%), and Rwanda (2.4%), these population growths require a modern solution to enhance the construction quality, sustainability, and timesaving.

These results might provide insight into the East African countries since the countries share the same cultures and are all developing countries. This study also can be used for managing the risks and investments of the PFC in the East African countries since similar risks were witnessed in terms of TMC. The modernization of the construction sectors in East African countries can be highly accomplished by the collaborative cooperation between the government and the investors in the PFC. This study also helps to provide insight to other investors searching for international investments in East Africa. This study further helps the contractors bidding for projects in Tanzania and East Africa in general, providing them with information on what the local contractors and engineering companies put more emphasis on regarding risk assessment before accepting a project.

The method used in this study has some limitations as well. The AHP technique utilized in this study disregards the interrelationship between the risk factors of different groups. The possibility of having an interrelationship between some risk factors can be considered. Moreover, a few studies have been conducted on the causes of delays in Tanzania's construction industry. However, since the construction method used in Tanzania is the TMC, all the significant risk factor analyses are based on the TMC. This paper provides an insight into a modern method of construction, the PFC. The contribution to the literature is providing the significant risk factors of PFC and comparing it with the critical risk factors of the TMC in Tanzania's construction industry. This study further extends the literature showing the manageability of the significant risk factors in the PFC. Since the PFC combines the manufacturing industry and the construction industry, a manufacturing facility is required. Thus, the PFC can be further analyzed by considering its initial investments and the rate of Investment. These can also be used to countercheck the overall impact of the two methods on an actual project.

Abstract

Asbestos has been used extensively in construction industry for its superior insulation properties before its health hazards were discovered and eventually getting banned. It would not be wrong to assume all residential buildings built before the 1980s in Turkey contain asbestos. Therefore, it is important to raise awareness about the potential asbestos exposure hazard during demolition work. This article summarizes the efforts being made in the "Asbestos Free Demolition" EU project, which is executed to educate the construction industry and public with courses and seminars. The project also included field study to determine asbestos presence in the buildings that were damaged during the 2020 earthquake. 505 specimens were taken from 50 buildings that would go through demolition process. 11 buildings were found to contain asbestos. Eternite is the most common asbestos-containing

material type found in that 11 buildings. Results demonstrate the findings of asbestos-containing buildings and suggestions for prevention strategies before demolition work.

Keywords: *asbestos, demolition, EU project.*

Introduction

Asbestos is a carcinogen material that could kill humans when it is inhaled or digested in certain amounts (TWA: 0,1 fb/cm^3) (Toyokuni, 2019). Breathing in asbestos fibers could cause asbestosis, pleural disease, lung cancer and mesothelioma (O'Reilly et al., 2007). The risk of contracting these diseases increases with the number of fibers inhaled. Asbestosis is scarring in the lungs by asbestos fibers. Oxygen and carbon dioxide could not pass in and out of scarred lungs and causes difficulties in breathing. Asbestosis usually occurs in people who have had very high exposures of asbestos over a long time. Pleural disease is a non-cancerous lung condition that causes changes in the membrane surrounding the lungs and chest cavity (pleura) (Cugell et al., 2004). Mesothelioma is a rare cancer of the membrane that covers the lungs and chest cavity (pleura), the membrane lining the abdominal cavity (peritoneum), or membranes surrounding other internal organs (Bianchi & Bianchi, 2007). The symptoms of these diseases do not usually appear until about 20 to 30 years after the first exposure to asbestos (Prazakova et al., 2014).

On the other hand, asbestos is a great material choice in buildings due to its superior insulation and fireproofing properties (Craighead & Mossman, 1982). It was widely used in buildings before its fatal health effects was discovered in 20th century and prohibited from usage around the world. It was applied on steel beams and columns during construction of multi-story buildings as a fireproofing material. Due to its strength, asbestos was added to concrete, asphalt, vinyl materials in roof shingles, pipes, siding, wall board, floor tiles, joint compounds, and adhesives. Asbestos was also used for thermal insulation in acoustical plaster and as a component of a mixture sprayed on ceilings and walls.

The Directive adopted by the European Union in 1999 (1999/77/EC) prohibits the use and marketing of all types of asbestos in all European Union countries. With the entry into force of the Directive on 1 January 2005 for all member states, the European Union has started a ban on asbestos (Giannasi, 2007). Today, asbestos is completely or partially banned in more than 60 countries. However, asbestos will continue to cause deaths for more than twenty years, even in countries where asbestos is banned. Although asbestos products are not produced today, maintenance, repair, dismantling, demolition of structures containing asbestos products continue to pose hazard to workers and public health. According to European Union experts, by 2030, the predicted number of deaths caused by asbestos-related cancers in Western Europe will be around 500,000 (Marchwinska-Wyrwal et al., 2011).

In Turkey, the usage, extraction, and marketing of asbestos were prohibited by the date of December 31, 2010, with the council of ministers' decision. According to records, approximately 500,000 tons of asbestos was used in many products in Turkey before the asbestos ban (Güneş, et al., 2017).

The Law of "Transformation of Areas Under Disaster Risks No. 6306" was issued on 16 May 2012. The objective of the Law was to determine the principles and procedures concerning improvement, demolition, and renewal at areas under disaster risk (particularly earthquake),

as well as any other lands and plots which accommodate risk-bearing buildings, in order to establish suitable, healthy and safe living environments compatible with standards. For that purpose, the buildings which are deemed as “under disaster risk”, are being demolished. As a result, there has been an increasing amount of demolition work over the last 7 years. It is estimated that approximately 7 million buildings will be demolished in 20 years and transformed to a new one as a result of the law (Bozdoğan, 2020). In addition to this Law, in İzmir province of Turkey, 117 lives were lost, 1034 people injured, and 1846 residential buildings had damaged due to an earthquake that has 6.9 magnitude in 2020. It was decided by the government those 488 buildings will demolish in the first place (Ekizler, 2021).

It is highly possible to encounter asbestos in buildings, which are being demolished as part of the urban renewal process and due to the earthquake of Izmir. Unfortunately, many buildings are being demolished without considering the risk of asbestos exposure; despite regulations established on asbestos and construction/demolition work in Turkey dictate otherwise. However, the existing information in regulations lacks details and the current pre-demolition processes are not being followed properly by contractor firms probably due to unawareness and misinformation. Usually, building owners declare that there is no asbestos in the building and the demolition is carried out without attempting any survey or testing to check asbestos presence. As a result, workers who are engaged in demolition and other people in the vicinity are presumably being exposed to unhealthy amounts of asbestos. There have been a few academic studies in the past to address the dire situation (Kurt & Yıldırım, 2016; Üzmezoğlu & Ocaktan, 2017; Taşbaşı, et al., 2017) and even a roadmap to assist contractors complying with current legislation was proposed by Akboğa et al. (2016). However, contractors and building owners’ unwillingness to cooperate in dealing with asbestos hazard has been a challenge and a roadblock to any attempts and studies so far to remedy asbestos detection and removal process.

The current procedures mandated by the legislation are far from sufficient because standards have not been set on how to test asbestos presence and how to remove it based on the test results. Moreover, parties contractually involved in demolition work (contractor firms and building owners) are usually not willing to deal with asbestos removal because they are eager to demolish the building as soon as possible and proceed with the new construction. It is also known by contractors that determination of asbestos-containing materials and the abatement process significantly enhance the cost of demolition work (Franzblau et al., 2020). Contractor firms tend to finish their job as soon as possible and move on to their next project, while building owners want their renewed property without any delays due to asbestos removal. As a result, most of the demolition work in Turkey is being carried out without testing asbestos presence or just assuming that the building does not contain asbestos.

Nevertheless, it is unacceptable to simply deny the presence of asbestos in buildings to be demolished and proceed with the demolition/construction, because this puts many people at risk. Workers who are engaged in demolition, engineers, and other personnel in demolition site, and even civilians in the vicinity could be exposed to airborne asbestos fibers (Khadem et al., 2018) and get cancer (asbestosis, mesothelioma, and lung cancer) in the long term. Depending on the type of building (residential, industrial, etc) to be demolished, a detailed determination of asbestos fibers reveals the exact situation of the environment. (Obminski, 2020; Zhang et al., 2021). In terms of health perspective, it is vital to determine the amount and type of asbestos-containing materials and the status of airborne asbestos (Neitzel et al., 2020). It should also be noted that Turkey is only in the beginning stages of urban renewal process and thousands of buildings nationwide will be demolished over the years as part of

this renewal process. Many lives will be in danger as long as demolitions are carried out without asbestos testing and removal.

This paper aims to determine the asbestos-containing buildings in Izmir. For that reason, 505 specimens were taken from different locations of 50 buildings in İzmir as a part of the "Asbestos Free Demolition (AFDem)" EU project. According to the results, it was obtained that 11 buildings contain asbestos. This work also demonstrates the findings of asbestos-containing buildings and suggestions for prevention strategies before demolition work.

Asbestos Free Demolition (AFDem) Project

"Asbestos Free Demolition (AFDem)" is an EU-funded project which has started on 1st February 2021 by Ege University, Department of Civil Engineering with a budget of 150,000 Euro. The project stakeholders are Turkish Chamber of Civil Engineers (IMO), Dangerous Good Safety Advisory Association (TMGDK-DER), Association of Asbestos Removal Experts (ASUD), and The Municipalities of Izmir province.

AFDem project intends to improve occupational health and safety conditions in demolition work, which is listed under construction industry, one of the very hazardous sectors according to NACE Coding system. As stated before, most of the demolition work in Turkey is being carried out without making any attempts to eliminate asbestos exposure. Not only the demolition workers but also the public in the vicinity are in danger of getting exposed to asbestos. This will lead to many asbestos related health problems and even deaths in the future, unless demolition work is carried out entirely free of asbestos.

The intended outcome of the AFDem project is to raise awareness about asbestos hazards in demolition work, not only for parties involved in demolition but also for public at large. Turkey is quite unfamiliar with asbestos hazard and how threatening it can be to human life. The public, who is oblivious to the asbestos hazard during demolition, foremost needs to be informed about the hazards of asbestos, where asbestos can be found in existing buildings and why it needs to be removed. In addition, they need to know that asbestos fibers can be released into the air during demolition of buildings (mostly as part of urban renewal process). Even people and companies who are actively involved in demolition are not well trained in dealing with asbestos. Therefore, a series of training seminars is going to encounter to fulfil this objective along with a website to promote the project and inform the public on the reality of asbestos hazard in buildings. Training sessions is directed at contractors, building owners, municipality representatives and other stakeholders from construction industry. Training program consists of 5 training seminars and a workshop. The topics of the training sessions include but not limited to general asbestos information, asbestos health hazards, demolition operations in Turkey, asbestos presence in demolition work, asbestos testing, asbestos removal procedures and how to handle pre-demolition process in Turkey. This training session will be in 5 different cities (Ankara, İstanbul, İzmir, Adana and Erzurum) in Turkey with the aid of IMO (Turkish Chamber of Civil Engineers - İnşaat Mühendisleri Odası).

Website of the project is also an important asset to inform the public, since educational slides, educational modules about asbestos, findings from the project and other facts and statistics about asbestos hazard during demolition is shared on the website (https://afdem.eu/).

A well-informed public, who are sensitive to the asbestos exposure risk, should be an important driving force to establish asbestos free demolition work nationwide. If the public were knowledgeable enough about the hazards, most of the demolition work wouldn't have been carried out without asbestos testing and removal. Public would have been more sensitive to the demolition operations nearby their house or work locations, building owners wouldn't allow demolition of their buildings without dealing with asbestos first and workers would refuse to work in buildings with asbestos presence.

Increasing awareness is a major component in achieving the asbestos free demolition goal. However, proper procedures to remove asbestos needs to be established as well. Unfortunately, Turkish construction industry is rather unfamiliar with asbestos testing and removal techniques due to lack of standards or best practices regarding either how to test asbestos presence or how to remove asbestos from the buildings in Turkey. AFDem project fills this gap in the practices by taking samples from buildings to be demolished in Turkey and propose a removal process that involves different techniques based on different demolition conditions, such as age and type of building, location of asbestos, existence of construction materials that could typically contain asbestos and other technical factors.

Removal process also aims to focus on asbestos testing as part of removal procedures, particularly where to look for asbestos in the building, how to take samples, which equipment to use and other technical issues. Since there are varieties of techniques to remove asbestos based on the amount, type and location of asbestos in the building, developed procedures should be able to direct practitioners to select the right technique and how to apply it properly.

In addition to the lack of technical information, there are also uncertainties in the administrative side of things. Dealing with the existence of asbestos in buildings to be demolished and how to handle the administrative process is not an easy task for contractors and building owners because there are no proper guidelines established in Turkey. Such as, who building owners and contractors should contact regarding asbestos, where to get permits and other documentation, applicable regulations, and other administrative procedures. It is also difficult for municipalities to oversee this process. There are regulations concerning this matter, however they are not detailed enough to direct involved parties or not being followed as intended. Therefore, a sustainable mobile application is developed to form a roadmap and help practitioners make decisions on how to proceed in asbestos handling process.

Asbestos Measurement and Analysis

Sampling asbestos-containing materials (ACM) was executed according to "HSE 248 Asbestos: The Analyst's Guide". It is preferred guidance by many asbestos specialists as a sampling strategy. Also, it is important to take samples from the various locations of a building to detect all ACM. It is known that asbestos is mostly find in insulation boards, roofs, pipe laggings, floor tiles and window panels (HSE 248, 2012). In this study, to determine the ACM in 50 buildings that are going to be demolished, 505 bulk samples were collected in total. One of the building's views from the outside which is samples are taken is given in Figure 1. Besides, the inside of the part of the building is also shown in Figure 2 regarding the sampling strategy.

Figure 1: Outside of the building.

Figure 2: Inside of the building.

Samples were evaluated by Polarized Light Microscopy (PLM) according to "NIOSH 9002: Asbestos (Bulk) by PLM" guidance. PLM provides asbestos existence information and information of the type of asbestos fiber (İŞGÜM, 2019). It is known that other analysis methods such as Phase Contrast Microscope (PCM), Scanning Electron Microscope (SEM) and Transmission Electron Microscope (TEM) can provide more information than PLM. For instance, SEM and TEM demonstrate the number of asbestos fibers and measures dimensions of them owing to their image amplification ability (Dodson et al., 2008). However, the reasons for employing PLM in this study are because it's easy to notice asbestos fibers, cheap in utilization and obtained information is sufficient. Sample results provide required data for depicting the ACM locations in buildings and guide to exhibit prevention strategies and removal processes. Therefore, many asbestos measurement firms prefer the PLM analysis method, especially in Turkey.

Results

The Asbestos measurements were executed by taking samples from 50 different buildings in different locations of Izmir. The number of bulk sample testing in buildings is 505. The

number of buildings with ACM is only 11. All the buildings are residential buildings with a reinforced-concrete structure. The detected asbestos type is chrysotile (white asbestos) with the percentage of 60%. The detailed information about these buildings is given in Table 1.

Table 1. Results of buildings with ACM.

No.	Location	Date of Construction	Floor area (m^2)	Number of Floors	Location of ACM (Eternite)	Amount of Asbestos (m^2)
1	Karabağlar	1995	300	5	Roofing	40
2	Bornova	1995	100	3	Roofing	15
3	Çiğli	1990	105	2	Basement	8
4	Bornova	1980	131.18	2	Roofing	20
5	Karşıyaka	1973	215	6	Basement & Roofing	30
6	Buca	1991	90	3	Roofing	30
7	Buca	1996	120	3	Roofing	30
8	Buca	1990	105	2	Roofing	10
9	Çiğli	1995	250	5	Garden	10
10	Bayraklı	1997	498	8	Roofing	25
11	Bayraklı	1997	198	10	Roofing	25

Asbestos removal operations are performed in 11 of the buildings which has detected with ACM. The detailed information about removal is given in Table 2.

Table 2. Asbestos removal from buildings.

No.	Location	Date of Construction	Location of ACM (Eternite)	Amount of Asbestos Removed (kg)
1	Karabağlar	1995	Roofing	250
2	Bornova	1995	Roofing	100
3	Çiğli	1990	Basement	100
4	Bornova	1980	Roofing	250
5	Karşıyaka	1973	Basement & Roofing	300
6	Buca	1991	Roofing	250
7	Buca	1996	Roofing	250
8	Buca	1990	Roofing	100
9	Çiğli	1995	Garden	400
10	Bayraklı	1997	Roofing	250
11	Bayraklı	1997	Roofing	250

Conclusion

Considering the existing building stock throughout the country, it is known that asbestos-containing materials are used in many buildings that were built in the past, continue to be used today and will be demolished within the scope of urban transformation. Therefore, those working in maintenance, repair, reinforcement and demolition works on the existing stock, their families and neighbors are at serious risk of exposure to asbestos. For this reason, within the scope of the study, it was aimed to determine the buildings containing asbestos in İzmir.

505 specimens were taken from different locations of 50 buildings in İzmir as a part of the "Asbestos Free Demolition (AFDem)" EU project. Results showed that, that 11 buildings contain asbestos. With the urban transformation process, the increase in the number of demolitions is quite high. During this transformation period, those around and those working in the demolition of buildings are exposed to dust containing asbestos.

In this study, the issue was discussed in detail to raise awareness about the hazards of asbestos presence in buildings. Demolishing the old or damaged buildings without testing asbestos presence is a high-risk operation. It threatens not only the workers health but also the people in the vicinity. The project discussed in this paper intend to address these problems and highlighted the importance of asbestos testing before demolition. If public is properly educated and companies follow regulations and procedures, it is expected that asbestos exposure hazard will be prevented and eliminated in the future.

Abstract

The construction, which is one of the locomotive sectors in the economy has risks similar to other sectors, as well as the additional risks it carries due to its complex structure and characteristics. Financial risk is the probability of actual deviation of expected return. In the globalizing world, especially in recent years, construction firms are taking more place in overseas tenders. In addition, various reasons such as the increase in importing construction materials, use of credit from abroad raises the financial risks which has existed for a long time but has increased dramatically in recent times. Increasing competition conditions have reduced profit margins compared to the past, which has made financial management more important because of the low profitability. Increasing and frequent economic crises have also increased sensitivity to the issue. All these conditions strengthen risk management, especially financial risk management for construction projects. Risk becomes more prominent on volatile conditions and the importance of financial management increases. This study is about financial risks in construction companies in volatile market.

Keywords: *construction, financial risk, project management, risk management*.

Introduction

It is known that the construction industry has a great contribution to the economy in Turkey as well as in the rest of the world, and Turkish construction companies have been constructing significant projects in foreign markets as well as in the domestic market in recent years. The size of the market emphasizes the importance of managing the risks, especially financial risks of the sector.

Construction companies undertake a significant risk in return for their expected profitability. Although the operational risks that are directly related to the execution of the work are taken into account, the financial risks that may not be seen from the construction side can gain great weight. For example, a construction company that has different credit currency and sales currency and works in two currencies carries exchange rate risk. In this case, the construction

company, which is in the opposite position, is at risk of losing all its profits, sometimes more, no matter how successful its production is.

Regardless of the size of the project, risk and uncertainty are inherent in construction work (Quayle, 1999). Considering the construction sector as one of the leading sectors of the country, and the increasing frequency of financial crises, increase the importance of financial risk in the sector. Sector carries high risk and low profit margin. Financial risks, such as operational risks, are among the most frequently encountered and risks to be managed in the construction sector. Financial risk appears to be the most effective risk when risk categories are ranked according to their loss effects. The integrated economy of the world creates many risks for the industries where financial risk is the most complex one especially for construction sector (Shibani et al., 2022)

This study aims to emphasize the importance of financial risks in the construction industry. The success of construction projects may depend on how well the project financial risks analysis and manages. In today's economy, effective financial risk management is a critical component of any winning management strategy.

Financial Risk

Financial risk can be defined in various ways;

• Financial risk is the probability that the expected return will deviate from the actual return (Hagin, 1979).
• Financial risk can be defined as the positive or negative difference between the expected value and the actual value. Risk can also be defined as the uncertainty of economic value (Bolgün & Akçay, 2005).
• Financial risk is the decrease in the solvency of the firm. The risk here arises depending on whether the firm finances its activities with equity or external resources. Financial risk is the danger that the firm's incomes will lose their continuity as a result of borrowing and fall below the income level that will make the interest and dividend payments by not keeping up with a special or general change in environmental conditions, especially in the economic (Sarıkamış, 2000).

Types of Financial Risk

Financial risk is examined in the literature under the subheadings of market, credit, liquidity and operational risk (Sevil, 2001).

Market Risk

Market risk is defined as the possibility of loss in positions held in on-balance sheet and off-balance sheet calculations due to price fluctuations in the financial market.

Market risk is the risk exposed as a result of price fluctuations in the market (Taş & İltüzer, 2008). There are 4 basic types of market risk: interest rate risk, exchange rate risk, stock position risk and commodity risk (Basel, 2004).

Liquidity Risk

Liquidity risk is the risks created by the difficulties encountered in converting a financial asset into cash on demand or the risk of disposing of this asset below its current market value.

Liquidity risk can be expressed as the sum of the following three definitions.
• Internal Liquidity Risk: As a result of the imbalance in cash flow, the firm does not have enough cash or cash inflows to meet the cash outflows fully and on time.
• Liquidity risk related to the market: It is the possibility of loss if the firm cannot enter the market properly, cannot close its positions at an affordable price, in sufficient amounts and quickly, or cannot exit positions due to the shallow market structure in some products and barriers and divisions in the markets.
• Liquidity risk related to funding: It is the possibility of not fulfilling the funding obligation at a reasonable cost due to the irregularities in cash inflows and outflows and maturity-related cash flow mismatches.

Operational Risk

Operational risk arises from oversight of errors and irregularities as a result of disruptions in internal controls, failure to act in accordance with time and conditions by management and personnel, errors in management, errors and disruptions in information technology systems, errors and disruptions in the conduct of business, and disasters such as earthquakes, fires and floods. It is defined as the possibility of loss or damage that may result from risks arising from human and technological errors or accidents can be defined as operational risk (Sevil, 2001).

Credit Risk

Credit risk is the possible change in net profit and fair value of equity due to non-payment or late payment (Mandacı, 2003). It refers to the risk that a business may be exposed to due to the failure of the counterparty to fulfill its obligations. Credit risk is the risk arising from the failure of the participant to fulfill their financial obligations according to the contractual time and circumstances (Sevil, 2001). It is defined as the situation faced by the institution due to the fact that the parties with which it has a credit relationship do not comply with the requirements of the contract and cannot fulfill its obligations partially or completely on time.

Other Financial Risks

In addition to the risks listed above, the following list can be given:

• The risk that the transaction cannot be concluded: The case where the institution cannot receive or obtain the financial instrument or cash subject to the transaction within the expected period from the counterparty,

• Risk occurring before the conclusion of the transaction: The situation where it is understood that one of the parties performing the transaction will not be able to fulfill its contractual obligations within the period of the transaction,
• Country risk: In international credit transactions, the possibility that the borrower or the institution may not be able to fulfill the obligation partially or completely on time due to the economic, social and political structure of the country in which it operates,
• Transfer risk: The possibility that the foreign currency debt cannot be repaid in the same type or another convertible currency due to the economic situation and legislation of the country where the borrower or institution is located,
• Risk of insufficient information regarding the legislation: As a result of the actions that can be taken by the Institution based on insufficient or incorrect legal information and documents, the possibility of lowering the rights and realizing the obligations above the expected,
• Reputation risk: Loss that may arise due to the loss of trust in the institution or damage to its reputation as a result of failures in its activities or non-compliance with current legal regulations,
• Risk of non-compliance with regulations: It is the loss that may arise as a result of non-compliance with the provisions of the legislation and legal obligations.

Risk is one of the inevitable facts of business life. There is no business that will carry out its commercial activities without risk. All of the above-mentioned risks are risks that need to be measured and managed.

Characteristics of the Construction Sector and Financial Risk

Although the size and importance of the share of the construction sector in the country's economy is known, it is a fact that it also faces risk factors that may arise from its structural features and other reasons. Most projects are done once, every project is new and has its own challenges and uncertainties. There are many presuppositions. Construction can take seasons. Job conditions can be very demanding. The use of resources is not uniform. Many environmental factors can change during the construction process, and they can all directly affect construction. Resolution of conflicts can take a long time and this can cause significant damage to all participants. When we look at the sector-specific risks in general, we can list the following elements;

• Widespread construction activity over the years
• Risks that occur depending on the contractor
• Rivalry
• Receiving the works through tender
• Deviations in the price given in the receipt of the works
• Inadequacy of the accounting system in the construction sector
• The construction industry is affected by climatic conditions
• Overseas construction activities
• Getting used to working in an insecure environment
• Other risk factors: In addition to the above-mentioned risk factors, there are many other situations that can be multiplied, such as the fact that the employers and institutions with which the construction companies are in contact do not make the payments on time, heavy conditions are imposed on the contracts, technical examinations of the works are not done carefully due to lack of time, ignorance or simply negligence may pose a risk in the industry (Tüz, 2013).

Financial Risk Perception in Construction Projects

The following determinations stand out regarding the risk perceptions, assessments and practices of construction companies in Turkey;

Firms perceive risk as the loss of money. The importance of planning and programming is recognized and it is widely believed that no problems will arise if they are done properly. Risk management is perceived as a problem related to planning, not a management element. It is considered important that the biggest risk is working without a program and that the program should reflect the truth.

When the risk categories are ranked according to the effects of material loss, the following order of importance emerges;
• Financial risks,
• Political risks,
• Construction manufacturing risks,
• Environmental risks

It has been determined that many companies do not have a special department dealing with risk management, but it is thought that teamwork should be done in this regard, and in some companies, risk management is carried out by different departments according to the nature of the risk. It is seen that firms add values between 5% and 25% to the offer, sometimes with intuition, sometimes with experience, and sometimes in order to put a price, without making any calculations against the risks that may occur in the contract price. The general prevention approach in the sector against risks is implemented by adding to the cost and time analyzes.

It is stated that there are traditionally four main ways of dealing with risk in the construction industry;
1. The umbrella approach, where every possible outcome is taken into account by adding a high risk premium to the price
2. The ostrich approach, where heads are buried in the sand and everything is assumed to be okay
3. Intuitive approach, which suggests relying on inner voice and intuition rather than relying on all the fancy analysis available
4. The brute force approach that focuses on out-of-control risk and states that everything can be controlled forcibly even though that is not the case in reality (Uğur, 2006).

These approaches can be seen as solutions in a narrow range that creates their own problems. However, their chances of winning against the prices and costs incurred in an effective risk analysis and management process are quite low. For example, it is almost impossible to price the currency risk by paying a very high premium and get the customer to accept it. Companies that analyze these risks correctly will reflect the risk premium correctly and will gain an advantage over other offers. The party that does not adopt risk analysis and management will have difficulty even understanding how the winning party creates this price. Those who bury their heads in the sand take their positions by chance unless market movements develop against them, they can continue but will have to pay for movements in the opposite direction. Those who take risks by relying on their intuition would get the same results if they tried their luck in the stock market. Brute force is useless in the markets, no speculator can significantly

change prices with brute force. If the business is left to a company that does not apply risk analysis and management, then profits or losses from market movements will be added directly to the profit and loss of the business. The profit or loss that occurs in this way does not arise from the business itself, it is no different from speculating in international markets, the firm is implicitly exposed to speculation. Positive results are perceived or reflected as a skill of management, and negatives as formed by market conditions that are impossible to resist and manage.

Results

Many organizations in the construction industry try to isolate themselves from risk. They think they can avoid risk by blaming unexpected costs on others. There may be examples where this approach has worked in the past. Although it seems to reduce the risk by reflecting the financial risk to the consumer as a price increase or transferring the risk to the subcontractor that can show the least resistance, it can either increase the existing risks or create new risks. The subcontractor's loss makes the continuation, quality, duration and prestige of the work difficult, and all these directly affect the construction company. Transferring risks to other parties by contract, or coaxing other parties to bear those risks, may seem like a skillful way at first, but it can turn into a game of clinging to false certainties. What matters is not who the risk is transferred to, but the actual capacity to bear the risk if the risk materializes.

The structure of the sector is very complex by nature, and in this case, it is exposed to a large number of risks of various sizes. It is extremely important to analyze and manage financial risks correctly.

H. Yaman
İstanbul Technical University, Faculty of Architecture, İstanbul, Turkey
yamanhak@itu.edu.tr

Abstract

Construction is one of the leading sectors in economy and the sector carries high risk and low profit margin. Currency risk, has a vital importance especially for the construction projects which have different currencies at their cash flows. The profit loss and cost changes of construction projects at volatile currency atmosphere, have made it important to measure the currency risk and to manage it rationally after determining the existence of this risk. İt is important to know how much the project's profitability can fluctuate with the effect of exchange rate risk to determine the budget to be protected from this risk effect. Currency risk management have to be done during the all project and construction phases to prevent the effects of currency changes on the costs.

Keywords: *construction, currency risk, financial risk, project management, risk management*.

Introduction

Turkish economy, which is opening up business abroad more than past and construction which is accepted its locomotive sector, has become to be influenced from the global crisis stronger in recent years by the unavoidable result of the globalization. At the last 50 years, the top sector of the list is construction which is being influenced faster by both the global scale changes and the local economic crisis in spite of having benefits at the latest.

Economic crisis caused risk management concept's appearance. Because of the influence of a crisis which appearance at anywhere of the world is being felt more than past, the sensibility to these risks and the importance of the risk management is enhanced. At the construction sector, financial crisis are conspicuous amongst the frequent and to be managed risks like operational crisis.

Currency risk has become one of the most important issues in international finance after the abandonment of the Bretton Woods System in the early 1970s. As a result of the end of the application of this system, countries left their currencies to fluctuate and the uncertainty of the future values of the currencies have become a risk factor in itself. Changing currency

inevitably affect the cash flows of companies. Currency risk is so important that it is in the top five in many countries in the construction sector (Sameh et al., 2021).

In this study, the impact of currency risks volatility on the cash flows and completion costs of the construction projects is studied. Matlab is used to calculate the currency effect and visualize the results. According to historical currency data, the project is floated over time and thus the effect of the currency risk that the project will be exposed to if it was constructed in the past is calculated. The results show how profits change with the effect of currency risks and can be used to establish the budget for hedging. The aim of this paper is to show the importance of impacts of currency risk to cash flow of construction companies.

Risk and Currency Risk

Currency risk is defined as the possibility of loss or profit that may arise in assets and liabilities depending on the fluctuations in the value of the currency. The importance of currency risk for construction projects is obvious. Various studies support that international construction companies are exposed to complex risks such as exchange rate, inflation, credit and other business risks (Lee & Waiters, 1989; Han, 1999). Today, construction companies have foreign currency assets, foreign currency receivables, foreign currency loan debts and other foreign currency debts in their liabilities, and all debts and receivables arising from foreign trade transactions. The fact that all these assets and liabilities are in different currencies is the source of currency risk. This risk, together with the increasing volume of international trade that emerged with the phenomenon of globalization, makes its impact more felt than before.

Conjuncture in Construction Sector

The successive economic crises have led to the emergence of the concept of risk management, and the fact that the effect of a crisis that has arisen anywhere in the world as a result of globalization is felt more than before has increased the importance of risk management. Financial risks, like operational risks, are among the most common risks that need to be managed in the construction industry. The increase in the diversity of financial risks and the frequency of global crises brought about by financial integration have further increased the need for asset liability management and risk management.

As Quayle points out, risk and uncertainty are inherent in construction work, regardless of the size of the project (Quayle, 1999). Construction projects begin in a complex and dynamic environment created by conditions of high uncertainty and risk factors combined with time limits demanded by the owner (Mulholland & Christian, 1999). For this reason, it is known that many issues foreseen in the planning process in the projects in the construction sector are realized differently than expected during the implementation phase and create the need for re-planning. Compared to other stages of planning, the need to be affected by uncertainties and to be monitored continuously is much more in financial planning. Because the disruption of financial planning will affect all other planning actors (finishing the project on time, construction at the planned quality, etc.) (Tüz, 2013).

Shin and Soenen (1999) argue that currency fluctuations can have a significant impact on the performance of firms with international activities by influencing the relative prices of

domestic and foreign products and their foreign currency-fixed liabilities (Shin and Soenen, 1999). Currency fluctuations were found to be one of the most critical factors causing budget overrun in East Asia (Chua et al., 2003). In some other studies, the risk arising from currency fluctuations has always been found to be significant for joint ventures at varying rates (Bing et al., 1999; Shen et al., 2001).

When Loderer and Pichler (2000) investigate possible reasons why firms do not take any action, it turns out that they have reason to believe that risk gaps are trivial and commonplace because they have difficulty understanding the importance of measuring the risk profiles of firms (Loderer & Pichler, 2000).

Construction Projects Cash Flow

Cash flow is the cash inflows and outflows that occur in the business as of a certain period. Cash flow statement is a statement that shows the cash flows of a business in a certain accounting period in terms of sources and places of use.

The cash inflow of the construction project includes progress payment income, employer advances, collateral deduction returns, and credit usage. In cash outflow, labor, equipment and material purchases, payments to subcontractors, transportation expenses, taxes, loan repayments and general expenses are seen.

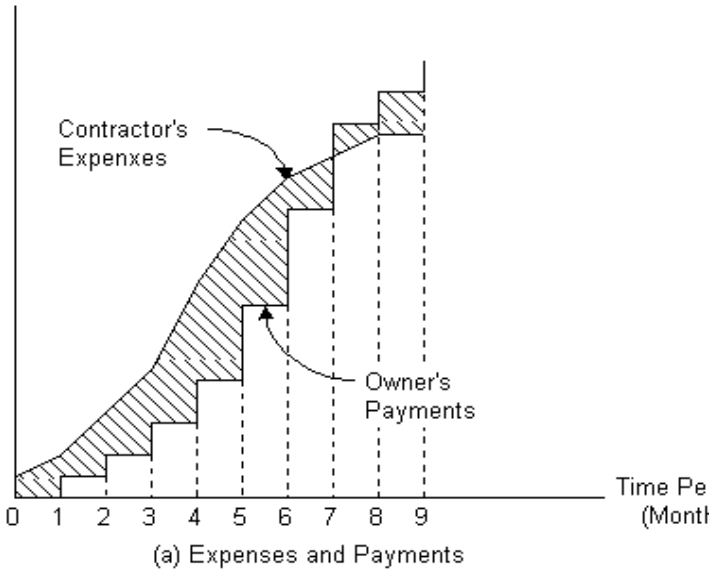

Figure 1: S curve (PMBOK, 2017).

The cost line used to measure, monitor, control and manage the overall cost performance of the project is the budget divided into time intervals. It is obtained by adding up the estimated costs for each period and is usually in the form of an S-curve (Figure 1). The S-curve is generally useful for a quick estimation of cash flow at any given moment (PMBOK, 2017).

Analysis

In this study, the effect of fluctuations in currency on the cash flow and project completion cost of a construction project is investigated. Matlab was used to calculate the exchange rate effect and visualize the results. According to historical currency data, the project is floated over time and thus the effect of the currency risk that the project will be exposed to if it was implemented in the past is calculated.

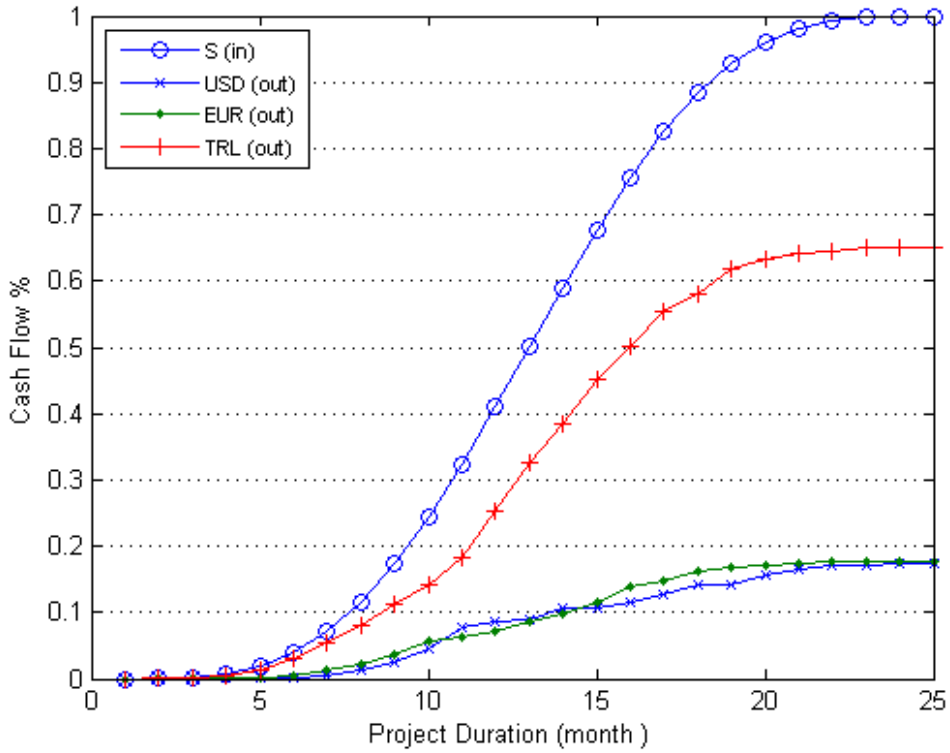

Figure 2: Example project cash flow.

The results found with the sample project data are shown in the histograms in Figure 3 and Figure 4.

As can be seen from the figures, the sample project can be completed between 0.97 times and 1.41 times the planned budget. The probability that the project will end at 1.08 times or less than the planned budget is 80%. There is a 20% probability that the project will be completed at a cost higher than 1.08 times the planned budget.

In the example project, the monthly cash flow fluctuation is between 1 and 2.21 times the planned one. The probability of project monthly cash flow fluctuation being 1.09 times or less than planned is 80%. There is a 20% probability that the project monthly cash flow fluctuation will be 1.09 times higher than planned.

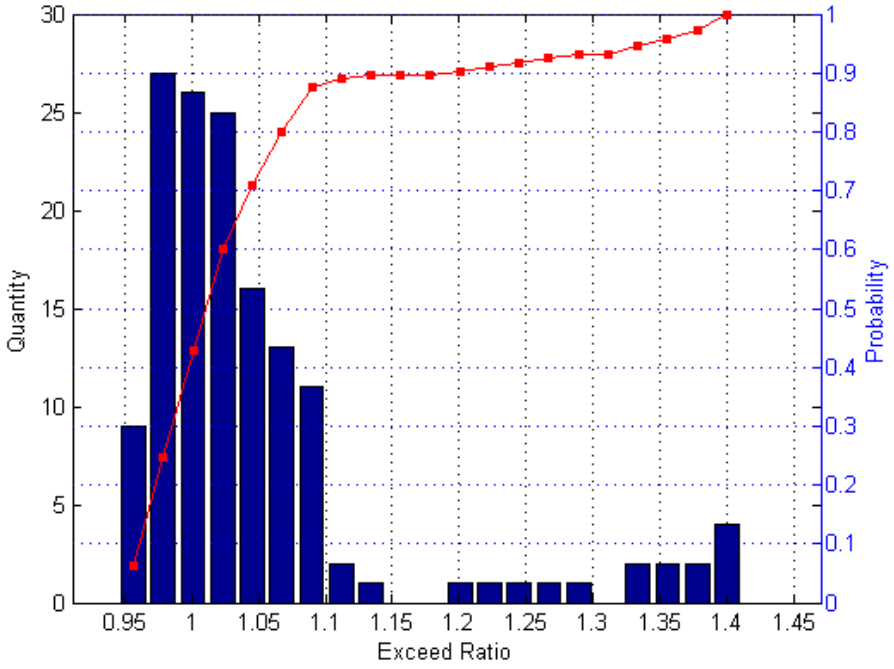

Figure 3: Sample project completion fee.

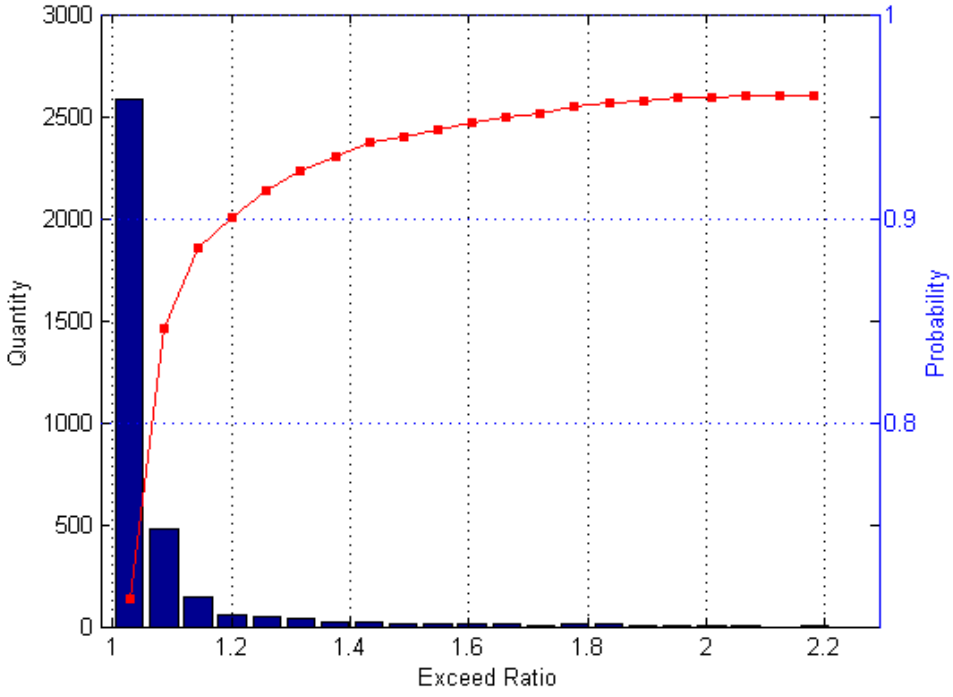

Figure 4: Example project monthly cash flow.

Results

The contractor can use cash flow forecasting techniques to understand his financial position and avoid the risk of bankruptcy. While this emphasizes the importance placed on cash flow, monitoring cash flow does not really eliminate the risk of bankruptcy. However, monitoring the cash flow and taking the right action on time will save the project from many risks.

The project completion cost may differ from the budgeted price depending on the cash inflows and outflows in different currencies and the effect of the volatility in the currencies. At the end of the project, although currency volatility did not make any difference in the completion cost, cash flows are under the influence of volatility. This situation can make great damage for construction companies that have not taken precautions by calculating their cash planning and financial risks, and it also puts the continuation of the business at risk. The firm fluctuates between raising additional resources and utilizing the surplus resources as cash flows remain volatile.

This budget overrun can destroy all the profits as well as cause losses. Fluctuating monthly cash flows and budget overruns can prevent work from being completed. On the contrary, when the currency supports the position in the cash flows, the tables that give the appearance of a very high profit are deceptive and are only speculative profits. This profitability has nothing to do with the business, so that the same profit can be obtained only by holding a foreign currency position.

The values obtained from the analysis show how sharply the profitability can fluctuate from time to time with the effect of currency risk and can be used to determine the budget to be created to protect from the effect of exchange rate risk. Currency Risk Management is a task that needs to be continuously monitored by analyzing the existing risk in all project processes.

Abstract

Sustainable development addresses today's requirements without compromising future generations' ability to satisfy their needs. The construction industry is well-known for being a big consumer of materials with high emissions associated with their production. Cement manufacturing accounts for 5% of total carbon emissions, with each ton emitting around one ton of CO_2, which has a negative environmental impact. Modern construction materials that consume a lot of energy and emit a lot of CO_2 should be gradually phased out with sustainable building materials. Due to low carbon footprint in adobe, it has gained popularity as a method of utilizing more sustainable resources. However, these buildings are highly susceptible to environmental change, and their low resistance to water and earthquakes necessitates their improvement. Istanbul Technical University invented Alker technology in 1978 to improve the properties of earthen constructions. Alker consists of 10% gypsum, 2% lime and 20-22% water, based on the dry weight of the soil. Stabilizing Alker with waste marble dust, polypropylene fiber, and shredded plastic waste, has been demonstrated to increase its mechanical properties and can help restrict the growth of cracks. Alker enhanced with these wastes has been proven to be a more sustainable building material with low carbon footprint.

Keywords: *alker, carbon footprint, earth buildings, eco-friendly materials, sustainable development.*

Introduction

Due to environmental and economic considerations, the usage and fabrication of materials has grown increasingly in recent years. It is well known that the construction sector consumes large amounts of materials with high CO_2 emissions associated with their manufacturing, particularly concrete. One of the most significant issues in cement manufacturing is the high temperature required to manufacture this material, which results in considerable energy usage. Sustainable building is seen as a means for the construction sector to protect the environment. Construction companies worldwide are becoming more conscious of the need for

environmental conservation. In order to reduce construction's negative environmental effects while still achieving industrial sustainability, three new concepts have emerged: resource efficiency, cost efficiency, and design for human adaption (Akadiri et al., 2012). Sustainable development aims to improve people's lives by addressing their social, economic, and environmental needs. Cement production accounts for 5% of total carbon emissions, with each ton emitting around one ton of CO_2. Sustainable building is done by utilizing natural resources, such as adobe, in such a manner that they satisfy economic, social, and cultural demands while neither depleting or degrading these resources to the point that they cannot supply these needs for future generations. The built environment accounts for nearly 50% of annual worldwide CO_2 emissions. Building operations account for 27% of total emissions each year, while building materials and construction account for an additional 20 % as shown in Figure 1.

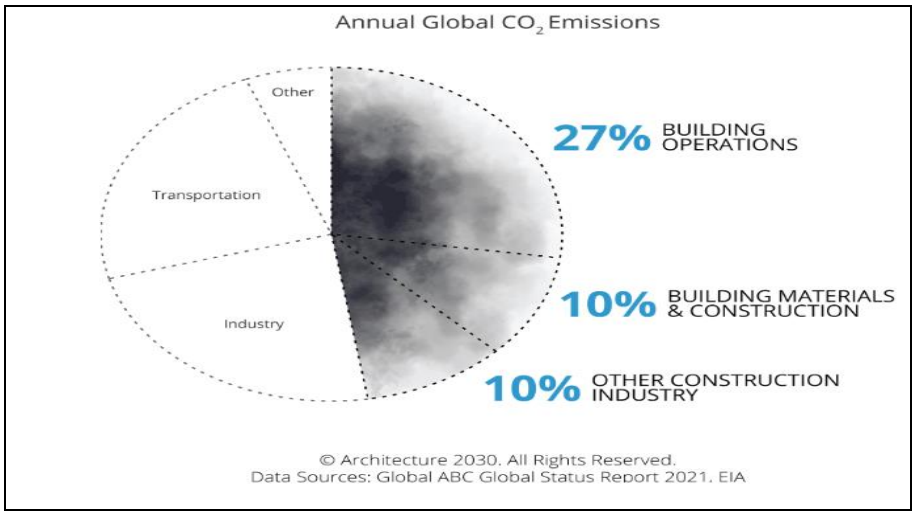

Figure 1: Annual global CO_2 emissions.

To achieve zero embodied emissions, the following principles must be followed:

- Reuse includes the renovation of existing buildings, the use of recycled materials, and the design for disassembly.
- Reduce by optimizing materials and specifying low- to zero-carbon materials.
- Carbon sequestration includes the design of carbon sequestering sites as well as the usage of carbon sequestering materials.

Figure 2 shows that only three materials (concrete, steel, and aluminum) account for 23% of total global emissions (the majority of which are used in the built environment).

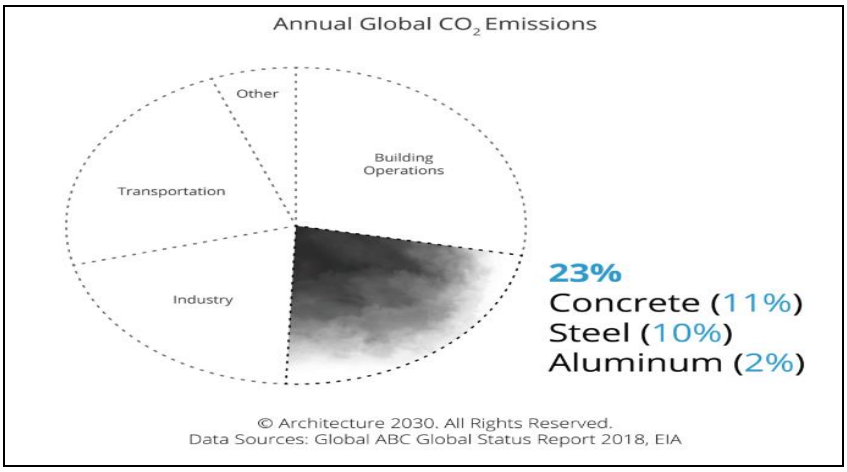

Figure 2: Annual global CO_2 emissions.

Characteristics of Adobe

Earth is an inexpensive, ecologically friendly, and abundant building material that has been widely employed in construction across the world. It is one of the oldest and most widely used building materials in the world. It is a natural building material made from sand, clay, water, and some kind of fibrous or organic material, such as sticks and straws. Earthen materials like stone and wood use less energy and require less resources. Some studies show that using earthen materials reduces the environmental impact of buildings (Hamard et al., 2016; Melià et al., 2014). Earthen structure, including rammed earth, adobe, and cob, that is warm in winter and cool in summer, is one of the oldest and most common structures in human history, and now about 30% of the world's population and 50% of the developing country population live in earthen shelters (Parisi et al., 2015; Silveira et al., 2012; Mateus et al., 2015; Silveira et al., 2018; Costa et al., 2019; Costa et al., 2016; Hoff, 2016; Varum et al., 2015). The affordability of new building materials and technologies makes earth construction a viable option for developing countries where modern building constituents and technologies are not readily accessible (Fratini et al., 2011). Adobe is a sustainable strategy having implications for social and cultural development. Costs are minimized due to the use of locally available materials and a straightforward construction technique. Earthen structures have a lower carbon footprint and embodied energy than structures composed of concrete, steel, or masonry (Bui et al., 2009). Because adobe does not require combustion before use as a building material, it eliminates the requirement for combustion.

The adobe building technique uses plastic earth and clay and is used mostly in locations with access to water. Using clay soil generates fissures upon drying due to shrinkage. To minimize cracking, adobe raw materials are typically mixed with straw or other plant fibers (Christoforo et al., 2016). To improve mechanical and thermal properties, adobe walls should be thick. Expert labor is required for specialized adobe making components. According to the literature, adobe soils must include 15–16% clay (Calatan et al., 2016). In order to achieve the best results, soils must be workable and malleable. Using fibers in adobes has caused controversy; some say it prevents cracking, others say it diminishes the mechanical strength of the earth bricks (Parisi et al., 2015; Sharma et al., 2015). Regardless of the weather, it can be claimed that adobe buildings have good energy management (Figure 3). Adobe buildings use less artificial heating and require less cooling in the winter. It is consequently

demonstrated that these buildings provide more comfortable interior areas in both winter and summer.

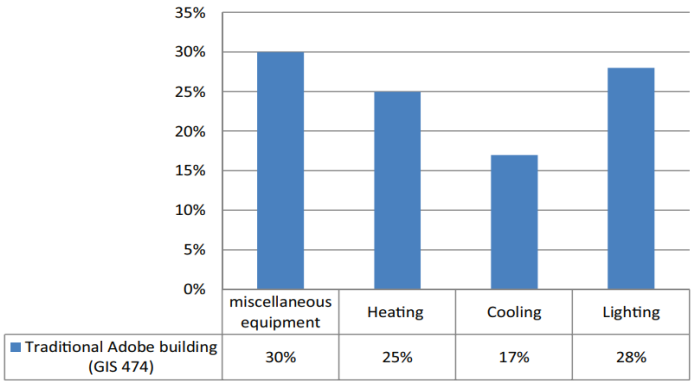

Figure 3: Yearly energy consumption in Adobe building (Obafemi & Kur, 2016).

Earthen Building Benefits and Limitations

Access to affordable housing for low-income people is linked to building materials and technologies (Adegun et al., 2017). According to Pacheco-Torgal and Jalali (2012), the use of traditional earth-based building materials has increased in recent decades due to their environmental friendliness. Earthen dwellings are eco-friendly due to limited manufacturing, recycling, and reuse. Earthen homes are thought to be healthy. The beneficial effect on health was unknown, but most people attributed it to a pleasant interior environment and the soil's ability to absorb toxins. Sanitation and rats were also mentioned. During the rainy season, moist feet enter the residence, polluting it and attracting parasites harmful to humans (Kulshreshtha et al., 2020).

While older building materials are considered "green", most current building materials are not recyclable (Pacheco-Torgal & Jalali, 2012). Manufacturing plastics, cement, and metals takes more energy. However, the building sector is now working hard to reduce embodied energy. It must be recyclable, reusable, have little embodied energy, and not emit dangerous particles to human health. Building materials have included stones, wood, earth, and plants. These are referred to as "conventional building materials". Materials derived from the earth or from biological sources (wood, fiber, and plant aggregates) that people have used for thousands of years are being reviewed as sustainable resources. Building materials and steel bars used in traditional construction need enormous amounts of extraction of raw material, this leads to resource depletion and environmental impact (Danso et al., 2015). It requires a lot of energy and generates pollutants like carbon dioxide and sulfur oxides. These pollutants are harmful to both the environment and human health. Traditional building materials like concrete, tiles, steel, bricks, solid blocks, hollow blocks, and pavement blocks have also become more expensive due to higher production energy costs, resource scarcity, and transportation costs. During the manufacturing process of those construction materials, different harmful chemicals such as high concentrations of carbon monoxide, sulfur oxides, nitrogen oxides, and suspended particulate matter are always released into the atmosphere. Emissions of harmful substances contaminate the air, water, soil, vegetation, and aquatic life, hence affecting human health and living conditions. Consequently, alternative building materials (such as earth blocks) and more sustainable construction procedures are being researched by Safiuddin et al.

(2010). Using earth saves energy (Costa et al., 2019), making it an eco-friendly material. In this environment, earth construction has increased in popularity as a way to create and use more sustainable resources (Laborel-Preneron et al., 2016).

Earthen materials, on the other hand, have weak mechanical properties, shrinkage, and low water resistance (Müller et al., 2016). Water movement (capillary action, rain, floods, etc.) causes clay particle swelling and shrinkage, finally resulting in cracks and material loss (Eires et al., 2017; Rainer, 2008). This mechanism has a stronger effect on montmorillonite clay (Lima et al., 2020; Minke, 2012). Although earth is one of the most often used building materials, it is also one of the most susceptible to moisture (Gomes et al., 2016). Water exposure reduces adobe's strength, resistance to erosion, dimensional stability, and durability. Additionally, long term exposure to water can cause adobe blocks to partially or entirely disintegrate (Murmu & Patel, 2018). The higher energy efficiency measures required to make on-site renewable energy sources possible, as well as the immediate awareness and greater understanding of energy consumption that they foster for its inhabitants, are major benefits of developing zero energy, zero carbon, or zero emission buildings. As long as onsite, near-site, and offsite renewable technologies are used, it is conceivable to reduce carbon emissions from energy use to zero in the majority of new non-domestic buildings (Hui, 2010).

Alker Technology: Proportions and Properties

Due to certain constraints, such as lower water resistance and earthquake resistance, Adobe does not satisfy today's needs. They are vulnerable to moisture and can be easily damaged by earthquake. Istanbul Technical University, which has been conducting research on earthen construction materials since 1978, discovered that earth may be stabilized with gypsum and lime, resulting in increased durability, physical and mechanical properties (Işık, 2011). This combination is known as "Alker" (an abbreviated form of the Turkish words for gypsum and adobe, meaning gypsum-stabilized adobe; gypsum = alçı, adobe = kerpic). The construction phase of the Alker Building, 1995, can be observed in Figure 4a, and the Urfa Pilot Building, 1999, can be seen in Figure 4b.

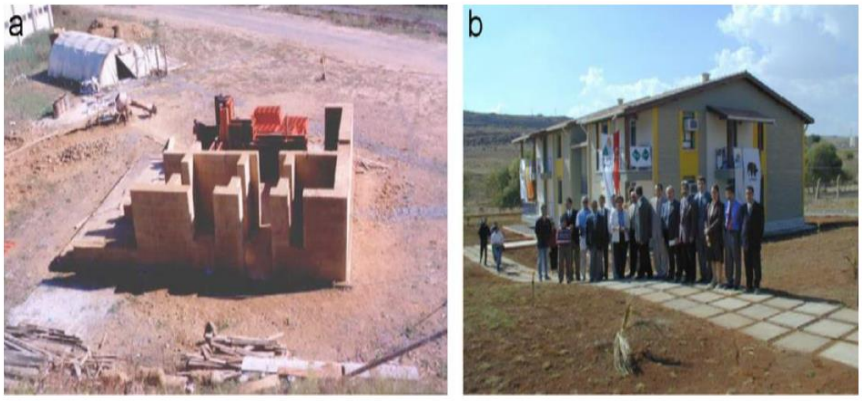

Figure 4: (a) Construction period of Alker building (b) Urfa pilot building (Işık, 2011).

The earth used in Alker technology is significantly more readily available than the earth required for traditional earthen construction due to its lower clay content. Alker is simply a soil that contains a large amount of clay and has been stabilized with lime and calcined

gypsum. It is composed of 10% gypsum, 2% lime, and 20% to 22% water, based on the dry weight of the soil (Balkis, 2017).

The binding property of the earth can be achieved with a clay content of about 30–50%. The addition of gypsum assists in this binding, and the earth's clay content of between 8% and 10% is sufficient to produce Alker (Isik, 2011). Table 1 displays the physical and mechanical properties of Alker.

Table 1. Physical and Mechanical properties of Alker (Işık et al., 1995).

Unit weight	**1.6 -1.7 kg/lt**
Shrinkage	%1.00 -1.50
Compressive strength	2- 4 N/ mm^2
Shear strength	0.9 - 1.3 N/ mm^2
Water absorption	Low
Long term water effect	Low
Thermal transfer coefficient	0.4 W/mK
Heat storage	1.0 kJ*/kgK

The use of lime and gypsum in mixes minimizes the time required for mixing, molding, compacting, and turning out of molds (Aydin & Balkis, 2017). Gypsum helps decreases the shrinkage of the building material, while Alker provides the durability required for load-bearing wall construction. Additionally, Alker is permeable and lighter than unstabilized earthen materials due to the fact that the gypsum hardens before the clay dries (Işık, 2011). Heat resistance and durability are particularly high in gypsum-stabilized earthy materials, especially in wet conditions. The manufacturing process is simple, and the energy usage in buildings constructed with this material is negligible. Buildings that are healthy also generate a healthy environment for people. The binding property of the earth can be achieved with a clay content of about 30–50%. The addition of gypsum assists in this binding, and the earth's clay content of between 8% and 10% is sufficient for the production of Alker. Isik (2011) discovered that a high clay content enhances shrinkage, whereas a low clay content reduces binding. The earth needed for Alker technology is much easier to obtain than the earth required for conventional buildings due to its low clay content. Although the earth's clay mineralogy has not been defined, a sufficient amount of clay is required in order to create a suitable bond (Onochie & Balkis, 2021). According to Balkis (2017), the use of Alker, a low-energy building material, helps achieve long-term sustainability in both indoor and outdoor construction.

Alker Stabilization

Onochie and Balkis (2021) investigated the effect of Polypropylene fiber alone on Alker. The results show that increasing the polypropylene fiber up to 0.5 % increased the 7-day compressive strength, but subsequent increases had no effect on the strength. The 28-day compressive strength increased by 0.5% as PPF content increased, however larger voids caused by increasing fiber content led in lower strength once the water in the pores dried. Moreover, Balkis (2017) investigated the mechanical properties of earth, polypropylene fiber, and waste marble dust (10% and 20% by dry weight of soil). PPF was found to reduce compressive strength by 0.5% while increasing flexural strength by 0.5%.

Plastic pollution is one of today's most pressing environmental challenges. Plastics are becoming more popular in construction due to a number of features such as their efficiency, strength and weather resistance, low maintenance, cost-effectiveness, light weight, and design flexibility (Akinwumi et al., 2019). Geotechnical applications, such as plastic stripes, can improve soil engineering qualities. According to the Statistical Service, the total municipal solid rubbish collected in Cyprus in 2017 was 547,000 tons, a 0.36% increase from 545,000 tons in 2016.

The use of plastic waste in the engineering sector for construction applications has a high potential for minimizing global environmental contamination and pollution. Innovative and sustainable use of plastic wastes in building applications will significantly reduce the amount of plastic waste disposed of into the marine environment while also providing alternative materials to meet the needs of the construction sector. The findings on the use of SPW-modified Alker as an alternative construction material for the sustainable manufacturing of earthen structures are based on the use of shredded plastic wastes in Alker (Ahmad et al.,2021).

Because of the use of shredded plastic waste, lime, and gypsum in the production of control and modified Alker samples, the compressive, flexural, and shrinkage properties of the design mixes had a positive effect on sustainability.

Alker's Housing Economy

When compared to other wall construction materials, the influence of gypsum stabilized adobe on construction costs or its part of the overall construction economics can be indicated. Figure 5 compares the cost and emissions of various outside wall materials with the same coefficient of heat transmission. These materials' heat transfer values U (W/ m2K) and wall thicknesses are also provided. Row 6 of Figure 5 illustrates the thermal insulation that is added to reduce both energy consumption and environmental pollution; row 7 illustrates the cost of one wall unit with insulation. Alker walls without insulation cost 1/3 the price of alternative material-based walls with insulation (Isik & Tulbentci, 2008).

	Concrete wall	Burned rick	Lightweight concrete	Alker block	Compactedalker
1. Wall properties					
2. U Value (W/m^2 K)	3.23	1.25	0.95	0.7	0.7
3. Physical properties	λ = 2.090 W/m K; γ = 2.4 kg/m^3	λ = 0.580 W/m K; γ = 1400 kg/m^3	λ = 0.240 W/m K; γ = 600 kg/m^3	λ = 0.40 W/m K; γ = 1600 kg/m^3	λ = 0.40 W/m K; γ = 1600 kg/m^3
4. Pollution (kg/yr)		CO_2 = 7090; SO_2 = 40.5; CO = 35	CO_2 = 5675; SO_2 = 32; CO = 27.5	CO_2 = 5151; SO_2 = 29; CO = 25.5	CO_2 = 5751; SO_2 = 29; CO = 25.5
5. Cost without heat insulation	3.3	9	9	4.4	4.4
6. Insulation required for equal U value (U = 0.7 W/m^2 K)					
7. Total wall cost ($/m^2, 1995)	11	14	12.9	4.4	4.4

Figure 5: Comparison of external walls with similar heat transfer coefficients (Isik & Tulbentci, 2008).

Conclusion

The implementation of sustainable development has compelled all industries, including the construction industry, to adopt and apply environmentally friendly practices. Due to contemporary worldwide concerns about sustainable development prompted by widespread environmental problems such as climate change and resource depletion, as well as the high rate of technical innovation in the building sector, interest in alternative building materials such as earth has grown. The majority of construction laws contain increasingly stringent criteria for a building's thermal performance, as well as for its ecology and sustainability. When it comes to energy-efficient and environmentally friendly architecture, soil as a construction material has excellent physical characteristics and also meets all strength requirements. It is expected that 50-55% of greenhouse gas emissions are planned by 2030, which will increase the use of adobe structure, which is both environmentally and economically. It is anticipated that Alker wall material, with its low embodied energy, low heat transfer value, and considerable health benefits, has the potential to make a significant contribution to the region's transition to sustainable housing

Earthen structures are extremely sensitive to the destructive impact of earthquakes, as sadly demonstrated by the extensive damage and loss of life caused by earthquakes in regions where earthen construction is widespread. For thousands of years, earthen materials have been employed due to their ease of availability and economic efficiency. Earthen materials have gained popularity in recent years as the world has recognized the need for sustainability in all aspects of life. It is mostly utilized for its sustainability and has little influence on the environment.

Alker production is relatively simple and inexpensive compared to reinforced concrete buildings. This lowers carbon emissions and makes it a sustainable building production technique. The cost estimation demonstrated that Alker buildings are 13% cheaper than other building materials.

In construction, plastics are gaining popularity due to numerous aspects, such as their efficiency, strength, and weather resistance, low maintenance, cost-effectiveness, light weight, and flexibility in design. These features make plastics the ideal construction product and an integral part of a sustainable environment.

Abstract

Waste is an important problem that should be handled due to the inadequacy of world sources. When the waste generation caused by economic activities are investigated, it is seen that construction industry (CI) has the largest share in waste generation with 35.9%. Therefore, taking precautions against to wastes and managing them should have the precedence in the CI as well as the other management facilities because of cost and source threats.

Material wastes, one of the physical wastes, have a strong impact on the waste generation. Being tangibility of material wastes makes them managed in sustainable way considering waste management strategies. Because of being material wastes are an urgent problem to be solved, in this paper it is aimed to investigate waste management strategies and material wastes which are occurred in the BCS. In this study, top material wastes, are produced in the BCS, are determined, and grouped whereas investigating the causes of material wastes and making suggestion for managing them during the construction process. Since it is thought that material waste could be minimized when it is known which material should be cared primarily and how they could be evaluated in the waste management process.

Keywords: *material wastes, waste management strategies, construction site waste management, building material wastes.*

Introduction

The construction industry is known for contributing development in many countries. As a result of playing a key role for economic growth, it needs to be improved in terms of managerial issues to control the building production processes. Waste management is one of the crucial parts that should be cared during the building life cycle since the construction industry generates immense amounts of wastes which are known as physical and non-physical (Can & Taş, 2020).

Construction industry has the largest share in waste generation with 35.9% (Eurostat, 2018). It is commonly acknowledged that the construction industry has a very high level of material wastes which are known one type of physical wastes. The generation of construction material wastes can cause economical, environmental and social problems in local and global scale as long as they are not managed well. Since the construction industry has a major influence on many other sub-industries by means of purchasing and providing products and services, managing material wastes can make a significiant contribution to circular economy (Agyekum et al., 2013).

Construction material wastes are mostly occurred during implementation and demolition sites of building and civil engineering structures (Ameh & Itodo, 2013; Dania et al., 2007). Building construction activities have been known to generate large and diverse quantities of waste (Dania et al., 2007). According to BigRentz's Construction Waste Statistics Research (2021), construction and demolition (C&D) material wastes such as concrete, asphalt, wood and other building wastes are estimated to be nearly one-quarter of national waste stream, which is the total material waste generated in the United States in one year. The research emphasizes that material waste generation is on the rise, and it is expected to skyrocket soon. In just United States, C&D waste generation increased by 342% from 1990 to 2018 and between 2005-2018, C&D waste generation levels grew more than 10 times faster than from 1990 to 2005 (EPA, 2022).

The United Kingdom generated 67.8 million tons od C&D material waste in 2018. In 2018, the Neherlands produced 25.12 million tons C&D material waste in 2018. Similarly, Germany generated 218.8 million tons material wastes in 2018 and this amount reached to 230.85 million tons in 2019. On the other hand, European Union are responsible for generating 850 million tons of C&D waste per year (Stone Cycling, 2021). Furthermore, Transparency Market Research (2022) states that annual construction waste is expected to reach 2.2 billion tons globally by 2025. This amount is expected to generate 2.59 billion tons of material waste annualy by 2030 and to rise further to 3.40 billion tons by 2050 (Stone Cycling, 2021). These statistics shows the importance of waste management in the BCS to manage the sources for circular economy and sustainability. Managing the material wastes brings not only sustainable construction sites but also new job opportunities in the near future.

Concrete and metals, relatively cost-effective to recycle, and brick, clay, gypsum boards, much less reusable, are the basic material wastes which ends up in landfills in plenty of quantities (BigRentz, 2021). EPA (2022)'s report emphasizes that more than 75% of all construction waste from wood, drywall, asphalt shingles, bricks and clay tiles ends up in landfills. BigRentz's Construction Waste Statistics Research (2021) combines some statistics about recycled construction materials. For instance, the research shows that over 95% of concrete and asphalt concrete waste, the largest contributors to total C&D waste, was recovered in United States in 2018 and a study in 2016 showed that in one year alone, C&D recycling oppotunities led to the creation of 175,000 United State jobs (EPA, 2022). In the United Kingdom, of the above amount, 62.6 million tons, recovery rate of 92.3%, were recovered from 2010 to 2018. This recovery rate is 88% in the European Union from 2018 and, 41% in the Netherlands while 88% in Germany in 2019 (Stone Cycling, 2021).

The challenge of material wastes in the BCS is a global problem which requires global solutions. Not only specific countries but also all countries should be aware of the waste problem for better source utilization.

Material Wastes

Construction wastes are the results of evitable and inevitable activities that do not create value, originate from different reasons such as stakeholders, building production processes, force majeure and occur in physical forms such as materials, labor, equipment or in non-physical forms such as cost, time, quality (Can, 2020). Can and Tas (2020) introduced a new construction Waste Classification System (WCS) according to the lean management approach with a holistic perspective considering current classifications. In this developed construction WCS, material wastes are evaluated as one type of the physical wastes which can be caused by stakeholders such as main contractor, sub-contractor, project team and by process like construction, post-construction and these wastes also can have environmental, economic, and social impacts.

Material wastes are evaluated as C&D wastes thanks to the highest resource usage level during the implementation process and the highest already used material production during the demoliton process. In the both process, material waste types can be evaluated in common perspective, but managing processes of them can be different due to resource usage and already used material production issues.

The actual course of waste management processes at the BCS can be produced on the basis of the observation of works (Sobotkaa & Sagan, 2016). Regarding to the observations and current researches, the material waste types substantially can be defined. Sobotkaa and Sagan (2016) states the BCS material waste types as concrete, bricks, tiles, ceramics, sawdust, shavings, cuttings, wood, particle boards and veneer other than tiles and ceramics, insulation materials, iron and steel. In the Nigerian BCS, material waste types are determined with their percentage compositon by Aboginije et al. (2021) as concrete (16.5%), wood (14.5%), reinforcement (12.1%), asbestos (10.5%), glass (9.4%), asphalt (7.3%), tile ceramics (6.1%), soil and stone (5.4%), plastic and packaging (5.2%), rubbles (4.4%), drywall (3.7%) and bitumen (2.8%). In addition to, Mahayuddin et al. (2010) state the material wastes and ratio in the Malaysian BCS as soil and aggregates, sand (44.3%), wood (12%), ceiling insulation materials (9.3%), concrete (7.2%), bricks (6.2%), tiles and ceramics (5.8%), lime (5.5%), cement (3.3%), metal (2.8%), glass (2.3%), gypsum board (1.2%).

Segregating waste into classes ensures more efficiency in the process of BCS to manage them. In Loch et al. (2019)'s research, the BCS material wastes are subdivided into four classes. These classes are named as A,B,C and D. These groups are:

- **Group A:** Reusable or recyclable wastes (metals, glass, cardboard etc.)
- **Group B:** Recyclable waste for other purposes (plastics, paper, cardboard, metals, glass, wood, empty packaging of paints etc.)
- **Group C:** Waste for no economically viable technologies or applications have been developed to enable its recycling (gypsum waste)
- **Group D:** Hazardous waste from the construction process (paints, solvents, oils and others, or those contaminated from demolitions, refurbishments etc.)

Similarly, C&D wastes have been classified with waste status and waste code by Government of United Kingdom (GOV.UK, 2022). Waste status has been defined as whether the material wastes are hazardous or not. In the each group, the material wastes' status has been defined with their own codes. The groups are:

- **Group 1:** Insulation and asbestos materials
- **Group 2:** Concrete, bricks, tiles, and ceramics
- **Group 3:** Wood, glass, and plastic
- **Group 4:** Bituminous mixtures, coal tar and tar
- **Group 5:** Metallic waste, including cable (copper, bronze and brass, aluminum, lead, iron and steel, tin, mixed metals etc.)
- **Group 6:** Soil, contaminated soil, stones, and dredging spoil
- **Group 7:** Gypsum
- **Group 8:** Cement
- **Group 9:** Paints and varnishes
- **Group 10:** Adhesives and sealants

There are many different categorisation in the literature for material wastes. Because of being many different materials and implemetation methods in today's construction, it is needed to control all the processes in an effective way. So, managing all the waste processes via basic steps makes whole the process more lean. Defining material wastes and categorisation is just one step of this waste management process as well as composing a lean and common categorisation of all the materials in basic way is extremely important preventing the information confusion.

Material Waste Management

Waste management is the collection, transport, processing, recycling or disposal and monitoring of waste materials and it deals with waste generated during construction and allied activities (Peddavenkatesu & Naik, 2016). According to Bilitewski et al. (1994), and Gilpin (1996), waste management encompasses collection, transporting, storage, treatment, recovery, and disposal of waste, and is defined as a comprehensive, integrated, and rational system approach towards achievement and maintenance of acceptable environmental quality and support of sustainable development.

Implementation of construction waste management can be one of the apparent solutions for the industry to minimize waste and waste disposal, ultimately reducing costs incurred during the process and contributing to the global "environmental-friendly" movement (Hwang & Yeo, 2011). Good practice in material waste management generate favorable results with various benefits such as cost savings, effective source usage, sustainability etc. Well organized and implemented material waste management in the construction industry provides reduced demand for landfill spaces, improved resource management, productivity, and quality improvement as well as economic benefits.

Given that the waste is a serious trouble for not only the construction industry sclae but also global scale, being aware of the wastes and managing them becomes mandotary day by day in terms of limited resources. The Construction & Site Waste Management Strategy has been improved by Hunt (2016) to manage the construction wastes in response both to existing legislation and rescinding of specific construction waste management regulations. The strategy sets out the responsibility for construction waste management and how the waste hierarchy can be applied. Three levels of construction work are identified, and these are covered in two processes which support this strategy, the Small Works Waste Process and the Construction Site Waste Management Process. Hunt (2016) evaluates the waste management strategy in three levels. First of them is defining responsibilities and drivers for the waste

management like external drivers, internal drivers, and responsibility for management of construction waste. Second of these steps is applying the waste hierarchy to construction works as reduce (designing out waste), reuse, recycle and recover. Last of these steps is defining levels (basic, minor, and major construction works) of site waste management which is tremendous management step.

Council (2017) prepared a vital report for construction waste management. In this report it is obviously seen that many countries such as United States, European Union, Japan, Singapore, Australia, Taiwan have started to take precautions against to construction wastes. In 2008 the Site Waste Management Plan (SWMP) Regulations were introduced which required construction works over £300K in value to have in place a Waste Management Plan, with the aim of reducing construction waste in United Kingdom (Hunt, 2016). In the United States (US), the government unit for supervising C&D waste management is the Environmental Protection Agency (EPA) which has a specific website for C&D waste management. EPA states implementation of source reduction given that it can be preventing waste before it is generated. In Europe, The Swedish Environmental Protection Agency (SEPA) is responsible for setting up the national plans and programmes for waste prevention for C&D waste management. Several regulations have been implemented for improving C&D waste management in the Netherlands. Similar with Sweden, there are two drivers for the successful C&D waste in the Netherlands: comprehensive regulatory framework and mature recycling market. The Japan Ministry of the Environment (JME) explained the main reason for the high recycling rate is the implementation of 'Construction Material Recycling Law', which was enacted in May 2000. According to this law, it is required that contractors should sort and recycle the demolition waste. In addition, some specific construction materials, such as concrete, asphalt/concrete and wood building materials are particularly suggested to be reused. Similarly, in Korea the Construction Waste Recycling Promotion Act, which was promulgated by the Ministry of Environment, has been put into effect in January 2005. The aim of this Act is to provide a legal basis for promoting construction waste management in an eco-friendly manner. Such as these samples, according to the Council (2017)'s detailed report, it is obviously seemed some successful experiences on C&D waste management in the countries including United States, European Union, the Netherlands, Japan, Singapore, Korea, Australia, and Taiwan as below:

- **United States:** Implementation of source reduction and development of mature waste trade market
- **European Union:** Implementation of Waste Framework Directive, mature reuse/recycling market, life cycle thinking, support for research projects
- **Sweden:** Implementation of legislative initiatives, improved and better controlled quality of C&D waste, implementation of landfill taxes and ban on landfilling of combustible waste fractions
- **The Netherlands:** Implementation of legislative initiatives, implementation of landfill and incineration taxes, development of mature secondary material market.
- **Japan:** Implementation of Construction Recycling Law, mature C&D waste recycling technologies and facilities
- **Singapore:** Efficient waste sorting, strict supervision on illegal dumping, mature waste recycling technologies and facilities
- **Korea:** Implementation of Construction Waste Recycling Promotion Act, quality certification system for recycled aggregates, construction waste information management system for waste exchange

- **Australia:** Implementation of legislative initiatives, implementation of landfill tax, supply chain management.
- **Taiwan:** Implementation of legislative initiatives, effective sorting.

The green building certificate systems also care the importance of waste management in the construction industry. One of popular green certificate systems, Leadership in Energy and Environmental Design (LEED), requests 13 credits from materials and resources category for new constructions in scope of LEED v4.1 for BD+C (USGBC, 2022). The prerequisite (P) and credits (C) in the materials and resources category are seen as below:

- **Materials And Resources Category**

P: Storage and collection of recyclables (required)
C: Building life cycle impact reduction (5 credits)
C: Building product declarations (2 credits)
C: Sourcing of raw materials (2 credits)
C: Material ingredients (2 credits)
C: Construction and demolition waste management (2 credits)

Another one of popular green certificate systems, Building Research Establishment Environmental Assessment Method (BREEAM), requests below assessments for material wastes in the latest version 6.0 (INC V6) (BREEAM, 2022):

- **Materials Category:**

Environmental impacts from construction products - building life cycle assessment (LCA) (up to 7 credits)
Environmental impacts from construction products - environmental product declarations (EPD) (1 credit)
Responsible sourcing of construction products (4 credit)
Designing for durability and resilience (1 credit)
Material efficiency (1 credit)

- **Waste Category:**

Construction waste management (5 credits)
Use of recycled and sustainably sourced aggregates (1 credit)
Operational waste (1 credit)
Speculative finishes (1 credit)
Adaptation to climate change (1 credit)
Design for disassembly and adaptability (2 credits)

The awareness of construction material wastes in terms of resources and circular economy is crucial step for all over the world. It is obviously seemed that rare of countries have started to take precautions for BCS waste management for recent years. Some legal regulations and related categories of green building certificate systems helps to improve the awareness and importance of managing the wastes regarding the very high level percentage of material wastes in the contruction industry as far as the other industries or waste sources. As a result of this, the material waste management should not be evaluated not only minimising them by means of waste hierarchy method (Council G. D., 2018). BCS material waste management

needs a holistic management steps at least as much the knowledge areas of project management.

Material Waste Management in the BCS

BCS material waste management is a vital principle to figure out and manage the wastes in the construction project. It involves a systematic approach to plan, identify, assess, response, implement and monitor process during the project that prevent the exposure waste using some the tools and techniques (Figure 1).

Figure 1: Material waste management.

"Plan material waste management" can be the first and tremendous step which the process of defining how to conduct material waste management activities for the BCS projects. The key benefit of this process is that it ensures that the degree, type, and visibility of material waste management are proportionate to both material waste procedures and the importance of the project to the organization and the stakeholders. This process is performed once or at predefined points in the project to define the material waste management strategy, methodology, roles and responsibilities, funding, timing, possible material waste categories. In this step different plan templates and guides can be used to improve and apply such cost-effective waste management plan, site waste management plan, material logistics plan, design out waste guide, procurement guide and demolition protocol (Akinade et al., 2016).

The second step is "identify material wastes" that is the process of identifying individual project material wastes as well as sources of overall project wastes and documenting their characteristics. The key benefit of this process is the documentation of existing individual project material wastes and the sources of overall project material wastes. It also brings together information so the project team can respond appropriately to identified material wastes. This process is performed throughout the project. In this process, expert judgement, data gathering like brainstorming, checklists, interviews, literature research, current categories, data analysis like root cause analysis can be used as tools and techniques for identifying material wastes. To illustrate, Construction Specifications Institute (CSI) Master Format divisions can be used for identifying material wastes in terms of applying and monitoring the wastes in common perspective. CSI codes describe 17 different divisions but one of them related to stakeholders and the other related to building types. So, 15 different divisions in 17 divisions are directly associated with construction materials for managing them (Url-1).

- **Site Construction** (site work supplier, aggregate manufacture supplier, demolition, hazardous material remover, off-site transportation and disposal, site preperation, landscaping, sewerage and drainage etc.)
- **Concrete** (concrete formwork, cast in place concrete, ready-mix concrete, precast concretei reinforcing steel, cement etc.)
- **Masonry** (mortar, washed sand & gravel, stone etc.)
- **Metals** (structural framing, structural steel, steel joists, metal decking, cold formed metal framing, load bearing metal studs, miscellaneous metal fabrications, metal handrails & railings etc.)
- **Wood & Plastics** (rough carpentry, wood and plastic fastenings, lumber, countertops, prefabricated structural wood, structural wood components etc.)
- **Thermal and Mositure Protection** (waterproofing/damp proofing, exterior insulation and finish systems, fireproofing, shingles, roofing tiles, preformed roofing and cladding/siding, skylights, firestopping, joint sealers etc.)
- **Doors and Windows** (metal doors and frames, special metal doors and frames, wood and plastic doors, folding doors and grilles, metal windows, wood and plastic windows, hardware etc.)
- **Finishes** (ceiling suspension, lath and plaster, drywall, tile and terrazzo, acoustical treatment, wood flooring, stone & masonry flooring, cultured marble, soft flooring, carpet, paint removal, wall coverings etc.)
- **Specialties** (chalkboards and tackboards, compartments and cubicles, specialty modules, lockers, protective covers, storage shelving, toilet and bath accessories, fireplaces, and stoves etc.)
- **Equipment** (maintenance equipment, air compressor, unit kitchens, laboratory equipment etc.)
- **Furnishing** (artwork, landscape partitions and components, multiple seating etc.)
- **Special Construction** (pools, solar energy systems, wind energy systems, building automation systems etc.)
- **Conveying Systems** (dumbwaiters, elevators, moving stairs and walks, lifts, scaffolding etc.)
- **Mechnaical** (mechanical insulation, fire protection, plumbing, heating, ventilating, and air conditioning (HVAC), process piping & equipment etc.)
- **Electrical** (lightning protection systems, communications, alarm systems, fiber optic cabling etc.)
- **ABC Miscellaneous** (lightning protection systems, communications, alarm systems, fiber optic cabling etc.)

The third step is “assess material wastes” that is the process of analyzing individual project material wastes and defining waste index. The key benefit of this process is that it quantifies overall project material wastes exposure, and it can also provide additional material wastes to support waste response planning. The quantities of waste can be estimated as one of techniques to assess the material wastes by the transportation records of waste disposed off from the construction sites (Poon et al., 2004) via (Mahayuddin et al., 2010) (Equation 1).

$$C = \frac{W}{GFA} \quad (1)$$

V = truck load (ton)
N = total no of truck for waste disposal

W = total waste generated from the project (ton) = V x N
GFA = gross floor area
C = waste index (construction of 1 m2 gross floor area generates C ton of waste)

Waste index, building waste assessment score (BWAS), environmental performance score (EPS), component-global indices, stock flow model, Spanish model, material flow analysis model, universal waste ratio, system analysis model are the some of waste quantification models. Similarly, Smart waste, net waste tool, design out waste tool for buildings, web-based estimation system, DeconRCM, demolition and renovation waste estimation system are defined as waste prediction tools while on-line waste control tool, waste management plan, CALIBRE, Webfill, Construct Clear, SmartStart, SmartAudit, true cost of waste calculater are known as the waste data collection and audit tools. Also, BREMap, GPS-GIS system, IRP-based barcode system, GIS-BIM supply chain management system are evaluates as GIS-enables waste tools (Akinade et al., 2016).

Figure 2: Waste hierarchy (Council G. D., 2018).

“Material waste response” is the fourth process to develop options, selecting strategies, and agreeing on actions to address overall project material waste exposure, as well as to treat material wastes. The key benefit of this process is that it identifies appropriate ways to address overall project material wastes. This process also allocates resources and inserts activities into project documents and the project management plan as needed. This process is performed throughout the project. This step is closely related to material waste management

plan step. In this step waste hierarchy, which has 6 steps (Reduce, Reuse, Recycling, Recovery, Treatment, Disposal) can be implemented as seen in Figure 2 (Council G. D., 2018). Reducing the material waste is the best option of waste hierachy while disposal is the worst. So, firstly (Reduce, Reuse, Recycling) 3R technique is one of lean management tools should be implemented then the other options should be cared.

The fifth step is "implement material waste responses" which is the process of implementing agreed-upon material waste response plans. The key benefit of this process is that it ensures that agreed-upon material waste responses are executed as planned to address overall project material waste exposure, minimize project material wastes, and maximize cost, quality, time opportunities. This process is performed throughout the project.

The last step of material waste management is "monitor material wastes". Monitor material wastes is the process of monitoring the implementation of agreed-upon material waste response plans, tracking identified material wastes, identifying, and analysing new material wastes, and evaluating material waste process effectiveness throughout the project. The key benefit of this process is that it enables project decisions to be based on current information about project material waste exposure. This process is performed throughout the project.

Conclusion

Because of being the biggest driver of waste generation, the construction industry should care wastes and manage them effectively to move resource usage from traditional linearity to a level of high circularity. Effective material waste management provides cost saving, reduced demand for landfill, improved resource management, profit and quality maximisation. As a result of the today's limited resources and sustainable development, it is believed that waste management in the construction industry should has needed priority.

Waste management closely associate with almost whole construction project stakeholders such as the client, the main contractor, design team, subcontractors, project employees, suppliers, government authorities and local residents. It is thought that improving legislative framework in each country will promote the sustainable resource management all over the world when the construction waste generation is taken into consideration.

In this study, it is recommended that waste management should not be evaluated just as waste hierarchy. Waste management is a process that should be cared during the construction project life cycle. In the BCS, material waste management can be implemented as one of the knowledge area of PMBOK. So, it is thought that waste management should has its own process groups while tools and techniques are improved for the construction waste management.

As a result of occuring large material wastes in the world, it is thought that each country also our country should manage wastes especially in the building construction sites because of having largest share of waste generation. Although it has started to be implemented with the standards and legal sanctions established in different countries in the management of construction material wastes, our country is at the very beginning of the road in this respect. This paper contributes the types of material wastes to manage them well while analyzing the current applications in the countries which they have already manage their contruction material wastes. So, with this paper it can be obviously seen the strategies, categories of the

construction material wastes and a material waste management proposal in scope of PMBOK knowledge areas. This paper can be a vital paper to start the manage construction material wastes in terms of classifying them and analyzing the steps of management to implement the management strategies basically for the countries which wants to manage their construction material wastes.

Evaluation of the Impacts of Mega Sports Events in Cities with the Sustainability Indicator: The Case of İzmir Olympic Village

B. E. Kaya
Akdeniz University, Institute of Natural and Applied Sciences, Department of Architecture, Antalya, Turkey
birsuece@gmail.com

İ. Erbaş
Akdeniz University, Faculty of Architecture, Department of Architecture, Antalya, Turkey
ierbas@akdeniz.edu.tr

Abstract

Large-scale events, which are called mega events in the international arena, are important activities in terms of ensuring intercultural interaction and communication, investing in cities, supporting the development of cities, and promoting them. In order to ensure the spatial, economic and social sustainability of mega sports events such as the Olympic Games and the Universiade, their utilization during and after the event should be planned. The aim of this study is to examine the effects and contributions of the Universiade event organized in İzmir and the Olympic Village, which was built for the event, to the city, citizens and sustainability during and after the event. In the study, the effects of the event on the city were evaluated with the sustainability indicator scale. As a result of the study, it was seen that the Olympic Village contributes to spatial sustainability in the long term, but the economic and social contribution was effective during the Olympics. This study contributes to the scientific and practical field in terms of analyzing the effects of mega sports events, which offer various interactions and opportunities on a global, national and urban scale, to the urban space, development and sustainability. It is aimed that the inferences obtained from this study will guide the cities where mega events will be held in the future.

Keywords: *İzmir olympic village, mega sports events, sustainability, sustainability indicator, Universiade.*

Introduction

Sports events are universal phenomenon for people who grew up in different cultures and speak different languages to meet in a common point and strengthen their social bonds (Yıldız & Bitirim, 2008). The Olympic Games, which have been organized since ancient times, have the goal of providing world peace through interaction with physical activity, reminding universal values such as equality and fraternity. Sports organizations that have an international impact are events that are demanded and given importance due to the development of intercultural relations and the economic, spatial and social contributions they provide to the country where the event is realized. Large-scale organizations appeal to a large part of the world's population

through their international feature and media, lead the development of cities by being carried out with the support of volunteers, institutions and states, and enable social, cultural and economic interaction among the citizens of the participating countries (Theodoraki, 2016).

Mega events are large-scale events that are organized periodically in different countries in a certain period, are realized with high costs, and appeal to large audiences on an international scale (Toksöz et al., 2014). After the Olympic Games, which are held every four years, the second largest sports organization in the world is the World University Games, known as the "Universiade". The University Games, which are organized by the "International Universities Sports Federation" (FISU), whose origins are based on the World University Games in 1923, are organized as summer and winter games every two years, with the participation of university athletes from different countries (Baydar, 2010).

Turkey applied to FISU for the Universiade 2005 to be organized in İzmir in 1999, and at the Federation meeting held in Beijing, it was decided to realize the 23rd World University Summer Sports Games (23rd Universiade) in İzmir (Baydar, 2010). This organization is the biggest international sports event in the city after the Mediterranean Games in İzmir in 1972 (Ekmekci, 2011). Mega events such as International İzmir Fair, Mediterranean Games and Universiade are important for the future and identity of the city and contribute to the city in the short and long term (İzmir Metropolitan Municipality, 2005). Within the scope of the Olympic preparations, one of the spatial legacies left by the event to İzmir was the Universiade 2005 İzmir Olympic Village. The Olympic Village (İzmir Games Village) was built on an area of 300 000 square meters in the Çetin Emeç Neighborhood of Limontepe, between Balçova and Karabağlar districts, for the athletes and officials who will participate to the event.

In 2005, 5372 athletes and 2512 officials from 131 countries in the five continents of the world participated to the University Games held in İzmir between 11-21 August. Competitions were arranged in 10 compulsory branches including athletics, tennis, basketball, artistic and rhythmic gymnastics, volleyball, football, water polo, fencing, jumping and swimming, and 4 optional branches such as sailing, wrestling, taekwondo and archery. A total of 274 260 visitors watched the 10-day event (İzmir Metropolitan Municipality, 2005; Aslan et al., 2019). In addition to the sportive activities, exhibitions were organized in galleries and cultural centers in the city, and traditional arts were promoted in the Olympic Village. (İzmir Metropolitan Municipality Communication Center, 2006, as cited from Yıldız & Bitirim, 2008)

Depending on the socio-economic and political conditions of countries and cities, their objectives and the results they will obtain from mega event vary. In this sense, the evaluation of the effects of mega events is very comprehensive and variable situation, including physical, economic, social and environmental at global, national and local scales. In the literature, there are studies evaluating Universiade 2005 İzmir in terms of socio-cultural, physical and economic conditions. Yıldız and Bitirim (2008) evaluated the Universiade İzmir through intercultural communication and made suggestions for sports games to be held in the future. Baydar (2010) examined the Universiade 2005 Olympic organization, the Olympic village and its facilities' settlement, according to the principles of landscape architecture design and planning. Ekmekci (2011) discussed the tangible and intangible benefits of the games for İzmir and Turkey five years after the Universiade 2005 Games. In these studies, information about the planning phase of Universiade 2005 and its effects were included, but the evaluation of the decisions taken in the planning of the event, the practices implemented during the event process and after, within the scope of sustainability was not mentioned. Therefore, in this study, it is aimed to examine the short and long-term effects and contributions of the Universiade İzmir and the Olympic

Village to the city, citizens and sustainability during and after the event. The originality of this study is the analysis of the İzmir Olympic Village, which was built as part of a mega sports event, with a sustainability indicator.

Background Information

Universiade 2005 İzmir and Olympic Village

In line with the scope and goal of Universiade 2005 İzmir, accommodation and sports areas were planned, and physical and social arrangements were made in different areas of the city. Before the event, 59 facilities in İzmir were maintained and repaired for competitions and training sessions in line with the criteria of the FISU and brought into compliance with international standards. Halkapınar Sports Hall, Karşıyaka Sports Hall and Karşıyaka Tennis Courts were brought to the city as new facilities. (İzmir Metropolitan Municipality, 2005; Saf, 2012). In addition to the renovation of existing facilities and the construction of new facilities, access roads, parking lots, landscaping and infrastructure works have been carried out around these facilities, contributing to urban development (Saf, 2012).

In mega sports events such as Universiade, many details such as accommodation, transportation, meeting participants' needs, ensuring their safety (Yıldız & Bitirim, 2008) need to be planned before the event. Olympic villages are residential areas that provide accommodation for the athletes and officials participating to the competitions, and contain various facilities for food, beverage and other needs. An olympic village was needed for the Universiade 2005 because the dormitories where university students stay in İzmir are scattered in the city and do not have sufficient physical and social infrastructure (Saf, 2012). Universiade 2005 İzmir Olympic Village was planned considering its use during and after the event, and the construction of the village, whose contract was made in 2002, started in 2003 (Figure 1).

Figure 1: Left: The Olympic Village built by terracing on a sloping land; Right: Olympic Village in 2004 (Baydar, 2010).

Olympic Village's architectural project was prepared by Merih Karaaslan, Şükrü Kocagöz and Mürşit Günday, 934 apartments were built in 64 blocks with an accommodation capacity of 9952 people for the athletes and officials who would participate to the event. The apartments, built in six different plan types as A, B, C, D, E and F, were offered to people living in İzmir as residences after the event was over (İzmir Olympic Village). There are 3+1 apartments in the terraced houses built on two slopes facing each other, and 2+1 apartments in the buildings behind the terraced houses (Figure 2). In the central area at the foot of the two slopes, there are

common and social areas such as sports and playgrounds, and swimming pool (Figure 3). In the area, transportation is provided from the main street called Universiade Street through side streets that provide access to the terraced residential blocks and buildings between the two slopes. Side streets are named with sports branches such as Athletics, Basketball, Football (Figure 3).

Figure 2. Left: Terraced houses; Right: View of terraced houses and apartments from the street (Personal Archive, May 2022).

Figure 3. Left: Terraced houses and swimming pool in the center; Right: Street signs (Personal Archive, May 2022).

Sustainability

The concept of sustainability emerged with the idea of reducing and preventing problems such as environmental situations and pollution caused by economic and technological developments, and protecting the ecosystem (Karakurt Tosun, 2009). In the national and international platforms organized after the 1980s, the concept of sustainability began to be discussed together with the urban space and urban life issues. World Commission on Environment and Development (WCED) published “Our Common Future” report in 1987, and sustainable development was defined as “meeting the needs of the present without compromising the ability of future generations to meet their own needs”. In the Brundlant Report, it was stated that sustainable development should be provided holistically in political, economic, social, technological systems and production systems, and after this report, the phenomenon of sustainable development began to be seen as a value system accepted all over the world (Karakurt Tosun, 2009).

In order to achieve sustainable development in cities, "architectural and urban design projects should be developed that will ensure that the environment is protected and developed together with its values, providing spaces suitable for present and future uses, and that will increase the physical quality of the environment and the quality of life" (Çahantimur & Turgut Yıldız, 2008). In this direction, for sustainability to be effective in the long term, sustainability criteria must be considered in each of the processes of planning, implementation, use, maintenance and repair, and re-functioning after use. In relation to these goals, various performance evaluation and indicator criteria have been established to measure the effects of sustainability in urban space (Couch & Dennemann, 2000; Hemphill et al., 2004; Yiğitcanlar & Dur, 2010). The reason for the creation of these measurements is to evaluate the concept of sustainability, which is becoming increasingly important, in line with spatial, social, cultural, economic, ecological and environmental criteria and to develop awareness in these issues.

Material and Method

Evaluating the effects of mega sports events is quite difficult due to the diversity and content of the effects. In general, these effects can be analyzed thematically in economic, social, environmental, and political framework, as well as their local and global effects, their effects before, during and after the event, and the effects of the actors involved (Theodoraki, 2016) (Figure 4). In this study, the effects of the mega sport event in the Olympic Village built for the Universiade 2005 were examined with the evaluation criteria adapted from the sustainability indicator scale developed by Couch and Dennemann (2000) to measure the sustainability in the urban renewal area in Liverpool, England. The scale consists of eight key assessment criteria and sustainability is evaluated with different statements in each evaluation criterion. The sustainability indicator scale developed by Couch and Dennemann has been discussed and used in different academic studies (Evans & Jones, 2009; Lombardi et al., 2010; Korkmaz, 2015; Gençer Özdemir, 2019). In this study, the statements in the sustainability indicator scale were adapted and developed in order to evaluate the planning, event and post-event processes of the mega event in line with the subject and content of this research.

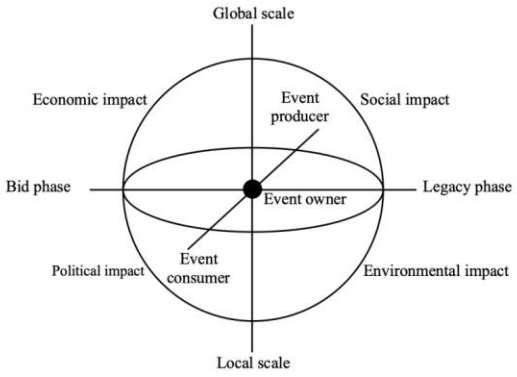

Figure 4. Effects of mega sports events (Theodoraki, 2016).

Evaluation of Universiade 2005 İzmir Olympic Village with the Sustainability Indicator Scale

In this study, the physical, social, economic and environmental sustainability of the Olympic Village, which was left to İzmir as the event legacy, was analyzed with the sustainability indicator scale adapted from the study of Couch and Dennemann (2000) (Table 1). Within the scope of the study, the subjects of community participation, economy and work, transport, pollution, energy, waste and resources, buildings and land use, wildlife and open spaces are evaluated as positive, neutral/mixed and negative impacts of the Olympic Village on the city, citizens, natural and built environment.

Table 1. Evaluation of Universiade 2005 İzmir Olympic Village with the sustainability indicator scale.

Sustainability Indicator	Positive Impact (+)	Neutral / Mixed Impact (*)	Negative Impact (-)
1 Community Participation			
(a) encourage local action and decision making in the planning and execution of the event			-
(b) involve the community in the development of the proposal/plan in the planning and execution of the event			-
(c) take into account under-represented groups		*	
(d) ensure the participation of local/foreign visitors during the event process.	+		
(e) ensure participation of local/foreign visitors after the event			-
2 Economy and Work			
(a) link local production with local and global consumption during the event process	+		
(b) link local production with local and global consumption after the event process			-
(c) increase employment during the event process		*	
(d) maintain/increase employment after the event			-
3 Transport			
(a) proximity of the event area to the city center		*	
(b) access from the event area to the city center (diversity of roads and transportation vehicles)			-
(c) encourage walking and cycling			-
(d) encourage use of public transport		*	
(e) discourage use of cars or lorries			-
4 Pollution			
(a) reduce local pollution (noise, air, water, soil)	+		
5 Energy			
(a) maximise energy efficiency			-
(b) generate energy from renewable reources or waste			-

6 Waste and Resources			
(a) reduce waste			-
(b) encourage reuse and/or repair			-
(c) encourage recycling or recycled products		*	
7 Buildings and Land Use			
(a) provide local materials and methods			-
(b) improve access for disabled			-
(c) reuse/conserve buildings	+		
(d) reuse of buildings after the event	+		
8 Wildlife and Open Spaces			
(a) encourage use of open space for community benefit	+		
(b) offer different possibilities like outdoor sports, cultural, social activities, etc.	+		
(c) encourage natural plant and animal life		*	
(d) protect and promote the use of the built environment and green space	+		

Community Participation

In the UN Environment and Development Conference organized in Rio de Janeiro in 1992, it was emphasized that sustainable development should be realized with the participation and cooperation of different actors, including central governments, local governments, non-governmental organizations, private sector and individuals (Karakurt Tosun, 2009). The planning and realization of the İzmir Olympic Village were determined by the central and local government, and the community was not included in the development of the plan. The Olympic Village served for the accommodation of foreign athletes between August 3-23 (Baydar, 2010) and hosted volunteers, local and foreign athletes during this time. After the event, with the settlement of the residents, it continues to be used as a closed and secure site, allowing foreigners to enter in a controlled manner. The lack of community participation in the planning of the Olympic Village and the transformation of the area into a closed site after the event negatively affect social sustainability.

Economy and Work

Hosting mega events, developing international relations, providing economic growth, and creating short and long-term benefits that will be effective in the city and the life of the citizens are considered as opportunities (Er & Güzel, 2019). When Universiade 2005 İzmir is evaluated in economic terms, the games and the arrangements made in the city cost 100 million dollars (Ekmekci, 2011), economic activity was created with the ticket revenues of the event and the expenditures of the visitors. (Saf, 2012). In this direction, when the economic sustainability in the Olympic Village is evaluated, it is seen that the economy was stimulated with production and consumption activities before and during the event, but after the event, the commercial activity in the region was limited to a few shops and restaurants.

A volunteer team of 18.753 people from 77 universities and 75 cities in Turkey, 84% of whom are from İzmir, was gathered to work in the Olympics and the Village (Ekmekci, 2011). During the event, jobs were provided by the assignment of volunteers and public service providers, and no direct contribution was made to employment. After the event, although a certain population

settled in the region, it did not have a positive effect on employment due to the limited commercial areas.

Transport

The distance of the Olympic Village to the city center is approximately 12 kilometers (Figure 5). Since the location of the Olympic Village is far from the facilities where the competitions were held, the athletes have had problems with distance and time (Baydar, 2010). In this sense, in determining the locations of the Olympic Villages, it is important to choose the closest point to the city center, which will not be far from the facilities during the event and will serve the citizens after the event. There is İzmir Freeway near the area and the city center can be reached by private vehicle and public transportation. Due to the location of the region, there are no regulations that encourage walking or cycling or discourage the use of large vehicles, which negatively affects economic and environmental sustainability.

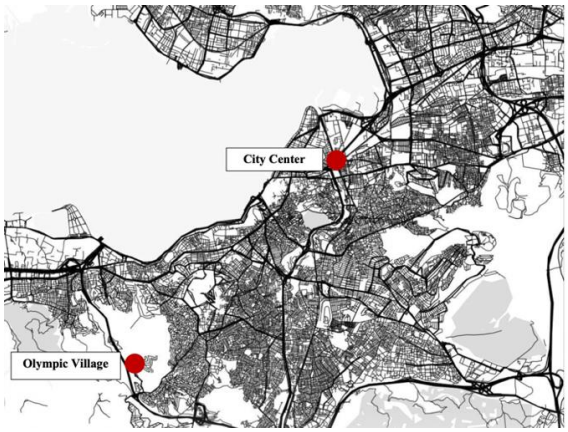

Figure 5. Location of Olympic Village in the city (URL 1).

Pollution

In İzmir Olympic Village, a large green area has been brought to the region with landscaping works, and air and noise pollution has been greatly reduced since motor vehicle use is not intense in the site. Maintenance and cleaning works are carried out by the site management on the roads and common areas, and these works help to prevent environmental pollution. In this respect, it can be interpreted that the impact of İzmir Olympic Village on sustainability is positive in terms of pollution criteria.

Energy

In today's conditions, where energy resources are rapidly depleted and energy efficiency has become an important issue, it is important to research and apply alternative energy sources for sustainable urban development and to ensure energy efficiency. In İzmir Olympic Village, blocks were built to meet the need for shelter during and after the Olympics, but no application was made in this project to increase energy efficiency in the settlement or houses, or to generate energy from renewable resources or waste. Therefore, the impact of İzmir Olympic Village on environmental sustainability is negative.

Waste and Resources

The protection of limited resources, the separation or recycling of wastes and their reuse contribute to sustainability economically and environmentally. On the streets of İzmir Olympic Village, there are waste collecting and recycling bins placed by the Balçova Municipality in order to separate the wastes and ensure their recycling (Figure 6). Glass, composite, cardboard, metal and plastic wastes are collected in these boxes. In addition, there are second-hand clothes, shoes and textile boxes placed by the Balçova Municipality on the streets. The products collected in these boxes are delivered to people in need by the municipality. Despite these practices, there is no information on what actions are taken to reduce waste or after waste collection.

Figure 6: Left: Waste and textile collection bins; Right: Recycle bin (Personal Archive, May 2022).

Buildings and Land Use

While planning the İzmir Olympic Village, the aim was stated that "it will be presented to the city as a part of it whose social and technical infrastructure has been completed with the transformation project after the games as an environmentally sensitive and city-related settlement", and it was aimed to hand over the residences to their owners after the event (İzmir Metropolitan Municipality, 2003). 934 residences in the Olympic Village, which were built for the athletes and officials participating in the event, were re-functionalized as a housing area where the people lived after the event. There are 742 3+1 flats of types A, B, C and D in the terraced blocks and 192 2+1 flats of types E and F in the buildings. The size and plan of each type of flat varies, and users can choose according to their needs.

Regarding the buildings and land use, the maintenance of the sports facilities in the city for Universiade 2005, the low number of newly built sports facilities, the active use of the sports facilities by the citizens after the event, the re-functioning of the Olympic Village as housing after the event, positively affects physical sustainability and the event legacy. However, it is seen that the use of local materials and methods is not included in the planning and implementation of the project, which negatively affects environmental sustainability. In addition, although the Awareness Center was opened in the Olympic Village to draw attention to the problems of disabled people and to organize educational and social activities for them (İzmir Metropolitan Municipality, 2018), there is no regulation to improve access for the disabled due to the sloping land structure and terraced houses.

Wildlife and Open Spaces

In the project of the Olympic Village, the planning of green areas in the open areas and common social areas between the terraced houses spread over the land, and the effort to establish a balance between the built environment and the green area affect social and environmental sustainability in a positive way. As each flat offers the opportunity to use open space on its own terrace, the presence of spaces such as playground, activity square, open sports fields and swimming pool in the village encourages the use of open space and offers the opportunity to socialize (Figure 7).

Figure 7: Left: Children's playground in the village; Right: Outdoor sports field (Personal Archive, May 2022).

Conclusion and Recommendations

Mega events, including sports activities, contribute to the country and city where they are organized, by making investments, improving political and social relations, increasing economic activity and making spatial arrangements. These organizations, which appeal to large audiences around the world, are also important tools for the promotion of countries, becoming touristic and cultural centers of attraction, and the realization of international interaction. However, in order to realize the impact of these organizations on the environment, city and citizens in a long-term beneficial way, it is necessary to make plans and practices based on physical, economic, social and environmental sustainability.

The University Games organized in İzmir became a mega event where incoming university athletes competed in sports competitions for 10 days and stayed in the Olympic Village. The effects of mega events on the city can be examined in the short and long term. The short-term effects of Universiade 2005 on the city can be expressed as the press members from all over the world introducing the country and the city to the world during the event, the visitors contributing to tourism by staying in hotels, the transportation of athletes, officials and visitors, and the creation of employment and economic mobility for their needs. The long-term effects of Universiade 2005 on the city can be expressed as the maintenance and repair of the existing sports facilities and the construction of new sports facilities, the construction of the Olympic Village, and the acquisition of the Olympic Village as a residential settlement addressing different economic and social needs. In this sense, it is seen that there is a spatial contribution to İzmir in the long term, but the effect of the economic and social contribution is short-lived.

In this study, the Olympic Village built for the Universiade 2005 in İzmir was evaluated with the sustainability indicator scale. According to the data obtained from the evaluation, although there are positive features in the event process, it is seen that the impact on social and economic sustainability in relation to community participation, economy and work is negative before and after the event. It might be said that environmental and economic sustainability are negatively affected in relation to transportation, energy use, waste and resources. On the other hand, the positive features of the project are the reduction of local pollution due to the built and natural environment balance created in the settlement area, the re-functioning of the accommodation areas built for the event as housing after the event, and the creation of social areas by encouraging the use of open space and green space. This situation positively affects physical, economic, environmental and social sustainability. In this sense, it is seen that the decisions taken during the planning and design of the event affect and direct the life and sustainability in the Olympic Village. According to the information obtained from the study, the recommendations for ensuring sustainable urban development that will be effective and efficient in the long term for the cities hosting mega events and their citizens are as follows:

- Organizing the events in developed regions in terms of physical and social infrastructure, quality and number of facilities,
- Determining the sustainability goals and practices in the planning, implementation, use and post-use processes of the event,
- Establishment of network and common studies between different actors such as international collaborations, central and local government, experts, private sector,
- Consulting the public about the project, assessing their needs and expectations, informing them about the implementations and ensuring their participation,
- Determining the needs and investments that will provide urban development and,
- Making budget, cost and income estimations,
- Organizing infrastructure works and building facilities that will contribute to the city in the long term,
- Determining the spatial uses during and after the event,
- Implementation of practices for the protection of natural resources and the environment,
- Making spatial and social arrangements for sharing of cultural and social values,
- Creating a good impression by promoting the country on an international scale

In this direction, planning should be done by evaluating the short-term and long-term effects of mega events on cities, and mega events should be made a tool of urban development. This study contributes to the scientific and practical field in terms of evaluating the effects of mega sports events, which offer various interactions and opportunities on a global, national and urban scale, on urban space, urban development and their contribution to sustainability and presenting suggestions. It is expected that the results of the study will guide the policymakers, and event organizers who would play a major act in mega events organized in the future.

Effect of Solar Shade Elements on Heating and Cooling Loads in Houses and Cost Relationship

A. Kazaz and E. Yetim
Akdeniz University, Civil Engineering Department, Antalya, Turkey
akazaz@akdeniz.edu.tr, ender-ytm@hotmail.com

Abstract

The world's population is growing rapidly, increasing the demand for energy in many sectors, such as industry, housing, transportation, etc. The high energy consumption in buildings has made efforts necessary for the effective use of energy. Energy efficient building design efforts are usually based on a building, floor, or apartment over the building envelope thermal insulation. What distinguishes this study from others is that it used shading elements in a block-based compound, taking into account the location, orientation, and distances between buildings. In addition, it performed energy analyses for the case where electrical energy, as well as natural gas, is used for heating buildings. This study focused on base buildings in a block-based compound in Antalya in the Mediterranean Climate Region. The study examined the effect of fixed sunshade systems on the energy performance of the building. Design Building Models were developed by applying sunshade systems to the Base Building Models. Energy consumption data of heating, cooling and ventilation systems were analyzed with the DesignBuilder simulation program. As a result of the analysis; It has been observed that the total annual energy savings of the Design Building Models reached 8.4%, and the building cost increase was 1.4 $/m² on average.

Keywords: *building energy simulation, cost analysis, energy efficient design, sunshade design.*

Introduction

One in every two people lives in urban areas worldwide, which is projected to increase to 75% by 2050 (European Commission, 2020). The world's population is growing rapidly. Therefore, cities are expanding at an unprecedented rate, with new residential areas and houses under construction. Due to rapid urbanization, millions of people are moving into cities, causing an increase in energy demand. People are consuming natural resources excessively to meet their energy needs. However, this trend is turning into a global disaster. Over the last decades, energy has become a critical issue for countries due to the increasing demand for energy and rising energy costs.

The European Union (EU) has set energy and climate targets within the scope of its 2030 strategy. The EU has aimed to reduce greenhouse gas emissions by 2030 by at least 40% (compared to 1990), increase the share of renewable energy sources in energy consumption to at least 32%, and provide at least a 32.5% improvement in energy efficiency (European

Commission, 2014). According to the Energy Efficiency 2021 Report by the International Energy Agency (IEA), the public and private sectors spent $188 billion in 2021 on energy efficiency in buildings, industrial structures, and transportation. In addition, annual clean energy investment worldwide is projected to increase to $4 trillion by 2030 to reach net-zero emissions by 2050 (IEA, 2021).

According to the Turkish Statistical Institute, less than a quarter of the residences in Turkey have thermal insulation on the wall (15%) and the roof (16%) (Kobalas, 2015). Most of the energy used in residences in Turkey is for heating (81%), indicating low energy efficiency. Turkey's energy-saving potential reaches 50% in buildings (Pamir, 2017). According to the Final Declaration of Combating Climate Change published by the Ministry of Environment and Urbanization of the Republic of Turkey (2021), Turkey will make smart city practices more common and build energy-efficient and eco-friendly residential areas.

Design decisions determine the amount of energy a building will likely consume throughout its service life. Every building needs energy for heating, cooling, ventilation, and lighting. We must apply energy-efficient construction criteria (zoning plans, plot location, situations with neighboring plots, setback distance, building envelope, user demand, etc.) to keep energy consumption to a minimum. Designers are most involved in the design of building envelopes.

Opaque components and glasses consist of wall elements and insulation materials. Transparent components consist of joinery. A building envelope is an energy-efficient building criterion that consists of transparent and opaque components. There is a large body of research focusing on opaque and transparent components to achieve energy efficiency in buildings (Vincelas & Ghislain, 2017; Koyun & Koç, 2017; Kon, 2018; Cüce et al., 2019; Aydin & Biyikoglu, 2020; Motlagh et al., 2021; Sayadi et al., 2021). Researchers address building envelope designs and consider building heating loads to make calculations.

This study investigated the effect of fixed sunshade systems on energy performance. Earlier research has examined energy efficiency based on a building, floor, or site. However, this study looked into energy efficiency based on a "block-based settlement" in buildings in Antalya, which is located in the Mediterranean Climate Region. People in Antalya widely use electricity for heating. Therefore, this study also developed scenarios where electricity, as well as natural gas, is used for heating to compare energy efficiency by fuel type.

Solar Control in Energy Efficient Building Design

We must develop “solar-friendly” designs to reduce energy consumption, energy costs, and carbon emissions in buildings. Integrating solar technology into buildings can ensure that they generate renewable energy and consume less energy through natural lighting depending on sunshine hours and daylight (Kazaz et al., 2019). Natural lighting depends on the climatic conditions, exterior barriers, orientation, shape, frame and glass properties and size of windows, and light reflectance factor of interior surfaces (Yüksel, 2019).

It is necessary to control the amount of solar radiation to prevent unnecessary heat gain in buildings in hot climate regions (Figure 1). Excessive heat gain increases cooling loads and thus the amount of energy consumed (Koca, 2006). Shading elements are part of energy-efficient building designs. Shading elements are artificial environmental variables that can be controlled according to window position and indoor solar radiation. Overheating due to solar radiation has adverse effects on users. Therefore, we should ensure as low heat gain as

possible to prevent this. We can reduce the thermal effect of the sun by placing shading devices in front of windows and opaque surfaces (Balcıoğlu, 2013).

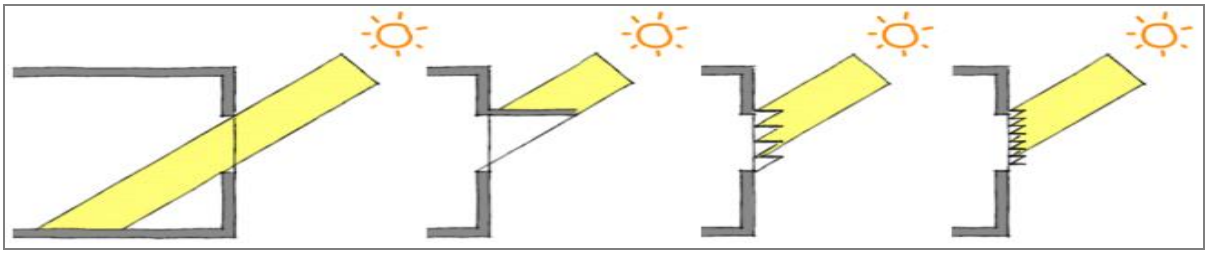

Figure 1: Solar shading design and solar radiation (Url-1, 2022).

The most common sunshade systems are consoles, shutters, and vertical-horizontal bars. These systems can be fixed or adjusted manually or mechanically. Sunshades are positioned outside buildings to prevent the thermal effect of daylight from penetrating the interior. These systems are designed according to the angle of light in summer (the sun is at its highest) and winter (the sun is at its lowest). While vertical bars are used on the east and west façades, horizontal bars are used on the south façades to prevent low-angle solar radiation in the morning and afternoon (Ofluoğlu, 2018) (Figure 2).

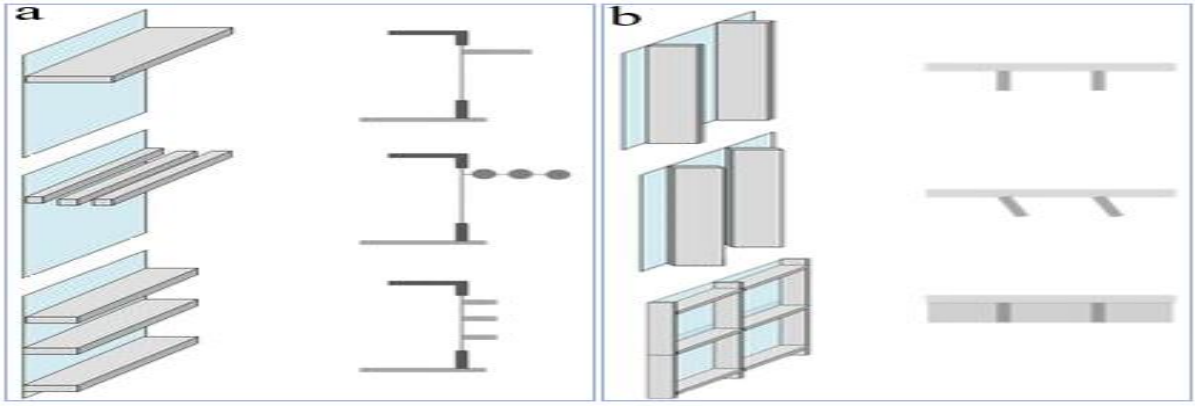

Figure 2: Horizontal and vertical sunshade design; a) south facade application, b) east and west facade application (Url-2, 2022).

Method

The sample consisted of a block-based urban transformation project in Antalya. The city has a hot-humid climate because it is located in the Mediterranean Climate Region. The study investigated how much solar shading systems could reduce the energy needs of buildings in block-based residential complexes.

This study had six stages. First, the buildings in the block-based settlement were determined as Block B, Block D, and Block F "Based Buildings" according to orientation, location, facade area, number of floors, and transparent surface ratio. Second, "Base Building Models" were developed modeling Block B, Block D, and Block F according to the current design parameters. Third, "Design Building Models" were developed by applying sunshade systems to the Base Building Models. The sunshade systems are recommended by the American

Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) according to climate zones. Fourth, the Base Building Models and Design Building Models were compared in terms of energy consumption to achieve energy cost, emission, and saving rates. Fifth, data were analyzed using the DesignBuilder dynamic thermal simulation program with a meteorological database and 3D modeling. Sixth, a cost analysis was made by calculating the investment cost of the solar shading systems.

Two Base Building models were developed according to the type of energy (natural gas and electricity) for heating. The "Design Building-1" model was developed by applying the sunshade systems to the "Base Building-1" (natural gas for heating; electricity for cooling) model, where natural gas is used for heating. The "Design Building-2" model was developed by applying the sunshade systems to the "Base Building-2" (electricity for heating; electricity for cooling) model, where electricity is used for heating.

Findings and Discussion

The research setting was a block-based urban transformation project consisting of six blocks and 317 residences on a 37,647 m^2 construction area (Figure 3). Block A consisted of 10 floors and 41 independent sections. Block B consisted of ten floors and 76 independent sections. Block C consisted of eight floors and 36 independent sections. Block D consisted of 11 floors and 41 independent sections. Block E consisted of nine floors and 72 independent sections. Block F consisted of 9 floors and 51 independent sections.

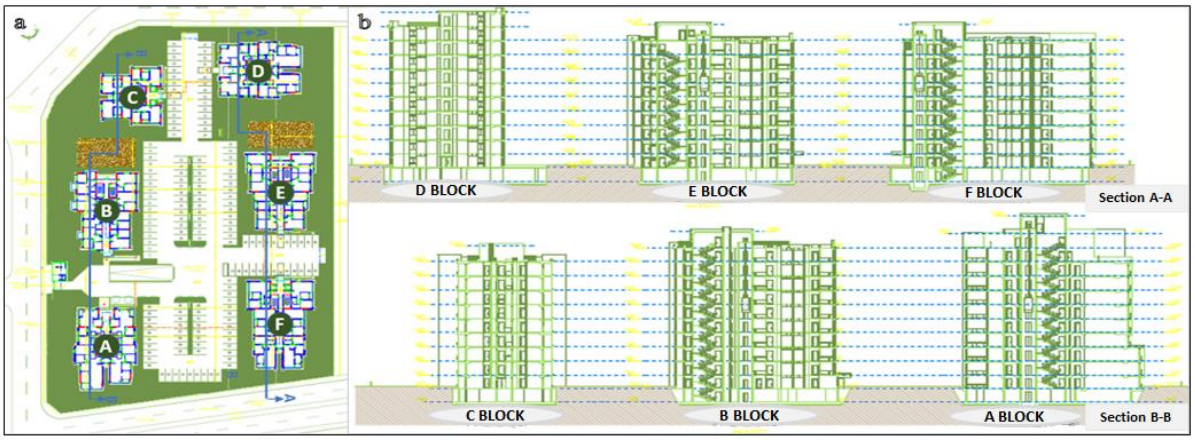

Figure 3: Urban transformation project; a) layout plan, b) sections.

The buildings were determined as Block B, Block D, and Block F "Based Buildings" according to orientation, location, facade area, number of floors, and transparent surface ratio. The base buildings were individually modeled according to the current design parameters (Figure 4).

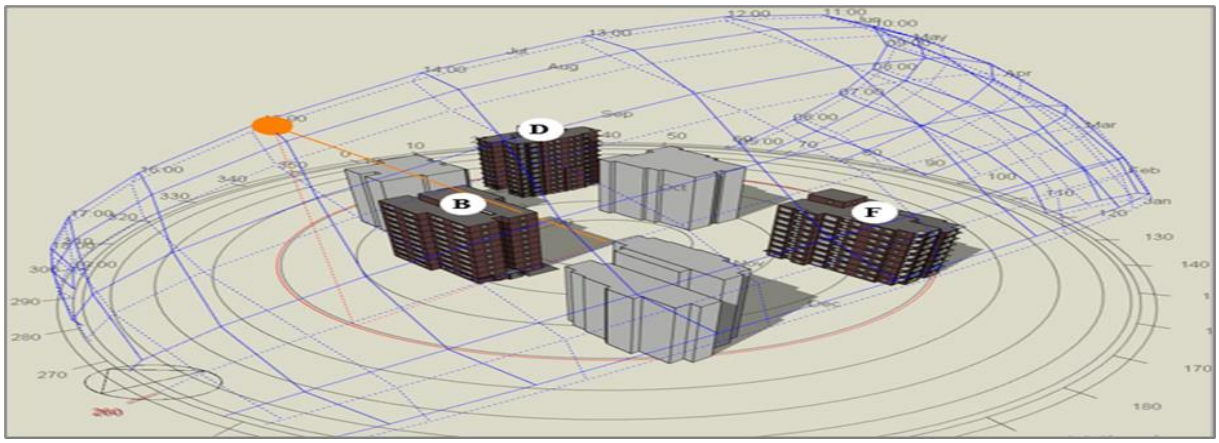

Figure 4: Model image.

The total area of the windows of Block B was 894.70 m^2 (60.60 m^2 south facade, 51.70 m^2 north facade, 388.30 m^2 east facade, and 394.10 m^2 west facade). The ratio of opaque surfaces to transparent surfaces on the exterior was 30% (Figures 5 and 6).

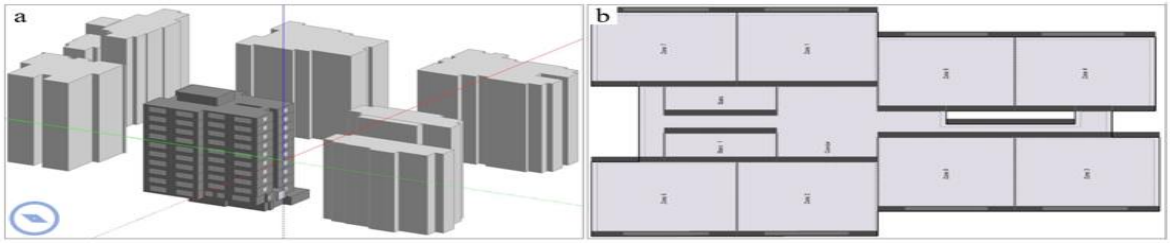

Figure 5: Block B model image; a) layout plan, b) floor plan.

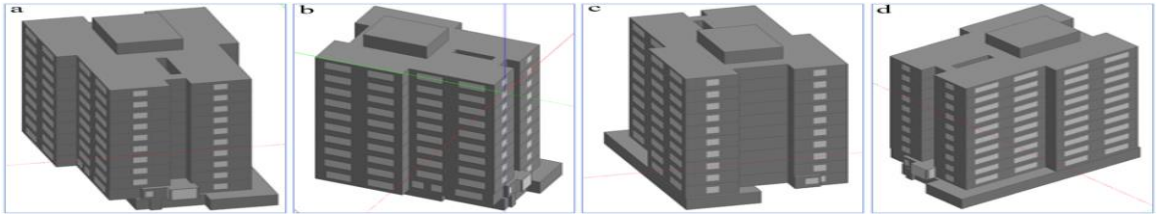

Figure 6: Block B model image; a) south facade, b) west facade, c) north facade, d) east facade.

The total area of the windows of Block D was 953.20 m^2 (278.70 m^2 south facade, 229.10 m^2 north facade, 309.70 m^2 east facade, and 135.70 m^2 west facade). The ratio of opaque surfaces to transparent surfaces on the exterior was 32.25% (Figures 7 and 8).

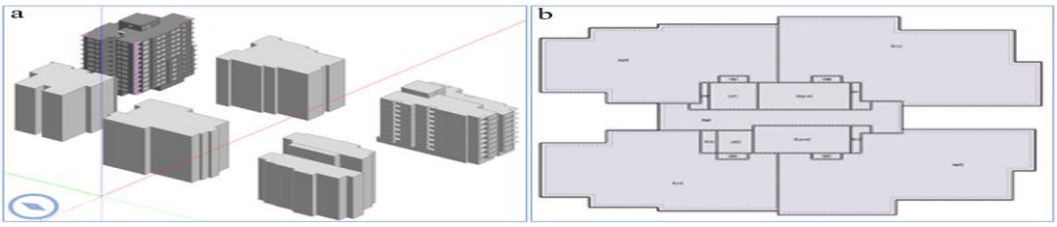

Figure 7: Block D model image; a) layout plan, b) floor plan.

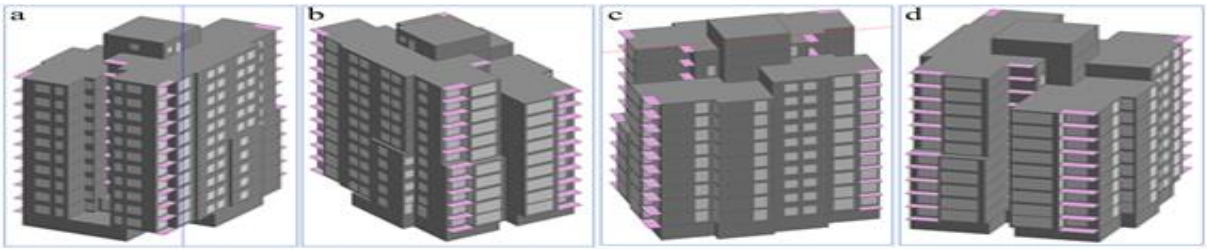

Figure 8: Block D model image; a) south facade, b) west facade, c) north facade, d) east facade.

The total area of the windows of Block F was 1023 m^2 (193.80 m^2 south facade, 24.05 m^2 north facade, 402.10 m^2 east facade, and 402.10 m^2 west facade). The ratio of opaque surfaces to transparent surfaces on the exterior was 39.41% (Figures 9 and 10).

The climate data of the ASHRAE Climate Zone 3A (Turkey's 1st Climate Zone) were used to calculate the heating and cooling loads for Antalya. The Base Buildings and Design Buildings were modeled according to the ASHRAE standard residential use profile.

The climate data of the ASHRAE Climate Zone 3A (Turkey's 1st Climate Zone) were used to calculate the heating and cooling loads for the Base buildings according to the ASHRAE 90.1-2010 standard recommended by ASHRAE. According to the ASHRAE Standard residential use profile, the Base Buildings and Design Buildings were modeled according to the number of occupants (20 m^2/person) and the operating hours/days (7/24).

Buildings can act as solar radiation barriers for each other according to distance, density, height, orientation, and positioning. This study examined the effects of these basic choices on energy efficiency. Figures 11, 12, 13 and 14 show the shadow effect of the buildings on equinox days.

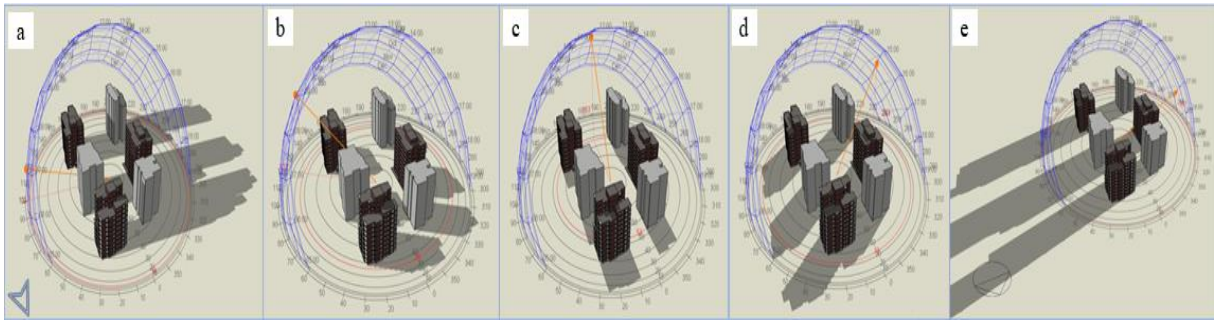

Figure 11: Shadow lengths formed by buildings on March 21; a) 7:00 am, b) 9:00 am, c) 12:00 pm, d) 15:00 pm, e) 17:00 pm.

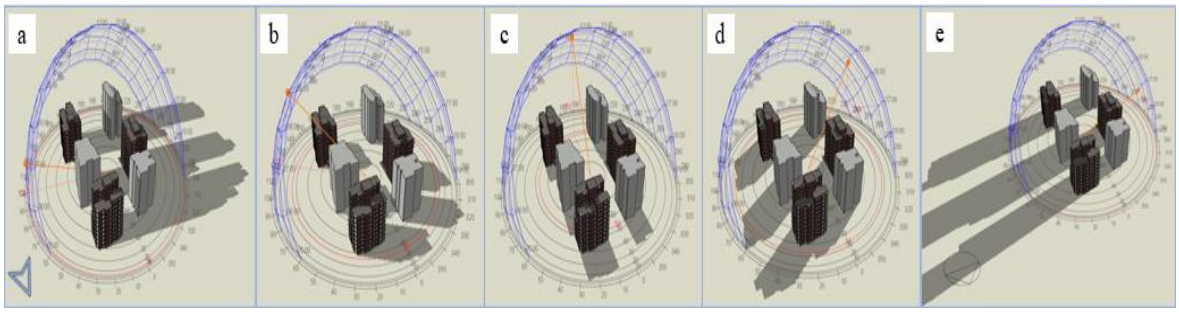

Figure 13: Shadow lengths formed by buildings on September 23; a) 7:00 am, b) 9:00 am, c) 12:00 pm, d) 15:00 pm, e) 17:00 pm.

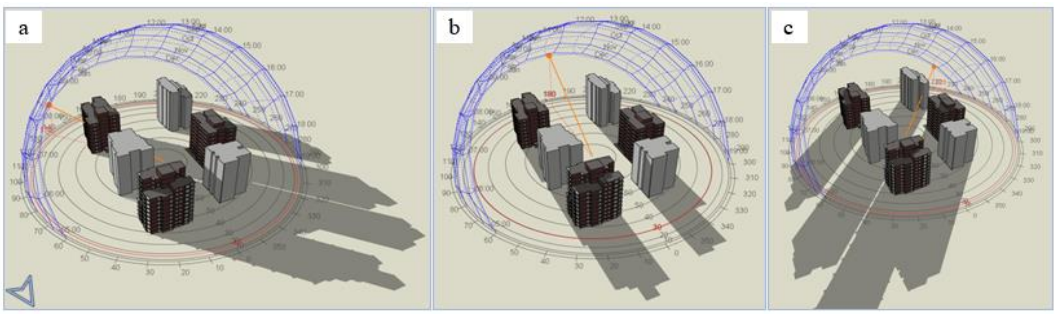

Figure 14: Shadow lengths formed by buildings on December 21; a) 9:00 am, b) 12:00 am, c) 15:00 pm.

Antalya is located in the First Region, according to TS 825. Horizontal sunshade systems on the south facades and vertical sun shading systems on the east and west facades were applied to the Base Building Models according to the ASHRAE criteria to reduce the cooling need of the building in line with the energy-efficient building criteria. The study investigated the effect of sunshade systems on energy performance. Vertical and horizontal sunshades were designed by taking the shadow element parameters as projection (60 cm), height (15 cm), depth (15 cm), and overflow (15 cm) (Figure 15). The investment cost of the solar shading systems was calculated based on the price of aluminum sunshade products (16.31$/m-12.01.2021) (Table 1).

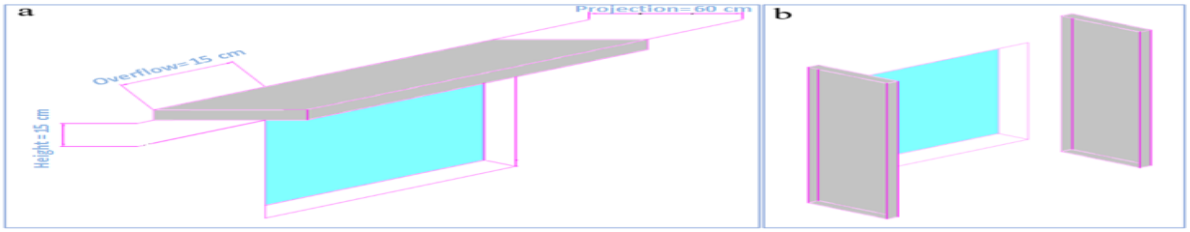

Figure 15: Sunshades applied to Base Building models; a) horizontal sunshade, b) vertical sunshade.

Table 1. Solar shading system cost analysis applied to base buildings.

Sunshade Design	Length (m)	Solar Shade Cost ($)		Cost Increase Rate ($)
		Current Status	Improved Status	
Block B				
South Facade Sunshades	35	–	570.82	
East-West Facade Sunshades	602	–	9818.08	
Total Cost		–	10388.90	100.00%
Cost Per Flat		–	136.70	
Unit Area Cost		–	2.19

Total Cost		–	5121.06	100.00%
Cost Per Flat		–	100.41	
Unit Area Cost		–	0.98	

The Base Building Models did not have shading systems. Therefore, the cost increase rate of integrating horizontal and vertical sunshade systems was 100% (Table 1). The effect of the sunshade system cost on the cost increase of the building was 1.4 $/m² on average. Hourly analyses were performed on the Base Building and Design Building Models using the Design-

Builder simulation program. Table 2 shows the heating and cooling energy consumption amounts of the buildings. Table 3 shows the total energy consumption, cost, emission, and energy-saving rates.

Table 2. Heating and cooling energy analysis of the solar shading system.

System/Usage (kWh)	Base Building-1	Design Building-1	Savings Rate-1	Base Building-2	Design Building-2	Savings Rate-2

The sunshade system increased the energy consumption for heating between 6.2% and 11.0%, while it provided annual energy savings between 8.2% and 26.0% in energy consumption for cooling (Table 2). We should use mechanical adjustable sunshade systems instead of fixed sunshade systems in order to make optimum use of solar energy and keep the increase in energy consumption for heating to a minimum in the Design Building Models. The Mediterranean Climate Region has more cooling degree-days (CDD) than heating-degree-

days (HDD). Therefore, we must create energy-efficient building designs that will keep energy consumption for cooling to a minimum. The sunshade system reduced total energy consumption in the Design Building Models (Table 3). Block B, Block D, and Block F Design Buildings achieved total energy savings of 6.6%, 1.2%, and 0.2%, respectively, when natural gas was used for heating. On the other hand, they achieved total energy savings of 8.4%, 3.1%, and 1.9%, respectively, when electricity was used for heating. The smaller the ratio of opaque surfaces to transparent surfaces in Base Buildings, the more energy the solar shading system saved.

Electricity allowed the buildings to save more energy than natural gas (Table 3). This can be explained by the fact that the electricity efficiency (Ƞh,s=0.99) is higher than the natural gas efficiency (Ƞh,s=0.93). In terms of energy cost comparison, natural gas should be used for heating for energy cost savings in buildings because the electricity unit price ($0.0790352/kWh, Ck Akdeniz Electric Inc.-Domestic-April 2021) is higher than the natural gas unit price (0.0241020$/kWh, Enerya Energy Inc.-Residential-April 2021).

Conclusion

This study examined the effect of a sunshade system on energy performance in buildings in a block-based settlement in Antalya, which is located in the Mediterranean Climate Region. The results showed that the solar shading system reduced annual energy consumption by up to 8.4%. The energy-saving rates indicate that costs are not obstacles to installing solar shading systems.

This study is important for two reasons. First, it took into account design parameters (location and orientation of buildings and distance between buildings) to evaluate energy efficiency on a block basis. Second, it performed energy analyses on scenarios where electricity replaced natural gas for heating.

In conclusion, solar shading systems provide energy savings in buildings in the block-based settlements in Antalya. We think our results will guide municipalities, academia, and the construction industry because this study focused on sustainable energy and examined the relationship between solar shading systems and energy costs.

Abstract

The world's population is growing rapidly, resulting in urban sprawl, increased demand for energy, and environmental pollution. This has promoted efforts to construct energy efficient buildings. Energy efficient building design efforts are usually based on a building, floor, or location through the building envelope design. What distinguishes this study from others is that it calculated energy efficiency in a block-based compound, taking into account the location, orientation, and distances between buildings. It also performed energy analyses for the case where electrical energy, as well as natural gas, is used for heating buildings. This study focused on three-block base buildings in a block-based compound in Antalya in the Mediterranean Climate Region. The study examined the effect of different orientation scenarios on the energy performance of the building. The energy cost, emission, and savings rates between the base building and design building models were obtained by performing hourly analyses using the DesignBuilder simulation program with the EnergyPlus dynamic thermal simulation engine. The results showed that the Design Building Models with south-east orientation, 90° angle to south, and about 90° angle provided annual total energy savings of 0.3%, 3.7%, and 4.3%.

Keywords: *building energy simulation, building orientation analysis, energy efficient design.*

Introduction

Urbanization increases energy demand worldwide. People consume natural resources excessively to meet their energy needs. However, excessive energy production and consumption causes environmental pollution and exacerbates global warming, affecting all living things and future generations. Over the past decades, "green building" has been a critical concept for minimizing environmental problems and leaving a better world for future generations.

The world's population has reached 7.8 billion as of 2021. China's population stood at 1.4 billion, equivalent to 18% of the total world population (UN.ESCAP, 2021). By 2030, only China and Indonesia will add 342 million and 80 million more people to the world population, respectively. Irregular population growth has led to environmental pollution and outbreaks, resulting in climate change and natural disasters (Erçoşkun, 2018). One in every two people lives in urban areas worldwide, which is projected to increase to 75% by 2050 (European Commission, 2020). The European Union (EU) biodiversity strategy for 2030 has set targets

for reducing greenhouse gas emissions by 2030 by at least 40% (compared to 1990), increasing the share of renewable energy sources in energy consumption to at least 32%, and providing at least a 32.5% improvement in energy efficiency (European Commission, 2014).

A building envelope is an energy-efficient building criterion that consists of transparent and opaque components. There is a large body of research on improving the thermos-physical properties of transparent and opaque components for energy efficiency in buildings in different climatic zones (Mahlia & İqbal, 2010; Kon, 2018; Çetintaş & Yılmaz, 2019; Alsayed & Tayeh, 2019; Aydin & Biyikoglu, 2020; Urbikain, 2020; Rosti et al., 2020; Aktemur et al., 2021). Most research focuses on building envelope design and calculates energy efficiency over building heating load.

Building orientation is a fundamental design choice defined as the method of setting the direction of a building in such a way that it derives maximum benefit from the elements of nature. This study investigated the effect of building orientation on energy efficiency. Earlier research has examined energy efficiency based on a building, floor, or site. However, this study looked into energy efficiency based on a "block-based settlement" in buildings in Antalya, which is located in the Mediterranean Climate Region. People in Antalya widely use electricity for heating. Therefore, this study also developed scenarios where electricity and natural gas are used for heating to compare energy efficiency by fuel type.

Building Orientation in Energy Efficient Building Design

The characteristics of the external climate elements (the angle and amount of sunlight and the direction and strength of the wind) of a plot of land depend on its direction. The heat transfer rate per unit area (a building envelope element) depends on building orientation (Tatar, 2015). The southern surfaces of buildings between 32º and 56º north latitude receive approximately three times as much sunlight in winter as the east and west surfaces. However, they receive approximately half as much sunlight in summer as the east and west surfaces depending on the direction and duration of sunlight (Karaaslan, 2011).

Buildings should be less fragmented and closed to the north and have wide south facades and compact forms to minimize heat loss depending on solar radiation (Erçin, 2005). Solar radiation and prevailing wind direction are critical for energy conservation in the positioning of buildings. Figure 1 shows that B and C experience 50% and 60% more heat loss than A, whereas D experiences 25% less heat loss than A (Soysal, 2008).

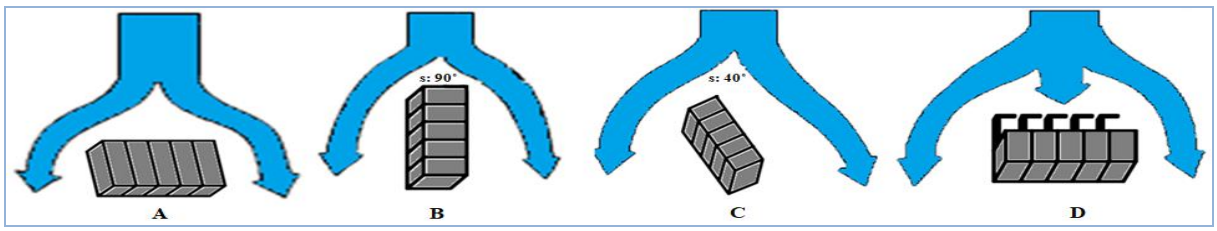

Figure 1: Building orientation according to the prevailing wind direction.

Research on energy-efficient building design addresses such parameters as optimum building location, shape, size, and distance between buildings in different climates. Figure 2 shows optimum orientations depending on climates (Tatar, 2015).

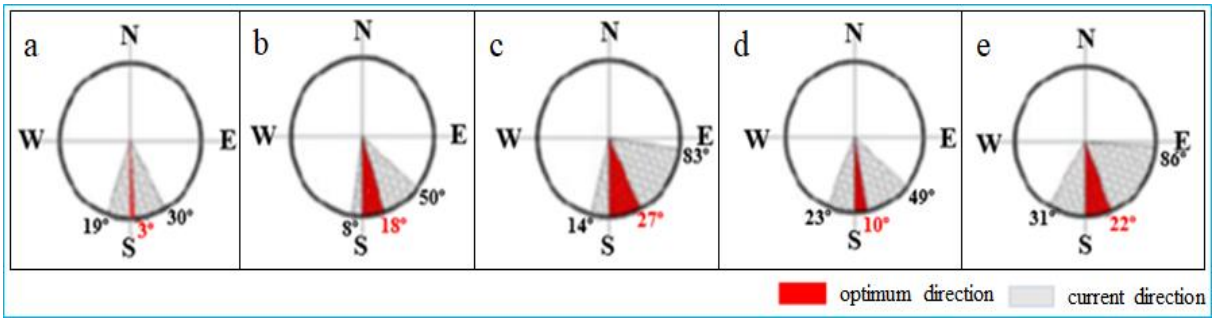

Figure 2: Optimum orientations depending on different climates; a) hot-humid climate, b) hot-dry climate, c) moderate-dry climate, d) moderate-humid climate, e) cold climate.

Method

The sample consisted of a block-based urban transformation project in Antalya. The city has a hot-humid climate because it is located in the Mediterranean Climate Region. It is classified in the first-degree day zone according to the Turkish Standards Institute (TSI). The study investigated how much optimal orientation could reduce the energy needs of buildings in block-based residential complexes.

This study had six stages. First, the buildings in the block-based settlement were determined as Block B, Block D, and Block F "Based Buildings" according to orientation, location, facade area, number of floors, and transparent surface ratio. Second, "Base Building Models" were developed modeling Block B, Block D, and Block F according to the current situations. Third, 19° (south-west) and 30º (south-east) reference ranges were determined for hot-humid climatic regions. Fourth, orientation scenarios of about 5° were applied to the Base Building Models according to the reference range to develop "Design Building Models." Fifth, the Base Building Models and Design Building Models were compared in terms of energy consumption to achieve energy cost, emission, and saving rates. Sixth, data were analyzed using a meteorological database, which is a dynamic thermal simulation program, and DesignBuilder and EnergyPlus dynamic simulation, which are capable of 3D modeling.

For each orientation scenario, natural gas and electricity were used as heating energy. For each block, two Base Building models were developed according to the energy type for heating. Orientation scenarios were applied to the "Base Building-1" (natural gas for heating; electricity for cooling) model based on natural gas for heating in order to obtain the "Design Building-1" model. Orientation scenarios were applied to the "Base Building-2" (natural gas for cooling; electricity for heating) model based on electricity for heating in order to obtain the "Design Building-2" model.

Findings and Discussion

The research setting was a block-based urban transformation project consisting of six blocks and 317 residences on a 37,647 m^2 construction area (Figure 3). Block A consisted of 10

floors and 41 independent sections. Block B consisted of ten floors, 76 independent sections, and a 4743.7 m^2 net usage area. Block C consisted of eight floors and 36 independent sections. Block D consisted of 11 floors, 41 independent sections, and a 5102.4 m^2 net usage area. Block E consisted of nine floors and 72 independent sections. Block F consisted of 9 floors, 51 independent sections, and a 5201.3 m^2 net usage area.

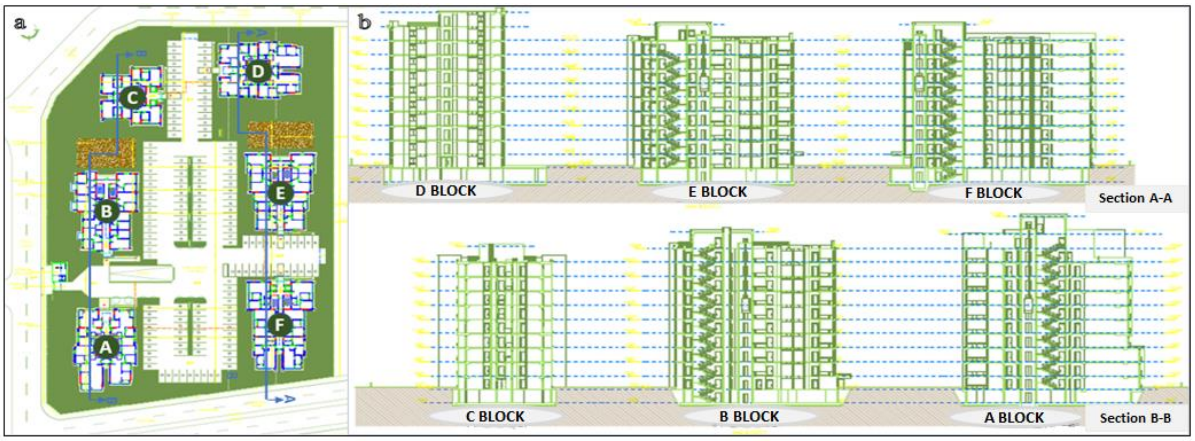

Figure 3: Urban transformation project; a) layout plan, b) sections.

The buildings were determined as Block B, Block D, and Block F "Based Buildings" according to orientation, location, facade area, number of floors, and transparent surface ratio. The block-based settlement representing the energy consumption behavior of the base buildings was modeled (Figure 4).

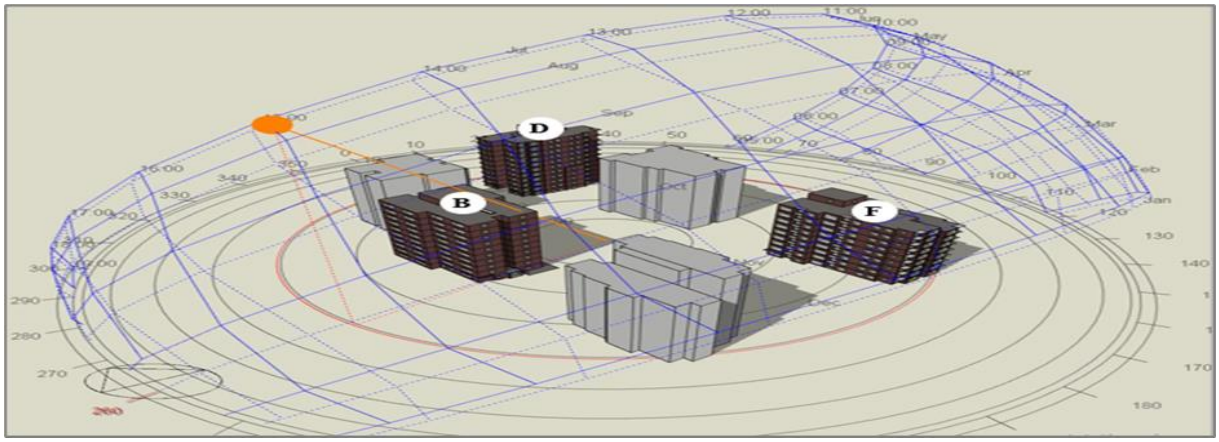

Figure 4: Model image.

The climate data of the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) Climate Zone 3A (Turkey's 1st Climate Zone) were used to calculate the heating and cooling loads for Antalya according to the ASHRAE 90.1-2010 standard recommended by ASHRAE. The Base Buildings and Design Buildings were modeled according to the ASHRAE standard residential use profile.

Buildings can act as solar radiation barriers for each other according to distance, density, height, orientation, and positioning. This study examined the effects of these basic choices on energy efficiency. Figures 5 and 6 show the shadow effect of the buildings on each other on equinox days.

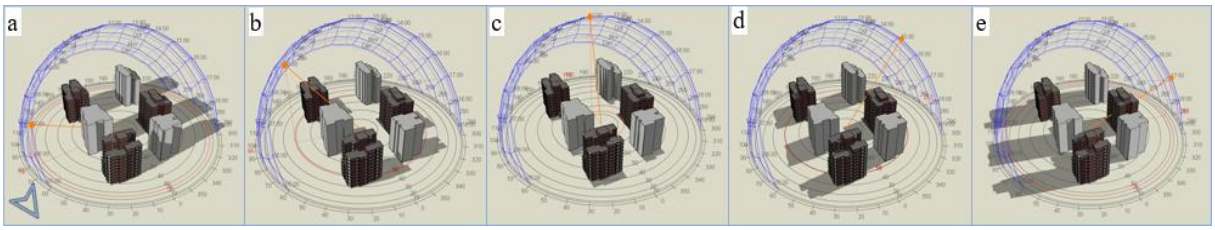

Figure 5: 21 Shadow lengths formed by buildings in June; a) 7:00 am, b) 9:00 am, c) 12:00 pm, d) 3:00 pm, e) 5:00 pm.

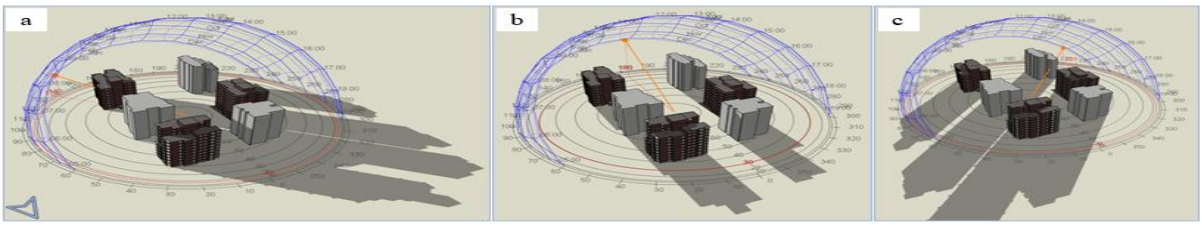

Figure 6: 21 Shadow lengths formed by buildings in December; a) 7:00 am, b) 9:00 am, c) 12:00 pm, d) 3:00 pm, e) 5:00 pm.

The most suitable orientation range is between 19° (south-west) and 30º (south-east) for energy efficiency in hot-humid climatic regions, where Antalya is located. The optimum orientation is 3° to the southeast (Figure 7). Design Building Models were developed, orienting the Base Buildings approximately 5 degrees in the reference range. The orientation scenarios in the Base Building Models were applied considering the plot boundary drawing distances and distances between buildings specified in the regulations.

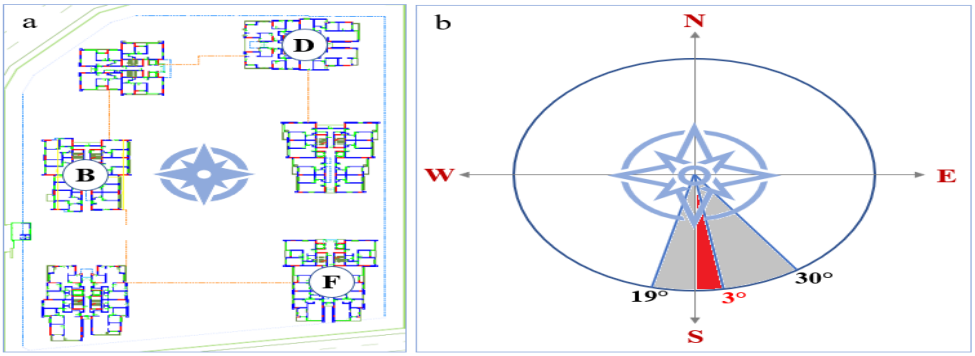

Figure 7: Optimum orientation analysis criteria; a) current orientation of base buildings, b) Optimum orientation range in hot-humid climate zone.

Table 1 shows the scenarios. The living spaces were predominantly in an east-west orientation in Block B and F Base Buildings. "Scenario 8" was developed outside the reference range so that the buildings formed an angle of 90º with the south to examine how their energy consumption was affected if the living spaces in those blocks had a north and south orientation. Figures 8, 9, 10, 11, 12, and 13 show the current orientations of the Base Buildings and the Design Building orientations after each scenario, respectively.

Table 1. Orientation scenarios applied to the base buildings.

The energy consumption of heating, cooling, and ventilation systems between the Base Buildings and Post-Scenario Design Buildings were compared to obtain optimum orientation scenarios using DesignBuilder and EnergyPlus dynamic simulation programs. Table 2 shows the annual energy consumption and energy and emission saving rates of the Base Buildings and Post-Optimum Orientation Scenario Design Buildings.

Table 2. Energy and emission saving rates after the optimum orientation of the base buildings.

Account Items	Base Building-1	Design Building-1	Base Building-2	Design Building-2

South-west Optimal orientation	10º		5º	
Consumption (kW)	325667.92	325034.41	275640.13	274758.00
Energy Saving (kW)	0.19%		0.32%	
Emission Saving (kg)	0.58%		0.32%	
South-east Optimal orientation	3º		30º	
Consumption (kW)	325667.92	326091.18	275640.13	275322.89
Energy Saving (kW)	-0.13%		0.12%	
Emission Saving (kg)	-0.13%		0.12%	
Block F				
South-west Optimal orientation	5º		5º	
Consumption (kW)	343797.47	343437.53	301847.12	301630.45
Energy Saving (kW)	0.10%		0.07%	
Emission Saving (kg)	0.18%		0.07%	
South-east Optimal orientation	90º		90º	
Consumption (kW)	343797.47	339479.26	301847.12	290695.18
Energy Saving (kW)	1.26%		3.69%	
Emission Saving (kg)	-4.32%		3.69%	

Block B and F Design Buildings (oriented 90º with south) had a total energy saving of 3.37% and 1.26%, respectively, when natural gas was used for heating. They had a total energy saving of 4.26% and 3.69%, respectively, when electricity was used for heating. The Design Buildings save energy for two reasons. First, the living areas in the Base Buildings, which have an east-west orientation, are exposed to the sun throughout the day. Second, other buildings act as sunshades for the Design Buildings. The optimal orientation angle of Block D varied according to east/west directions and the type of energy for heating. Block D had the highest energy saving when the building formed a 5º angle with the south in the south-west direction and when electricity was used for heating. Blok D Design Building-1 had an energy increase of 0.13% when it formed a 3º angle with the south in the south-west direction, while Design Building-2 had a maximum saving (0.32%) because Blok D Base Building had approximately optimal orientation. This can be explained by the north-south orientation of the living areas in Block D.

Electricity provided more energy savings than natural gas (Table 2). This can be explained by the electrical efficiency being higher than the natural gas efficiency. However, natural gas is an ideal choice for heating in terms of energy cost savings because the unit price of electricity is higher than that of natural gas.

Conclusion

This study investigated the effect of optimal orientation practices on the energy performance of buildings in a block-based settlement in Antalya in the Mediterranean Climate Region. The results showed that building designs based on optimal orientation reduced annual energy consumption by up to 4.3%. Optimal orientation is a critical design parameter because it has

no investment costs and keeps the energy consumption required in artificial air conditioning to a minimum throughout the service life of buildings.

This study is critical because it considered design parameters, such as the location of buildings and the distance between them in block-based settlements. Another essential feature of this study is that it analyzed scenarios where electricity, as well as natural gas, is used for heating because buildings in Antalya widely use electricity for heating.

In conclusion, the optimal orientation for the buildings in the block-based settlement in Antalya in the Mediterranean Climate Zone is 90º or about 90º south to south-east. When buildings with optimal orientation use electricity for heating, they achieve maximum energy savings. We think our results will guide municipalities, academia, and the construction industry because this study focused on sustainable energy to examine the relationship between energy and cost through energy-efficient optimal orientation applications.

Evaluation of Smart Sustainable Building-City Integration Level: An Analysis for Criteria in Building-City Intersection

F. H. Sarigul and H. M. Gunaydin
Istanbul Technical University, Department of Architecture, İstanbul, Turkey
sarigul18@itu.edu.tr, gunaydinhm@itu.edu.tr

Abstract

City and building labels such as sustainable and smart have gained popularity in politics and academia for nearly 40 years since the world urban population demanding more facilities is increasing rapidly. Currently, since ICT (Information Communication Technologies) supports urbanism, the concept of a smart city, which increases the welfare of citizens, is popular. Moreover, buildings that are the inseparable components of cities contribute to environmental sustainability and improve occupants' well-being by providing personalized comfort conditions via ICT. Smart sustainable building-city integration can provide social, economic, and ecological sustainability with mutual resource use beyond the sum-up of smartness and sustainability of buildings and cities individually. In this paper, firstly, frequency analysis takes place on the tool's criteria in the literature that measure the smartness and sustainability levels of cities for the last 8 years and buildings over the previous 28 years published in refereed journals and institutional works. Secondly, researchers used the content analysis technique to define the intersection area for the buildings and cities. Research findings underline the importance of thirteen criteria in resources, technology and innovation, mobility, security and safety, welfare, and management. The determined intersection criteria can establish a scientific model for evaluating the building-city integration level.

Keywords: *evaluation, ICT, integration, interoperability, smart building, smart sustainable building, smart sustainable city.*

Introduction

A smart city aims to ensure sustainability, increase efficiency, and improve the quality of life in many important aspects of city life such as governance, mobility, health, and safety (Mosannenzadeh & Vettorato, 2014). The emergence of smart cities and similar city improvement activities has created the need not only to evaluate the city's development over time but also to make performance comparisons between different cities of a country or cities of different countries (ISB & SEF, 2017). A generally accepted smart city evaluation model to evaluate smart city initiatives makes it possible to compare results from one sample to another (Hemment et al., 2016). Such a benchmarking encourages cities to be more smart and sustainable through competition. There are over 200 city evaluation tools worldwide (ISB & SEF, 2017). Literature review, expert opinion, and stakeholder consultation determine smart city indicators in a smart city evaluation (Sharifi, 2019).

Although a smart city aims for sustainability, all smart city solutions do not include sustainability, and thus the smart sustainable city (SSC) concept derived (Ahvenniemi et al., 2017). In order to measure the realization level of SSC goals, there is a need for new evaluation tools that meet the requirements of the two concepts together. Institutional standards can be a measure of evaluation. ETSI, ITU-T, ISO, and UN are SSC standards.

Like in cities, the concepts such as smart, intelligent, and sustainable describe buildings. Buildings are responsible for 36% of world energy consumption and approximately 40% of CO2 emissions, according to 2019 data (European Commission, 2021). Rapid consumption of sources has been the driving force in designing sustainable and smart buildings. The characteristics of sustainable or green building terms take place in building evaluation tools and it is obvious that intelligent and smart buildings evaluation criteria are less prominent in the literature (Ghaffarianhoseini et al., 2018). In certificate systems of some countries (such as Japan and Hong Kong), while there are criteria that provide smart and green building features together, in some countries (like Korea) have completely different (Ghaffarianhoseini et al., 2015). Buildings that meet the characteristics of being smart and sustainable are based on advanced technologies and efficient use of ICT (Zhuang et al., 2020).

A building can meet the requirements of smart or sustainable building evaluation criteria, but this is not enough to achieve the sustainable city goal. Stieninger (2016) defines the relationship of the smart building with the city as follows:

A smart building should interact with other sustainable components/systems of the city while supporting reuse and recycling; it should use its inputs and outputs (what they take from nature and what it can give back to nature) in a balanced exchange of giving and receiving. A smart city can operate in a healthy and environmentally friendly manner only if it benefits from a constant flow of change while providing information and feedback loops on all system components, required inputs, and outputs.

Although there are evaluation tools for smart and sustainable buildings and cities, the issue of defining building city intersection criteria and evaluating SSB-C integration is a potential gap in the literature. Only one research has proposed a framework for evaluating smart building city integration (Apanaviciene et al., 2020). This paper firstly touches on smart and sustainable buildings-cities main criteria. Frequency analysis is an effective study in determining the main criteria most used in evaluating smart and sustainable buildings and cities. Combining the frequency analysis results creates the new main criteria for evaluating SSB and SSC. The criteria set will be specific to this study for the new evaluation model. The study based on determining intersection criteria is the final analysis. SSB main criteria and related SSC evaluation criteria are combined for the intersection criteria.

Literature Review

Smart and Sustainable City Evaluation Studies

Academic, public, and private institutions prepare smart and sustainable city evaluation tools. A smart city evaluation tool consists of main criteria and indicators. Research that present these evaluation tools and analyzed them according to related the concept (Patrão et al., 2020; Sharifi, 2019). The smart city criteria developed by (Giffinger et al., 2007) to rank European

cities constitute the most cited, used, and most applied evaluation framework in this field (Bibri & Krogstie, 2017). The model as follows:

Smart economy. Innovative spirit, entrepreneurship, economic image and trademark, productivity, flexibility of the labour market, international residency, ability to convert.

Smart mobility. Local accessibility, International accessibility, Availability of ICT infrastructure, Sustainable, innovative, and safe transportation systems.

Smart environment. The attractiveness of natural conditions, Pollution, Environmental protection, Sustainable resource management.

Smart people. Proficiency level, proximity to lifelong learning, social and ethnic pluralism, flexibility, creativity, cosmopolitanism-open-mindedness, participation in public life.

Smart living. Cultural opportunities, health conditions, individual security, housing quality educational opportunities, tourist attraction, social solidarity.

Smart governance. Participation in decision making, public and social services, transparent governance, political strategies and perspectives.

The standards developed by ITU-T in evaluating a SSC provide a basis for cities and communities to create an integrated IoT environment, use collected data, and deploy reliable technology (ITU, 2021). The contents of these standards as follows: the use of information and communication technologies in SSC and the impact of sustainability, KPIs on the evaluation of achievements in achieving sustainable development goals, maturity model, impact evaluation, a guide for city leaders, master plan, increasing innovation and participation in SSC, master plan, setting the stage for stakeholder engagement (ITU, 2021).

Smart and Sustainable Building Evaluation Studies

LEED (Leadership Energy and Environmental Design) Certificate (USGBC) for evaluation of sustainable building and SRI (EU) are widespread systems. SRI has nine technical domain: Heating, domestic hot water, cooling, ventilation, lighting, electricity, electric vehicles, dynamic facade, monitoring and control headers (Verbeke et al., 2018). LEED has nine credit category: Integrative process management, location and transportation, sustainable sites, water efficiency, energy and atmosphere, materials and resources, indoor environmental quality, innovation, regional priority (USGBC). SSB studies are a relatively new compared to smart and sustainable building studies, and there are fewer studies in the literature.

Methodology

The increase in the number of SSB-C evaluation tools necessitated the determination of the limitations of the research. This paper analysis includes 15 cities (previous eight years) and 15 buildings (previous twenty-eight years) evaluation tools that have been the research subject in the last years. Selection criteria as follows: The most up-to-date, 2. The oldest and most accepted, 3. Developed technical standards by institutions, 4. Presented research in article, 5. Tools that evaluate cities in different geographies (continent, country), 6. Evaluation tools that

evaluate cities with multiple goals such as sustainability and happiness as well as smartness, 7. Different qualities such as standard, index, model, methodology, and guide. This paper has three-stage findings and discussion sections for the defining SSB-C integration necessities: 1. Main criteria frequency analysis for smart and sustainable city evaluation tools, 2. Main criteria frequency analysis for smart and sustainable building evaluation tools, 3. Defining SSB-C intersection main criteria.

Findings and Discussion

The main criteria in the evaluation tools selected by literature review on SSB-C in Table 1 and Table 2. The common main criteria of SSB-C evaluation tools are in Figure 1 and Figure 2. In tables, while the black-colored tics are the criteria found directly in the main headings, the red ticks express the criteria closely related to the scope of the main headings.

Smart and Sustainable City Evaluation Tools: Main Criteria

The selected evaluation tool's titles are closely related to the subtitles in the research by (Giffinger et al., 2007) or the indicators of some tools are the main criteria for other tools. The evaluation tools' main criteria most frequently used are economy (Ec), environment (En), governance (Go), people (Pe), mobility (Mo), and life (Li), followed by technology and infrastructure.

Table 1. The relationship of the main criteria of the selected smart and/or sustainable building assessment tools with the 6 main criteria.

No	Title	Ec	En	Go	Pe	Mo	Li	Other Criteria
1	Happiness Driven Smart City (Zhu et al., 2022)	✓	✓	✓	✓	✓	✓	Efficient and green physical infrastructure, Labour-friendly and innovative economy, inclusive and attractive society, sustainable and eco-friendly natural environment

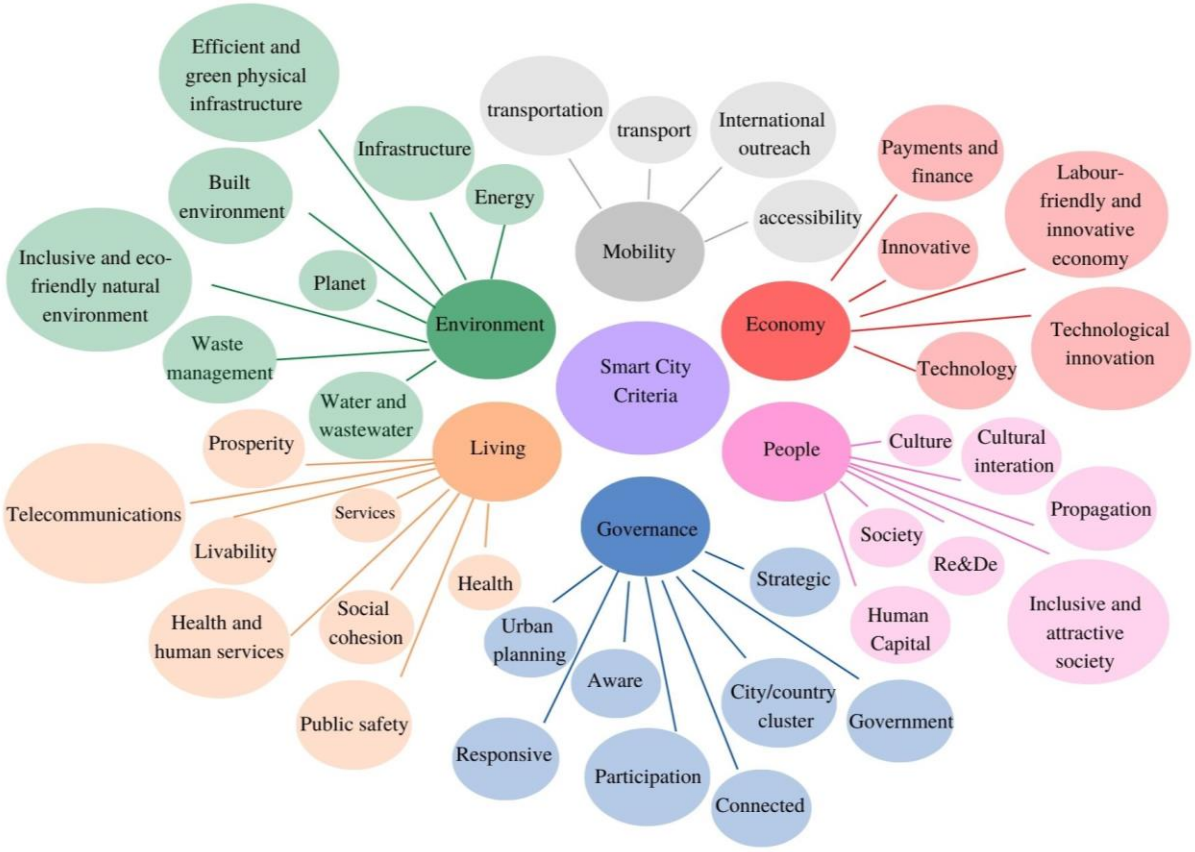

Figure 1: Main smart city criteria and other related criteria in literature (criteria in Table 1).

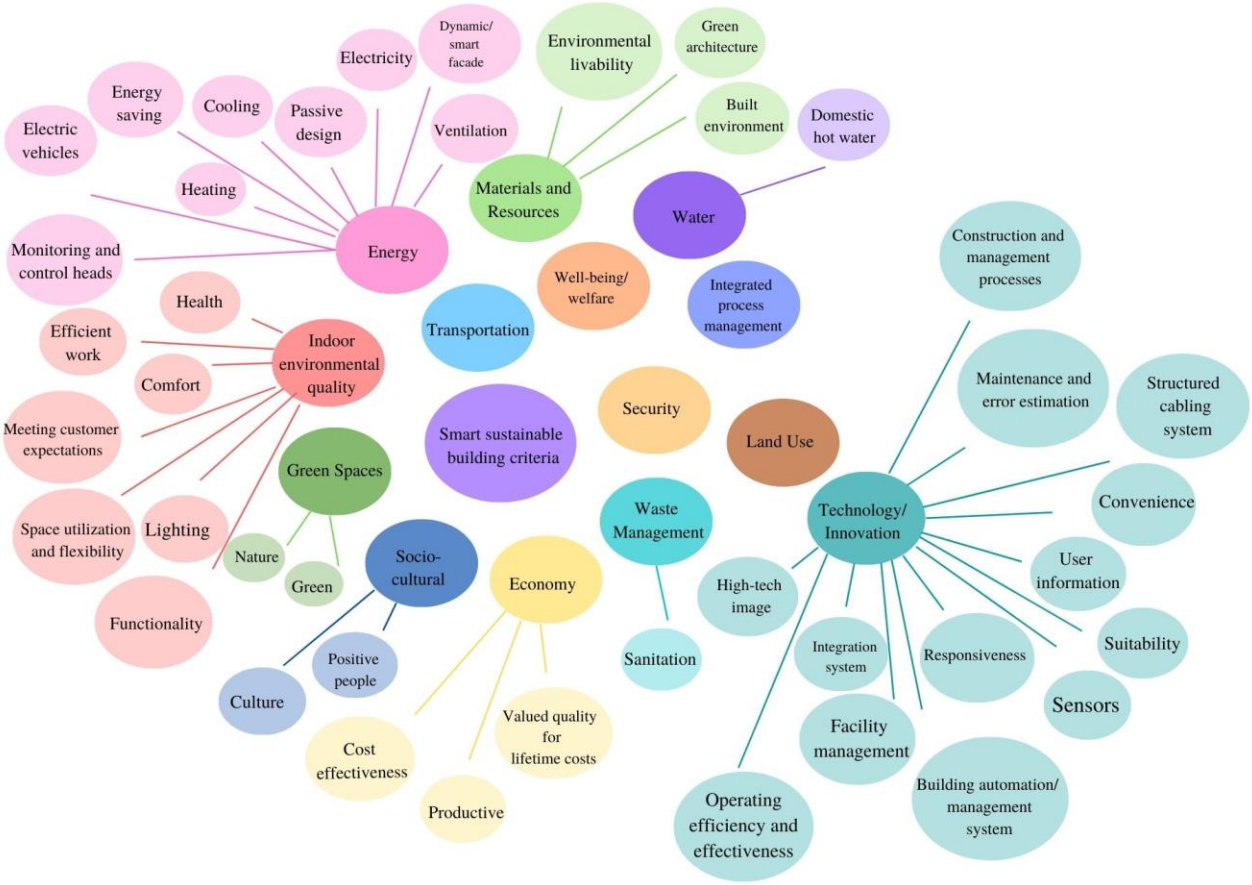

Smart and Sustainable Building Evaluation Tools: Main Criteria

According to selected 15 smart/intelligent and sustainable building evaluation tools, frequency analysis is 1-Energy 2-Material and Resources 3-Water 4-Waste Management 5-Technology/Innovation/integration process management 6-Transportation 7- Security 8-Indoor environmental quality, well-being, welfare are most used criteria. The renovation criterion is not included because the research investigates new construction projects and infrastructure especially ICT is related and included all of criteria. In table 2, Criteria 1-8 are based on LEED certification system credit categories (USGBC) because of includes Table 2 criteria mostly. IPM requires the use of BIM (Building Information Modeling) in a SSB, and it is appropriate to be evaluated under the technology title. After the frequency analysis, SSB main criteria will become obsolete.

Table 2. The relationship of the main criteria of the selected smart and/or sustainable building assessment tools with the 8 main criteria.

No	Title	1	2	3	4	5	6	7	8	Other Criteria
1	MIASBP (Meryem et al., 2018)	✓	✓	✓	✓	✓			✓	Socio-cultural, economic

Conclusions

Although the evaluation tools are based on main criteria in general; they also include criteria with other names related to these criteria. The intersection area of smart sustainable cities and smart sustainable buildings mainly covers thirteen criteria in six main areas namely; (1) resources, (2) mobility, (3) security and safety, (4) technology and innovation, (5) welfare and (6) management. Since the initial investment cost is required to establish smart sustainable buildings and cities, the economy title forms the basis of all criteria.

Resources (energy, material, water, land). It focuses on using clean energy resources throughout the building lifecycle, recycling and reusing building materials, and environmental livability to effectively and efficiently use limited planetary resources. The building can meet the resources (water, energy, material) it needs from the city capacity with the help of ICT and give the resources it produces to the city network.

Mobility. It is positioning the buildings as close as possible to buildings containing business, education, health, culture, arts, recreation, and trade services, providing a multimodal (bicycle, cable car, subway, electric vehicle) transportation system in cities that uses clean energy sources, and multimodal buildings according to their locations. It is sharing real-time transportation information (time, occupancy, and route) between transportation systems with ICT.

Security and safety. The location and resilience design of the buildings according to the site of the city in the disaster area, the use of detectors in case of disaster, and the establishment of a system that provides 24/7 monitoring with cameras and information flow to the city system.

Technology and innovation. With the ICT infrastructure established in cities and buildings, it is to inform building users, provide building-specific services, to develop advanced green systems for energy and water needs in building operation.

Welfare (socio cultural, indoor environmental quality and well-being, green space). It is related to the fact that the buildings have socio-cultural activities and green areas, and they bring these areas to the city, as well as benefit the city residents from the city equipment—moreover, housing prices and the purchasing power of city dwellers.

Management (waste management, integrated process management). It links managerial activities (such as integrated process management, building operation, building waste

management, and demolition management) between building and city throughout the building lifecycle with the help of ICT.

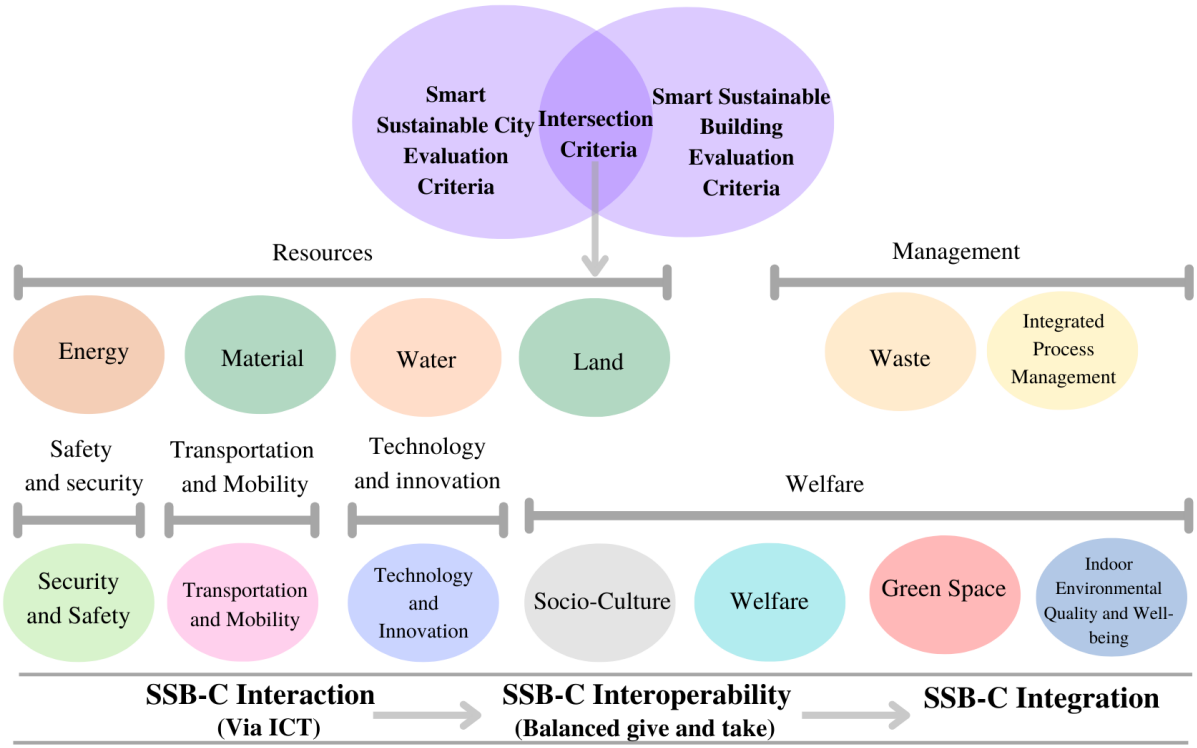

Figure 3: SSB-C intersection criteria and process of SSB-C integration.

This paper is limited to the specified method and analyzed selected smart sustainable city and building relevant criteria. Future research may address the identification of new intersection criteria through additional evaluation tools, analysis of key criteria, and indicators that change in line with advancing technologies and current needs. SSB-C integration evaluation tools that include these main criteria have significant benefits for solution providers and policy makers such as city managers, citizen welfare, and industrial stakeholders. The determined intersection criteria can establish a scientific model for the evaluation of building-city integration with the indicators to be determined later.

Abstract

Renewable energy generation grew at its fastest rate in recent years due to the various benefits that renewable energy has over traditional fossil fuel sources. However, not selecting the appropriate location for renewable energy projects may weaken these benefits. Wave energy is one of the important renewable energy sources in coastal areas. Therefore, the selection of the most appropriate location where wave energy converters can be situated is a critical endeavor. Indeed, the most appropriate location is expected to maximize the energy that can be generated by wave energy. This study proposes a multi-attribute decision-support system to determine the most appropriate location where wave energy converters can be installed. A total of 4 main criteria and 17 corresponding sub-criteria are considered in the proposed model, which integrates the critic method to calculate the weights of the criteria and the complex proportional assessment (COPRAS) method to rank the alternatives. The value of the proposed model is demonstrated through an example. Armed with such a decision support tool, decision-makers should be able to maximize their energy production by locating wave energy converters in the most favorable sites.

Keywords*: decision-making, site selection, wave energy, wave energy converter*.

Introduction

Energy is key to development and economic growth. However, development comes with growing populations that demand more energy. Global organizations, which are deeply concerned by the increasing energy demand, set their goals by taking this need into consideration. For example, one of the United Nation's Sustainable Development Goals is ensuring global access to affordable and clean energy by 2030. These goals bring us to the use of renewable energy. There are several renewable energy sources, namely, solar energy, wave

energy (a.k.a. ocean energy), wind energy, hydropower, bioenergy, geothermal energy. Wave energy stands prominent among these renewable energy sources for having a lower environmental impact, a higher energy intensity and being more predictable (Chakraborty, 2019; Bertram et al., 2020). In addition, it is claimed that 10% of the global energy demand can be satisfied by using wave energy (Iglesias et al., 2010). Even though wave energy has a great potential to satisfy the growing demand, this potential depends on selecting the appropriate location for wave energy converters (Wang et al., 2019). Therefore, the selection of the right location for the installation of wave energy converters is one of the crucial decisions to ensure the maximum utilization of wave power potential (Carballo et al., 2014). Nevertheless, it is not an easy task since several conflicting criteria should be considered simultaneously. Hence, the site selection for wave energy converters should be considered as a multi-criteria decision-making problem (Cavallaro, 2009).

The main objective of this study is to develop a decision-making model that can be used in the selection of the most appropriate location for the installation of wave energy converters. To achieve this objective, first, an extensive literature review was performed. Even though the current literature reveals that there are existing decision-making models proposed to solve the selection problem, there is still a need to extend the existing research by proposing models developed via using different multi-attribute decision-making (MADM) methods. For this purpose, this study aims to improve Turkoglu et al.'s (2020) integrated MADM approach via using methods that may provide more benefits to decision makers in determining the right location for the installation of wave energy converters. The proposed model uses Criteria Importance Through Intercriteria Correlation (CRITIC) and Complex Proportional Assessment (COPRAS) methods. CRITIC method is used to calculate the weights of the criteria, while COPRAS is used to rank the alternatives. A case study was carried out to illustrate how the proposed model can be applied in a real-life case. Results showed that this tool can be helpful in the selection of the most appropriate location for the installation of wave energy converters.

The Proposed Model

The proposed model is developed in two stages. In the first stage, the process starts by defining the wave energy site selection problem. Then, the evaluation matrix is constructed. The previous step is followed by the organization of the decision-makers who are associated with the wave energy site selection process. The decision-makers are also involved in the identification of the criteria (main and sub-criteria) that have impact on the selection of wave energy site. The final step of the first stage includes the calculation of the weights of the main and sub-criteria using the CRITIC method.

CRITIC method is proposed by Diakoulaki et al. in 1994 with the purpose of determining the weights of the criteria in MADM problems. This method is based on the analytical examination of the evaluation matrix. The first of the two important features that CRITIC method offers to decision-makers is that there is no need for the independence of attributes. The second feature is that the qualitative attributes can be transformed into quantitative attributes (Diakoulaki et al., 1995; Alinezhad & Khalili, 2019). Its calculation steps are presented below (Vujicic et al., 2016):

- Step 1: Constructing the decision matrix;
- Step 2: Determining the normalized the decision matrix;

- Step 3: Computing the standard deviation for each criterion;
- Step 4: Constructing the symmetric matrix;
- Step 5: Calculating the value that represents the measure of conflict;
- Step 6: Using the multiplicative aggregation formula to compute the amount of information (C_j);
- Step 7: Determining the weights.

In the second stage, the computation steps of COPRAS method are followed to develop the model. First, the initial decision matrix is constructed. After the normalization of the initial decision matrix elements, the weighted normalized decision matrix is generated. Then, the sums of weighted normalized values for both the beneficial and non-beneficial criteria are calculated. In the next step, the relative significances of the alternatives are calculated which is followed by the computation of the quantitative utility for each alternative. In the final step, alternatives are ranked according to their quantitative utility values.

COPRAS was introduced by Zavadskas et al. in 1994 as a MADM method. It is employed in the ranking process of alternatives according to their associated weights. COPRAS method evaluates these alternatives in terms of significance and utility degree (Stefano et al., 2015). COPRAS has been used in many studies due to its ease of understanding and application (Zavadskas et al., 2007; Bardauskienë, 2007; Malinauskas & Kalibatas, 2005). The calculation steps of COPRAS method are listed below (Organ, 2016):

- Step 1: Constructing the initial decision matrix;
- Step 2: Normalization of the initial decision matrix;
- Step 3: Constructing the weighted normalized decision matrix;
- Step 4: Computing the sums of weighted normalized values for beneficial and non-beneficial criteria;
- Step 5: Calculating the relative significances;
- Step 6: Calculating the quantitative utility for each alternative;
- Step 7: Ranking the alternatives.

Case Study: Wave Energy Site Selection Using the Proposed Model

The illustration of the proposed model can be best demonstrated by a real-life problem. For this purpose, the case presented by Turkoglu et al. (2020) is also used in this study for the selection problem of the most appropriate site to install wave energy converters. The case consists of two different locations (i.e., Kefken (A1) 41.25° N, 30.20° E and Karaburun (A2) 41.50° N, 28.70° E) in the Black Sea. There is a reason for choosing two different locations in the Black Sea. It is one of the coastal regions of Turkey that offers a great wave energy potential (Sağlam et al., 2010). Furthermore, the criteria identified in Turkoglu et al.'s study (2020) after performing a literature review and conducting interviews with decision makers are also used in this study. There are four main criteria that have been considered in the proposed model, namely, (1) locational aspects factors (LF), (2) efficiency of the wave energy converter factors (EF), (3) cost factors (CF), and (4) environmental aspects factors (EA). Each main criterion has different sub-criteria. The first main criterion (i.e., locational aspects factors) has nine sub-criteria, namely, incident wave power (LF_1), incident significant wave height (LF_2), incident

wave period (LF_3), water depth (LF_4), maritime transportation density (LF_5), extreme wave height (LF_6), time variation of incident wave power (LF_7), shape parameter of incident wave spectrum (LF_8), and currents (LF_9). On the other hand, the second main criterion does not have any sub-criteria. The third main criterion (i.e., cost factors) has four sub-criteria, namely, material cost (CF_1), installation cost (CF_2), operation and maintenance costs (CF_3), and accessibility (CF_4). Finally, the fourth main criterion (i.e., environmental aspects factors) has three sub-criteria, namely, water quality (EA_1), endemic species (EA_2), and migration routes (EA_3). Figure 1 shows the decision hierarchy of the wave energy site selection problem.

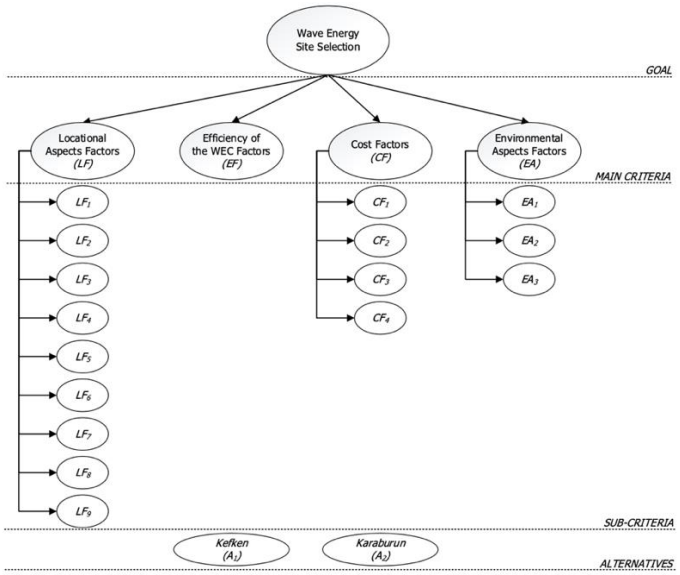

Figure 1: Decision hierarchy of the wave energy site selection problem.

In order to use CRITIC and COPRAS methods, the first step is constructing the initial decision matrix. Table 1 shows the initial decision matrix and data used for performance evaluation of alternatives. The data for water quality (EA_1), and migration routes (EA_3) criteria are qualitative. Water quality (EA_1) criterion is measured on a scale of 1 to 5 (i.e., 1: Very Bad; 5: Very Good). Besides, migration routes (EA_3) criterion is measured on a scale of 0 to 1.5 (i.e., 0: not on the migration route, 0.5: only on the migration route of birds of prey, 1: only on the migration route of marine animals; 1.5: on the migration route of both). On the other hand, the criteria other than water quality (EA_1) and migration routes (EA_3) are quantitative. Furthermore, LF_5, LF_6, LF_7, LF_9, CF_1, CF_2, CF_3, CF_4, EA_1, EA_2, and EA_3 are non-beneficial criteria for which lower values are desirable, while greater values are desirable for the rest of the criteria considered in this study. Stated in other way, LF_5, LF_6, LF_7, LF_9, CF_1, CF_2, CF_3, CF_4, EA_1, EA_2, and EA_3 criteria should be minimized, while the rest of the criteria are being maximized.

Table 1. Initial decision matrix of evaluation criteria for two wave energy sites.

Criterion	Measurement Unit	A_1 (Kefken)	A_2 (Karaburun)	Best	Worst
LF_1	kW	3,198.69	4140.54	4,140.54	3,198.69
LF_2	m	3.05	3.42	3.42	3.05
LF_3	s	7	7.2	7.2	7
LF_4	m	20	20	20	20
LF_5	point	1	0.17	0.17	1
LF_6	m	9.2	6.4	6.4	9.2
LF_7	m	0.84	1.01	0.84	1.01
LF_8	s	0.28	0.33	0.33	0.28
LF_9	cm/s	10	10	10	10
EF	%	70	70	70	70
CF_1	$	3,882,403	4,696,916	3,882,403	4,696,916
CF_2	$	685,130	828,867	685,130	828,867
CF_3	$/year	280,204.91	362,711.51	280,204.91	362,711.51
CF_4	km	1.4	0.6	0.6	1.4
EA_1	1-5 scale	4	3	3	4
EA_2	point	30	15	15	30
EA_3	0-0.5 scale	1	1.5	1	1.5

In this study, Özhan and Abdalla's (2002) metocean model is used to obtain the data for the For LF_2, LF_3, LF_4, LF_6, LF_7 and LF_8 criteria. The value of LF_5 criterion was computed using Eq. 1. On the other hand, Eq. 2 was used to measure EA_3 criterion. The value of LF_1 criterion was calculated by employing Eq. 3 (Chakraborty et al., 2019).

$$P_{LF_5} = \sum_{i=1}^{N} \frac{1}{d_i} \tag{1}$$

where d_i is the distance of any maritime facility which may cause potential interference to the point where the wave energy converter will be installed, and N is the total number of facilities ($i=1, 2, \ldots, N$) within a 10 km radius of the specified point.

$$P_{EA_3} = (a + b) \times 0.2 + c \times 1 + d \times 0.6 \tag{2}$$

where a, b, c, and d are the number of plant species unique to the region in question, the number of animal species unique to the region in question, the number of marine species unique to the region in question, and the number of amphibians unique to the region in question, respectively.

$$P_w = \left(\frac{\rho \times g^2}{64\pi}\right) \times T_p \times H_s^2 \tag{3}$$

where P_w is the average wave power, H_s is the incident significant wave height, T_p is peak period, ρ is the density of water, and g is the gravitational acceleration.

In this study, CRITIC method is used to determine the weights of the criteria. First the initial decision matrix is normalized (Table 2) to compute the correlation coefficient of the criteria. Lastly, the weights of the criteria are determined (Table 3). In Table 3, W_j is the weight of the j^{th} criterion and C_j is the quantity of information contained in j^{th} criterion.

Table 2. Normalized decision matrix.

	A_1 (Kefken)	A_2 (Karaburun)	σ_j
LF_1	0.000	1.000	0.707
LF_2	0.000	1.000	0.707
LF_3	0.000	1.000	0.707
LF_4	0.000	0.000	0.000
LF_5	0.000	1.000	0.707
LF_6	0.000	1.000	0.707
LF_7	1.000	0.000	0.707
LF_8	0.000	1.000	0.707
LF_9	0.000	0.000	0.000
EF	0.000	0.000	0.000
CF_1	1.000	0.000	0.707
CF_2	1.000	0.000	0.707
CF_3	1.000	0.000	0.707
CF_4	0.000	1.000	0.707
EA_1	0.000	1.000	0.707
EA_2	0.000	1.000	0.707
EA_3	1.000	0.000	0.707

Table 3. Criteria weights.

Criteria	C_j	W_j
LF_1	9.192	0.059
LF_2	9.192	0.059
LF_3	9.192	0.059
LF_4	0.000	0.000
LF_5	9.192	0.059
LF_6	9.192	0.059
LF_7	14.849	0.095
LF_8	9.192	0.059
LF_9	0.000	0.000
EF	0.000	0.000
CF_1	14.849	0.095
CF_2	14.849	0.095
CF_3	14.849	0.095
CF_4	9.192	0.059
EA_1	9.192	0.059
EA_2	9.192	0.059
EA_3	14.849	0.095

The findings of the CRITIC method reveal that material cost (CF_1), installation cost (CF_2), operation, maintenance costs (CF_3), time variation of incident wave power (LF7), and migration routes (EA_3) have the highest weight among all criteria. They are followed by the incident wave power (LF_1), incident significant wave height (LF_2), incident wave period (LF_3), maritime transportation density (LF5), extreme wave height (LF6), time variation of incident wave power (LF7), shape parameter of incident wave spectrum (LF8), accessibility (CF_4), water quality (EA_1), endemic species (EA_2) which have the second highest weight.

After determining the weights of the criteria via CRITIC method, COPRAS method is used to determine the ranking of the location alternatives where wave energy converters can be installed. The method starts by constructing the initial decision matrix (Table 1). Then, elements of the initial decision matrix are normalized (Table 4) to construct the weighted normalized decision matrix (Table 5).

Table 4. Normalized decision matrix.

	A_1 (Kefken)	A_2 (Karaburun)
LF_1	0.436	0.564
LF_2	0.471	0.529
LF_3	0.493	0.507
LF_4	0.500	0.500
LF_5	0.855	0.145
LF_6	0.590	0.410
LF_7	0.454	0.546
LF_8	0.459	0.541
LF_9	0.500	0.500
EF	0.500	0.500
CF_1	0.453	0.547
CF_2	0.453	0.547
CF_3	0.436	0.564
CF_4	0.700	0.300
EA_1	0.571	0.429
EA_2	0.667	0.333
EA_3	0.400	0.600

Then, the sums of weighted normalized values for both beneficial and non-beneficial criteria are computed to determine the relative significances of the alternative locations. Finally, the ranking of the alternatives is obtained after calculating the quantitative utility for each alternative. The results obtained via COPRAS method (Table 6) show that A_2 (Karaburun) is the most appropriate alternative as it has a greater utility value when compared to the utility value of A_1 (Kefken).

Table 5. Weighted normalized decision matrix.

	A_1 (Kefken)	A_2 (Karaburun)
LF_1	0.026	0.033
LF_2	0.028	0.031
LF_3	0.029	0.030
LF_4	0.000	0.000
LF_5	0.050	0.009
LF_6	0.035	0.024
LF_7	0.043	0.052
LF_8	0.027	0.032
LF_9	0.000	0.000
EF	0.000	0.000
CF_1	0.043	0.052
CF_2	0.043	0.052
CF_3	0.041	0.053
CF_4	0.041	0.018
EA_1	0.033	0.025
EA_2	0.039	0.020
EA_3	0.038	0.057

Table 6. Results of COPRAS method.

Relative significance of alternatives					Utility values and ranking of the candidate alternatives	
	P_j	R_j	$1/R_j$	Q_j	N_j	Ranking
A_1 (Kefken)	0.109	0.406	2.465	0.428	88.258	2.000
A_2 (Karaburun)	0.125	0.360	2.777	0.485	100.000	1.000

The findings of this study are consistent with the findings of the authors' previous study (i.e., Turkoglu et al., 2020). Even though the same location is favored in both studies, studies (e.g., Polat et al., 2019) exist revealing the fact that using different MADM methods for the very same problem may end up with different results. Therefore, this study gives decision-makers the opportunity to use the proposed model in different locations which allows them comparing the results to make sure that the most appropriate location is selected.

Conclusion

Renewable energy generation grew at its fastest rate in recent years. Wave energy is one of the important renewable energy sources in coastal areas. But, not selecting the appropriate location for a renewable energy project may weaken its benefits. Therefore, the selection of the most appropriate site for the installation of wave energy converters is very important to get the maximum utilization of wave power potential. In this study, a multi-attribute decision-support system to determine the most appropriate location where wave energy converters can be installed has been proposed. The proposed multi-attribute decision-support system integrates

CRITIC and COPRAS methods. The weights are calculated via CRITIC method and the alternatives are ranked via COPRAS. The findings of this study show that Karaburun is the most appropriate alternative as it has the greatest utility degree. It should be also noted that the finding of this study is consistent with the findings of the authors' previous study. However, decision-makers should be aware that studies exist revealing that the use of different MADM methods may give different results for the very same problem. Discussion with decision makers reveals that this method is reliable and usable in any wave energy site selection as it provides a reasonable and rational results. An in-depth study that includes additional criteria and different locations my shed further light to the site selection of wave energy converters.

Abstract

Construction and demolition wastes (CDW) accounts for nearly 40% of total waste in the European Union (EU) in recent years. EU with the Waste Framework Directive (WFD), which is the basic law of the waste policy, has set various targets for the member countries to reduce CDW. However, this directive does not specify a common definition or approach for CDW and the application does not clearly define the evaluation categories. This has led to various strategic differences in CDW management among member states. Therefore, in this study, the correlation of CDW generation with national construction turnover, gross domestic product, and number of people in EU MS are examined and compared. These data were evaluated to analyze the relationship between landfill tax, CDW recovery rates, and landfill bans. However, according to the obtained correlation graphs, there is no particularly significant relationship between landfill or recovered CDW rates and CDW tax. Finally, the current situation in Turkey was analyzed, and the processes and strategies to be followed according to the important gaps and concerns regarding the credibility of the CDW definition and data specified in the EU were determined.

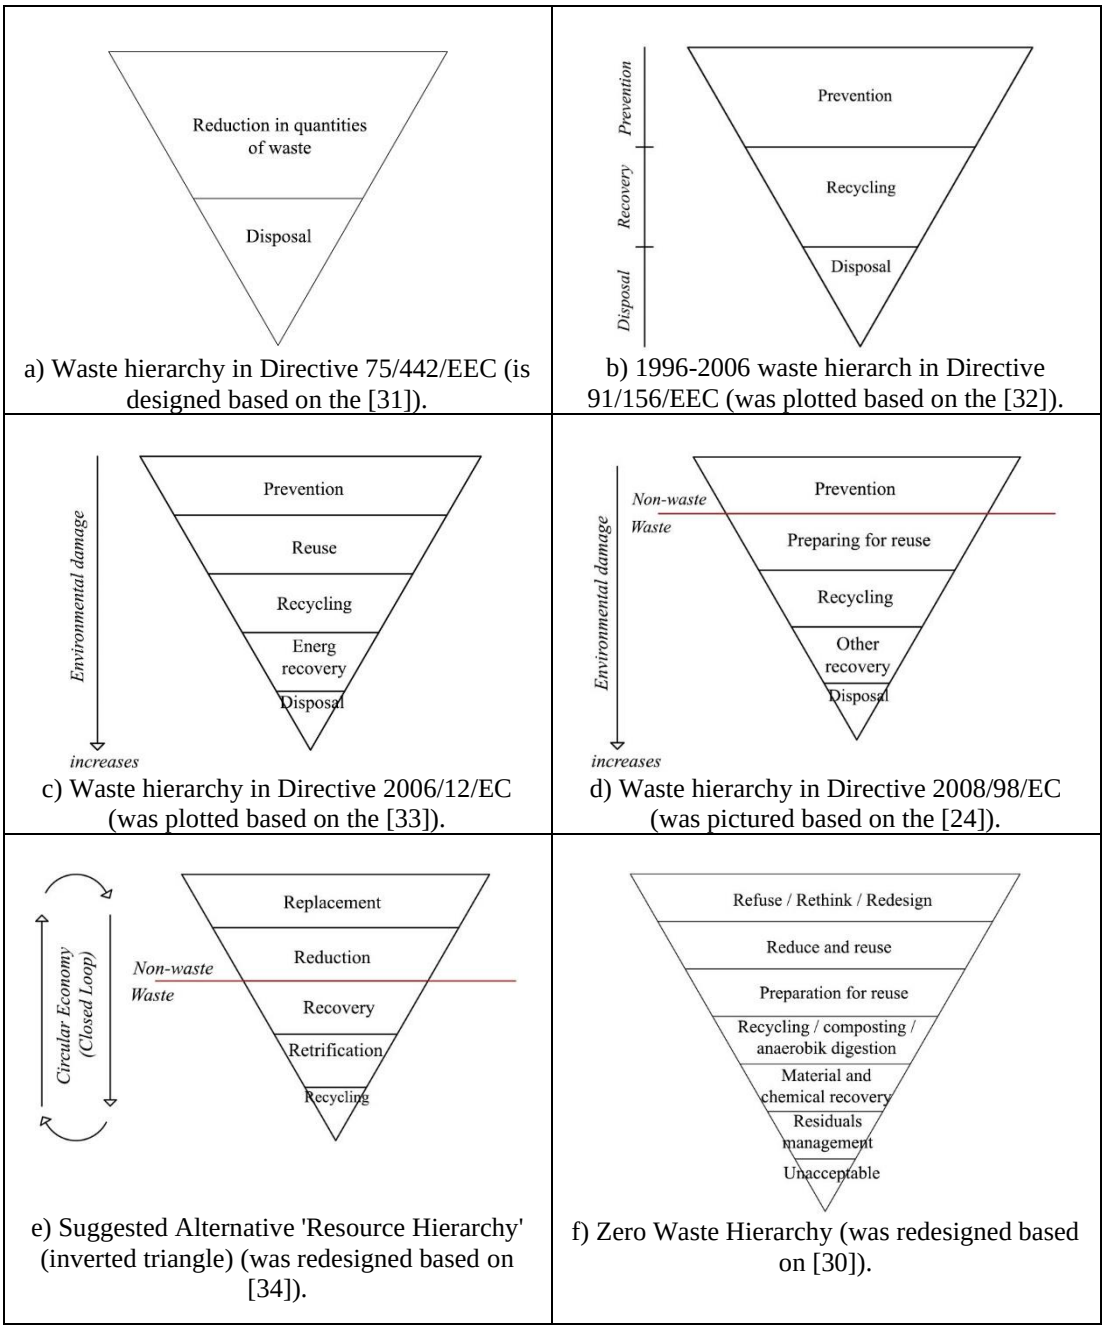
Keywords: *construction and demolition waste, European Union, Turkey, waste management.*

Introduction

Construction and demolition wastes (CDW) have increased significantly as a result of urbanization (Saez & Osmani, 2019). This has made CDW a global issue (Shi & Xu, 2021). CDW accounts for nearly 30-40% of total waste globally (Chen et al., 2002). When CDW generated by natural disasters is added to these, this rate rises to 50% (Öztürk, 2005). China, the United States of America (USA), and the European Union (EU) are the top three CDW producers, as well as the three largest economies (Kabirifar et al., 2020). China nearly 400 million tonnes (CABR, 2014); the USA nearly 700 million tonnes (Wu et al., 2019) and the EU 850 million tonnes (Saez & Osmani, 2019) are responsible for generating construction and demolition waste per year. The recovery rate of CDW in 2018 was 5%, 76%, and 88% in China, the USA, and the EU, respectively. In China, although 95% of these wastes are

recyclable, they reach landfills without any waste separation (Wang et al., 2021). Worse still, most of them are disposed of in illegal landfills (Xu et al., 2018). In the USA, the recycling rate is nearly 25% (Yu et al., 2021). Eurostat (EU statistics website) (Eurostat, 2018) according to 2016 data, nearly 71% in the EU; while the Netherlands, one of the EU member states (MS), reached 100%, Italy and Slovenia exceeded 97%; Ireland, Croatia, Cyprus, Malta, Portugal, and Romania have a recycling rate of less than 50%.

CDW threatens many countries as it constitutes a large part of solid waste (Elgizawy et al., 2016). CDW, by EU definition, are the wastes with the highest volume and weight. The percentage of CDW in total waste are 36% in the EU (Eurostat, 2018), 36% in Japan (Tam & Tam, 2008), 38% in Hong Kong (Tam & Tam, 2008), nearly 40% in China (Huang et al., 2021) and 44% in Australia (Tam & Tam, 2008); from EU MS, Austria, Malta and Luxembourg have percentages of 75%, 79% and 81.2%, respectively (European Commission, 2022). In this case, CDW determined by the EU as a priority waste stream due to its significant generation level and high recycling potential (Borghi et al., 2018). This study explores the practice of CDW management in the EU. Due to the uncertainties and gaps in the Waste Framework Directive (WFD), there is no common definition and approach for CDW in MS. There are differences in implements and evaluations. To compare these differences in EU-27 MS, CDW generated with 2018 data from Eurostat has been analyzed by taking into account factors such as construction turnover, GDP, and population. The study, considering the per person CDW rate generated in each MS examines the relationship between CDW bans and taxes, CDW landfill, or recovery rates in MS. The current situation in Turkey was analyzed and the process to be followed was briefly stated.



Waste Framework Directive

This stage adopts the EU Waste Framework Directive (WFD) and the waste hierarchy and uncertainties in the WFD.

Waste Framework Directive and Waste Hierarchy

In the European Union, waste management policies first started in 1975 with the WFD (SOER, 2015). With this directive, waste has been recognized as an environmental problem for the first time. However, waste prevention and recycling have been defined as an intention rather than an attainable goal (SOER, 2015). The WFD has served as an important harmonization tool for nearly 30 years without significant change (Elni review, 2010). After 1975, the Directive was changed to 2006/12/EC in 2006 (Neubauer, 2007) and 2008/98/EC in 2008 (Wang & Xie, 2021). WFD is the basic law of the EU Waste Policy. The WFD determines waste-related definitions for the EU-27 MS (European Commission, 2008) and provides a general framework for waste prevention and management (Römph & Cramer, 2020). Article 4 of the WFD requires the MS to define a waste management hierarchy incentived by law and policy (European Commission, 2012). WFD is implemented taking into account the waste management hierarchy (European Commission, 2008). The waste management hierarchy in the EU is prevention, reuse, recycling, energy recovery, landfill, and disposal (European Commission, 2008). In addition, the EU's action plan adopted in 2015 was revised and adopted the circular economy with the WFD No. 2008/98/EC in 2018 (European Commission, 2014). The main goals of the 2008 WFD are to transform the EU into a 'recycling society', prevent waste generation, use waste as a resource, reduce the negative

environmental and health impacts of waste and provide resource efficiency towards the creation of a circular economy (Ponce del Castillo, 2014). Despite these goals, the current waste hierarchy still allows disposal, not reflecting a circular economy framework (Zhang et al., 2022). The proposed hierarchy is a closed-loop, resource-use hierarchy, which is identified with the concept of the circular economy. Along with this concept, the Zero Waste Hierarchy was formed (Figure 1). The zero waste hierarchy proposed by Zero Waste Europe (ZeroWaste Europe, 2019) proposes to preserve value by designing wastes outside the system.

a) Waste hierarchy in Directive 75/442/EEC (is designed based on the [31]).

b) 1996-2006 waste hierarch in Directive 91/156/EEC (was plotted based on the [32]).

c) Waste hierarchy in Directive 2006/12/EC (was plotted based on the [33]).

d) Waste hierarchy in Directive 2008/98/EC (was pictured based on the [24]).

e) Suggested Alternative 'Resource Hierarchy' (inverted triangle) (was redesigned based on [34]).

f) Zero Waste Hierarchy (was redesigned based on [30]).

Figure 1: Waste management hierarchy development framework.

Uncertainties of Waste Framework Directive

WFD adopted by the EU; A common definition for CDW does not specify an approach and the application does not clearly define evaluation categories. Previously, construction wastes were simply debris from construction sites (Taylor, 2011). However, there is currently no consensus on the definition of CDW (Yuan, 2017; Wang & Xie, 2021). For example, in CDW report data provided by EU MS include: Germany excavated/non-excavated soil (Deloitte, 2015a); Finland (Deloitte, 2015b), Spain (Deloitte, 2015c), and the Netherlands (Deloitte, 2015d) with/without hazardous waste; Finland (Deloitte, 2015b), Spain (Deloitte, 2015c), Sweden (Deloitte, 2015e), Austria (Deloitte, 2015f), Belgium (Deloitte, 2015g), Bulgaria (Deloitte, 2015h) and Romania (Deloitte, 2015i) with/without excavation or soil and stone. Since illegal disposals are not included in these reports, there is a great variation in reported values between countries (Saez & Osmani, 2019). Also, the CDW group may or may not be dangerous. However, Eurostat only analyses non-hazardous CDW. The non-hazardous category has a higher volume, increasing the chance of reuse (Carcel-Carrasco et al., 2021). However, it does not give the total amount of CDW generated. In this case, there are problems with the accuracy and completeness of the recorded data collected and summarized by the MS. In addition, quantitative data CDW of illegally disposed of are not available. In addition, while the WFD does not provide a definition for backfilling, the term backfilling is evaluated differently between MS as recovery or disposal (Deloitte, 2017). According to Eurostat 2018 data (EEA, 2020), the including or excluding backfill of amounts reported affects the calculation of the recovery rate and causes large differences between some MS. Furthermore, the Directive indicates a shift from a policy based on waste disposal to a policy that prioritizes its use through recycling to conserve natural resources (Malia et al., 2013). The 2008/98/EC WFD includes the option to set end-of-waste (EoW) criteria for recycling waste-derived materials. However, the criteria have not yet been defined (Carcel-Carrasco et al., 2021). Only five MS (Austria, Belgium, France, the Netherlands, and Romania) have end-of-waste criteria in their national legislation (Deloitte, 2017). In this case, the targets set do not directly contribute to recycling.

Management Performance of CDW in EU-27 MS

The analytical methodology of this research comprises five stages corresponding to the third part (Figure 2): CDW data framework, CDW Data reliability, analysis of CDW generation rates, analysis of CDW recovery rates, and CDW policy framework.

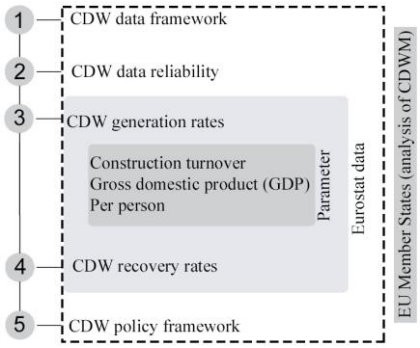


Figure 2: Framework of this study.

CDW Data Framework

EU adopted waste data for the first time in 2002 with regulation 2150/2002/EC on waste statistics. The regulation obliges EU MS to provide data on waste generation, recovery, and disposal every two years since 2004. As of this year, data on waste generation and treatment are available. However, CDW landfill data has been included in Eurostat since 2010 (Wang & Xie, 2021). In 2010, statistics on CDW generation were calculated using data sources such as surveys and interviews. As of 2011, CDW data is transferred directly to a central database by collection and processing companies (Deloitte, 2015f).

CDW Data Reliability

Data in this stage are from Deloitte, which provides source data to the EU. The European Commission (Deloitte, 2017) assesses the data quality of the MS and divides it into three parts (Table 1).

Table 1. CDW data quality levels and data collection (is designed based on the (Deloitte, 2017) source).

Good	Modest	Poor
Germany [1]	Belgium [2]	Bulgaria [3]
Austria [1]	Estonia [1]	Finland [3]

Slovenia [3]	Hungary [3]	Greece [3]

Data collection: [1] ADS: Administrative data sources; [2] S: Survey; [3] ADS and S

Analysis of CDW Generation Rates

Large amounts of CDW are generated in the EU, but there are significant differences between MS (Iacoboaea et al., 2020). In EU MS, the highest and lowest rates were 81.2% in Luxembourg and 0.1% in Bulgaria in 2018 (Figure 3).

In Table 2, Germany and France generated more than 60 million tonnes of CDW in 2018. These countries are followed by Italy, Belgium, and the Netherlands, respectively. However, it will not be an accurate and quality measurement to evaluate only by considering the amount of CDW generated. Factors such as construction turnover, Gross domestic product (GDP), and population are very important as that affect the amount of CDW generated. Table 2 was created with data on these parameters in each MS.

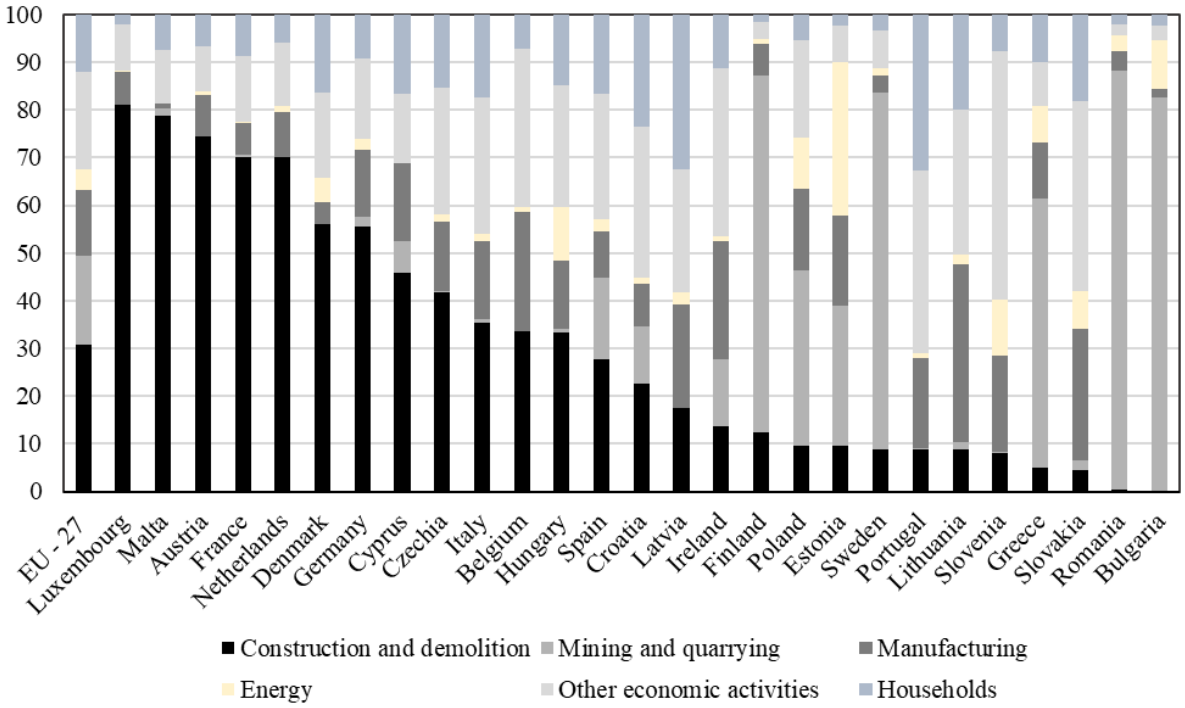

Figure 3: Waste generation (total waste percentage of CDW) by activities of EU MS in 2018 (Neubauer, 2007).

Table 2. Amount of CDW, analysis of construction turnover, GDP, and per person of each MS during 2018 (data from Eurostat, 2022).

MS	CDW (Mt)	Parameters analysed			Tonnes of CDW per parameter		
		CDW turnover (M€)	GDP	Person	t/M€	t/GDP	t/person
EU - 27	303.17	1.584.448	13.531.537,0	446.834.500	191,34	22,40	0,68

Lithuania	0.80	6.172,0	45.514,8	2.794.200	129,22	17,52	0,29
Luxembourg	0.64	6.251,4	60.362,2	613.900	102,16	10,58	1,04
Hungary	3.47	14.065,0	136.073,4	9.772.800	246,60	25,49	0,35
Malta	1.88	1.251,6	12.954,8	493.600	1500,1	144,93	3,80
Netherlands	21.20	105.000,5	773.987,0	17.282.200	201,91	27,39	1,23
Austria	11.16	52.893,8	385.424,0	8.858.800	211,02	28,96	1,26
Poland	6.76	78.186,1	497.842.3	37.972.800	86,41	13,57	0,18
Portugal	1.56	20.150,7	205.184,1	10.276.600	77,33	7,59	0,15

Romania	0.73	20.458,2	204.496,9	19.401.700	35,56	3,56	0,04
Slovenia	1.07	5.580,2	45.864,2	2.080.900	190,87	23,22	0,51
Slovakia	0.85	11.078,3	89.430,0	5.450.400	76,64	9,49	0,16
Finland	1.25	38.638,7	233.462,0	5.517.900	32,36	5,35	0,23
Sweden	2.88	81.864,7	470.673,1	10.230.200	35,14	6,11	0,28

For each parameter analyzed according to Table 2, values higher than the EU mean are shown in gray (Table 3). In Table 3, Belgium and Estonia have the highest; Bulgaria and Ireland have the lowest construction turnover. Belgium and Estonia exceed 300 tonnes/M€; Ireland generated at such a low level that it could not exceed 20 tonnes/M€. The average CDW/GDP rate in the EU-27 MS were 22.4 tonnes in 2018. Belgium, Estonia, Czechia, France, Austria, Netherlands, Germany, Hungary, Italy, and Slovenia were the MS exceeding the average. In contrast, Ireland and Bulgaria have the lowest CDW/GDP ratios.

Table 3. Ranking of EU MS by the amount of CDW generated per parameter analyzed for 2018 (data from Table 2).

	CDW and Turnover		CDW and GDP		CDW and Person	
	MS	t / M€	MS	t / GDP	MS	t / Person
1	Belgium	317,71	Belgium	47,30	Belgium	1,90
2	Estonia	309,72	Estonia	46,68	Austria	1,26

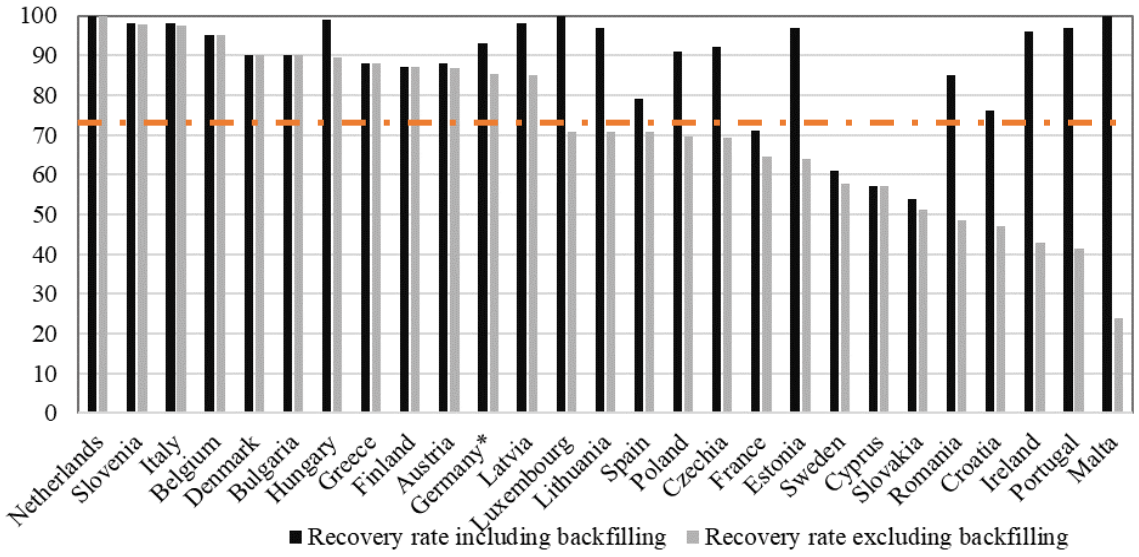
*	Malta	1500,10	Malta	144,93	Malta	3,80

* Malta has been excluded due to data quality as data rates are too high.

Analysis of CDW Recovery Rates

The WFD has set a target of at least 70% non-hazardous CDW (excluding soils) recovery by 2020 (European Commission, 2008). Figure 4 shows the recovery rates of EU-27 MS from



2010 to 2018, with data from Eurostat (2022). In Figure 4, recovery data is very volatile in some MS (such as Bulgaria, Cyprus, and Romania).

Data is confidential (Czechia –2018; Germany -2014 and 2016)
Data not available (Denmark –2010; Latvia – 2010 and 2012; Slovakia -2010 and 2012).

Figure 4: Recovery rate of construction and demolition waste.

In Figure 4, nearly 88% of total CDW was recovered in the EU in 2018. However, this rate also includes the filling rate, which is called backfilling. Most of MS accept backfilling as recovery. However, backfilling is a disposal method and refers to a process that cannot be recovered even if disposal results in the recovery of materials or energy (Deloitte, 2017). In Figure 5, Malta has a 100% recovery including backfill, while it has a recovery rate of 24% excluding backfill. In addition to the country of Malta, similarly, MS failed to exceed the EU 2020 70% recovery target excluding backfilling; Poland, Czechia, France, Estonia, Romania, Croatia, Ireland and Portugal. The MS of Sweden, Cyprus, and Slovakia failed to achieve this target in both cases, with or without backfill.

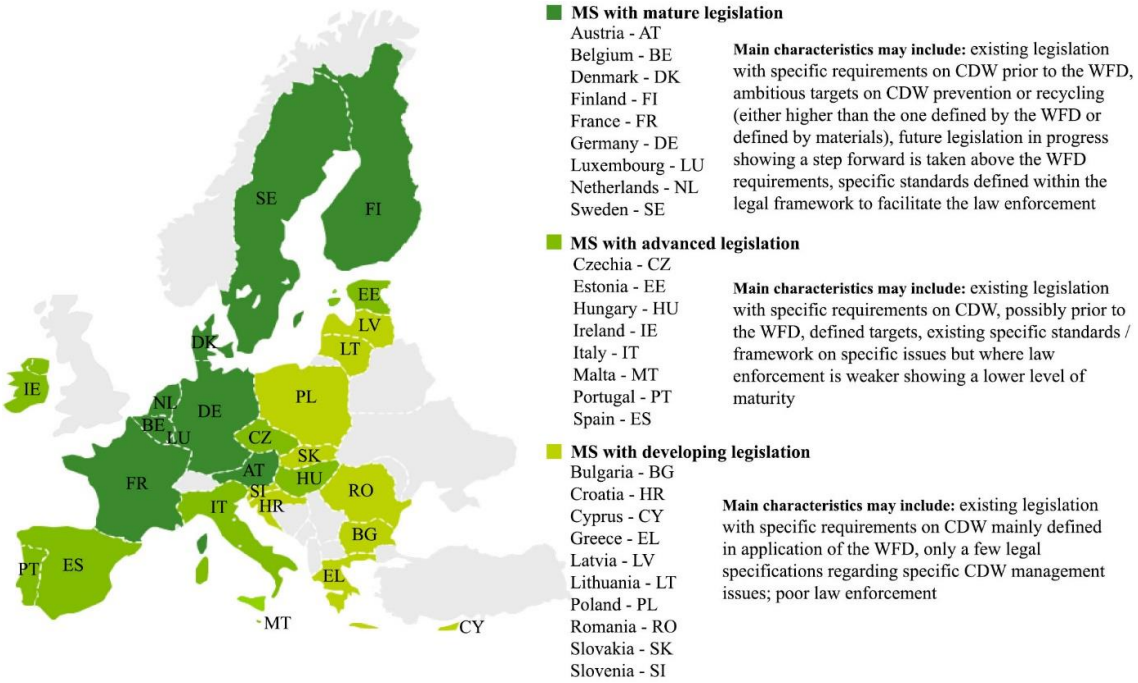
*Recovery rate including backfilling data was not available for the year 2016, so data from 2018 was used.

Figure 5: Recovery rates of CDW including and excluding backfilling in EU MS in 2016 (the figure (EEA, 2020) was created from the data in the source).

CDW Policy Framework

Through the WFD, EU MS has established different waste management implements and policies. Combined with the increase in CDW and the lack of local government policies for CDW management, the problems associated with the collection, transportation, and disposal of waste increase (Nunes & Mahler, 2020). These problems cause significant adverse effects on the environment, increased energy consumption, and consume finite landfill resources (Brandao et al., 2021). In this case, a lack of landfill will be inevitable over the years (Doan & Chinda, 2016). Although all MS have adopted the WFD into their national regulations, only Portugal, Slovenia, Spain in 2008 and in 2019 France developed national regulations for CDW management (Saez & Osmani, 2019). Because of the remaining MS rely on waste management plans; they do not have specific national CDW regulations (Saez & Osmani, 2019). Deloitte (2017) has divided EU MS into 3 categories according to their CDW legal framework (Figure 6).

The level of CDW management varies considerably in EU MS. For example, the landfill rate for CDW ranges from 0% for the Netherlands, Ireland and, Malta to 76% for Bulgaria Eurostat, 2022). Table 4 shows the member states' classification of CDW landfill bans and landfill taxes according to the high and low CDW generated per person identified in Table 3.



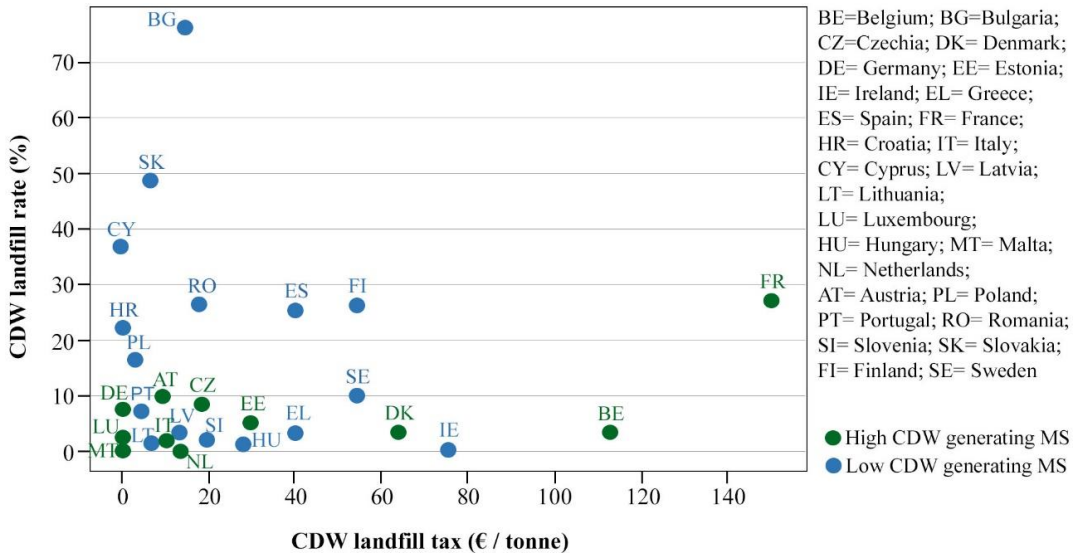


Figure 6: Level of maturity of the legal framework in MS (was redesigned based on Deloitte, 2017).

Table 4. Landfill ban and landfill taxes for high and low CDW generating per person in EU MS (the table (Saez & Osmani, 2019; Eurostat, 2018; Deloitte, 2015a,b,c,d,e,h,j,k,l,m,n,o; Deloitte, 2017; European Commission, 2018; CEWEP, 2017) was created from the data in the sources).

High CDW generating				Low CDW generating			
MS	Ban	Tax	€ /ton	MS	Ban	Tax	€ /ton
Belgium	✓	✓	56,05-113,01	Slovenia	✓	✓	19,2
Austria	✓	✓	9,20	Cyprus	-	-	-
Netherlands	✓	✓	13,07	Hungary	✓	✓	28
Germany	✓	-	-	Spain	-	✓	5-40
Luxembourg	✓	-	-	Lithuania	✓	✓	7,14
France	✓	✓	40-150	Sweden	✓	✓	54
Estonia	✓	✓	29,84	Finland	✓	✓	55
Denmark	✓	✓	49-64	Latvia	-	✓	13
Czechia	-	✓	18,50	Poland	✓	✓	2,7
Italy	-	✓	1,03-10,33	Slovakia	✓	✓	0,33-6,64
Malta	-	-	-	Portugal	-	✓	4,27
				Ireland	-	✓	75
				Croatia	✓	-	-
				Greece	-	✓	40
				Romania	-	✓	18
				Bulgaria	-	✓	14,3

In Table 4, according to the data in Table 3, the ones that are above the EU-27 average of the MS according to the amount of CDW generated per person (0.68 tonnes/person) are high; others are defined as low CDW producers. Figure 7 was created to classify the analyzed CDW policy framework for EU MS by per person CDW rates and analyze the relationship of these rates to CDW landfill tax and landfill rates. In MS, CDW landfill taxes differ by region or province, or by type of construction waste. The highest of the different CDW landfill taxes applied for countries such as Belgium, Denmark, France, Italy, Spain, and Slovenia were taken.

Data were not available for Czechia's CDW landfill rate in 2018, so data from 2016 were used.

Figure 7: Relationship between CDW landfill rate and landfill tax in EU MS in 2018.

Landfill taxes and bans may be two of the most effective practices for increasing CDW recovery rates (Deloitte, 2017). However, in this correlation graph, no direct relationship was found between the CDW landfill tax and the CDW landfill rate, or recovery rate (Figure 7).

Turkey

In Turkey, the first study on CDW was in 2004. There are four regulations for CDW conducted by the Ministry of Environment, Urbanization, and Climate Change:

- Excavated Soil, Construction, and Demolition Waste Control Regulation – 2004 (Official Journal of the Republic of Turkey, 2004)
- Regulation on Landfilling of Wastes – 2010 (Official Journal of the Republic of Turkey, 2010)
- Waste Management Regulation – 2015 (Official Journal of the Republic of Turkey, 2015)
- Zero Waste Regulation – 2019 (Official Journal of the Republic of Turkey, 2019)

Turkey has not yet adopted the Waste Framework Directive (2008/98/EC) into its national legislation and current regulations are not enough for CDW management. Available regulations are only theoretical and are not implemented. In Turkey, for the implementation of these regulations, first of all, CDW data must be available. However, there are currently no legal or economic mechanisms in Turkey to assist in reducing the amount of disposal and landfill of CDW. In Table 5, CDW management comparison chart between Turkey and the EU is given.

In Table 5, in the 2016-2023 Action Plan (European Commission, 2018), the only target for CDW as the future target are to promote the importance and management of CDW and excavated soil. This action plan is not a policy that contains or proposes specific solutions for CDW. When we compare it with the EU; EU MS have much better policies and practices than Turkey (Table 5). However, according to Table 5, this situation differs between MS.

Table 5. Comparison of CDW management in Turkey and the EU.

Indicators	European Union (EU-27)	Turkey
Waste Framework Directive	Available in all 27 MS	No
CDW Management Plan	Available in all 27 MS	No
Specific Regulations for CDWM	Available in 4 of 27 MS	No
CDW data	Available in all 27 MS, although the quality of data varies	No
CDW landfill ban	Application in 16 of 27 MS	No
CDW landfill tax	Application in 22 of 27 MS	No
CDW recovery rate	88%	No data
CDW recycling rate	71%	No data
Backfill definition	Available in 12 of 27 MS	No
End of waste criteria (EoW)	Available in 5 of 27 MS	No
Distribution of CDW recycling facilities	Available in all 27 MS, although their number may differ	In some developed cities, facilities for aggregates have been operation
National/regional sorting obligation	Application in 16 of 27 MS	No
National/regional separate collection obligation for different materials	Application in 13 of 27 MS	No
Obligation separate collection and management of hazardous CDWs	Application in all 27 MS	No
Pre-demolition audits	Application in 16 of 27 MS	No
Green Public Procurement	Application in 11 of 27 MS	No
Future target	70% recovery	To disseminate the importance and management

Results

This study presents an analysis of firstly WFD's uncertainties about CDW then the EU member states' CDW generation and recovery rates, policy frameworks, and the situation in Turkey. The study reached the following conclusions:

- The CDW defined by the EU's WFD demonstrated the lack/inadequacy of existing legislation and policies (significant uncertainties and gaps in the definition, scope, standards, policies, and data quality of the CDW).
- The study shows that current strategies are diverse and fragmented among MS and are not equally promoted. This case prevents MS from developing models to help estimate the amount of CDW and each MS from constitute an efficient infrastructure for CDW in line with the 'Circular Economy'.
- Belgium, Germany, and Estonia were found to be the highest ranked according to parameter analyses such as CDW-construction turnover, CDW-GDP, and CDW-person, and Bulgaria, Ireland, and Romania were the lowest.
- No correlation was found between CDW landfill tax and CDW landfill rate or recovery rate in EU MS. This may be due to the different quality levels of CDW data provided by MS or the main goal in taxation.
- European Union target of recovery rate for the year 2020 has not achieved, including backfilling three MS and excluding the backfilling of twelve MS.
- Turkey is very deficient in CDW management, practices, and policies.

Recommendations for this study should include a quantitative recycling target rather than an EU CDW recovery target. To achieve this goal, effective recycling facilities will be needed. EU CDW management protocol; It has already stated (Elshaboury & Marzouk, 2021) that the identification, separation, and collection of CDW will assist in the improvement of reverse logistics of CDW, CDW processing and quality, and management of recycled products from CDW, and appropriate policies. Solving the CDW management problem will lead to better strategic development with the application of new technologies (such as BIM, artificial intelligence, big data, internet of things). Using these technologies that automatically identify different materials, on-site waste separation has the potential to aid CDW classification and reduce costs (Davis et al, 2021). Appropriate policies should be implemented for these. In particular, more effective and coordinated actions and policies should be encouraged for the definition of waste end criteria, traceability guidelines, pre-demolition inspections, and the development of harmonized supporting guidelines for material (such as the taxation of raw materials) and tools. Turkey should immediately begin initiatives to develop prevention, reduction, and recovery programs for CDW in national, regional, and local policies. Regional planning and policies would be more beneficial because of the amount of CDW generated and the type of waste generated are different in each region.

How to Measure the Social Sustainability? Measurement Criteria for Architectural Design

E. Ulu and Ş. Emekçi
Ankara Yıldırım Beyazıt University, Department of Architecture, Ankara, Turkey
bagcivanelif@gmail.com, semekci@ybu.edu.tr

Abstract

Social sustainability requires a multifaceted understanding of the relationship between structure and human. Social interactions between people and the nature of their interactions are regulated through structures. On the other hand, structure also plays an important role in facilitating or preventing the development of actions in social life. The promotion and development of social sustainability through the structure depends on the creation of appropriate physical conditions within the structure by addressing the issues of social sustainability and the opportunities offered to the users of the structure in the architectural design process. Although the social sustainability criteria were mentioned in the content of the articles in the examined literature, the issue of determining the measurement criteria of social sustainability was found to be insufficient. Based on this analysis, the potential of the social sustainability approach to provide data support to the architectural design process has been analyzed and the measurability part has been presented to designers according to the criteria determined from the literature. According to the data obtained as a result of this analysis, a list of criteria has been created according to the social sustainability criteria that will shed light on the designers and are of primary importance in the construction process. Social sustainability is an approach aimed at defining, regulating and improving social life based on human and human relationships and interactions in public life. In this context, the aim of this study is to shed light on future social sustainability studies and to provide data support.

Keywords: *measurement criteria, principles of social sustainable architecture, social sustainability, social sustainability literature.*

Introduction

It is possible that many of the issues addressed in the architectural design process are directly or indirectly related to social sustainability due to the fact that people are the focus of architecture. The architectural design action, which is the decenter of the interaction between the environment and man, is very important because it is a process of creating and developing criteria that will determine the quality of settlements. Architectural design is a process that is staged as defining the problem, collecting data, revealing the first thoughts about the solution, creating alternative designs, choosing the most optimal model/design and evaluating the result by re-comparing the final model with the initial data. It is inconceivable that at every point in this process, this discipline, which has a human being at its center and has lost all meaning in

the absence of its user, lacks social sustainability. Human being, which has been forming and regulating its relations with the built and natural environment using many principles it has acquired from nature for hundreds of years, has maintained its mutual interaction with nature accompanied by the excellent teaching of nature. However, a number of global disasters have arisen due to the weakening of relations with nature for a wide range of reasons, the dominance of the point of view that sees nature as a resource in life. This situation has brought about a mental awakening and efforts to make life sustainable. The beginning of this effort dates back to 1972, when the issue of the environment was discussed for the first time at the Stockholm Conference (Boudes, 2014). However, the meeting of the Brundlant Commission in 1987 was remarkable because it was the first time that the concept of sustainability was defined. With the report published by the Commission, the concept of sustainability has settled in the world literature. According to the report, also known as the "Our Common Future Report", sustainable development is defined as "Development that meets today's needs without compromising the ability of future generations to meet their own needs (WCED, 1987)". The concept of sustainability has thus become a concept that has been discussed in almost every field from the moment it was first defined to the present day. While these concepts are being developed on the basis of, the evaluation criteria in the literature on behalf of social sustainability, which is the sub-heading of sustainability in architecture, stand out. In this context, the aim of this study is to shed light on future generations and architectural discipline in the construction process by converting these criteria into an evaluation criterion.

Literature Review

Social Sustainability

Indicators of social sustainability in architecture should be discussed in order to provide people with the highest quality living standards and liveable conditions for future generations. The principle of equality and accessibility should not be ignored for this discussion. In declaration on social sustainability, it is necessary to understand that the relationship between structures and society is multifaceted. All kinds of social interactions between people, the quantity and nature of these interactions are provided through these structures located in the environment. On the other hand, it is possible to achieve or prevent social interaction of people through these structures. Since this interaction between people and structures is continuous, the most important factor in the evaluation of spaces should be social sustainability indicators. In this context, a guide that can help architects in the social sustainability dimension of design should be examined. Determination of appropriate sustainable design strategies in sustainable design and social design as a tool to determine the performance criteria to guide decision-making processes involved in the design process from the first phase and sustainable architectural design, architectural and social priorities and objectives should be used.

In social sustainability indicators, the spatial quality of the architectural structure to be examined is first examined in order to determine the elements that need to be adapted to architecture and that require the design of the design in this context through a specific guide. Social sustainability, as a conceptual definition, includes the definition of a quality of life standard, as well as social sustainability in architecture should include the concept of quality of space. Words image within the concept of spatial quality, accessibility, identity, accessibility and parking facilities can be sorted in the following manner, imagination,

productivity, spatial orientation, flexibility, privacy, security, meaning, health, construction, health, physical and mental relaxation, comfort, status, etc. it could belong.

A sustainable building is defined as designing quality living conditions that are ecologically compatible with its environment, economically feasible, and prioritize user needs. In other words, a sustainable structure should have positive effects on the environment, its economic effects should be minimized and it should have sociocultural factors (such as quality and healthy space). At this point, it can be said that social sustainability has been left in the background as a result of not studying it much in the theoretical field. Berardi (2013), who works in the field of architecture, has determined a number of indicators of social sustainability. Substances can be listed as follows:

- Ethical standards should be followed throughout the supply chain with ethical trade and by providing healthy and safe working environments.
- Spaces should be designed according to user needs and provide flexibility in spaces.
- It should preserve the local heritage and culture.
- It should be integrated into the local context and ensure users' access to infrastructure services.

At this point, Berardi (2013) mentioned the keywords of social sustainability such as **flexibility** and **adaptability** when talking about sustainability.

In order to determine the architectural criteria of social sustainability, it is first necessary to analyse the relationship of space with people and society well. Man has tried to shape the place where he is located according to himself for ages. Initially, people made the cave where they lived a shelter for themselves, and over time they built their own unique structures. As the process of building this structure progresses, it has also been learned that spaces affect people. This bilateral interaction and its consequences have revealed the concept of social sustainability. In other words, spaces have the capacity to guide society and social relations. One of the concepts included in the concept of social sustainability, "quality of life", is a measurable level of well-being while receiving high-level efficiency in the space where a person is a user. It is a requirement of social sustainability with the concept of equality that all people achieve this "**quality of life**" equally. With the concept of "the right to life that should be passed on to future generations" contained in the definition of the concept of sustainability, it is one of the main goals of social sustainability to be able to leave and achieve this level of well-being equally to future generations. Prosperity includes the place where people are located and includes their daily lives in this place and their satisfaction arising from this life (Bacon et al., 2013). Since prosperity is shaped according to needs, space must have a flexible design in order to be socially sustainable in the face of changing needs. A definition of social sustainability made by Palich and Edmonds (2013) describes it as "a process aimed at designing sustainable and successful spaces to increase people's well-being by understanding what they need where they live". Another important concept that social sustainability includes is health. In the ISO 21929-1:2011 document submitted by the International Organization for Standardization, it is explained that social sustainability is the right of all mankind to benefit equally within the scope of health. Human health, both physically and spiritually, is affected by the design of the structure. Factors such as material quality, the amount of light the space receives, and the designs of the energy production-consumption relationship, directly affect human health. As it can be seen from this, human health is one of the factors affecting the "quality of life". In the ISO 21929-1:2011 document submitted by the International Organization for Standardization, another concept mentioned is security. Aside from the importance of security for human life, security also provides a person

with the feeling of "belonging" necessary for a "quality life". As it can be seen from here, security is one of the indicators of social sustainability in architecture. Another of the indicators of social sustainability in architecture is social equality.

Quality of life is conceptually directly related to the well-being of people. Human-centred quality of life, “human well-being", nature-cantered "environmental well-being" and it refers to the situation of “having a good place” based on space. The department, which is based on space, stands out in this research (Ministry of Development, Eleventh Development Report).

Methodology

In order for the systematic analysis to cover a sufficient number of articles, the research databases “Web of Science”, “Scopus”, “EBSCOhost” were used. In order to contribute to the development of the concept of social sustainability and to fully its measurability, the articles published between 1972 and 2020 were examined. The reason why 1987 was chosen as the starting date is that the concept of sustainability and the concept of social sustainability, which is the subject of the study as a subheading, were first included in the Brundtland Report in 1987 (WCED, 1987). In this direction, the data mentioned in the study were reached by means of a literature review in such a way that the date 1987 was the starting point. As a research term, the keywords “social sustainability”, “social sustainability indicators”, and “measurement criteria” were searched in the entire article, publication titles and/or keywords. In this context, the whole of the study reveals a comprehensive and important approach to the promotion and development of social sustainability through structure.

Social Sustainability Indicators in Architectural Design

Space is not something that can be expressed only by physical forms. When it is considered that its subject is a person, space, physical forms and social relations become a whole. In this whole, there is a structure of space that shapes, regulates, develops social life and relationships, and is also affected by relationships in social life. It is obvious that the designers who founded this two-way design should act with an emphasis on social sustainability. Within the scope of social sustainability of a structure, space has a stimulating and developing quality of social interaction (Talen, 1999), a sense of place (Relph, 1976), a sense of trust and confidence (Newman, 1972) and a sense of comfort (Carr, 1992). However, in order to develop a space encourage social, flexible and adaptive qualities to occur in the desired place as supporting activities in an effective and efficient manner (Wegen, 2005; Mzoori, 2014), it is important to visualize the interactions of social life. The perception of security in the structure is also important for the development of community ties and the formation of a sense of community. By Bramley (2009), one of the indicators of social sustainability has been the element of security, as it was revealed that the sense of security in the structure strengthens social ties.

In this context, the titles in the literature that stand out with social sustainability and structure design are listed in Table 1.

Table 1. Social sustainability indicators in architectural design (source: authors).

SOCIAL SUSTAINABILITY INDICATORS IN ARCHITECTURAL DESIGN
Accessibility
Reachability/Parking Facilities
Space Efficiency
Flexibility
Security
Spatial Orientation

Accessibility

On the axis of social sustainability information, accessibility is at the top of maintaining the principles of social sustainability in architecture, as it emphasizes the principle of "**equality**" for all users. When referring to the phenomenon of accessibility in the context of social sustainability in architecture, 21542-2011 ISO standard (building construction: accessibility and usability of the Built Environment-Building Construction: built environment accessibility and availability) has defined accessibility of construction with the following ingredients:

- accessibility in the use of certain buildings
- outdoor accessibility
- indoor accessibility
- accessibility of traffic and transport services.

The first priority in building accessibility belongs to outdoor accessibility. Because no matter how flawlessly the structure is designed as spatial accessibility, if users or visitors cannot reach the structure, this will start to create chaos before the structure is used. Therefore, disabled access to the group structure should be pioneered within the scope of outdoor accessibility.

Reachability/Parking Facilities

Feitelson and Salomon (2000) establish relationship between the location of the structure and accessibility. Accordingly, the spatial patterns formed depending on the location choices of the uses in the built environment are influenced by a number of qualities such as ease of access to the transport network, speed of movement in the transport network, reliability and cost of access and movement on the network. These qualities vary depending on the location of the land and the type of transport network. In this context, the relationship of the location of the structure with the transportation network is important because it indicates the ease of access to the structure. In terms of accessibility, the presence of public transportation facilities and the provision of access to these facilities have an important place in promoting and developing social sustainability through the structure. Because transportation facilities and accessibility play a fundamental role in terms of human rights and equal opportunities. The fact that the structure has a location that can allow physical activities directly affects the availability and livability of the structure and the built environment. Therefore, in terms of social sustainability, location and orientation decisions should be made taking into account transportation facilities and ease of access to these facilities.

Space Efficiency

According to Hillier et al. (1984), the function is a characteristic spatial pattern and a characteristic part of the general spatial pattern. It is possible to express the concept of spatial pattern in this definition as the organization of the ways of decoupling of spaces and relations between spaces. Hillier et al. (1984) questioned the relationship between the form and function of the building, and on the overall structure of the spatial organization of the relations between the various spaces indicate that it has an effective role. Preiser (1983) states that user needs arise together with the built environment and user interaction, stating that user needs are actually indicators that reveal the performance and quality of the built environment. The performance levels that it considers in three groups as ”health, safety and security level“, ”functionality and efficiency level“ and ”psychological comfort and satisfaction level", in other words, reflect the needs of users in the physical environment. These three performance levels are also indicators of the liveability level of the spaces.

Flexibility

Flexibility is basically the ability of a place to adapt to new situations/relationships. According to Sinclair (2012), static spaces that are physically arranged according to very specific parameters show resistance to adaptation to other uses that may occur in space over time. Because fixed spaces usually have a single function and therefore exhibit an overly rigid behavior. According to Blakstad (2001), flexibility covers only one aspect of the change in buildings. Flexibility here is considered as a way to provide technical solutions by changing, moving, relocating elements such as walls, movable panels, and furniture within the basic structure of the building. Blakstad (2001) states that flexibility is a method for providing physical adaptability.

Security

According to Maas (2009), a sense of security is a prerequisite for health, well-being and quality of life. Promoting and developing social sustainability through a built environment is associated with the ability to use the structure without being threatened or experiencing a sense of fear. The perception of security in the built environment and in the structure is important for the development of community ties. According to Kent and Thompson (Jul, 2014), safe, clean and interesting areas in the structure can support the development of community ties and the strengthening of the community.

Spatial Orientation

The organization of space is important spatial information that supports in terms of an individual's understanding of the relationship between spaces and forming an image of this relationship. The fact that the relationships between horizontal and vertical spaces cannot be deciphered by users is an element that makes it difficult to find direction in the structure. It can be said that it is possible to direct human movements by determining the main axis of space and the direction of movement in the structure. According to Passini (1998), who drew attention to the importance of the circulation system in terms of direction finding, horizontal and vertical circulation systems are part of the architectural sense of direction finding.

How to Measure the Social Sustainability Indicators

In the articles containing the social sustainability indicators examined, the lack of the measurability part is noticeable in the literature. The fact that the determined indicators are grouped one by one or two and included in the articles and not made into the main headings makes the measurement standard difficult. Assessing the impact of structure on social sustainability, Bramley (2009) states that social sustainability includes two important dimensions, namely “social equality” and “sustainability of society”. In this case, the measurement criterion of social sustainability within the scope of the subtitle "Equality and justice for all" is the presence of Pedestrian Path, Use of Green Space, Accessibility and Parking Facilities. Hami and Emani (2015) state that planting has a negative relationship with total crimes in neighbourhoods, crimes against property, and violent crimes. In this context, Hami and Emani (2015) state that green areas in residential areas are positively related to increasing social security and draw attention to the nature of vegetation. Schulz (1980), in his work Geniuc Loci, stated the identity of the place as a prerequisite for human identity. The feeling of living in a residential building with local architecture is the measurement criterion because the buildings contribute to the identity creation process with their mass and superficial shapes. Subheadings such as the use of local materials, giving direction to the design by taking into account local typologies can be created. To Mclntyre (2006), according to the exterior view, fresh air circulation, access to sunlight, user-centred design and an interior that encourages interaction to allow, aesthetic and high-quality social structures are structures that can be design driven. Here, these issues are collected under the heading of Quality of Life/Health Compliance. In the Maslow hierarchy of needs, which are listed as physiological, security, social, self, realization needs, the need for security constitutes the most basic requirements that come after physical needs. The security element is one of the most important measurement criteria of social sustainability. In this context, the security indicator is examined under security measurement criteria : presence of security guards inside or outside the building, whether there are surveillance systems at the entrance to the structure of education, urban safety features such as pedestrian paths, in the area of the school gates.

Results

In the light of the information obtained from the literature, the characteristics and measurability levels that a structure must have in order to be socially sustainable are indicated in the Table 2.

Table 2. The characteristics and measurability in social sustainability (source: authors).

SUSTAINABILITY CRITERIA	MEASUREMENT CRITERIA
Equality/Justice/Social Justice	Pedestrian Path / Use of Green Space / Accessibility / Need for parking / Use of public transport
Social Sustainability/ Social Gain	Neighbourhood Relations / Public Use of Community Areas / Garden Use / Park Use
Liveability/ Social Sustainability	Positive-Negative Features of the Use of Living Space/
Quality of Life/Health Compliance	The desire to move to another dwelling/ The problem with housing/The level of income/ownership/The network of social relations
Perception of the City and Sense of Belonging	Social exclusion status / sense of belonging / Urban activities in which he can participate in public life/
Identity	The feeling of living in a residential building with local architecture
Aesthetic Perception	Satisfaction with the Facade of the Dwelling, Its Colour, Appearance
Security	Presence of security guards inside or outside the building / Whether there are surveillance systems at the entrance to the structure / Examination of urban security features such as pedestrian paths, school gates in the area
Accessibility	The presence and transportation of elevators in the structure for the convenience of transportation of disabled people / Examination of disabled roads and access facilities in the current region/
Flexibility	Evaluation of the suitability of housing for changes in user requests / Evaluation of the ability to shape environmental urban furniture on an urban scale in the inhabited area according to user requests
Economic Equality	Property status / Income status of persons / Finding out if there are energy-efficient uses of the structure in which they live/

In order to promote and improve the social sustainability of the structure, it is necessary to understand the effects of the structure on social sustainability with awareness of social sustainability. In this context, the whole of this study has revealed a comprehensive and important approach to the promotion and development of social sustainability through structure. Within the scope of this approach, the principles set out in the measurability criteria in Table 2 are the priority items encountered in the literature review.

Conclusion

Social sustainability is one of the most important indicators that reveal the quality of life and well-being of people and communities. In a structure where social sustainability is promoted and developed, the physical conditions related to the structure and the facilities offered by the structure to its users are very important. In this study, these possibilities have been collected under six main headings in the light of the results of the literature review:

- Accessibility
- Reachability/Parking Facilities
- Security
- Spatial Orientation
- Space Efficiency
- Flexibility

Due to the fact that the spatial requirements related to social sustainability, which should be taken into account decently in the architectural design process, are scattered in the literature, the evaluation criteria in this study have been collected from the literature and presented to the reader. Social sustainability in the construction sector in our country to be considered for the development of awareness of all stakeholders, universities, local governments, professional associations and cooperation between civil society organizations must be. Based on this, it is necessary to create social sustainability and awareness in society. In this context, this study has been prepared in order to shed light on future studies and to determine the measurement criteria of social sustainability criteria in the construction process.

Abstract

Construction project management is experiencing challenges with respect to sustainability and competitiveness. Supply chains and supply chain management in the construction industry (CI) can influence footprint and sustainability of this industry. Furthermore, lean and sustainable construction supply chain management (LSCSCM) can have impact on the competitiveness and core competencies of the construction companies. For this reason, application of effective strategies and principles in the supply chain management to enhance lean and sustainability performance of the entire supply chain need to be fostered. Based on the literature review, this paper aims to investigate sustainable and green building certifications (the BREEAM, CASBEE, DGNB and Greenstar certifications) and their potential contribution to the LSCSCM. This paper emphasizes that all four sustainable and green building certifications can have potential to provide a method for delivering information on the leanness and sustainability of construction activities and supply chains in CI. This paper is expected to provide valuable input to the stakeholders of the supply chains in the CI.

Keywords: *construction supply chain, supply chain management, lean, sustainability, sustainable and green building certification.*

Introduction

For construction companies to stand out in the market, it is important that they target useful utilization of their resources and creation of unique abilities so that product quality, and novelty and effectiveness, client gratification and client reaction can be enhanced (Racela, 2014). Companies need to search for innovative ways to deal with intensified competition in the global CI market. At this stage, supply chain (SC) plays an integral part as SC is vital for construction projects and has impacts on the circular economy (Tatlici & Sertyesilisik, 2019). While managing the SC, one has to make sense of the breakdown and traceability of a range of factors such as services and products, logistics, people, information, activities and

resources (Designing Buildings, 2014). To effectively manage the SC, it is important to offer an approach that suits the project program (Designing Buildings, 2014).

In the last decade, companies and academics have focused on new trends in construction management at the SC level due to advances in technologies and increasing importance of environmentalist approach and information systems (Ghadge et al., 2020). Competitive advantage factors at the SC level can be supported through the lean and sustainable approach (Tatlici & Sertyesilisik, 2019). Adaption of the sustainable and green building certifications criteria to SC at relatively early stages of projects can have potential to improve process and achieve lean and sustainable SC. This can result in an association of lean and sustainable construction supply chain management (LSCSCM) among contractors and designers to benefit all parties to outperform their competitors. This study focuses on green building certifications that can contribute to the lean and sustainable SC.

Research Method

This paper aims to investigate sustainable and green building certifications (the BREEAM, CASBEE, DGNB and Greenstar certifications) and their potential contribution to the LSCSCM. The research objectives are to determine the criteria by certification, and the way of collaborative use of lean and sustainable approaches and certifications at the SC level. A systematic literature review (SLR) has been applied within the scope of this research. In this study, based on the literature findings, the factors that are important for the success of supply chain management (SCM) practices and SC relations in the CI were investigated. In line with the research aim and objectives, Sustainable and Green Building Certifications were examined to determine the factors for contractor companies to achieve lean and sustainable SC in the CI. The study is to determine the criteria that can be used/considered in supplier selection for contractor companies in the CI to support achievement of lean and sustainable SC. 4 certificates have been examined within the scope of this research. These 4 certificates are: BREEAM, DGNB, Greenstar and CASBEE.

Construction Supply Chain Management

CI is affected by the competitive environment in the world. In order to be successful in compelling competition conditions; supply, design, production, marketing and logistics need to be managed effectively and companies need to control their product efficiency, costs and prices (Salami et al., 2016). Ability to control the construction process from the beginning to the end can influence ability to compete in the CI (PYM, n.d.). CSCM is an approach inspired by manufacturing SCs and in recent years has attracted attention of academics and professionals in the CI (O'Brien et al., 2008). SCM can eliminate costs and timeouts in the CI and improve performance in the construction process (Egan, 1998).

The fundamental differences between processes of construction and of other industries as well as the nature of these processes challenge application of manufacturing SCM practices directly to the CI (Young et al., 2011). For this reason, the CI needs different SCM solutions from other industries such as manufacturing and retail (Segerstedt & Olofsson, 2010). According to Sullivan et al. (2011), the established relationships and processes carried out are not seen as a SC connection for each project. This makes it difficult to optimize construction SCs over the long term (Garcia & You, 2015). As SC complexity increases, it becomes more

difficult to balance the needs of all members in the SC (Dunakin, 2022). Monitoring and measurement activities are critical success factors in ensuring mutual trust among members (Tan, 2001). In the development of SCM in the CI and in the success in relations, factors such as mutual trust between the parties, senior management support, consideration of mutual interests, manpower development, uninterrupted information flow and frequent meetings are the most important factors (Akintoye et al., 2000).

Sustainable and lean approaches are important in SC. Sustainable SC is expressed as a SC that ensures that the leading companies continue to protect their brand integrity, and that the entire SC communicates more easily with each other and constantly shares product details (Gedik, 2021). Furthermore, protecting and improving the environmental and economic values are among the objectives of the sustainable SC (Wu & Pagell, 2010). In this way, the long-term plans of the companies can be protected, and the company's earnings can be guaranteed (Sheffi, 2001). Sustainable SC, which enables the development of social skills of companies, is one of the most fundamental points that can affect long-term earnings (Gedik, 2021). In a sustainable SC, it is necessary for the company to be in constant communication with all other companies and customers (Sisman, 2018). Weakening of communication in certain periods can prevent the efforts for achieving the desired success (Sisman, 2018).

Sustainable and Green Building Certifications

As the world is changing-over towards a more sustainable economy, it is important to anticipate a continued increase in green building certifications in CI (Kurnaz, 2021). The construction SC should be checked whether it complies with the certification principles.

In the CI, triggering the SC with lean and sustainability can be obtained through the integration of the principles of sustainable and green building certifications into the SC. There are a range of green building certifications, which are global or being offered in specific countries (Yun et al., 2018). Within the scope of the research, the principles/criteria of the following 4 certificate programs were examined to be integrated into the construction SC.

BREEAM: In 1990, BREEAM was created in the United Kingdom and turned out to be the world's first technique through which buildings could be assessed for sustainability (BREEAM, 2009). BREEAM is a global initiative measuring the infrastructure projects and sustainability of buildings (BREEAM new construction technical manual, 2018). The BREEAM certification measures sustainability in a series of categories including transport, energy, innovation, health and well-being, materials, pollution, land use, waste, water and management (Parker, 2012). It includes new construction, existing buildings, and refurbishment projects (BREEAM, 2022). BREEAM has a specific BES 5058 standard called BRE Environmental & Sustainability Standard focuses on the sustainability (BREEAM, 2009). In BES 5058, environmental problems, which leave an impact on buildings all through their functioning life, are addressed (BREEAM, 2009).

CASBEE: The certification involves urban advancement, city administration, housing, and commercial building (SharpLaunch, 2022). CASBEE's aim is to offer a good lifestyle to people and minimize the life-cycle resource usage and environmental masses linked with the built environment, ranging from single home to an entire city (CASBEE, n.d.). Hence, it is easy for the system to conduct evaluation in every step of the building's design and

construction (CASBEE for building technical manual, 2014). The evaluation offers enhancement in all phases (CASBEE for building technical manual, 2014).

DGNB: DGNB has been constantly improved since its inception and it is considered not just the most progressive system in the world but is also globally renowned as the Global Benchmark for sustainability (DGNB System, n.d.). Different stages are involved in every building from its planning to deconstruction (Bertino et al., 2021). The DGNB certification system might accompany these stages with regards to an all-inclusive sustainable construction technique (DGNB System, n.d.). DGNB produces two certificates (Uruk & Islamoglu, 2019). The first certificate is awarded in the initial assessment phase, which is known as the design phase, whereas the main certificate is awarded once the construction is completed (Uruk & Islamoglu, 2019).

Greenstar: Green Star is an initiative that was developed in Australia and covers building design, energy performance, interiors and complete societies (Illankoon, et al., 2019). Through Greenstar, a building's design, construction and management procedures are measured under the optimal conditions (Anbarcı et al., 2012). Greenstar includes nine categories covering the environmental impacts that result directly from the site selection, design phase, construction phase and maintenance phase of a project (Greenstar, 2013a). These are; energy, materials, management, water, indoor environment quality (IEQ), ecology and land use, transportation, innovation and emissions (Green star, 2018).

Results and Discussion

Green building approaches are more easily adopted by increasing the performance more tangibly during the construction (Hwang & Tan, 2012). The construction SC is one of the most critical processes in terms of time and cost performance (Salami et al., 2016). Therefore, focusing on the construction SC based on the sustainable and green certificates, and lean and sustainability approaches can have potential to provide a competitive advantage and make a positive contribution.

The standards can offer a technique for the CI through which information is provided on the leanness and sustainability of tasks (Aristizábal-Monsalve et al., 2022). In general, they can be implemented on the evaluation of incorporated performance of works throughout the life cycle of a structure (BSI, 2021). For this reason, within the scope of current research, the four sustainable and green building certifications (i.e., BREEAM, CASBEE, DGNB and Greenstar) were examined in detail for CSCM.

The objectives and principles of these certificates were examined one by one under the filter of leanness and sustainability. Criteria that can work together with the construction SC and that can contribute to both economic, social and environmental impacts at the SC level have been determined. The most important point in the criteria obtained is to receive a positive answer to the given question; Does it add value to the project in terms of sustainability dimensions when integrated into the construction supply chain process?

Table 1. Criteria obtained through BREEAM, CASBEE, DGNB and Greenstar.

BREEAM criteria as follows:		**Reference**
1	Consideration of environmental criteria in the management of the site and use of the building.	BREEAM (2018)
2	Minimizing the energy consumption of buildings.	BREEAM (2009)
3	Encouraging designs to increase human health and comfort of building users.	BREEAM (2018)
4	Paying attention to the ease of transportation and location is important.	BREEAM (2018)
5	Using systems that reduce water consumption.	BREEAM (2009)
6	Paying attention to the selection of the building materials used in our company and our suppliers from materials whose environmental effects are approved.	BREEAM (2018)
7	Paying attention to the recycling of wastes generated during the building production process and the evaluation of the wastes generated during the building operation and use process is important.	BREEAM (2018)
8	Protection of uncontaminated lands and biodiversity is aimed.	BREEAM (2009)
9	Encouraging designs that prevent harmful fluids, light-noise pollution, soil and water resources pollution that have an impact on global warming.	BREEAM (2018)
10	Taking risks into account.	BREEAM (2009)
11	Encouraging contributions to innovative ideas, designs, management processes or technological development in the field of sustainability.	BREEAM (2009)
DGNB criteria as follows:		
1	Measuring global warming potential in the materials used.	DGNB (2020)
2	Measuring the ozone layer depletion potential in the materials used.	DGNB (2020)
3	Measuring the photochemical ozone creation potential in the materials.	DGNB (2020)
4	Measuring the risks to the local environment in the materials used.	DGNB (2009)
5	Measuring sustainable use of resources.	DGNB (2018b)
6	Measuring the use of non-renewable resources.	DGNB (2018b)
7	Organizing the wastes according to their categories.	DGNB (2009)
8	Evaluation of building-related life-cycle costs.	DGNB (2018b)
9	Evaluation of materials for their suitability for use by third parties.	DGNB (2009)
10	Paying attention to thermal comfort in the materials in winter.	DGNB (2019)
11	Paying attention to thermal comfort in the materials in summer.	DGNB (2019)
12	Paying attention to the safety and risk of dangerous accidents in the materials used.	DGNB (2009)
13	Paying attention to the accessibility of the disabled.	DGNB (2018a)
14	Paying attention to field efficiency.	DGNB (2009)
15	Paying attention to the suitability of the materials used in our company and our suppliers for translation.	DGNB (2009)
16	Consideration is given to design assurance in the materials.	DGNB (2009)
17	Paying attention to the adaptability of technical systems in the materials used.	DGNB (2009)
18	Paying attention to the ease of use of building services.	DGNB (2009)
19	Paying attention to the durability of the materials used.	DGNB (2009)
20	Paying attention to the ease of cleaning and maintenance in the materials used.	DGNB (2019)
21	Consideration given to the ease of recycling and separation of the materials used.	DGNB (2019)
22	Paying attention to the design concept in the materials.	DGNB (2019)
23	Consideration of sustainability aspects at the tender stage for the materials used.	DGNB (2009)
24	Paying attention to the quality/pre-screening of the contracts.	DGNB (2009)
25	Paying attention to the quality assurance for construction in the materials used in our company and our suppliers.	DGNB (2009)
26	Paying attention to the state of the micro-environment.	DGNB (2018a)
27	Paying attention to the proximity to transportation and their connections.	DGNB (2019)
28	Paying attention to the proximity to the use of basic services.	DGNB (2018a)
29	Paying attention to the proximity to public services.	DGNB (2018a)
Greenstar criteria as follows:		
1	The use of practices and procedures of sustainability throughout all stages of	Green star (2018)

	design, building and continuing procedure.	
2	Promoting initiatives that increase the comfort and well-being of users.	Green star (2013b)
3	Reducing greenhouse gas emissions from production from alternative sources such as reducing energy demand, efficiency and use in various phases of design, construction and ongoing operation.	Green star (2018)
4	Reducing greenhouse gas emissions (e.g., reducing the dependence on the use of personal private vehicles).	Green star (2013b)
5	Paying attention to the environmental impacts of 'point source' pollution from projects on the atmosphere.	Green star (2013b)
6	Openness to recognizing innovative practices that promote sustainability.	Green star (2013b)
7	Improving the sustainability performance of the project.	Green star (2013a)
CASBEE criterion as follows:		
1	Improving the environmental quality.	CASBEE (2014)

11 criteria in BREEAM, 1 in CASBEE, 29 in DGNB and 7 criteria in Greenstar have been identified (Table 1). The BREEAM criteria generally focus on environmental factors of projects under construction and waste management (Table 1). When the documents published in BREEAM (2009) and BREEAM (2018) are compared, it is seen that the focal points of BREEAM (2018) are detailed to respond to new trends. BREEAM (2009) examined general environmental factors such as energy and water consumption of buildings whereas BREEAM (2018) has expanded and detailed its point of view and explained the issues with statements that include the solution along with the problem in its criteria (Table 1). BREEAM's focus is on green material selection, waste material management, transportation and location, and promoting designs that take into account environmental factors (Table 1).

DGNB criteria were obtained from 5 different documents (Table 1). 13 criteria from DGNB (2009), 7 criteria from DGNB (2018a) and DGNB (2018b), 6 criteria from DGNB (2019) and 3 criteria from DGNB (2020) were determined. The focus of DGNB (2009) has been the materials and materials used and among the most striking criteria are the environmental effects, efficiency, durability, sustainability and quality control of materials (Table 1). DGNB (2018a) and DGNB (2018b) focus on 3 main issues (Table 1), where: the first of them is the sustainable use of resources and the measurement of and monitoring the rate of use of non-renewable resources; the second issue is to pay attention to define the factors of their micro-environment well; and the final issue is proximity to public services or ease-of-use access to essential services. The ease of recycling and separation of the materials used in DGNB (2019) comes to the fore. By looking at this environmental approach more holistically, attention should also be paid to logistics and transportation. Logistics must be carefully planned, both in the procurement process of the materials and in the distribution of the wastes to the relevant companies. This multiple logistic circulation will significantly increase the carbon footprint. In order to minimize the carbon footprint, proximity and ease of transportation should not be disregarded in the supplier's selection. In DGNB (2020), there is a particular focus on construction materials.

Greenstar criteria were obtained from 3 different documents and five of the criteria out of seven are Greenstar (2013a) and Greenstar (2013b) (Table 1). Environmental impacts, sustainability and performance were the focus points of Greenstar (Table 1). Greenstar (2018) focuses on sustainability and energy efficiency in various phases of design, construction and ongoing operation.

CASBEE, on the other hand, has the least criteria compared to the other 3 certificates as only one criterion was obtained when considered with the LSCSCM filter (Table 1). CASBEE's main focus is on improving the environmental quality of construction (Table 1).

As with the increase in the importance given to the CSCM, the search for and application of new techniques has increased, the importance given to lean and sustainability approaches in the SC has increased. Within the scope of this study, the 4 main green building certifications were reviewed in the SC filter to identify potential criteria suitable to be used to support achievement of a lean and sustainable SC. It is also important to determine the implementation way of obtained criteria to make a maximum contribution to the construction SC. In order to achieve a lean and sustainable SC and to meet the certification principles more holistically, the focus should be on the beginning of the chain. Lambert et al. (1998) emphasized the need to focus on the supply chain organizational structure and construction process components in the SC management implementation process. With the accurate subcontractors and the accurate system, the SC can take the burden of management and make the construction process more fluid. The criteria identified based on certifications can be used in the selection phase of suppliers. Working with the suitable supplier plays an important role in achieving company goals, maintaining and strengthening their competitive level in the long run. For this reason, the supplier selection process, which is a strategic decision for businesses, should be done in a more scientific and systematic way, not based on intuition and experience (Çakın & Özdemir, 2013). The 48 criteria provided systematically in Table 1 can be considered as input to supplier selection and establishment of LSCSCM.

Conclusion

This research investigated sustainable and green building certifications (the BREEAM, CASBEE, DGNB and Greenstar certifications) and their potential contribution to the LSCSCM. Main contractor and supplier relationships are critical to improve the coordination between the parties in the construction SC (Salami et al., 2016). Relationships with suppliers can lead to higher productivity, higher profits and a reliable environment (Singh et al., 2017). To improve the coordination and obtain those benefits, some approaches should be integrated to the CSCM. In this study, primarily importance of the construction supply chain management was examined. In addition, the concept of green building, which gained importance with the reflection of this concept on architecture, was investigated. General information about the certification systems and legal regulations developed to assess the performance of green building applications was given. In this direction, literature review was carried out. The 4 main certificates (i.e., BREEAM, CASBEE, DGNB and Greenstar) that can contribute to obtain a lean and sustainable SC have been examined. A total of 48 criteria have been identified as the basic principles to be used in the creation of a LSCSCM. The criteria were obtained by passing through multidimensional filters where the first of them is to have a contribution of economic, social and environmental impacts on the SC and the second is including same targets in line with lean and sustainability approaches. Adaptation of the identified preliminary criteria (Table 1) to the supplier selection process can have potential to support the LSCSCM establishment.

Abstract

Society faces many global problems due to the Anthropocene era, where human activity is the dominant force on the planet's climate and environment. Continuation of current behaviors will cause the failure of many significant life support systems that affect society. Therefore, resource flows must be balanced with the ecological system. At this point, how materials are produced, used, and consumed is very important in terms of lasting sustainability. Production, consumption, and the functioning of the economic system must change to survive the worst or adverse anthropogenic effects. For the construction industry to avoid anthropogenic impacts, it must integrate minimally harmful solutions to the environment, even carbon positive. Adapting naturally biodegradable materials to the construction industry will be a solution. The increasing use of bio-based building materials is important as it will improve the circular economy in terms of bioeconomy and shape the transition to a bio-based circular economy. The main aim of this study is to investigate the potential of bio-based materials, especially agro-materials, and the circular economy in the construction industry based on a bibliometric analysis of literature. It is anticipated supporting bio-based materials will inevitably contribute to the environment, support local production, and create new job opportunities.

Keywords: *Bio-based construction materials, bioeconomy, circular economy, construction industry, sustainability.*

Introduction

Global problems due to the Anthropocene era create economic and ecological crises due to increased energy consumption, abused natural resources, and released greenhouse gases (GHG). The need to implement sustainable solutions in many industries has arisen to handle these problems. Due to the adverse environmental consequences of the construction industry, the reflection of sustainability has peaked in this sector as well. Minimizing waste and CO_2 emissions, increasing energy optimization, saving natural sources, reducing the impact of climate change and preventing it have become a priority to create a more sustainable built environment. Therefore, each process has been reconceptualized from design and construction to operation and demolition. Within this context, the circular economy (CE) concept has gained importance as a sustainable, innovative paradigm among researchers, scholars, and policy-makers (Kirchherr et al., 2017), and has become popular in the construction industry. Adopting CE principles will promote an important contribution to reducing GHG emissions

by implementing circular strategies. The circular transition of the construction industry focuses more on waste and material recycling. For the construction industry to avoid anthropogenic impacts, it must integrate minimally harmful solutions to the environment, even carbon positive. Within this framework, this study seeks to investigate the potential of bio-based materials, particularly agro-materials, and CE in the building sector using a brief bibliometric analysis of literature. The adoption of bio-based materials could empower the local suppliers as well as national development. By enhancing the efficient flow of information and materials among the construction stakeholders, environmental, economic, and social development could ensure in the construction industry. It is anticipated supporting bio-based materials will inevitably contribute to the environment, support local production, and create new job opportunities.

Circular Economy vs. Bioeconomy

The circular economy (CE) concept is a promising approach to changing how the economy works. It offers a systemic perspective on how resources (materials, energy, information) flow and cycle within systems. The core principle of CE is to expand the use of valuable resources brought into the system through the renewal of circular designs (EMF, 2013b). CE helps to increase resource efficiency by separating economic growth from resource utilization (van Stijn & Gruis, 2020). Originating from various schools of thought (Weigend Rodríguez et al., 2020), it aims to develop the current production model by altering consumption patterns (Leising et al., 2018) and optimizing efficient resource use. In this way, CE focuses on the underlying causes of global issues like contamination, habitat destruction, and climate change, seeks to prevent waste generation by creating a regenerative economy, and provides opportunities for better growth (EMF, 2021). *The technical cycle*, that includes the recovery of technical materials and the management of finite stocks of materials, and *biological cycles*, that covers the flow of renewable materials, are indicated in the framework of CE (EMF, 2013a). It is stated that the basic rules of the restorative CE will be complemented by the cycle of materials based on technological and biological ingredients throughout the economic system (EMF, 2013a).

On the other side, European Commission (EC) (2012) defined the bioeconomy as "*the bioeconomy encompasses the production of renewable biological resources and the conversion of these resources and waste streams into value added products, such as food, feed, bio-based products and bioenergy*" (EC, 2012). Furthermore, EC has pointed out the importance of the bioeconomy as being part of CE by setting up five-bioeconomy strategies for Europe to achieve a carbon-neutral world in accordance with the Paris Agreement's climate goals: "(i) *ensuring food and nutrition security,* (ii) *managing natural resources sustainably,* (iii) *reducing dependence on non-renewable, unsustainable resources whether sourced domestically or from abroad,* (iv) *mitigating and adapting to climate change,* and (v) *strengthening European competitiveness and creating jobs*" (EC, 2018). In the publication (2018) prepared by EC, it was introduced that "*The bioeconomy covers all sectors and systems that rely on biological resources (animals, plants, micro-organisms and derived biomass, including organic waste), their functions and principles. It includes and interlinks: land and marine ecosystems and the services they provide; all primary production sectors that use and produce biological resources (agriculture, forestry, fisheries and aquaculture); and all economic and industrial sectors that use biological resources and processes to produce food, feed, bio-based products, energy and services. To be successful, the European bioeconomy needs to have sustainability and circularity at its heart. This will drive the*

renewal of our industries, the modernisation of our primary production systems, the protection of the environment and will enhance biodiversity." (EC, 2018).

Alongside the EC, the Organisation for Economic Co-operation and Development (OECD) (2009) also emphasized the bioeconomy's importance. Highlighting the great contribution of biotechnology to the development of the bioeconomy, three sectors with great potential in biotechnology have been identified: agriculture, health, and industry. On the other hand, it is thought that without proper local, national, and global policies to promote its development and use, biotechnology cannot fulfill its full potential. The need for a multi-layered policy framework that fosters knowledge diffusion across sectors and addresses application-specific technological, economic, and institutional challenges are noted to come through the obstacles for the bioeconomy to succeed (OECD, 2009).

Since biowaste, surpluses, and discards may be converted into useful resources, the bioeconomy is viewed as the regenerative part of CE. It is considered that by creating innovations and incentives, food waste can be reduced by 50% by 2030, and the strengthening of European Union (EU) industries will be promoted through the creation of new value chains, and more eco-friendly and economic processes. Furthermore, the creation of one-million new jobs in rural and coastal areas for the growth of local bioeconomies could be achieved by installing bio-based industries. Thus, cities can become a major circular bioeconomy hub by reinforcing environmental, social, and economic development as the strengthening of the biocycle of CE would support both environmental and economic and social development by providing many new job opportunities (EC, 2018).

Bio-based Materials in the Construction Industry

Bio-based materials offer numerous positive impacts and other beneficial qualities in the environment, economy, and social well-being compared to many fuel-based materials. Bio-based materials are organic resources either forest products or agriculture/animal products and are naturally breathable and regulate moisture (Yadav & Agarwal, 2021). They also have the potential to reduce global GHG emissions due to the low amount of energy required for production. Since the current trends in the construction industry cause detrimental problems, researchers, practitioners, and policymakers have turned their attention to bio-based alternatives having more benefits than conventional materials. These benefits are: "(i) *renewable,* (ii) *long-term use,* (iii) *absorbing carbon during cultivation,* (iv) *moisture absorption and breathability,* (v) *less harmful pollutant emissions,* (vi) *disposed easily at the end of their life*" (Varriale, 2021), "(vii) *abundance,* (viii) *ease of use,* (ix) *globally distributed in a variety of forms,* (x) *easily sourced,* (xi) *readily adapted to the needs,* (xii) *hygroscopic,* (xiii) *versatile,* (xiv) *porous and nonabrasive,* (xv) *biodegradable,* (xvi) *compostable* and (xvii) *reactive*" (Jones, 2017). Along with these benefits, energy savings, life-cycle objectives, global warming, and climate change mitigation contribute to the rapid evolvement of bio-based materials in the construction industry (Jones, 2017). Carcassi *et al.* (2022) pointed out those benefits in their recent study by confirming that bio-based insulations could achieve climate goals at the building level before 2050 (Carcassi et al., 2022).

Bio-based materials and components have a great potential for a lower-impact building. Furthermore, they are light and easy to work with that makes them suitable for prefabrication and fast installation (Yadav & Agarwal, 2021). Therefore, many bio-based materials inspired from nature are explored to be adapted to the construction industry. Agriculture-generated

materials such as flax, hemp, lignin-based fibers, mycelium, sunflower, wood wastes, corn cob, bamboo, rice husk, cork, coconut, and timber (Yadav & Agarwal, 2021) might be used to gain bio-based construction materials by enhancing the ecological benefits (Amziane & Sonebi, 2016). These materials might compete for farmland against the food and bio-energy industries. More sustainable rural growth could be achieved, especially in less developed countries, when agricultural wastes are treated properly (Varriale, 2021).

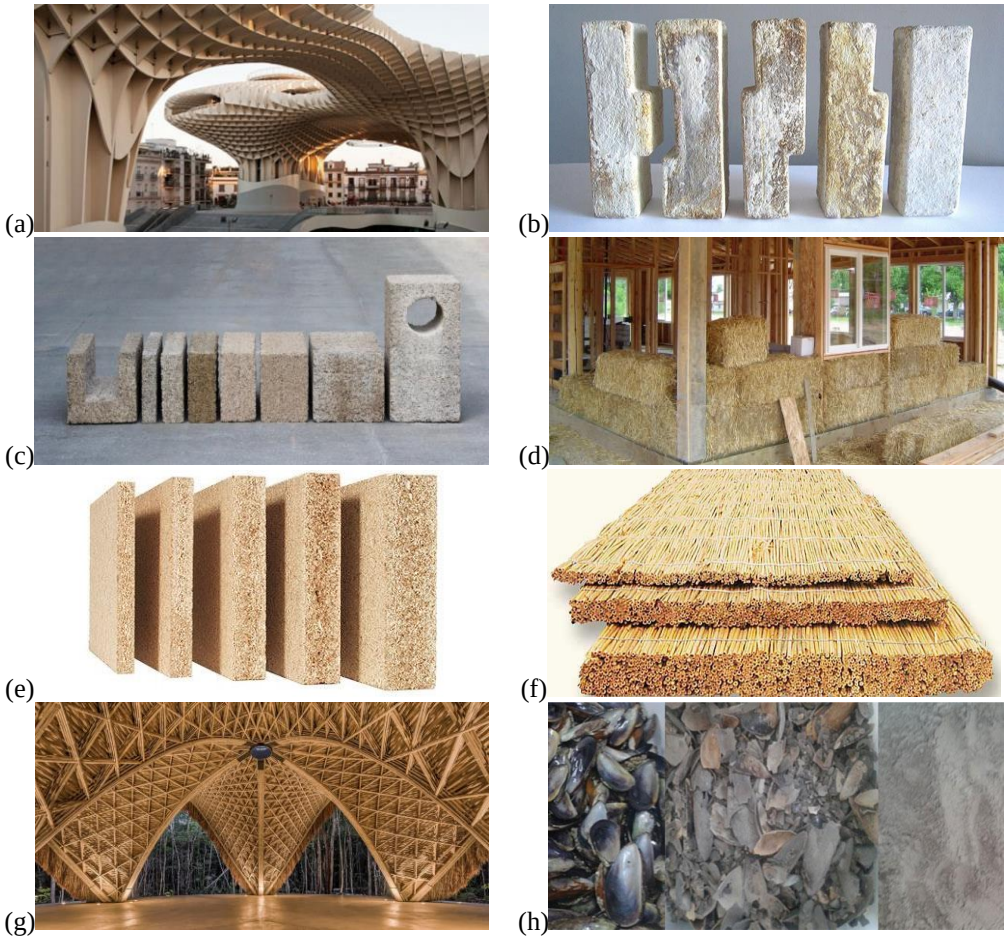

Figure 1. Bio-based materials: (a) Wood structure, Metropol Parasol in Seville, Spain, (b) Mycelium brick, (c) Hempcrete blocks, (d) Strawbale in construction, (e) Flax boards, (f) Reed material, (g) Bamboo structure, Luum Temple in Tulum, Mexico, (h) Mussel shell

Timber-Wood

The most common bio-based material used in building projects is wood/timber. After discarding the conventional passion for steel and concrete, new-wave architects frequently started to choose wood for iconic architectural landmarks, like the Metropol Parasol (Figure 1a). Although the usage of timber structures was not limited to landmarks (Varriale, 2021), its installation was restricted to low-rise buildings depending on a variety of factors, including structural performance and fire protection concerns (Blok et al., 2019). However, the focus on high-rise timber buildings is progressing in the last few years thanks to technological breakthroughs (Ijeh, 2019).

Mycelium

Mycelium (Figure 1b) is a promising material as a vegetative part of fungi. Mycelium-based composites have many enablers thanks to their low cost, energy consumption, density, regenerative features, low environmental impact, and carbon footprint when these materials are compared to traditional materials (Jones et al., 2020). Therefore, they promise sustainable and biodegradable design and fabrication processes. Fungal-based biotechnology can speed the shift from a linear economy towards a bio-based CE. This advancement enables to produce more sustainable resources for the transportation, automotive, and construction industries that are more robust in terms of fuels, food, textiles, chemicals, and other materials (Meyer et al., 2020). Although the potential area of this promising material ranges from food production to medical biotechnology, the research in the construction industry is still underexplored (Modanloo et al., 2021) because using fungal-based materials as an alternative to conventional construction materials could be an inherent problem (Campbell et al., 2017) due to weaknesses in load capacity, unfavorable water affinity, and unknown reliability (Sydor et al., 2022). On the other side, some researchers studied how to install mycelium into architecture and construction projects by exploring various design and fabrication methods such as additive manufacturing (Modanloo et al., 2021), multi-scalar assembly system (Campbell et al., 2017), and conventional growing process (Bruin, 2018). Besides these, Cerimi *et al.* (2019) concluded that fungal-based materials are an excellent choice for the future due to its enormous potential for innovation and ability to be both renewable and biodegradable (Cerimi et al., 2019). Jones et al. (2020) concluded that fungal-based substances are environmentally sustainable alternatives compared to wood, foam, and plastic insulation for panels, flooring, door cores, and furnishings thanks to their thermal conductivity, low density, fire safety, and strong acoustic absorption (Jones et al., 2020). It is a general belief that innovative breakthroughs depending on the transdisciplinary studies with stronger collaboration between researchers, designers, industrial stakeholders, the public, and policymakers on fungal-based materials facilitate the shift to a bio-based CE (Meyer et al., 2020).

Hempcrete

One of the fastest-growing biomasses in the world, hempcrete (Figure 1c) is a combination of hemp, water, and lime, and weights one-eighth as much as typical concrete. Used in France as non-bearing infill walls, the lightweight nature of this bio-based material can reduce a building's energy by reducing the embodied emissions. Hemp-based panels and structural blocks can replace many old wood frames and cement blocks thanks to their rapid growth. Thus, it supports the reduction of deforestation, so of increasing carbon sequestration (Yadav & Agarwal, 2021). In addition to its biological properties, such as breathing and allowing evaporation, its non-toxic and lightweight properties ease movement on the construction site (Roberts, 2020). Although hempcrete-based materials cannot be installed as load-bearing, they can be used to create screeds, roofing, and self-insulating walls as finishing plasters, insulators for roof and floor (BCB Tradical, n.d.). As long as they are shielded from moisture and water, hempcrete walls, which can be created on-site or through a manufacturing process, can be left uncovered or coated with plasters. These materials have a negative carbon footprint and serve as carbon sinks as a result of biogenic CO_2 absorption during hemp growth and via carbonation (Arrigoni et al., 2017). Thanks to the environmental advantages and ease of use, the interest in these promising bio-based materials is gaining momentum.

Strawbale

With its durability, longevity, high load carrying capacity, and insulating qualities, straw (Figure 1d) is a material with potential for enhancing building energy performance (Yadav & Agarwal, 2021). This material demonstrates versatile usage since it could be used in a variety of industries such as for soil productivity in agriculture, insulating the existing structures or constructing new structures in the construction. It can also be used to transform biomass into usable chemicals or alternative energy sources through pyrolysis processes (Tlaiji et al., 2022). Contrary to conventional construction materials, the use of straw made from agricultural waste promotes sustainable development since it has a very low embodied energy over its whole life cycle. It also has a direct bearing on the preservation of natural resources and land use (Gupta et al., 2019). Furthermore, It is emphasized that due to the possibility of prefabrication, it can contribute to the production of low-cost social and affordable housing (Gupta et al., 2019).

Flax boards

Flax board (Figure 1e) is an engineered and non-bearing sheet material. It is lightweight and fire resistant. For this reason, they are used in door sections, fire resistant doors, cores and partition walls in dry conditions (GreenSpec, n.d.; Yadav & Agarwal, 2021).

Reed

Reed (Figure 1f) is one of the most common wetland plants in the world, mostly used for roof construction thanks to its high productivity. Its rapid growth and widespread availability make the reed an inexpensive and durable option for natural building material. Reed contains the highest silicon concentration among all plants, responsible for water resistance and high flammability. However, the thermal conductivity of the reed makes it suitable as an insulating material compared to timber shingles and clay. In addition, the reed's thermal conductivity optimizes indoor temperature in all seasons by providing good moisture conduction together with large air content (Critical Concrete, 2017; Yadav & Agarwal, 2021). However, they are suitable for hot and humid climates. Reed is widely used because it is inexpensive and readily available, easy to maintain, highly ventilated, has thermal insulation capabilities, and requires a low-tech construction technique. It is also resistant to seismic effects. It has the potential to be a performance efficient and natural low-carbon material, as it requires minimum amount of energy during the whole life cycle (Dabaieh & Sakr, 2015).

Bamboo

Bamboo is a promotive material to avoid the deforestation of tropical forests. It is widely known as a sustainable building material because it can be easily grown, harvested in a short time, and reusable (Nurdiah, 2016). Due to their ability to absorb carbon and to require low life-cycle emissions, herbaceous and fast-growing materials like bamboo and straw are considered an efficient alternative. Selecting these biomasses is advantageous as they exhibit a shorter regrowth period, thus higher yields. They are often the by-products of cropland that could be converted into high-value products, preventing competition in land usage between construction and agriculture (Carcassi et al., 2022). It also makes possible more complex and organically shaped architectural structures (Figure 1g) because they bend easily (Nurdiah, 2016).

Mussel shell

It has been determined that the mussel shell has thermal and acoustic properties that make them suitable for use as a building insulation material. Contained in a closed space, the mussel shell (Figure 1h) can be regarded as a substance with low thermal conductivity (Martínez-García et al., 2019). It can potentially be used as a concrete filler, reducing the porosity in the concrete microstructure, thereby reducing the amount of water used to maintain concrete workability (Wang et al., 2021). Several acoustic tests, however, have proven that a portion of the closed shell behaves in a manner that is comparable to that of the widely used insulating material. The mussel shell has a similar amount of embodied energy to other bio-based insulating substances when used as loose infill material, however, it has a significant advantage over other bio-based insulation substance for being resistant to biological attacks and fire. It can be used on the walls in a wooden frame, on roofs as a heat and sound insulation material, and on the ground instead of traditional drainage materials (Martínez-García et al., 2019).

The increasing usage of bio-based building materials is important as it will improve CE in terms of bioeconomy and shape the shift towards a bio-based CE depending on the features: (i) renewable source of agricultural or forest material, (ii) land management in life cycles of the materials, (iii) supported by renewable energy for harvesting and other processes (iv) enabling process flow from cradle to cradle. Considering that building materials account for a significant portion of harmful emissions that are generated and utilized, bio-based construction materials can be regarded as a fundamental part of the bioeconomy. In addition, it is a fact that these materials cannot be considered independent from CE, as bio-based construction materials contain a low amount of carbon in the production and operation processes compared to conventional materials (Suttie et al., 2017). As a result, supporting bio-based materials will inevitably contribute to the environment. Since it is stated that the bioeconomy will support local production and create new job opportunities, it is also clear that the bioeconomy is completely sustainable development.

Bibliometric Analysis Regarding Bioeconomy and Bio-based Materials

Method

Based on the literature research, it has been realized that the research on the circular transition of the built environment mostly focuses on waste management and material recycling. In addition, it has been observed that traditional materials in the technical cycle, such as concrete, brick, steel, and others, are more often considered within the scope of the circular economy. Since the business models in the construction industry are based on traditional materials, bioeconomy and the bio-based materials in this sector is not at the expected level. A bibliometric analysis was conducted in the Scopus database to prove this claim. The two-step analysis contained the journal articles in the English language. The phrases below were employed for corresponding steps (data update time August 14, 2022):

The first step:

- (“bioeconomy” OR “bio economy”) AND (“built environment” OR “construction industry” OR “construction sector”),

The second step:

- ("bio-based materials" OR "biobased materials") AND ("built environment" OR "construction industry" OR "construction sector")

Firstly, the identified phrases were searched within "Article Title, Abstract, and Keyword". As a further step, the obtained data were exported in .csv file format from the Scopus database and analyzed in VOSviewer. The focus of the bibliometric analysis was the co-occurrence of author keywords thanks to employing the most prominent terms to understand the methodological structure of a research domain. The "Full counting" technique was employed in VOSviewer.

Findings

As a result of the analysis on the Scopus, the following results were gained for the steps:

The first step:

- 22 documents were resulted in the Scopus (16 articles, 3 conference papers, 2 book chapters, and 1 review).
- The minimum frequency distribution of a term was adjusted as two in VOSviewer.
- 5 out of 81 keywords met the threshold and 5 keywords were mapped (Figure 2a).

The second step:

- 54 documents were resulted in the Scopus (26 articles, 14 conference papers, 10 book chapters, 3 review, and 1 book).
- The minimum frequency distribution of a term was adjusted as two in VOSviewer.
- 9 out of 122 keywords met the threshold and 9 keywords were mapped (Figure 2b).

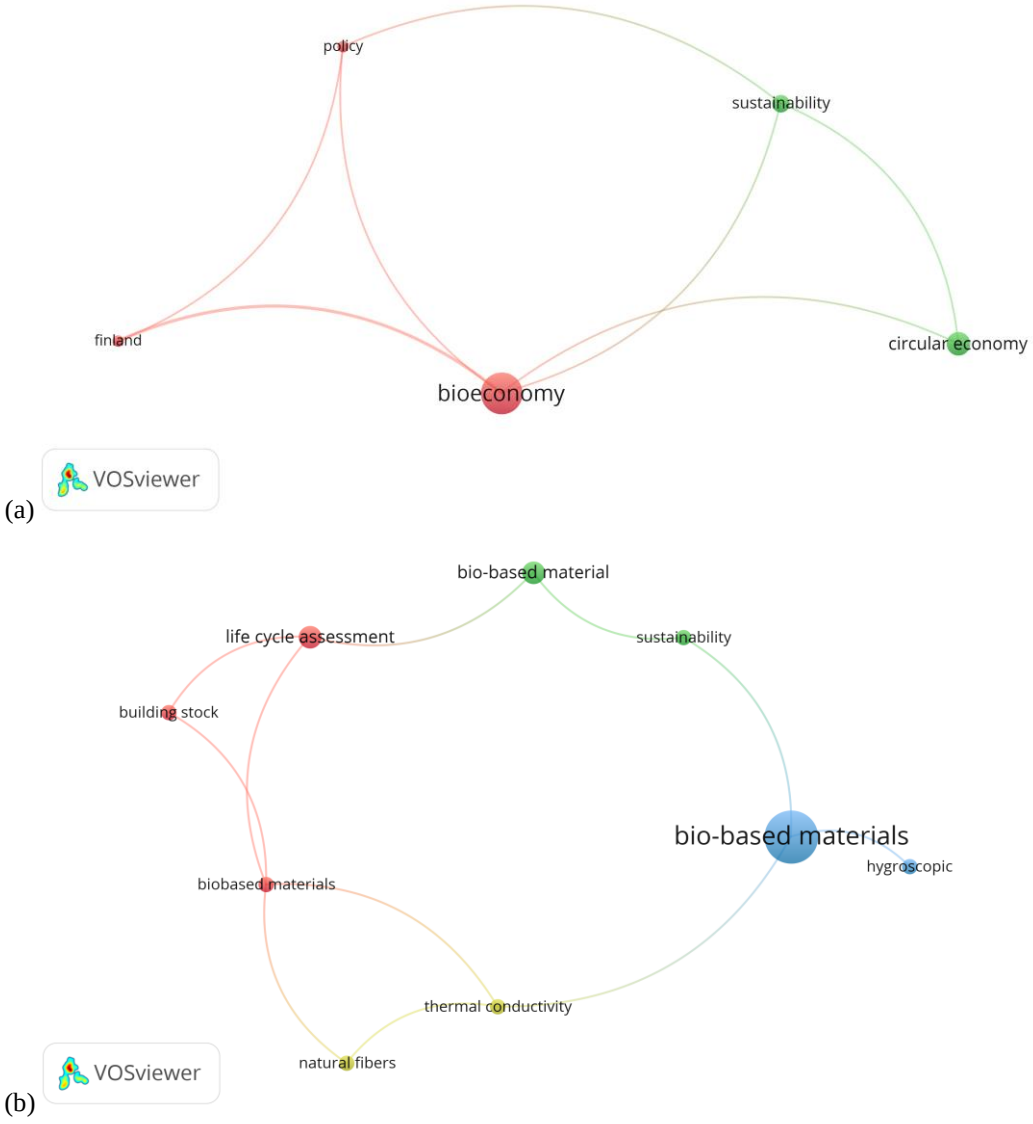

Figure 2. Keywords map of bibliometric analysis:
(a) Result of the first step, (b) Result of the second step.

As seen in Figure 2a and 2b, the outcomes of the first step contain the most core keywords such as “bioeconomy, circular economy, sustainability, policy, and Finland”, the results of the second step contain similar keywords as “bio-based materials, bio-based material, biobased materials” because of the different understandings for the term. The other keywords regarding the second step are related to the fundamental terms of the industry such as “hygroscopic, life cycle assessment, thermal conductivity, and natural fibers”. Based on the bibliometric analysis conducted by VOSviewer, it can be considered that the reflections of bioeconomy and bio-based materials on the construction industry and the built environment are still in their infancy.

Conclusion

Advances in the construction industry, which play a pivotal role worldwide, are strongly linked to the economic strength of the global community. The construction industry has a societal impact as it also employs many people and is responsible for supplying basic human needs and shaping the built environment. The depletion of natural resources has led designers, practitioners, and governments to seek new materials within this industry as well. For this reason, bio-based materials, which are also encouraged by the EU, have started to be applied in various sectors. These completely natural materials without creating waste are compatible with the conceptual framework of CE. However, since the business models in the construction industry lean on traditional materials, the employment of bio-based materials in this sector is not at the expected level. Besides, the reflections of these promising concepts, bio-based materials and bioeconomy, are still underexplored within the construction industry. Within these claims, it is anticipated that promoting bio-based materials will give broad meaning to the transition to bio-CE in the construction industry, and the harmful environmental impacts of the construction industry can be reduced thanks to the use of bio-based materials. Furthermore, the production of bio-based materials will boost the local economy by supporting the local producer, and thus environmental, economic, and social development can be achieved.

Transitioning to a Circular Economy in the Construction Industry: Enablers and Barriers

Zelal Koksal and Guzide Atasoy
Middle East Technical University, Department of Civil Engineering, Ankara, Turkey
zelal.koksal@metu.edu.tr, guzide@metu.edu.tr

Abstract

Considering the increasing population and building demand, the construction industry has become one of the leading causes of waste production and resource consumption. Accordingly, the construction industry's impact on the economy and the environment is increasing. Contrary to the traditional linear economy, adopting the circular economy model can help cope with such issues, reducing the environmental impact of buildings and the consumption of natural resources. Research on the circular economy in the built environment has been increasing in recent years, with varying focuses and scopes on strategies (e.g., design for deconstruction), indicators (e.g., amount of construction and demolition waste), and requirements (e.g., regulations). For successfully transitioning into a circular economy, especially for developing countries, it is necessary to understand how to apply circularity in the construction industry, to identify the barriers to its integration into the sector, and the enablers to eliminate such barriers. This study aims to accumulate and demonstrate the existing knowledge by identifying, categorizing, and mapping the enablers (e.g., integrating circularity into education) and barriers (e.g., lack of awareness) to the construction industry. This study is planned to guide future research on facilitating a circular economy in the construction sector more effectively.

Keywords: *barriers, built environment, circular economy, construction sector, enablers.*

Introduction

With the development of conditions and technology in developing countries, the overall population, infrastructure needs, and the demand for consumption of materials in the construction industry are increasing. Considering the emerging needs, the construction industry is one of the largest raw material consumers and waste producers. Accordingly, problems related to climate change and resource scarcity are increasing. The linear economy model, which is based on high natural resource consumption and neglects resource recovery, is being questioned; therefore, there is a need for a new practice to reduce this consumption and the amount of waste (Cruz Rios et al., 2021). The increase in the demand for recycling within the sector worldwide and the desire to reduce carbon emissions and material consumption facilitated the use of the circular economy (CE) model to come to the fore and be investigated in the last few years.

Circular economy (CE) offers a comprehensive strategy model for sustainability to minimize environmental and economic costs for construction projects (Shooshtarian et al., 2022). Three

main stages where the strategies identified for CE can be beneficial are design and planning (e.g., design for disassembly, specifying recyclable materials), material and component manufacture (e.g., use of secondary material), and end-of-life stages (e.g., selective demolition, closed-loop recycling) (Sáez-de-Guinoa et al., 2022). Decisions made in the design phase are influential in determining the factors that affect the buildings until the end-of-life. Circular design principles aim to design structures that use fewer resources, protect and expand natural and man-made resources, adopt designs for long-term use and recycling, taking into account technical and biological cycles (Cruz Rios et al., 2021). The manufacturing and production phase is significant to ensure that materials and components are recyclable and the life span can be extended. The end-of-life stage is essential for implementing strategies, as it determines the demolition techniques and recovery percentages necessary for the materials to be reused with the highest possible value to be reintegrated into the chain (Sáez-de-Guinoa et al., 2022). Additionally, innovative systems can create scenarios and strategies to reduce the impact of traditional systems by improving circularity (Tirado et al., 2022). CE is thought to increase competitiveness and help create new job opportunities by protecting businesses against resource scarcity and volatile prices (Kanters, 2020). CE facilitates cities reduce their ecological footprints and improve the economy by reducing the amount of waste and imported raw materials to be processed, incorporating secondary materials into the cycle, and creating local employment (Tirado et al., 2022). Although there is a general incentive for the development and use of CE strategies, it is necessary to continue studies on developing criteria and determining strategies to support urban sustainability to measure resource flow, resource use and associated environmental impacts (Hossain et al., 2020). The local awareness level of CE principles is generally in line with the global level, but the understanding of CE application in construction is insufficient worldwide compared to other industries (Torgautov et al., 2021).

In transitioning into a circular economy in the construction sector, interventions of different stakeholders are needed because the circular economy requires collaborative, interdisciplinary work in terms of strategies for better consumption and waste management (Tirado et al., 2022). For the process to be properly controlled and maintained, it is necessary to review the existing knowledge, understand the roles of the stakeholders in this practice, and understand the main indicators, barriers, and enablers of adopting circular economy strategies in construction projects (Guerra & Leite, 2021). Such barriers and enablers vary according to the needs of countries/regions. Existing studies in the literature have generally focused on specific countries. For example, Cruz Rios et al. (2021) identified barriers in the USA, Charef et al. (2021) in the UK, and Shooshtarian et al. (2022) in Australia. Variations in these studies reflect the differences in the level of understanding and adoption in different countries. In addition, the literature generally focused on specific strategies (e.g., construction and waste demolition, circular design), limiting the observation of the general understanding of CE, especially in developing countries, where CE has been practiced in a limited capacity. Moreover, for transitioning into CE, the enablers and barriers should be linked with the related stakeholders to better understand their roles and responsibilities. However, such an exploration is scarce in the literature. Hence, the aim of this study is to analyze the current literature to identify the barriers and enablers of CE, and to map these factors to related stakeholders. Such an understanding will be used to map and prioritize the enablers and barriers of CE in connection with the relevant stakeholders in Turkey, with the participation of practitioners in the following stages of this study. At this stage, this conference paper presents the results of the preliminary study on the synthesized literature on enablers, barriers, and stakeholders.

Methodology

This study adopts a literature review method using the Web of Science database to identify barriers and enablers for integrating CE into the construction industry. The most prominent fifteen articles, which did not specialize on specific CE strategy (e.g., construction and demolition waste management, demolition for deconstruction) or specific materials but instead addressed CE in general, were used to identify and group barriers and enablers. Although it did not comply with the set limitations and was not within the scope of this research, Adams' research was included in the scope of the research due to its high number of citations. Sources have followed many different methods while identifying the barriers. In general, each barrier and enabler was listed by evaluating the literature where there were articles that used both qualitative and quantitative methods within their study. Some studies incorporated practitioners' perspectives. For instance, Bilal et al. (2020) eliminated and listed barriers based on the overall cumulative scores obtained for the barriers through the evaluation of the literature and expert opinions. Following the review of the literature, barriers and enablers were identified, synthesized, and presented in a tabular format.

Circular Economy in the Construction Industry

In a recent study, Cruz Rios et al. (2021) stated the existence of limited literature on identifying barriers and facilitators of CE strategies that can be used in buildings and the construction sector. However, research on this topic is accelerating, considering both general CE findings and strategies. Identifying the main barriers to the integration of CE is based on the interplay of many factors and indicators that influence the adaptation of CE in the construction sector (Bilal et al., 2020). The identified barriers can be attributed to the characteristics of the construction industry. The recent literature mainly focuses on two aspects of CE; the level of awareness on CE, and enabling strategies (Torgautov et al., 2021). Considering the integration of the CE into the construction industry, practices, such as the reuse of existing components (e.g., doors, windows) and the use of salvaged materials can be counted as CE strategies (Cruz Rios et al., 2021). Strategies within the built environment may include the design for disassembly (DfD) and adaptability, reuse of building components, adaptive reuse, and use of biodegradable building materials. Charef et al. (2021) identified and classified the barriers associated with strategies such as prefabrication, design for change, design for demolition, reverse logistics, waste management, and closed-loop systems to assess the sustainable management of an asset's lifecycle and adopt CE in the AEC sector. Giorgi et al. (2022), on the other hand, grouped the strategies to implement CE at the building level in three main application areas: business and stakeholder networks, resource and waste management, and reversible building design. In addition, one of the strategies affecting the development of CE is waste management. The inability to reach a sustainable solution due to unspecified rules and guidelines on waste management is also a situation that should be taken into consideration. In addition to the necessary policy implications, it should also be considered that companies would not want to abandon the current practice of landfilling waste not to increase their costs. Besides, it is possible to state that the construction and demolishing waste management could not develop due to the poor performance of the contractors and the lack of appropriate infrastructure and facilities (Torgautov et al., 2021).

In this study, the barriers obtained as a result of literature review were identified and grouped under five main categories: economic, behavioral, technical, political, and environmental. The importance of the economic benefit was emphasized when considering the use of

environmentally friendly technologies and the reuse of construction materials (Torgautov et al., 2021). Table 1 presents the synthesized economic barriers for CE, along with the related stakeholders stated in previous studies. Implementing certain circular strategies may require upfront costs to enable future reuse of materials and components. In addition, the expertise of the people working for these strategies can be cited as a potential additional cost (Guerra & Leite, 2021). The project constraints may make it difficult to adopt circular strategies for the contractor. Similarly, the consequences that may arise due to constraints may affect the owner's willingness to implement other strategies, such as selective destruction or deconstruction (Guerra & Leite, 2021).

Various employee surveys in Torgautov et al. (2021) revealed that companies generally prefer cheaper and less time-consuming options. Such cases imply that CE strategies are not common and preferred, and even if they were, the motivation would be financial profit rather than the circular economy target. It has been argued that the applicability of strategies such as DfD may increase if economic benefits are provided, necessary regulations are presented, and responsibility is shared among stakeholders (Torgautov et al., 2021). Within the construction industry, a clear economic situation supported by metrics, tools and guidance is crucial to enable greater application of circular economy principles and to encourage stakeholders to

adhere to these principles (Adams et al., 2017). However, high material and construction costs may affect the use of CE principles, especially for owners and contractors. According to Torgutov's research results, the inability to take risks affecting profits is also one of the reasons why the economy is seen as the main obstacle. Companies generally lag in adapting to CE by considering the current economic situation and profit rates, instead of taking risks and using more environmentally friendly technologies (Torgautov et al., 2021).

Table 2 presents the behavioral barriers. The resistance of the sector to change, dependence on other sectors, high labor costs, lack of access to materials that can be adapted to CE, and the lack of regulations specific to the CE can be counted among these obstacles (Kanters, 2020). Similarly, Guerra and Leite (2021) emphasized that budget and costs, project planning, deficiencies in implementation and regulations, lack of awareness in the industry, the industry's resistance to change, and the current construction business model are the main obstacles on circularity. In addition, the industry's adaptation to CE brings along some fears. For example, the possibility of traditional building materials not reaching the target (because they are not intended for CE), the need for certain occupational groups, and the compliance problems of employees may trigger these fears (Kanters, 2020).

The fact that construction projects often have high risks and low profit poses an obstacle to testing and adopting innovative technological methods (Guerra & Leite, 2021). Complexity of building design, lack of standardizations, data management, adequate technology, and awareness of future needs pose technical barriers to a variety of stakeholders (Table 3). Unconsciousness about circularity and lack of awareness of resource consumption are

important obstacles to the adoption of the circular economy. It can be difficult for stakeholders to appreciate something they may need in the future, and this is one of the major barriers to understanding why transitioning into CE is needed.

In addition, not updating existing standards and practices is seen as an obstacle to the advancement of more sustainable and circular technologies. Table 4 presents political barriers, mainly associated with governments. Lack of specific regulations and legislation is the barrier that is emphasized by most literature. Lack of commitment, fiscal and regulatory incentives is another main political obstacle posed by the governments to the implementation of circular strategies. Where regulations are less stringent and environmentally conscious, the industry can more easily meet the requirements for the implementation of strategies, with less fear of taking risks and feeling more secure (Guerra & Leite, 2021). On the other hand, existing mandatory documents required to obtain the permit for buildings are based on static structures and do not take into account the possibility of structural change during use, which is a barrier to strategies such as reuse (Giorgi et al., 2022).

Failure to understand the buildings' environmental impact and to recycle materials are among the mostly cited environmental barriers. Table 5 presents the environmental barriers, which are not as much cited as the other barriers. It is evident that one of the most influential and influenced stakeholders is the recycling enterprises. Moreover, the literature supports the fact that limitations in the utilization of digital technologies, such as material passports and Building Information Models, pose environmental barriers for CE.

The literature presents several enablers, aimed at many stakeholders, to improve or eliminate these barriers (Table 6). One of the biggest challenges in the CE approach to optimizing the use of materials and energy is not knowing at which stage of a project material or service should be intervened (Hentges et al., 2021). Giorgi et al. (2022) emphasized that researchers could be involved in all construction phases, while designers in the decision-making (planning and design) phase. The most commonly aggreged enabler is setting and using standards to develop CE strategies, targeting researchers and governments. Raising awareness, collaboration and information sharing among all stakeholders are undeniably significant enablers. It is envisaged that it may be necessary to use special policies for companies in the sector (Torgautov et al., 2021). Local governments are also considered to play an important role in planning CE strategies. Local stakeholders can support the development of CE by providing opportunities and solving challenges that may arise in adapting the CE to the construction sector (Tirado et al., 2022). Regarding the integration of CE and the construction sector, Kanters (2020) emphasized the responsibility of stakeholders, and presented separate dependent variables for each stakeholder that should be controlled. Budget, company image, project risks, client flexibility, materials and tools used, construction management, and methodology are given as examples of these variables (Kanters, 2020). It is emphasized that CE integration and applications in the construction industry can result in success with a client who is willing, supportive, and ambitious for change, a contractor who has mastered the circular economy in terms of materials, technology, and skills, and an architect with the necessary skills (Kanters, 2020). In addition, Cruz Rios et al. (2021) indicated which stakeholders can take an active role for each facilitator, and such mappings are utilized in the tables above. Recognizing the disadvantages of the linear economic model in the construction industry and taking countermeasures can ensure the adoption of a CE model.

The main purpose of this study is to synthesize and present the literature that will lay the foundation for research that aims to provide an overview of the barriers and enablers of CE, with related stakeholders, in Turkey.

Conclusion

Considering that the construction industry is one of the largest consumers of raw materials and generators of waste, it is necessary to minimize such practices. The application of CE in the construction sector will not only provide many benefits in this sense but will also help develop many new applications and tools for the future. In this paper, a literature review has been conducted to compile previous studies to learn and understand readiness on circularity. The aim of the study was to identify the barriers to the adaptation of the circular economy in the construction sector and to identify the facilitators offered against these barriers. Literature lists many enablers and barriers of CE. To overcome the barriers, and facilitate CE transition, the related stakeholders and responsibilities should be identified as well. Some studies (e.g., Hentges et al., 2021; Wuni & Shen, 2022) mapped enablers to construction stages, and some (Guerra & Leite, 2021) CE strategies to construction stages, and some enabler to stakeholders (e.g., Cruz Rios et al., 2021). While all the findings are dispersed, many of these studies include research specific to a particular region or country, while others include research on specific methods and strategies rather than investigating the general applicability of CE. In this study, the barriers extracted from the literature are compiled and classified into five categories, including economic concerns, environmental factors, lack of regulations on circularity, low awareness of circular economy, and resistance to change in the construction sector. Enablers of CE, and related stakeholders are mapped in a tabular format. Future studies should represent of the interrelations between CE-related concepts, including enablers, barriers, and stakeholders, to support transitioning into CE in the construction industry. Due to differences in culture, geographical location, and existing regulations, the priority and challenges of CE-related strategies, enablers, and barriers would differ in different regions/countries. Future research directions include assessing the applicability of identified barriers and enablers to Turkey and assessing the priority of the relationship of such CE concepts.

Sustainability Analysis for the Construction of Rural Houses

T. Erzurum and Ö. H. Bettemir
Inonu University, Department of Civil Engineering, Malatya, Türkiye
tugbaerzrm@gmail.com, onder.bettemir@inonu.edu.tr

Abstract

Sustainability is one of the major concerns for the construction sector as the construction activities damages the environment significantly. The accommodation units were used to construct by stone or adobe in the rural settlement regions. However, because of the increase in the life quality and the increased rural life enthusiasm of the people living in the highly urbanized regions initiated the escalation of the construction activities in the rural region. In this study, sustainability of construction of a typical one story house suitable for rural settlement is analyzed in terms of CO_2 emission and embodied energy of the utilized construction materials. The analysis is conducted by preparing the quantity take-off of construction items. The material, workmanship and construction machine requirements for unit construction are determined for every construction item. The embodied CO_2 amounts of the construction materials are computed by pairing the unit CO_2 emission amounts of the materials. In addition to this, embodied energies of the construction materials are computed by the same method. Energy consumptions of construction machines are estimated by the data provided by the manufacturers. The computations are linked each other and change in the quantity take-off data directly effects the presented CO_2 emission and embodied energy computations. The developed approach might help to conduct environmental analysis of rural buildings.

Keywords: *carbon emission, embodied energy, sustainability.*

Introduction

Past experience revealed that there is a reverse correlation between the economy and the environment. The growing economy and increasing population damage the environment and the nature. The center of the life cycle of the earth is ecosystems. Unsustainable growth leads to degradation of ecosystem and eventually extinction of species.

When the research trends of the last 25 years in the field of construction are examined, it is seen that more than 80% of the related documents published after 2010 has the keyword "sustainable construction", which is a very novel literature. The subject is a global literature with significant contributions for both economically developed and developing societies. The dominant research on the sustainable construction consists of four main frameworks. These are; alternative materials for sustainable construction, sustainable construction management, recycling and waste reduction, and social sustainability in construction management. On the other hand, the weak chain of the aforementioned four titles is “social sustainability” and the

dominant dimension is “alternative materials” (Udomsap & Hallinger, 2020). The word sustainability comes from the Latin “sus tenere”, meaning to protect or to endure (Jaques, 2020). There are many approaches and definitions on this concept in different fields (Pamuk & Kuruoglu, 2016). However, it basically means that a resource can be used in the future without being destroyed.

In 2011 the United Nations Environment Program (UNEP) organized the International Natural Resources Panel. In this Panel it is stated that if serious steps are not taken, the amount of mineral, ore, fossil fuel and biomass used by human beings will reach approximately 140 billion tons by 2050. The aforementioned amount is three times the annual consumed value today (IRP, 2021). There are stress limits of the Earth, which can be defined as the threshold for the emergence of the negative effects of the specified consumption. Some of the stress limit categories are; climate change, biodiversity loss, ocean acidification, the ozone hole and land use. Even tough exceeding the limit of even one category poses a threat to sustainability, many systems have exceeded the limit value, and the rest have approached the limit. This trend became obvious especially after the industrialization.

For example, the biodiversity loss extinction rate limit value has been exceeded more than 10 times. Alongside, electricity generation, automobile use, and the construction industry are the three largest contributors to greenhouse gas emissions that threaten the Earth's climate (IPCC, 2019). Recognition of this impact on society has led the global construction industry to take increasingly prominent steps aimed at adopting more sustainable practices (Kibert, 2007). While cost reduction, operational efficiency, quality and profitability were the key factors in construction management in the past, project owners and managers are increasingly concerned with the environmental and social impacts of construction projects in the present case (Ortiz et al., 2009). The point to be noted here is; environmental problems always have a connection with the construction sector. This is because the construction industry forms the basis of living spaces. The other reason is that while environmental problems are mostly the result of backwardness in developing countries, the source of this problem in developed countries arises from industry and technological advances.

Developing countries need growth in the construction industry to meet their increasing needs. Construction projects on transportation/infrastructure, energy, residential areas, landscape, dams, and harbours are the main necessities to sustain their economic growth. It is clear that these projects would have a share in the economies of the countries. According to 2012 data, the construction sector constitutes 13.4% of the world production with 7.5 trillion dollars, 6.47% of the gross product of the OECD countries and 10% of the gross product of the European countries (Pamuk & Kuruoglu, 2016). According to the Global Construction 2030 report, the volume of construction production is estimated to increase by 85% worldwide to $15.5 trillion by 2030, accounting for 57% of all global growth (Global Construction Report, 2021). When the situation in Turkey is analyzed, the construction sector constitutes approximately 7 percent of the Turkish economy in 2020 (TR Presidency, 2020). These data support that the construction sector is important even in the global crisis environment. In addition, targets for the construction sector have been determined in the national energy efficiency plans. However, the energy efficiency index does not show the desired development for the housing sector (TR Precidency, 2018). As a result, it is clear that the volume, importance and impact of the construction sector on sustainability cannot be denied today and in the future. While sustainability practices meet basic needs, they should prevent the destruction of the nature and the resources. In other words, unless there is environmental welfare, it is not possible to mention sustainability and welfare in social and economic terms.

To conceptualize sustainability in construction, Kibert argued that the construction industry should move towards the use of 'sustainable practices' that conserve limited resources and promote a healthy environment (Kibert, 1994). In the 2000s, "green construction" and "green building" emerged as umbrella terms denoting a shift towards environmentally friendly construction practices (Ali & Al Nsairat, 2009). The initiation of the 'sustainable development goals' by the United Nations has brought attention to social and environmental responsibility and impact by removing the construction industry from being an economic tool. Moreover, the emergence of these umbrella terms has forced developers and builders to adopt a "sustainability mindset" for the design and management of construction projects (Seyfang, 2010). Practice of sustainability has implications for land selection, land use, design practices, material selection and application, project management, and stakeholder engagement (Barlow & Jashapara, 1998). For example, Horvath (2004) investigated the environmental impact of different choices in construction materials used in infrastructure projects.

The construction industry is heavily dependent on non-renewable resources. Green construction idea basically aims to produce less waste and to alleviate the impact of resource usage by using reusable and less energy-consuming construction materials (Hoşkara, 2007). According to the 2007 data, 50% of the energy, 42% of the water, 48% of the agricultural areas and 50% of the other materials are consumed in the construction, utilization and operation processes of the buildings. At the same time, 50% of the greenhouse gases that cause global warming, 40% of the pollution of the drinking water, 24% of the air pollution, 20% of the surface solid wastes and 50% of the carbon dioxide emissions are caused by the practices associated with the buildings (Ovalı, 2009; Edwards, 2007). The construction industry consumes the resources on earth to a great extent which creates stress in many ways such as global warming, acid rain, waste generation, and artificial environmental pressure.

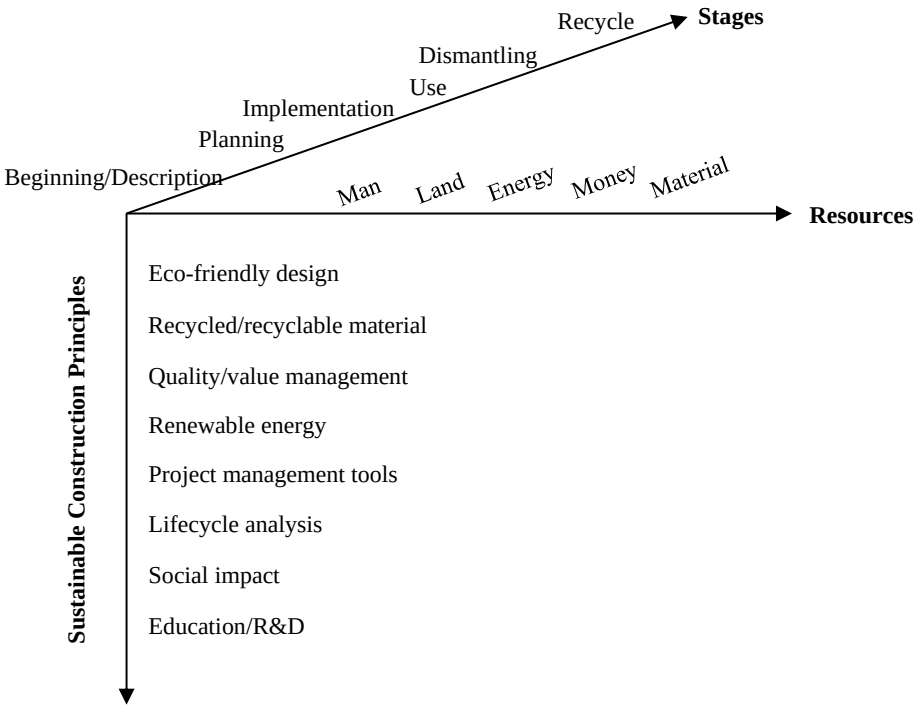

Figure 1: Three-dimensional conceptual model of sustainable construction practices.

Kibert (1994) gathered the sustainable construction principles to be developed under six headings and created a conceptual model. The conceptual model of sustainable construction principles created by Kibert (1994) is presented in Figure 1. The model has been revised based on today's project construction processes, requirements and terms.

Green building evaluation systems and certificate programs have an important role in revealing the environmental effects of buildings in an objective and concrete way. It is mainly divided into two groups as Life Cycle Assessment (LCA) methods and criteria-based certificate programs developed for this purpose. LCA methods are generally used in the design phase of buildings, for purposes such as material and product selection, evaluation of service system options, and their scope is limited (Sev & Canbay, 2009).

Hussin et al. (2013) investigated the necessity, fundamentals and challenges of sustainable construction. To reduce the adverse affects, new project management tools and techniques about sustainability are recommended and application examples are given in the study. Overall energy consumption can be reduced and the utilization of renewable energy can be maximized, wastes can be minimized, water resources can be conserved, water quality can be improved, vulnerability to flooding, polluting emissions, noise, and light pollution can be prevented by adopting sustainable construction. Aforementioned problems can be addressed with the Green building approach, which is more sustainable than existing practices.

Bae and Kim (2008) discussed the concept of sustainability in construction projects and lean construction. The positive and negative aspects of several lean methods on the sustainability principle are evaluated. The negative impacts are based on the fact that environmental and social principles are not directly felt by the project stakeholders. But despite this, lean techniques are beneficial for sustainable construction. Economic benefits are listed as; possible upfront cost reduction, resource savings, operating cost reduction and high performance capability. Workplace safety, user health, community welfare, loyalty among stakeholders and improving external image are the social benefits. Reduced resource consumption, preventing pollution by eliminating waste, and conserving resources are the environmental benefits.

Chen et al. (2010) examined sustainable performance criteria for the selection of construction management in traditional in-situ reinforced concrete works and precast/prefabricated concrete works. At the end of the study 33 sustainable performance criteria are determined. The results reveal a total of seven factors to present the structure that forms the basis of the sustainable performance criteria used to choose a construction method in concrete buildings. These factors are listed as; economic factors (long-term cost-constructability-quality and initial cost), social factors (impact on health and society-architectural impact) and environmental factor (environmental impact). In addition, survey results indicate that social awareness and concerns are increasing.

Yiğit and Şeneren (2018) compared the carbon footprint and cost differences of the construction of a traditional building and a green building, and the amount of emitted carbon dioxide (CO_2), by designing a single-storey building. The comparison revealed that even a small building can be built as a green building with reduced carbon emissions, and even if the initial investment cost is high, this cost will be paid back over time. Bettemir (2012a, 2012b, 2016, 2018) compared the environmental impact of temporary accommodation utilities constructed after a destructive earthquake. Erzurum and Bettemir (2021) estimated the CO_2 emission and embodied energy of temporary accommodation facility.

Method

In this section the computation steps of the embodied energy and the CO_2 emissions are described. The computations of embodied energy and the CO_2 emissions of the building involve the quantity take-off of the construction items. The quantity take-off provides the amounts of the construction works; however this data do not directly give the amounts of materials to be used. In order to obtain the amounts of used materials, job definitions including the workmanships and material requirements of the construction items are required. The mentioned data is obtained by the Ministry of Environment and Urbanization of Turkish Republic. Definitions of construction items are used for the estimation of the required materials and the consumed energy.

Construction activities sometimes require the execution of another construction activity. To illustrate, construction of brick wall involves regularly placement of bricks, as well as preparation and spreading mortar. However, preparation of mortar is another construction activity which involves mixing of cement, fine aggregate, and water. Construction items may require usage of more than one type of construction materials. For example, preparation of the formwork activity requires consumption of plywood or timber for the formwork, utilization of supporting braces for the formwork, consumption of oil, and nails. The total amounts of materials are computed by multiplying the unit requirements mentioned in the activity definition and the quantity take-off amount.

Some of the construction materials can be reused. Timber for the formwork can be given as an example for this situation. Same timber can be used for the formwork of the foundation, columns, beams, and slabs of the building. Therefore the amount of the required timber is less than the total area of the formwork. In addition to this, wooden support for the formwork can be reused for the bracings of the roof system. As a result, reuse can reduce the amount of the required materials. In this study, reuses of wooden elements are taken into account when computing the amount of embodied energy of the utilized materials.

Amounts of utilized materials are multiplied by the unit embodied energy of the considered material and the total embodied energy of the specific material is obtained. The unit embodied energy and CO_2 emissions of the materials are defined in a similar way to the job definitions. The unit embodied energy and CO_2 emissions values per one kg of the material is determined by literature survey and the provide values are matched with the materials of the job definitions of the construction activities. The material units of the job definitions may not be coincident and the units are converted into kg by using the material properties. The procedure is repeated for every construction material and the obtained embodied energy amounts are summed and the total energy content of the accommodation utility is computed. In addition to this effect of utilization of different floor covering materials on the carbon emission and embodied energy is analyzed.

Case Study

In this study, a typical one storey accommodation facility whose floor plan is given in Figure 2, is designed and used as case study. Cost of the building and the effects on the environment are examined. The load bearing system of the examined struction is masonry. In rural areas, masonry structures are more common since the preparation of the reinforced concrete is more

expensive because of the transportation costs and shortage of skilled workers on the reinforcement works.

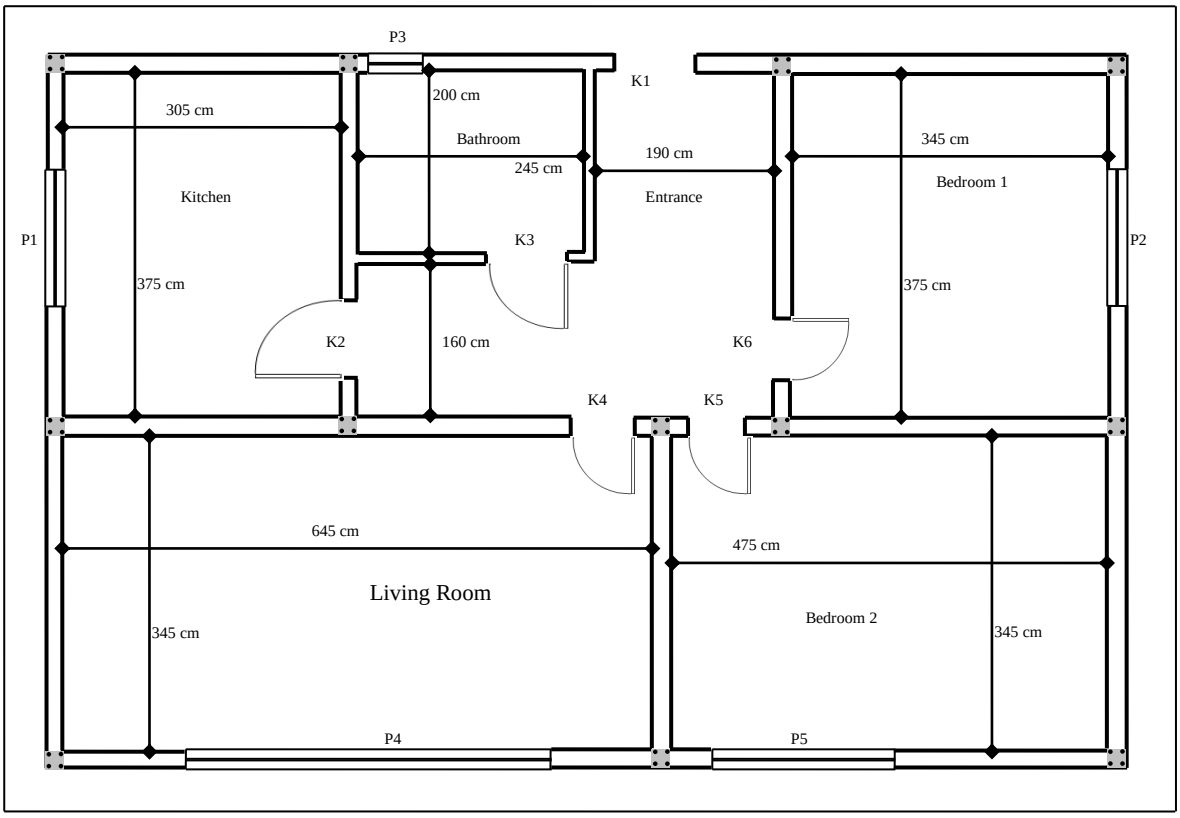

Figure 2: Floor plan of the examined accommodation facility.

Top view of the examined accommodation facility is shown in Figure 2. Foundation, excavation and section drawings are not given because of the space limitations. There are lintels on every door and windows, and the wall thickness of the load bearing walls are 20 cm. The load bearing walls are supported by horizontal and vertical reinforced concrete beams and columns. Walls of the bathroom, floors of the kitchen, entrance and bathroom are covered by ceramic tiles. Floor covering of the living room, bedroom 1 and 2 are laminate parquet. Continuous foundation type is preferred. Foundation elongates under the load bearing walls. The foundation is constructed below the frost depth. The bottom side of the foundation is 2 meters below the ground surface. Width of the foundation is 70 cm and its thickness is 25 cm. At the top of the foundation, 125 cm height stone wall is constructed and a 25 cm reinforced concrete horizontal beam is placed on the stone wall. The top of the reinforced concrete horizontal beam reaches ground surface. The load bearing system of the foundation is covered by water insulation material and this material is protected by thin brick wall.

The walls are plastered by 200 kg dosage cement mortar. Then the plastered surfaces are painted. The tile covered walls are not plastered. Roof eaves are 60 cm by the edge of the walls. Top of the ceiling is covered by heat insulation material. The roof is constructed by plywood boards. Top of the board is covered by bituminous water insulation material. Tiles cover the water insulation. The roof is reinforced by wooden truss system. The wooden truss elements are obtained from the supports of the formwork. Window and door frames are made of wood. The computed quantity take-off of the construction items are presented in Table 1.

Table 1. Quantity take-off of construction items.

Work Item	Quantity	Unit
Excavation	211.463	m^3
Drainage Pipe	41.6	m
Gravel	31.18309746	m^3
Plain Concrete	13.108	m^3
Water Insulation	216.72	m^2
Formwork	217.735	m^2
Reinforcement	3701.39	Kg
Concrete	32.7975	m^3
Stone wall	36	m^3
Load Bearing Brick	137.66	m^2
Partioning Brick Wall	11.42	m^2
Thin Brick Wall	137	m^2
Backfill	77.5	m^3
support for scaffolding	309.3075	m^3
Plastering	416.155	m^2
Ceramic tiles	55.3235	m^2
Concrete tiles	47.96	m^2
Concrete tile baseboard	37.96	m
Painting	400.2376	m^2
Laminate parquet	51.5775	m^2
Ceramic baseboard	22.12	m
Laminate baseboard	47.18	m
Door frame	7.118	m^2
Door Casing	13.454	m^2
Window frame	11.25	m^2
Scaffolding (outside)	119.56	m^2
Window sill	2.85	m^2
Gutter	44.4	m
Downspout	6.30	m
Elbow pipe	6	pieces
Heat insulation (Roof)	117	m^2
Plywood board (roof)	126.01	m^2
Water insulation (roof)	126.01	m^2
Tiles (roof)	126.01	m^2
Ridge Tile	30.45	m
Plumbing	28.40	m
waste water piping	17.35	m

After the coputation of quantity take-off, the next task is to compute the required amounts of construction materials to execute the work items. This is done by identifying the required material to accomplish one unit of each work item. Unit material requirements of the construction items are given in Table 2.

The fourth column of the Table 2 lists the amount of the require materials to construct the complete house. The material amount lists are used to compute the embedded energy which is required to produce the aforementioned material. Total material requirements are computed by multiplying the unit material requirements and the corresponding quantity take-off amount given in Table 1. Table 3 lists the unit embedded energy of the listed construction materials and the unit requirements are multiplied by the material amounts in order to obtain the embodied energy of the consumed material. Unit embodied energy values of the construction materials are obtained by Hammond and Jones (2008).

Table 2. Unit material requirements of the construction items.

Work Item	Unit Material Requirement	Unit	Total Material Requirement (kg)
Drainage Pipe	1.80	kg/m	74.88
Gravel	1800	kg/m3	56129.57542
Plain Concrete	2400	kg/m3	31459.2
Water Insulation Ply1	0.4	kg/m2	86.688
Water Insulation Ply2	2.3	kg/m2	498.456
Formwork Board	4.576	kg/m2	996.35536
Nails	0.3	kg/m2	65.3205
Lubricant	0.1	kg/m2	21.7735
wood timber	1.17315	kg/m2	255.4358153
Reinforcement	1.05	kg/kg	3886.458051
Concrete	2400	kg/m3	78714
Stone wall	2400	kg/m3	86400
Load Bearing Brick Wall	400	kg/m2	55064
Partioning Brick Wall	270	kg/m2	3083.4
Thin Brick Wall	180	kg/m2	24660
Backfill	1800	kg/m3	139500
support for scaffolding (steel pipe)	0.4	kg/m3	123.723
support for scaffolding (steel plate)	0.12	kg/m3	37.1169
Plastering	2000	kg/m2	16646.2
Ceramic	2600	kg/m3	2876.82
Concrete tile	2200	kg/m3	3165.36
Concrete tile baseboard	2200	kg/m3	66.8096
Painting	1500	kg/m3	1801.07
Laminate parquet	1.05	kg/m2	54.16
Ceramic baseboard	1400	kg/m3	24.77
Laminate baseboard	1.05	kg/m2	3.96
Door frame	600	kg/m3	85.42
Door trim	600	kg/m3	161.45
Window frame	1500	kg/m3	843.75
Scaffolding (outside steel pipe)	0.4	kg/m3	47.82
Scaffolding (outside steel plate)	0.12	kg/m3	14.35
Windowsill	2800	kg/m3	159.6
Gutter, downspout, elbow pipe	0.85	kg/m	43.93
Heat insulation (Roof)	120	kg/m3	702
Plywood board (roof)	800	kg/m3	2016.21
Water insulation (roof)	7.68	kg/m2	967.78
Roof Tiles and ridges	45	kg/m2	5944.63

The provided embodied energy values contains the energy required for the transportation of raw materials from the mine or the supplier, energy required for the manufacturing of the construction material and the energy required for the transportation of the material to the construction site. However, the computations involve many assumptions so that the unit embodied energy values are computed for general cases and the values may vary significantly based on the manufacturing techniques and transportation distances. Average values are assigned for the transportation distances and the manufacturing techniques. In this study, the facility is assumed to be built at a rural place which increases the transportation distance between the supplier and the construction site. In addition to this, in Turkey timber and some of the insulation materials are imported. This tremendously increases the transportation distance, thus the embodied energy of the product.

Table 3. Total embedded energy of the construction materials.

Work Item	Total Material Requirement (kg)	Unit Embodied Energy (MJ/kg)	Unit Embodied CO_2 (CO_2/kg)	Total Embodied Energy (MJ)	Total Embodied CO_2 (kg)
plastics/pvc pipe	74.9	67.5	2.5	5054.4	187.2
stone/gravel/chippings	56129.6	0.3	0.0	16838.9	954.2
concrete/general conc.	110173.2	1.0	0.1	104664.5	14322.5
Bitumen	1552.9	47.0	0.5	72987.4	745.4
timber/plywood	3268.0	15.0	0.8	49020.0	2647.1
steel/bar&rod steel	3886.5	36.4	2.7	141467.1	10415.7
stone/general stone	86400.0	1.0	0.1	86400.0	4838.4
clay and bricks/general	82807.4	3.0	0.2	248422.2	18217.6
Soil	139500.0	0.5	0.0	62775.0	3208.5
steel/pipe	171.5	34.4	2.7	5901.2	463.2
steel/plate	51.5	48.4	3.2	2490.9	164.2
plaster/general plaster	16646.2	1.8	0.1	29963.2	1997.5
stone/marble tile	2876.8	3.3	0.2	9579.8	538.0
clay and bricks/tile	9176.8	6.5	0.5	59649.2	4221.3
Paint	1801.1	68.0	3.6	122472.8	6411.8
vinyl flooring	54.2	65.6	2.3	3555.1	124.0
stone/marble tile	24.8	3.3	0.2	82.5	4.6
vinyl flooring	4.0	65.6	2.3	259.9	9.1
timber/general	246.9	8.5	0.5	2098.4	113.6
windows/pvc framed	5.0	2250.0	115.0	11250.0	575.0
stone/marble tile	159.6	3.3	0.2	531.5	29.8
plastics/pvc pipe	43.9	67.5	2.5	2965.3	109.8
insulation/rockwool	702.0	16.8	1.1	11793.6	737.1

The analysis reveals that the total embodied energy of the construction materials is equal to 1,050,223 MJ and the embodied CO_2 is 71,035.7 kg. The exact embodied energy is expected to be more than the computed value, since the facility is assumed to be built at a rural place which would increase the transportation distance of the construction materials.

Discussion of Results

The embedded energy and CO_2 emission computations are automated by forming semantic relations between the construction activities. To illustrate, the support for the scaffolding and the scaffolding activities require the same materials which are steel pipe and steel plate. The mentioned activities are joined so that their material requirements are summed and the embedded energy and CO_2 emission computations are executed simultaneously. This method reduces the computational errors and makes the lists clear and comprehensible.

The rural building is analyzed by preparing the quantity take-off of each construction item which is given in Table 1. Then the job descriptions of the construction items are joined with the quantity take-off data and the material, energy, and equipment requirements for the corresponding construction item is computed as given in Table 2. The material requirements are matched by the embedded energy and CO_2 emission definitions of the corresponding materials as given in Table 3. The material definitions are prepared for unit weight of the material which is kg. The job definitions may not be coincident with the material definitions so that the required material can be defined in length, area or volume. Therefore the material requirements are converted into weight and the pairing became consistent.

Production of the most of the construction material such as cement, steel, aluminum, glass, ceramic, and tiles require important amount of energy. The construction items which utilize

the mentioned materials constitute the most of the embedded energy and the CO_2 emission for the construction. The walls have the %25, cocrete has the %10, reinforcement bars has the 14%, and the paintings has the 12% share of the embodied energy of the construction.

Conclusion

In this study, embodied energy and embodied carbon of a typical one story accommodation facility are computed. Quantity take-off of the construction items is computed according to the technical drawings. The quantity take-off data is matched by the job descriptions of the construction activities. This enabled the estimation of the requited amounts of construction materials, energy and machine usage. The list of the construction materials is prepared and the unit embedded energy values and the CO_2 emissions of the construction materials are derived from the literature. The unit values and the material requirements are matched and multiplied and the total embedded energy and CO_2 emission to construct a typical rural building is computed.

The analyses show that the total embedded energy of a typical rural house is more than one million MJ excluding the additional material transportation. The analysis provided the contribution of each construction material on the embedded energy and the CO_2 emission. The material list gives adequate information for the design of an environmentally friendly house. The designer can detect the worst part of the material selection if an environmentally building certification is aimed. The design can be improved by utilizing lower embodied energy and CO_2 emission materials. This study provides a guideline for the construction of sustainable houses which utilizes construction materials with minimum embodied energy and CO_2 emission.

Abstract

Renewable energy utilization and energy efficient buildings are very important for the Earth, due to rising population. Many studies have been carried out investigating the subject of sustainability and sustainability in architectural education in Turkey. Architectural Education supports sustainability. The subject of sustainability and environmental systems are included among the knowledge and skills of the Architectural Accreditation Agency (MIAK) that must be acquired by every graduate. Along with the developing technology in the construction sector, many current concepts related to sustainability are encountered. In this study, it is aimed to determine the level of inclusion of current concepts related to sustainability in undergraduate Architectural programs. Within the scope of the study, content analysis method will be used to determine the current concepts in sustainability practices from the publications related to sustainability in the last five years. The current concepts determined from the literature by content analysis will be scanned in the elective course contents of the Architecture Departments of 12 Universities in the sample and the number of repetitions will be reached. Thus, the rate of inclusion of current concepts in sustainability practices in Architecture undergraduate programs will emerge.

Keywords: *architectural education, content analysis, current concepts, sustainability.*

Introduction

There is a much greater requirement for energy today. Studies on renewable energy sources have grown because of the depletion of fossil fuels. Visual and climatic comfort of people should be satisfied with minimum energy. Energy resources have been utilized carelessly for many years. It is known that the energy sources used over time decrease, may run out, and do significant harm to the environment. The necessity for efficient energy use and the hunt for alternate energy sources have resulted correspondingly. Renewable energy utilization is one of the best strategies to improve the energy efficiency of buildings.

Buildings that are environmentally friendly, healthful, and resource-efficient are referred to as “green buildings”. Sustainable building practices is actively aided by the performance

evaluation systems for green buildings. The number of certificated buildings has increased rapidly around the world. LEED, BREEAM, CASBEE, GREEN STAR, DGNB, and SBtool are the primary green building rating systems today. The B.E.S.T. certification system has been established in Turkey as a mean of certifying green buildings by CEDBIK (Environmentally Friendly Green Buildings Association). There are currently 518 certified projects in Turkey, of which 498 are LEED, 70 are BREEAM, and 23 are B.E.S.T. certified as of August 2022 (cedbik.org.tr). The number of certified projects has increased over time in Turkey.

Green building production still faces significant challenges within the context of project management in our country, notwithstanding the rise in the number of green buildings. Lack of education, one of the challenges faced in project management for the construction of sustainable buildings, has a significant role in the acceptance of green buildings (Bicer et al., 2020), and (Ceylan, 2016). If the architects are sufficiently aware of and knowledgeable about sustainability, the environment can be protected during the construction and utilization stage of the buildings. Sustainability principles have been emphasized in architecture education to protect environment.

The publications investigating the relationship between sustainability and architectural education have been analyzed for this study. Keskin et al. (2019) examined the relationship between sustainability and undergraduate diploma projects. Sustainability criteria were determined based on LEED criteria, passive design principles, and information and skills for undergraduate architecture students determined by MIAK (Architecture Accreditation Board). The relationship between sustainability criteria and diploma projects were assessed. Ibrahimgil (2019) identified the role of the sustainability in architectural education and examined the sustainability approach of architecture students in the universities of Turkey. He suggested a curriculum structure for the sustainability approaches. Karadag (2018) assessed the rate and format of ecological approaches in architectural education by examining the course content and the findings of a survey he conducted among architecture students. Ceylan (2016) compared the architectural education in Turkey and abroad. He developed a new model for an undergraduate architecture program. The suggested program included modern ecological and energy-saving practices. Yurtsever et al. (2013) evaluated sustainable building design as part of the architectural education through the experiences of students and instructors. The project course was conducted on the concept of “sustainability” through the Architectural Project Competition hosted in Canakkale. Gulec and Utkutug (2010) considered that traditional architectural design approach in architectural education was not appropriate for putting theoretical knowledge of energy and ecology to practice. As a result, they implemented a test project at Gazi University for a semester to incorporate simulation-supported building performance analysis into architectural education. Several academicians have publications in “Mimarist” Magazine issue titled “Sustainability in Architectural Education,” and many viewpoints on the connection between sustainability and architectural education are offered. Altomonte discussed the qualifications of undergraduate architectural education in this study. He presented the EDUCATE (Environmental Design in University Curricula and Architectural Training in Europe) project (Altomonte, 2011). Esin gave a hint tips on sustainability assessment techniques in the scope of MIAK (Esin, 2011). Oktay (2011) discussed the importance of the environment in architectural education. He proposed a table to measure the competency of Architectural Education Institutions in environmental issues (Oktay, 2011). Ciravoglu analyzed the undergraduate and graduate curriculums of 42 architecture schools in Turkey in the context of the environment. She assessed the environmental issues in curriculums of undergraduate and graduate architectural education.

(Ciravoglu, 2011). Caglar and Aksu presented a 10-point manifesto. They compared the qualifications of the studio indicated in the manifesto and the traditional studio. The studio indicated in the manifesto included sustainability (Caglar & Aksu, 2011)

The literature review revealed that there are a lot of studies about the sustainability in Turkish architectural education. “Sustainability and environmental systems” is the “information and ability” that is expected to obtain by the students of architecture programs according to MIAK. “Sustainability” should be in the content of the curriculum of architecture program according to most recent researches and MIAK’s knowledge and abilities. New concepts related sustainability have been developed with technological development of the construction industry. It should be given the importance to sustainability in architectural education, and architects should know the current sustainability concepts. It has been observed that the majority of the assessments in the current studies are made on required courses. The subjects are treated exhaustively by the elective courses, so current concepts for sustainability practices will be scanned on the elective courses in this study. This study aims to measure the existence of the current concepts for sustainability practices in the undergraduate architectural education curriculum with the rise in certified buildings in Turkey.

Method

After the publications about current sustainability concepts have been scanned on Web of Science, current sustainability concepts will be determined. Current concepts will be scanned on the elective courses of Architecture Department curriculums with content analysis method. The existence of the current concepts for sustainability practices in the undergraduate architecture program curriculum will be determined.

Content analysis is a method of analyzing written, oral, or visual communication messages (Cole, 1988). It allows the researcher to test theoretical issues to enhance understanding of the data. Through content analysis, it is possible to distil words into fewer content related categories. It is assumed that when classified into the same categories, words, phrases and the like share the same meaning (Cavanagh, 1997). It is the systematic examination of text and field notes by identifying and grouping themes and coding, classifying, and developing categories (Jonge et al., 2007). Content analysis is an appropriate method that can be used to scan the texts in the literature to determine the current sustainability concepts. When scanning the relevant literature within the scope of the content analysis method, the frequency of the current concepts for sustainability practices in undergraduate architecture programs will also be revealed.

Determination of the Sample

The sample consists of 12 universities that provide undergraduate degrees in architecture. The sample consists Architecture Programs located in various parts of Turkey. As many of Architecture Programs located in Istanbul, 5 of the programs have been selected from Istanbul. 2 programs from Ankara and one program each from Izmir, Trabzon, Bursa, Gaziantep, Cyprus have been selected. 7 of them are public universities and 5 of them are foundation universities. When the sample has been determined, the accredited Architecture Programs are preferred. The sample consists Istanbul Technical University (ITU), Middle East Technical University (METU), Yildiz Technical University (YTU), Mimar Sinan Fine

Arts University (MSFAU), Karadeniz Technical University (KTU), Uludag University (UU), Dokuz Eylul University (DEU), Istanbul Kultur University (IKU), TOBB University, Hasan Kalyoncu University (HKU), Eastern Mediterranean University (EMU) and Bahcesehir University (BAU). Architecture Programs of ITU and YTU are accredited by National Architectural Accrediting Board (NAAB). Architecture Programs of YTU, MSFAU, IKU, EMU and BAU are accredited by MIAK.

Determination of Current Concepts Regarding Sustainability Practices

The determination of the sample step is followed by the determination the categories step in content analysis method. Current concepts regarding sustainability practices have been determined from the literature. Similar concepts have been collected under a same category.

The publications mentioning sustainability practices have been searched on Web of Science from 2017 to 2022. 40 publications on Web of Science have been scanned to determine the current sustainability concepts. 38 publications are articles. Abstracts and keywords of the publications have been scanned to determine the current concepts (Table 1).

Table 1. Determination of current concepts related to current sustainability practices.

Current Concepts	References & Year
Green Architecture	Ibrahim, 2022; Grover et al., 2020

Smart City	Han & Kim, 2022; Çetin & Çiftçi, 2019; Ahmed et al., 2019
Eco- City	Deng et al., 2021
Certification Systems	Kaçar et al., 2022; Leringer, 2020; Georgievska et al., 2018

27 concepts have been determined at the end of the literature survey. When similar concepts have been collected under a same category, 12 categories have been determined for current concepts. “Sustainable Architecture”, “Green Building”, “Zero Energy Building”, “Biomimetic Design”, “Kinetic Facade”, “Smart Facade”, “Double Skin Facade”, “Green Roof”, “Shading Elements”, “Smart Building Materials”, “Smart City”, and “Certification Systems” constitute the categories (Table 2).

Table 2. Categories of current concepts.

Current Concepts	Reciprocal Concepts
Sustainable Architecture	Green Architecture, Green Construction, Sustainable Construction
Green Building	Green Technology, Green Building
Zero Energy Building	Net-Zero Energy Building, Zero Energy Building, Near Zero Energy Building, Nearly Zero Energy Building, Low-Carbon Buildings, Ecological Building, High Performance Building, Smart Building
Biomimetic Design	Biomimetic Architecture, Biomimicry, Regenerative Design
Kinetic Facade	Kinetic Facade
Smart Facade	Smart Facade
Double Skin Facade	Double Skin Façade, Double Facade
Green Roof	Green Roof
Shading Elements	Shading Elements
Smart Building Materials	Smart Building Materials, Smart Material
Smart City	Smart City, Eco- City
Certification Systems	Certification Systems

Assessment of Current Concepts Regarding Sustainability Practices in Undergraduate Architecture Programs

Frequency of the data has been considered as counting system in content analysis method. The current sustainability concepts in elective courses of 12 Undergraduate Architecture Programs have been assessed (Table 3). Absolute frequency of the concepts has been calculated from Table 3.

Table 3. An assessment of current sustainability concepts in elective courses of 12 Undergraduate Architecture Programs.

Results and Conclusion

The contents of the elective courses of 12 Architectural Programs in Turkey have been scanned. “Sustainable Architecture” and “Green Building” have been the most frequently used current concepts in the elective course contents. “Smart Building Materials,” “Certification Systems,” and “Shading Elements” have been repeated four times. Although there are several green building projects in Turkey, the concept of “certification systems” has repeated four times. “Green Roof” and “Zero Energy Building” have been repeated three times. “Double Skin Facade” has been repeated twice. “Biomimetic Design,” and “Smart City” have been repeated once. The elective course contents have never included the concepts of “Kinetic Facade” and “Smart Facade”.

7 current concepts have been featured in the contents of IKU and 6 concepts have been featured in the contents of DEU. 5 current concepts have been featured in the contents of MSFAU and BAU. The courses with the most concepts in their contents are “Ecology and Architecture” (DEU) and Ecological Architecture (IKU). 5 of the 12 current concepts have been included in the contents of these courses.

Current concepts regarding sustainability practices have been determined from the recent five years of publications. As a result of the study, it has been noticed that awareness of the current concepts related to sustainable practices have been occurred in Turkish Undergraduate Architecture Programs. “Sustainable Architecture” and “Green Building” have been the most frequently used current concepts and they are sustainability practices in building scale. Sustainability practices in building element and material scale are important for green buildings, but these concepts are rarely included in the course contents. “Double skin facade”, “smart facade”, kinetic facade”, “green roof”, “shading elements”, etc. should be included in the courses for the increase of the sustainability practices. We hope current concepts regarding sustainability practices will increase in the content of the courses of Undergraduate Architecture Programs in future and architects in Turkey will have sufficient knowledge about current sustainable practices.

Analyzing the Effects of Occupants' Demographic Characteristics on Indoor Thermal Sensation in Office Buildings

E. Kocaman and G. Çalış
Ege University, Faculty of Engineering, Department of Civil Engineering, Izmir, Turkey
ezgkcmn@gmail.com, gulben.calis@ege.edu.tr

Abstract

Maintaining comfort requirements of occupants in buildings are a challenging task for facility and building managers since the diversity of occupant profiles might result in different comfort requirements. One of the factors causing this difference is occupants' demographic characteristics such as gender, and age. This study aims at investigating the effects of occupants' demographic characteristics on occupants' thermal satisfaction levels in an office building. Within this context, a case study was conducted in 3 enclosed and 12 open-plan offices during the cooling season. Five demographic characteristics including gender, age, thermal history, education level, income level as well as occupants' thermal satisfaction levels were obtained via a survey campaign. Next, statistical analyses were conducted to understand the effects of demographic characteristics on thermal satisfaction levels. The results show that occupants' gender, age, education level and income levels impact occupants' thermal satisfaction in office buildings.

Keywords: *thermal comfort, thermal satisfaction, occupant demographic characteristic, office buildings.*

Introduction

Thermal comfort can be defined as the conditions that occupants feel themselves physically and mentally comfortable in indoor environments (Mıhlayanlar et al., 2017). Maintaining a satisfactory thermal environment for occupants is as an important part of the built environment that affects not only health and wellbeing but also productivity of occupants (Kocaman et al., 2021). There are widely accepted standards that define reference values for environmental (indoor air temperature, relative humidity, air velocity) and personal (metabolic rate, clothing insulation) variables for thermal comfort. These are namely "ISO 7730 (2005): Ergonomics of the thermal environment – Analytical determination and interpretation of thermal comfort using calculation of the PMV and PPD indices and local thermal comfort criteria" used in European countries (ISO 7730, 2005) and "ASHRAE Standard 55 (2017): Thermal Environmental Conditions for Human Occupancy" used in America (ASHRAE Standard 55, 2017).

Building occupants' thermal satisfaction also depend on environmental and personal variables (Maiti, 2014). However, thermal satisfaction of the occupants may not be understood by only considering the variables defined in the standards. In addition, the diversity of the occupant

profiles in the buildings might cause different occupant thermal satisfaction levels (Brown et al., 2010; Frontczak & Wargocki, 2011; Klepeis et al., 2001). One of the factors causing this difference is the demographic characteristics of the occupants, including gender, age, hometown, education level and income level. In the literature, there are studies investigating the effects of demographic characteristics of occupants on thermal satisfaction. Bae et al. (2020) focused on identifying the effects of gender, age, tenure, and weekly working hours spent in office environment on indoor environmental quality satisfaction. In this context, the responses obtained from the surveys of 2275 occupants in 30 office buildings were analyzed. The results showed that male occupants were more satisfied than female occupants. In addition, it was determined that the middle age group satisfaction was less than younger and older groups. Indraganti et al. (2015) investigated the impacts of age, gender and anatomy on thermal comfort in India from January 2012 to February 2013. A thermal comfort questionnaire was applied to 2787 occupants in 28 office buildings and the responses were statistically analyzed. The results showed that gender have a statistically significant difference on thermal satisfaction. In addition, it was concluded that younger occupants preferred higher temperatures than older occupants.

As seen above, studies on the effects of demographic characteristics on thermal satisfaction in the literature generally focus on age and gender. Therefore, the effects of demographic characteristics on thermal satisfaction needs to be investigated extensively. This study aims to investigate the association of demographic characteristics including gender, age, hometown, education level, income level of the occupants with thermal satisfaction levels. In this context, 15 offices located in Izmir were selected as a test bed and thermal satisfaction levels of the occupants were obtained via surveys. The responses were analyzed by statistical methods. Next sections introduce the material, explain the methodology and present the results.

Material

The study was conducted between July and August 2019 in an office building located in Izmir, Türkiye. The office building has open-plan offices as well as enclosed offices and the building has a central air-conditioning system for cooling and heating. In addition, enclosed offices are equipped with split air conditioners that allow occupants to manually change the indoor air temperature. The surveys were conducted in a total of 15 offices including 3 enclosed and 12 open-plan offices. The detailed specifications of the offices are described in Table 1.

Table 1. Specifications of the offices.

		Area (m^2)	Number of Tables	Air Conditioning System	Indoor Air Temperature Control
Enclosed offices	E1	192	20	Central	Unavailable
	E2	130	20		
	E3	130	20		
Open-plan offices	O1	12	1	Split air conditioners	Available
	O2	12	1		
	O3	45	5		
	O4	56	5		

	O5	35	3		
	O6	20	3		
	O7	30	4		
	O8	50	4		
	O9	12	1		
	O10	12	1		
	O11	25	4		
	O12	40	4		

The survey data contains (i) gender, (ii) age, (iii) hometown, (iv) education level, (v) income level and (vi) thermal satisfaction level. Thermal satisfaction was evaluated according to the commonly used 7-point Likert scale (Kandasamy et al., 2020). According to the scale, thermal satisfaction ranges from (-3) very dissatisfied to (+3) very satisfied (Aryal et al., 2020). A total of 83 occupants participated in the study. It should be noted that each occupant participated in the survey only once to avoid response bias. Incomplete surveys were omitted and a total of 80 surveys were included in the analysis.

Methodology

Statistical analyzes were carried out by using the SPSS 20.0 (IBM Corp., 2011) statistical program. Chi-square test was performed to determine the relationship between demographic characteristics and thermal satisfaction. This test is selected since it is applied to find the relationship between the variables in the data where the independent variables are categorical (Fayyaz et al., 2022). In the chi-square test, three p values are used based on the Asymptotic (Pearson chi-square test), Exact (Fisher's exact test) and Monte Carlo methods (Elmalı, 2005; Mehta & Patel, 2007; Ramos et al., 2021). The p value to be used in the further analysis is decided according to the chi-square test results. Chi-square test method calculates the Chi-square for each category as shown in Eq. 1:

$$X^2 = \frac{(OF - EF)^2}{EF} \tag{1}$$

where OF is the number of class observations and EF is the number of expected class observations to estimate whether there is a relationship between the variables.

Results

This section presents the results of chi-square analysis between demographic characteristics of the occupants and their thermal satisfaction. The results of chi-square analysis between gender and thermal satisfaction are given in Table 2.

Table 2. Results of chi-square analysis between gender and thermal satisfaction.

		Value	df	Asymptotic p-value	Ex. p-value
Thermal satisfaction	Pearson Chi-square	12.269	6	0.056	0.046
	Fisher Exact test	11.922	-	-	0.047

Exact p-value was based on the chi-square analysis between gender and thermal satisfaction. As can be seen from the table, there is a statistically significant relationship between gender and thermal satisfaction since the significance level (0.047) is less than 0.05. In other words, the gender of the occupants is effective on thermal satisfaction. The results of chi-square analysis between age and thermal satisfaction are given in Table 3.

Table 3. Results of chi-square analysis between age and thermal satisfaction.

		Value	df	Asymptotic p-value	Exact p-value
Thermal satisfaction	Pearson Chi-square	23.704	12	0.028	0.022
	Fisher Exact test	23.697	-	-	0.014

Exact p-value were based on the chi-square analysis between age and thermal satisfaction. As can be seen from the table, there is a statistically significant relationship between age and thermal satisfaction since the significance level (0.014) is less than 0.05. In other words, the age of the occupants is effective on thermal satisfaction. The results of chi-square analysis between hometown and thermal satisfaction are given in Table 4.

Table 4. Results of chi-square analysis between hometown and thermal satisfaction.

		Value	df	Asymptotic p-value	Exact p-value
Thermal satisfaction	Pearson Chi-square	25.613	36	0.901	-
	Fisher Exact test	33.848	-	-	0.678

Exact p-value were based on the chi-square analysis between hometown and thermal satisfaction. As can be seen from the table, there is not a statistically significant relationship between hometown and thermal satisfaction since the significance level (0.678) is more than 0.05. In other words, the hometown of the occupants is ineffective on thermal satisfaction. The results of chi-square analysis between education level and thermal satisfaction are given in Table 5.

Table 5. Results of chi-square analysis between education level and thermal satisfaction.

		Value	df	Asymptotic p-value	Exact p-value
Thermal satisfaction	Pearson Chi-square	21.756	12	0.040	0.042
	Fisher Exact test	19.503	-	-	0.024

Exact p-value were based on the chi-square analysis between education level and thermal satisfaction. As can be seen from the table, there is a statistically significant relationship between education level and thermal satisfaction since the significance level (0.024) is less than 0.05. In other words, the education level of the occupants is effective on thermal satisfaction. The results of chi-square analysis between education level and thermal satisfaction are given in Table 5.

Table 6. Results of chi-square analysis between income level and thermal satisfaction.

		Value	df	Asymptotic p-value	Exact p-value
Thermal satisfaction	Pearson Chi-square	20.808	12	0.053	-
	Fisher Exact test	19.331			0.037

Exact p-value were based on the chi-square analysis between income level and thermal satisfaction. As can be seen from the table, there is a statistically significant relationship between income level and thermal satisfaction since the significance level (0.037) is less than 0.05. In other words, the income level of the occupants is effective on thermal satisfaction.

Conclusions

This study aimed to investigate the effects of occupants' demographic characteristics including gender, age, hometown, education level, income level on thermal satisfaction levels. In this context, thermal satisfaction levels of the occupants were obtained through questionnaires. The main findings can be summarized as follows:

- There is a statistically significant relationship between gender and thermal satisfaction.
- There is a statistically significant relationship between age and thermal satisfaction.
- There is not a statistically significant relationship between hometown and thermal satisfaction.
- There is a statistically significant relationship between education level and thermal satisfaction.
- There is a statistically significant relationship between income level and thermal satisfaction.

It is well known that occupant complaints can arise when there is a mismatch between indoor environmental conditions and actual occupant needs (Kocaman et al., 2021). The findings of the study are beneficial to building owners and facility managers to understand the occupant complaints from the perspective of occupants' demographic characteristics. However, this study only focused on office buildings. Future studies can incorporate different types of buildings (i.e. residential) to validate the results of this study.

Abstract

The price of electricity generated through fossil fuels has gone very high putting up a significant burden on household earnings. Renewable energy generation can provide the best alternative to reduce such expenditures in a household. This can also help reduce the pollution generated during conventional power generation. The rooftop of houses in most cases has significant solar energy generation potential, which can be the cheapest way to generate alternative power and energize the dwellings. This paper deals with the simulation-based assessment of the solar energy potential of existing houses in district Central of Karachi. The simulation was done using a building information modeling tool integrated with a cloud-based energy assessment tool that can provide Photovoltaic (PV) i.e. solar energy generation potential. The assessment was done based on the useable rooftop area of the houses. Results show that the solar energy generation potential of the modeled houses of district Central Karachi can be almost two times the amount of electricity being currently used by the same dwellings based on yearly electricity consumption data collected from their bills.

Keywords: *energy analysis, residential buildings, solar energy potential, useable area.*

Introduction

In Pakistan, most of the primary energy supply is obtained from burning fossil fuels like oil and natural gas. Renewable energy resources are beginning to dominate the power sector without emitting high carbon footprints and protecting the environment from hazardous gas emissions. According to a press release from the International Renewable Energy Agency in July 2021, the cost of a solar energy producing alternatives is reduced by 7% (Zhongming et.

al., 2021). According to the current statistics from The News International of Pakistan, residual furnace oil-based electricity has a 16.84 percent stake in the energy mix, or 6,274 MW, whereas coal-based power has a 12.80 percent share, or 4,770 MW (Aslam, 2021). Natural gas accounts for 12.15 percent of total electrical generation, or 4,529 megawatts. Nuclear power now accounts for 6.68 percent of total energy generation or 2,490 megawatts. Similarly, wind-generated power accounts for 3.31 percent of the total energy mix, or 1,235 megawatts. And power through solar is at 1.07 percent with 400 MW and through baggase has a share of 0.98 percent that stands at 364 MWs (Aslam, 2021). Due to the need to limit the health and environmental risks associated with electricity generation using fossil fuels, renewable energy sources are now universally viewed as a legitimate substitute for fossil fuels in supplying the rising demand for power throughout the world. RE sources are growing more popular as carbon-based fossil fuels become scarcer, and they are taking center stage in policy choices all around the world.

At the household level, building envelops, specifically house geometry, do provide a significant opportunity to generate localized solar energy using the rooftop area of a house. However, often this potential remains unused due to unawareness regarding such potential and also the initial cost of investments in solarizing a house. For solar energy generation, rooftops, and the usable area of houses play an important role. In Karachi complete rooftops of houses are not available for the installation of PhotoVoltaics panels. To estimate the usable area of the rooftop house visual analysis is required to be done by eliminating the rooftops of the mumty room and overhead water tanks (OHWTs). This paper provides an assessment of the solar energy generation potential of houses in the district centra of Karachi using information modeling, energy simulation, and comparison of results with the electricity bills for one year.

Objective Scope And Methodology

The objective of the study was to assess the solar energy generation potential of houses in Karachi using information modeling and energy simulation. The scope of the study is limited to the 15 existing dwellings of the district Central of Karachi in the range of 80 to 400 sq yds.

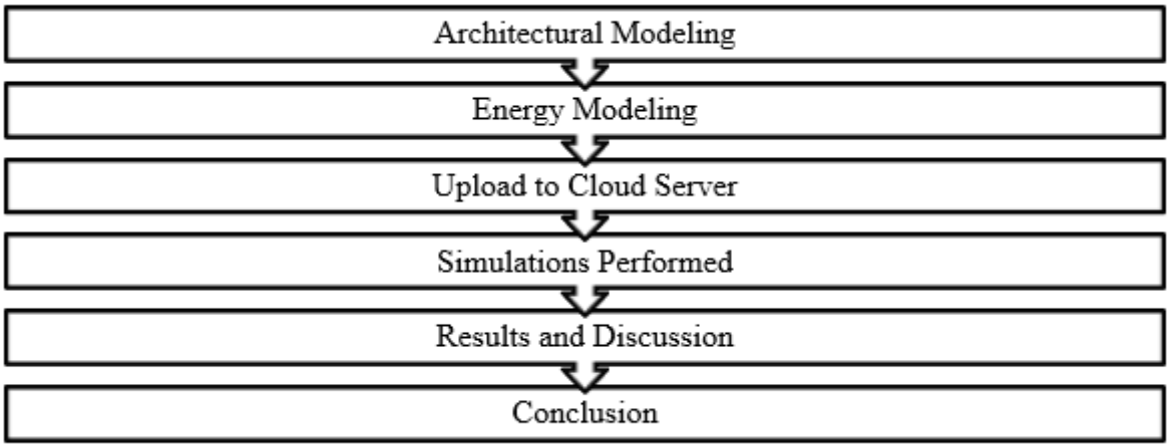

Figure 1: Research methodology.

The step-wise methodology was adopted which is illustrated in Figure 1. The first step was to generate the architectural model of the houses using building information modeling tools using realistic values collected by performing energy walkthrough audits of particular houses. The second step was to develop the energy model by providing real-world energy settings (i.e. lighting density, power density, occupancy schedule, etc.) of a house. In the third step, the developed energy model was uploaded to a cloud server for performing energy simulations as the fourth step. As a result of simulations, the solar potential of each house was found in the form of energy use intensity (KWhr/m^2/yr). This value was converted into solar energy potential in KWhr by multiplying it by the usable area for solar panel installations on the rooftop of each house. Finally, the solar energy potential of each house was compared with actual yearly energy consumption gathered through electricity bills of houses to conclude solar energy potential.

Literature Review

Aslani and Seipel (2022) proposed a methodology in which they performed automatic extraction of building footprints, automatic segmentation of roof faces, and automatic identification of utilizable areas of roof faces for solar infrastructure installation. The study shows a high success rate with 95% correctness and completeness in extracting building utilizable areas. Furthermore, results show that the methodology adopted was effective in identifying the roof occlusions and roof superstructures satisfactorily and Rooftop PhotoVoltaic (RPVs) assessment is effective in an urban region. Thanh et. al. (2021) studied the performance of rooftop solar power generation in which they assess the office building in the northeast region of Vietnam by integrating solar panel systems with and without battery storage. As a result, they found out that both the options are viable as the benefit to cost ratio is greater than one. However, the grid-tied rooftop solar power generation with storage is not quite feasible due to the capital cost invested in the system and the payback getting over a long period. Ayodele et al. (2021) investigated the growing electrical energy demands of a cosmopolitan city in Nigeria using rooftop solar PV systems. Mohajeri et. al. (2016) conducted research to identify the impact of roof types on solar potential generation by integrating solar photovoltaics (PV). They calculated the ratio of useful roof area and building footprint area that is near one. They find out that footprint is a good measure of useful area for PV and ranked the roof types concerning the PV generation efficiency. The highly efficient rooftop is gable whose ratio is greater than 1 (i.e. 1.18) than the flat roof and in the end, the hip roof has the least PV potential. Izquierdo et al. (2011) quantified the amount of energy used for electricity using Photo Voltaic solar systems in buildings. They also use a geo-referenced method to find out the available roof area for solar facilities. They installed solar hot water systems (SHWS) and Solar Photo Voltaic systems on the rooftops and results show that SHWS contributes up to 1662 ktoe/y of primary energy however, PV systems would provide 10 T W h/y of electricity.

Modeling And Simulation

The first step towards the analysis is the architectural modeling of the houses collected from the district Central of Karachi. Each house was first architecturally modeled in Autodesk Revit using the 2D architectural plans and the information gathered from the physical energy walkthrough audit of each particular house. Figure 2 shows the architectural model of a house.

After generating an architectural model real-world energy settings (i.e. lighting density, power density, occupancy schedule, etc.) were provided to the model to develop the energy model of the house. According to Arif and Zaman (2021), when real-world energy settings were provided as input to the energy model the results generated had a 7% variation from the actual values.

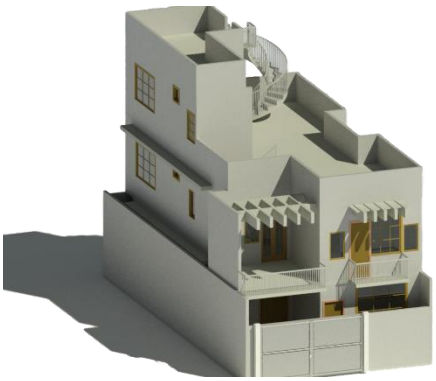

Figure 2: Architectural model of a house.

Figure 3 shows the energy model of a house which was uploaded to the insight 360 clouds for energy simulations.

Figure 2 and 3 shows the architectural and energy models of a single house as an example. However, the rest of the houses were also modeled similarly and simulated after being uploaded to the cloud.

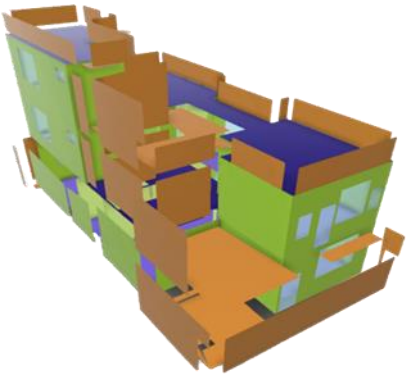

Figure 3: Energy model of a house.

Results And Discussion

After getting simulations were performed, the result of each house was generated in the form of Energy Use Intensity (EUI) which means the energy consumed per meter square in a year by that house (kW.hrs./m2/yr). Results show the solar energy generation potential of each house in the form of EUI which was converted into per year generation potential by taking a product with the useable area of that house. Two types of areas were presented to calculate the per year solar energy generation potential of houses one was the available rooftop area which is the total roof area excluding the openings. The second was the useable area which shows

how much of the available area can be used to generate solar energy. Analytical calculation of the useable area can be comprehensible from Figure 4, the blue shaded area is the available rooftop area, while the area that can be used for solar PV panel installations is shaded with an inclined hatched lines pattern.

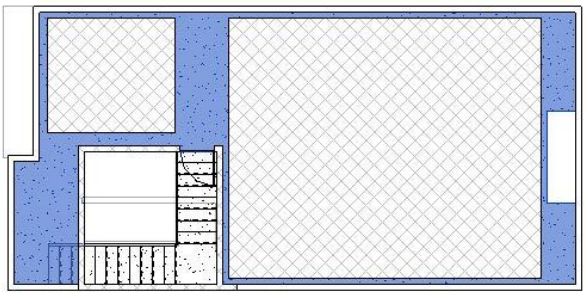

Figure 4: Useable area.

The result of all analyzed houses from district Central of Karachi city is tabulated in the form of Table 1which is as follows

Table 1. Solar energy generation potential of houses.

S.No.	ID	Available Rooftop area (m^2)	Useable area (m^2)	Solar Potential from Simulation		Actual Electricity kW.hrs. *(Jun 20-May 21)*
				kW.hrs./m^2/Yr.	kW.hrs./Yr.	
1	C-01	348	278	103.98	28906.44	15682.0
2	C-02	99	62	184.98	11468.76	5979.9
3	C-03	102	82	125.11	10259.02	2564.3
4	C-04	94.11	71	133.7	9492.7	6846.3
5	C-05	206	123	177.95	21887.85	6482.0
6	C-06	99	44	141.71	6235.24	5510.0
7	C-07	96	67	37.88	2537.96	1627.6
8	C-08	93	63	74.88	4717.44	4631.1
9	C-09	76	44	229.04	10077.76	3709.0
10	C-10	93.16	70.5	297.73	20989.965	4702.0
11	C-11	86	67	231.16	15487.72	6629.0
12	C-12	63.5	37	192.43	7119.91	1720.0
13	C-13	99	76	104.59	7948.84	4026.0
14	C-14	106	92	219.85	20226.2	2563.0
15	C-15	91	69	66.95	4619.55	2660.0

Table 1 shows the solar energy generation potential in kW.hrs./m2/Yr. from simulation and actual annual electricity consumption which was calculated from the electricity bill of that house. Results show that the solar potential is approximately two times the electricity consumption. This shows that if the solar PV panels get installed on the rooftops, then these rooftops not only reduce their energy bills but will be able to supply to the grid which will ultimately be in the benefit the house owner as well government.

Conclusion and Recommendation

The study shows the simulation-based assessment of the solar energy generation potential of the houses of district central of Karachi city. This study also concludes that useable area is approximately equal to 70% -80% of the available area of the house. If the house owners in the district central of Karachi get installed solar PV panels on their rooftop they can reduce their energy bills and transfer the surplus amount to the grids.

Acknowledgment

Abstract

This work investigates the effect on Embodied Energy (EE) of concrete when in-situ reinforced concrete (ISRC) is partially substituted with Pulverized Fly Ash (PFA) and Ground Granulated Blast Furnace Slag (GGBS) at the building scale and on material efficiency. The goal of the research project is to demonstrate potential improvements to the EE of a university building by comparing the EE of the cement mix with PFA and GGBS replacement to that of baseline case of traditional concrete by using EDGE application. The current study utilizes supplementary cementing materials (SCM) data to provide insight into EE reduction from a material to building scale. The change in the final EE of the building was observed by using two different types of in-situ reinforced concrete, "ISRC with > 30% PFA" and "ISRC with > 25% GGBS", instead of the concrete used in the original university building construction. It has been determined that the final EE of the existing ISRC in the building is 1200 MJ/m2. It was observed that the final EE of the building decreased from 1200 MJ/m2 to 1015 MJ/m2 when the ISRC with >30% PFA was used instead of the ISRC used in the building. The use of these materials also increased the material efficiency of the building such as the efficiency of ISRC which was 22.43% at the base case. The results show that the use of "ISRC with >30% PFA" and "ISRC with >25% GGBS" content, increased the material efficiency by 34.43% and 34.72%, respectively. The demonstrated reduction in EE values were calculated by using EDGE application were illustrated: Increasing the percentage of recycling materials like GGBS and PFA lowers the total EE of the building.

Keywords: *conventional concrete, embodied carbon energy, ground granulated blast furnace slag, pulverized fly ash, sustainability.*

Introduction

The most recent report of Intergovernmental Panel on Climate Change (IPCC) warns of observed changes in weather extremes such as heat waves, heavy precipitation, droughts, and tropical cyclones (IPCC, 2021). In order to prevent global temperatures from exceeding 1.5°C, global net anthropogenic carbon dioxide (CO2) emissions must decline by about 45% from 2010 levels by 2030 and reach net zero by 2050 (IPCC, 2018). Under the light of these scientific findings, there is an urgency for the decarbonization of the building industry until 2030. When considered over their full life cycle, the building industry influences nearly every

major sector of global GHG emission. The largest contributor to global emissions by end use is the industrial sector, contributing 30% of global emissions (IEA, 2021). Building materials are one of the largest sources of industrial emissions, meaning they are potential drivers to reducing emissions from this sector. A significant portion of the materials are used in buildings and other infrastructure.

Concrete is the material with the most carbon in the world due to the small quantify of EE (carbon) in 'one tonne of concrete' multiplied by the vast volume of concrete utilized (Crawford & Stephan, 2013). The single most significant part of decreasing the effect of EE is to design long-life, resistant, and resilient buildings (EE). Wherever possible, building materials with a lower EE should be used. (Rawlinson & Weight, 2007). Since concrete is the most abundant man-made material in the world, cement production has a major impact on the world's increasing CO2 emissions and is the largest contributor to tangible carbon in the built environment. The concrete is the pourable mix of cement, sand, water, and gravel which hardens into a super-strong building material. The cement which is part of concrete is a fine powder made up of crushed minerals such as limestone and clay. The cement industry is responsible for about 8% of global carbon dioxide emissions. Key strategies to cut carbon emissions in cement production include improving energy efficiency, switching to lower-carbon fuels, promoting material efficiency and advancing process and technology innovations such as Carbon Capture and Storage (CCS) (IEA, 2021).

Embodied carbon (EC) refers to CO2 emissions related to building or infrastructure construction materials and techniques. EC is the carbon footprint that exists prior to the building or infrastructure project's development. It also covers the CO2 generated for waste transportation and recycling, building maintenance, and eventual demolition. Up to now very little attention was paid to embodied impacts in building-related energy research. One of the difficulties is the life cycle of buildings include both energy consumption and GHG emissions. Both multidisciplinary collaboration and research is needed in order to use the top-down statistics and environmental considerations which are typically broken down by economic sectors (Röck et. al., 2020). The most recent IPCC report aimed to overcome this division by including a short discussion of embodied energy in buildings (de Coninck et al., 2018). The results of their study highlight the need to address and further reduce the life-cycle-related GHG emissions of buildings by optimizing embodied emission investments for new construction and promoting 'carbon-effective' investments for the refurbishment of existing buildings. Concrete required binders and binders like cement production need high temperature calcination which is an energy intensive process (Benhalal, 2013).

There are various methods and approaches to reduce the EE level of the concrete. Rebuilding buildings is a manufacturing approach that aims to keep materials in use by extending product life and returning waste as a resource. Reusing buildings instead of building new ones, compared to constructing a new building, renovation and refuse projects generally save between 50 and 75 percent in EC emissions. At first, determining the low carbon concrete mixes is the most important factor. Although the emissions per tonne are not so significant, concrete is often the largest (EC) resource on any project in practice, due to its weight and ubiquity in a structure. In terms of concrete content, this high level of EC is due to cement. A common strategy to reduce CO2 emissions is to replace Portland cement with supplementary cementitious materials (SCM). Options are to work with your structural experts to create lower carbon concrete mixes using fly ash, granulated blast furnace slag, or even low-strength cementitious concrete because it is important that a structure is not a structural problem. When it comes to the reuse of material, there will be a significant reduction in the level of EC.

Recovered materials (such as cracked concrete) typically have a much lower carbon footprint than newly manufactured materials because the carbon needed to produce them has already been spent.

Energy and pollutant emissions, such as carbon dioxide (CO2), may be considered "embodied". So, EE might be defined as the amount of energy needed to process and procurement the material under discussion to the construction site (Australian Government, 2013). To calculate the magnitude of this EE, an accountancy system that averages the energy inputs over a significant portion of the material supply chain or life cycle is required (Hammond & Winnett, 2006). EE has since been recognized as a principal or intrinsic component of the whole energy required to create and operate processes or other equipment. Similarly, EE (and carbon) is increasingly seen as equally essential in the context of structures and building materials (Menzies et al., 2007). The benefits of each construction material in terms of increasing the building's performance over its life cycle should be considered when choosing a material. Identifying the EE of a substance, component, or entire building is a challenging undertaking. Every building is made up of a complex combination of materials, each with its own production history and contribution to the EE of the structure. Because the efficiency of processes, energy sources, and material transit varies among companies, EE for the same type of product might also vary (Strine, 2013). The embodied carbon in building materials comes from two sources: fossil fuel inputs (which are pertinent with EE) and that released, during the limestone-to-cement conversion process (Rawlinson & Weight, 2007). EE must become a major factor to evaluate in building design for a variety of reasons. The first is the building industry. Second, shorter renovation cycles, lower-quality materials, and various energy-intensive maintenance practices can all raise a building's EE. Recycling and reuse, on the other hand, help to minimize landfill waste by repurposing previously used resources to create new items (EIA, 2012). This helps to reduce the consuming of virgin raw resources. Although recycling requires more transportation, energy consumption, and carbon emissions, the overall savings in EE and carbon emissions surpass the costs (Rahman et al., 2018). “Preservation Green Lab” conducted a study on the environmental benefits of building reuse vs new construction, comparing the environmental impacts of new versus reused and rehabilitated structures over a 75-year life cycle. According to this study, the environmental savings of building reuse can range from 4 to 46 percent, depending on building location and type, as well as energy efficiency level. They determined that building reuse always saves carbon when compared to new structures of comparable function, size, and energy-efficiency level. These savings have been demonstrated to be evident even in the majority of newer types of buildings with better levels of energy efficiency (Rahman et al., 2018). The building envelope has a considerable impact on the EE and operational energy use of structures. According to Mithraratne and Vale's research results, the building envelope (floors, walls, roof, and finishes) contributes around 48–50% of the EE of a typical house (Mithraratne & Vale, 2004).

Concrete's cementitious component contributes considerably to embodied CO2 emissions. Concrete is held together by cementitious materials, which act as a glue. Among these components are traditional portland cement (PC) and various cementitious additives such fly ash (FA), ground granulated blast-furnace slag (GGBS), limestone fines, and silica fume. These ingredients are either blended at the cement plant (to make composite cement) or mixed at the concrete plant (the cementitious product is called a combination in this case). Cement manufacturing is the world's single largest source of carbon pollution, accounting for 8% of worldwide emissions. Limestone is a significant raw material for Portland cement, as it emits

carbon dioxide when heated in a cement kiln. Over 55 percent of cement-related emissions come from this process (Beyond, 2017).

Methods

Methodology

The methodology was set to replace Portland cement with supplementary cementitious materials (SCMs) as well as using different cement types for a pilot building. Since the manufacture of Portland cement is energy intensive, to goal is to replace it with SCMs to lower the high EE content. These SCMs are Pulverised Fly Ash (PFA) and Ground Granulated Blast Furnace Slag (GGBS). PFA, also known as fly ash, is a waste product of coal fired at power stations. This research use PFA as one of the cement replacements. Ground granulated blast-furnace slag (GGBS) is obtained by quenching molten iron slag (a by-product of iron and steel manufacture) from the blast furnace in water or steam, producing a glassy, granular product which is then dried and ground into a fine powder.

Using the latest experimental data from replacing OPC with PFA and GGBS, provides an insight into EE savings from material up to a building scale. At the same time, the embodied energy levels of OPC, PFA, and GGBS-containing concrete when used in a building were determined.

The research is conducted by using an online green building certification system-EDGE. EDGE, an innovation of International Finance Corporation (IFC), focused on making new residential and commercial buildings more resource-efficient (EDGE, 2022). Using the EDGE application, initially the effect of different cement types on the embodied energy level of the building was determined. To lower operating costs and environmental impact, EDGE enables the early design stage identification of technological solutions. The researchers also used EDGE system to forecast operational savings and decreased carbon emissions based on the information inputs and choice of green initiatives. The EDGE application is used to determine the correct embodied energy level. It was applied as 25% and 30% by mass as complementary cementitious materials (SCMs). The effects of changes in the amount of cementous materials were also detected.

The pilot building is chosen as the Istanbul Medipol University D2 block which is an existing building. By collecting all the available information about this building (within the scope of energy, water, and material efficiency) from the facilities engineer and entering the data into the EDGE application, embodied energy savings of the building was calculated in the Giga joules (GJ) unit and instant available embodied energy level was calculated in MJ/m2 unit (Mega Joule). OPC was used throughout the building construction. The available data were recorded and the embodied energy level of the pilot building in its current state was calculated in the EDGE application. Using the same model building data, the embodied energy levels that would occur if the pilot building concrete was replaced with PFA values 25% and 30%, and then GGBS values 25% and 30% instead of OPC was calculated. As a result of the study, 5 different results were obtained.
To apply material data to achieve building-scale EE results, PFA and GGBS substituted concrete were integrated into the entire building by using EDGE application, and results are

analyzed. Two key variables were used in the embodied carbon calculations for buildings; cement types and percentage of cement types by mass as can be seen from Table 1.

Table 1. Substitutions used during the study and their percentages.

Number	Cement Type	Mixed Ratio
1	Ordinary Portland Cement	%100
2	Pulverised Fly Ash	%25
3	Pulverised Fly Ash	%30
4	Ground Granulated Blast Furnace Slag (GGBS)	%25
5	Ground Granulated Blast Furnace Slag (GGBS)	%30

If OPC is replaced with other SCMs, it is critical that the concrete does not show any weakness in strength. It must be superior to, or at least the same, strength as OPC. When examined based on the strength issue, various data were obtained when the research was conducted for both PFA as can be seen from Table 2 and Figure 1 and GGBS from Table 3.

Table 2. Concrete mixture proportions (kg/m3).

Series	Mix ID	Binder			Aggregate		Water (kg/m^3)	Superplasticiser (kg/m^3)	w/b	Slump (mm)

Materials

Pulverised Fly Ash (PFA)

Pulverised Fly Ash or Fly Ash is the inorganic mineral residue obtained after burning coal/lignite in boilers. Fly ash is a pozzolan containing aluminous (Al2O3) and siliceous (SiO2) material that forms cement in the presence of water. *The chemical reaction between PFA, Calcium Hydroxide, and water, to form additional cementitious products that improve many of the desirable properties of concrete (Formula 1).*

Fly ash chemically reacts with calcium hydroxide, a by-product released by the chemical reaction between cement and water, to form additional cementitious products that improve many of the desirable properties of concrete. Fly ash shows varying degrees of cementitious properties depending on the chemical and physical properties of both the fly ash and the cement.

FLY ASH + Ca (OH)2 + H2O (1)

The use of industrial waste pozzolans (Fly Ash, Ground Granulated Blast-Furnace Slag) which are not directly used due to the by-products formed at the end of industrial processes, but show pozzolanic properties, can be used in the production of cement with additives, or they can be used instead of cement to a certain extent. These artificial pozzolans, which have low EE values due to being by-products, also reduce the EE value of the concrete they are included in.

In line with the research, it has been observed that SCMs do not pose any strength problems. In fact, it has been determined that PFA and GGBS substituted concrete samples have more strength than OPC. When the 25% and 30% SCM substitution rates by mass used in the EDGE application are examined as can be seen from the Tables 2, 3, 4, 5 and Figure 1, they provide the desired strength.

Ground Granulated Blast Furnace Slag (GGBS)

Ground Granulated Blast Furnace Slag (GGBS) is the material formed by rapid cooling of the slag, which is formed as a by-product during the extraction of cast iron in the blast furnace, and exhibits pozzolanic properties when ground and turned into fine particles. Iron ore is melted in blast furnaces at 1400-1600 °C for smelting. During this process, while the cast iron with high specific gravity stays at the bottom, slag containing lime, silica, and alumina is formed on it because it is lighter. Thanks to SiO2 and Al2O3 coming from GGBS iron ores, which have an amorphous structure due to their rapid cooling, it exhibits pozzolanic properties when finely ground and combined with Ca(OH)2 in an aqueous medium.

Blast furnace slag is used as coarse aggregate in concrete in an unground state, but it is also used in concrete production by replacing cement. In this way, CO2 emissions can be greatly reduced. The reduction of clinker as much as the slag added in the slag cement production from the mixture and the decrease in the clinker demand will reduce all the negative effects that are harmful to the environment in the process until the clinker production. Chief among these is the CO2 gases released from the rotary kiln, from which clinker is obtained. CO2 emissions occurring during both coal and so on will reduce the consumption of resources.

Results and Discussion

A base case is created for the building in the EDGE application.

The floor ceramics used for the building construction had high EE. A lower EE product is found from the market research and used for the pilot project. The improved case is obtained with the EDGE application. The building's embodied energy drop can be seen from Figure 2 by changing the floor product of the building. The trials with GGBS and PFA started once the improved case is obtained. Different types of cement to reduce the EE of concrete is studied for the pilot building project. The whole building concrete is used for the calculations. The results show that, the use of industrial waste pozzolans (such as volatile, silica fume, blast furnace slag, rice husk ash, and metakaolin) in concrete reduces the EE value of concrete. Because these pozzolans are by-products, they have low EE values and contribute reducing the EE value of the concrete in which they are incorporated. Since 25% ''GGBS'' and 30% ''PFA'' types of these alternative cement added concrete types are available in EDGE application, the use these pozzolanic concrete ingredients in order to reach the results were possible. In the EDGE application, the final EE of the building decreased below 1200 MJ/m2

when these types of cement additives are used instead of the Portland cement. The change in the final EE of the building was observed by using two different types of in-situ reinforced concrete, “ISRC with> 30% PFA” and “ISRC with> 25% GGBS”, instead of the concrete used in the initial building construction. It has been determined that the final EE of the existing ISRC in the building is 1200 MJ/m2. It was observed that the final EE of the building decreased from 1200 MJ/m2 to 1015 MJ/m2 when the ISRC with >30% PFA was used instead of the ISRC used in the building. The use of these materials also increased the material efficiency of the building such as the efficiency of ISRC which was 22.43% at the base case. The results show that the use of “ISRC with >30% PFA” and “ISRC with >25% GGBS” content, increased the material efficiency by 34.43% and 34.72%, respectively. The demonstrated reduction in EE values were calculated by using EDGE application showed that increasing the percentage of recycling materials like GGBS and PFA lower the total EE of the building.

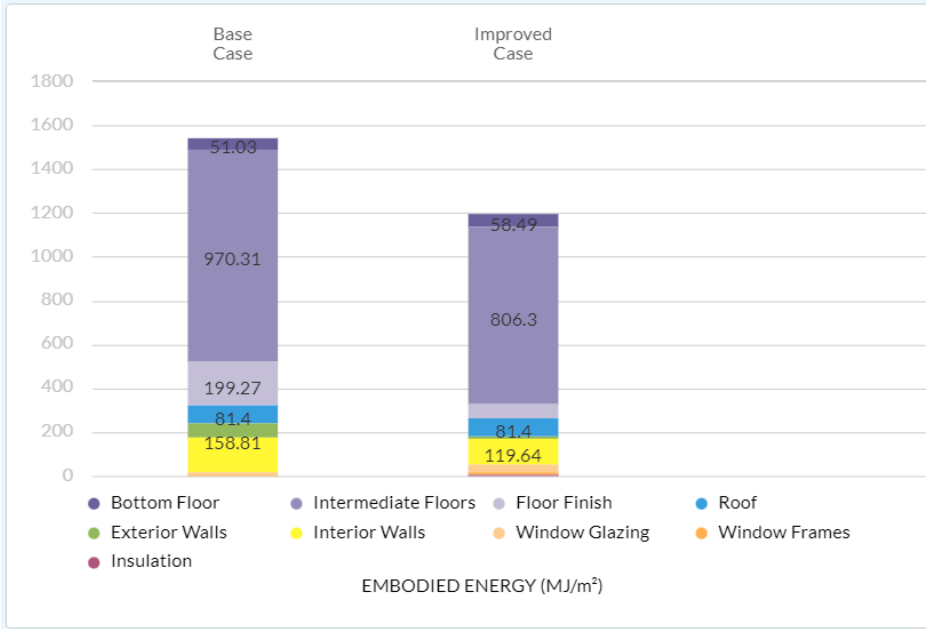

Figure 2: Base case vs improved case result for the pilot building.

Conclusions

In-situ reinforced concrete (ISRC) is partially substituted with Pulverized Fly Ash (PFA) and Ground Granulated Blast Furnace Slag (GGBS) to observe the effect on embodied energy (EE) at the building scale and on material efficiency. The results show that the final EE and EE saving in the existing pilot building was found 1200 MJ/m2 and 40164,22 GJ. Calculated EE savings- 40164.22 GJ in the pilot project showed substantial savings. The results also show that the use of “ISRC with >30% PFA” and “ISRC with >25% GGBS” content, increased the material efficiency by 34.43% and 34.72%, respectively Based on the methodology used, substitutions succeeded in reducing the final EE both on the building scale and on material efficiency. These results show that the use of recycled materials like PFA and GGBS is very important to drastically reduce the EE in a building. Replacement levels for GGBS and PFA in the research varied from 25% to 30% as applicable. Future research can use higher levels since it is common in the industry. Using GGBS and PFA also helps to reduce air and water pollution, leading to more sustainable construction.

Abstract

As technology advances and resource reliance grows, destruction of the environment and the threat of exhaustion of natural resources have increased. To address these issues, a global framework has been developed, most notably the Paris Agreement, which was signed in 2015. Industries have been given social and environmental duties in this path. Construction companies are among those that take over these duties, as they consume a lot of energy across the globe. Therefore, sustainability research in the construction industry has gained prominence such as sustainable construction and green building practices. Even so, as the most powerful influencer on sustainable innovation, the government does not necessitate contractors to build higher grade green construction, and little does, while the overwhelming number of buyers have little desire for sustainable green houses. While this real-life relation between two parties forms a conflict, on paper this represents a suboptimal equilibrium. This paper utilizes game theory, particularly the Prisoner's Dilemma model, to illustrate strategies to emission reduction and greenhouse gas (GHGs) mitigation measures in Turkey's construction industry, as well as to forecast whether incentives might help eliminate those barriers. As a result, it states that in order to encourage better level green building, the government now must offer incentives to both contractors and buyers, which would be relatively inexpensive for the Reserve Bank. Finishing up with lower energy costs and gain of support, prestige, and unity as the market moves to a new equilibrium, better for all involved throughout the construction industry.

Keywords: *construction industry, construction management, game theory, green building, prisoner's dilemma, sustainable building, Turkey.*

Introduction

Greenhouse gas levels are currently at their greatest in 2 million years and continue to grow (World Meteorological Organization, 2021). Climate change has become one of the most critical issues ever tackled in the areas of civil society stability and security, access to natural resources, and the environmental preservation of the ecosphere. Accelerated warming and the expected high rate of climate change consequences will create a new and unpredictable world, necessitating adaptation by both human society and natural ecosystems. Sustainable

infrastructure, as stated in the United Nation's (UN) 9th Sustainable Development Goal (SDG), is one of the most lucrative techniques of fostering innovation for a greener future. Green construction has a significant impact on climate change mitigation. Green buildings have earned popularity in past years as a notion that aims to satisfy both ecological and financial goals by utilizing resource-efficient procedures through a building's existence. To support the green construction approach, numerous nations, including Turkey, have created a wide range of grading standards as well as other regulatory measures (Karademir, 2021). This study not only offers a decision making foundation for the construction industry have optimum strategies within diverse situations, but it also serves as a guideline for the administration to develop a suitable procedure that is favorable to a sector that reduces carbon emissions in order to combat climate change.

Green Building Evaluation Tools

The present movement to promote constructing energy efficient buildings date back to the early 1970s, as oil prices skyrocketed and concern over future fuel resource got tangible. Through the development of solar, wind energy and insulation systems, the advancement of green technology has surged, not just for transportation but also for buildings. However, as oil prices got less towards the 1980s, green initiatives were stalled. Based on the current political and administrative circumstances, green construction in the United States as well as Europe, has grown with occasional government backing. The environmental movement gained traction in Europe and the United States, with green building evaluation methods first appearing in the early 1990s (Cohen, 2017).

Although, the criteria considered while developing the green building evaluation are expressed with different names in different systems, in general, the criteria cover a variety of corresponding subjects. These subjects mainly include but are not limited to the following:

1. The selection of the land where the building is located,
2. Its location on the land,
3. Its relationship with its physical and social environment,
4. Its ability to provide the users with comfort needs such as,
    a. thermal, visual and acoustic ease,
5. The CO_2 emission,
6. The amount of water consumption,
7. The need for operation and maintenance/repair and
8. The materials used in the building.

Certification systems do not go beyond the scope of their own standards and regulations of the countries in which they are developed, and they also provide a general framework for sustainable buildings, as they provide a community of information by referencing these documents (Kobaş, 2011). In general, it is aimed to encourage the buildings to be environmentally friendly and to be built in a way that causes the least damage to the nature. However, since the development level and geographical conditions of the countries are different, each country has its own priorities. For instance, the most important criterion for arid countries is the efficient use of water and the energy efficiency criterion is considered in energy-importing countries. Due to the conservation of natural resources, attention is paid to the effective and efficient use of materials (recycling, reuse of materials) in developed countries (Işıldar, 2018). In each certification system, there are criteria such as energy and water efficiency, interior space, environmental quality improvement, operation and maintenance and

repair optimization, waste and toxic reduction, and each criterion is determined in line with the characteristics of the regions where the need arises. Hence, the scores vary in this context.

Green Building Standards in Turkey

The first developments in green buildings in Turkey started with the establishment of the Turkish Green Building Council (ÇEDBİK) in 2007. Then the establishment was followed by, the "First International Summit of Green Buildings" event held in Istanbul in February 2012, and in this event, beneficial information was shared about environmentally friendly policies, green economy, greening existing buildings, life in green buildings, smart cities, environmentally friendly building materials and their production (Gelişen & Güzelkokar, 2019). Now, ÇEDBİK has certified 518 projects throughout Turkey, in addition to its 425 LEED and 70 BREEAM projects (ÇEDBİK, 2022).

In Turkey, no insulation element has been applied to approximately 77% of the building stock (Ministry of Industry and Technology, 2021). When the existing construction in Turkey is compared to an average building in Sweden, a building in Sweden can be constructed approximately 2.8 times less than a building in Istanbul and 3.6 times less than a building in Ankara, with less fuel consumption. These data are remarkable in terms of understanding how much green building practices are needed in Turkey and the distance to be covered even in terms of insulation and green material.

Ever since the green building certificate systems emerged, it has been observed that the logic of the systems resembled each other. While the countries issuing the systems implemented their own directives, the countries that had no certificate systems had started developing their own systems based on the universal standards. As of 2007, ÇEDBİK pioneered the studies carried out in this context in Turkey. The certification system, called "B.E.S.T." was prepared for the development of the National Green Building Certificate for Turkey, with the guidance of the members of the association and the international certification systems (ÇEDBİK, 2019). Valid only for the housing category, from newly built single-family houses to residences with a total usage area of over 20,000 m^2, the system is applicable for a wide scale. Main criteria considered for the BEST Certification is shown below.

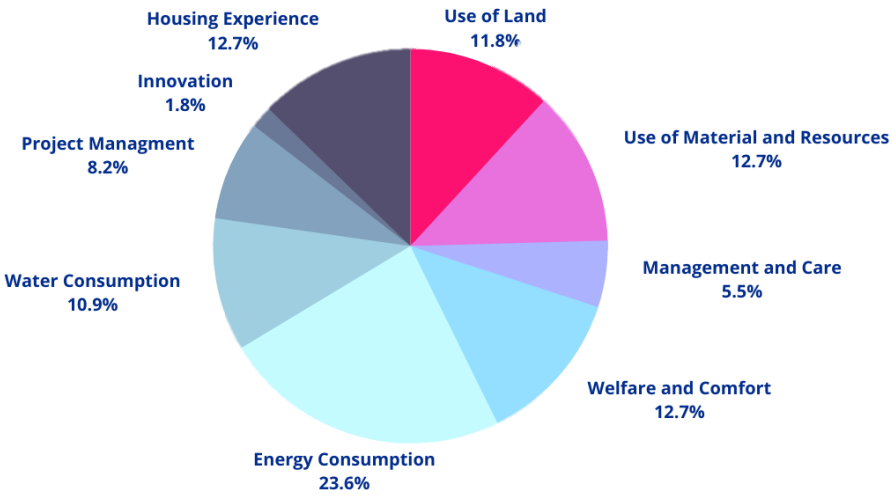

Figure 1: B.E.S.T. certification score distribution.

Case Study

The utilization of mathematical models to anticipate the behavior of sophisticated logical individuals in scenarios of dispute or collaboration is known as game theory (Owen, 2012). It is used in many areas, such as industries, politics, and entertainment. It can be used to manufacture strategies that steer collaborating or warring players in the way that the game planner desires. Game theory may detect and interpret the behaviors of different parties involved in construction project obstacles, as well as define how relations between multiple parties can result to a project's evolution. A few of the issues come from distrust among social, political, and economic parties, that leads inevitably to suboptimal activity patterns. The Prisoner's Dilemma game is built upon the same distrust concept, and this paper examines how to lessen it through the context of green building. The minimization necessary to describe a complicated and layered real-life situation as a game is a major constraint of game theory. Yet, this does not subtract from their predictive potential. Foundationally, game theory is the investigation of strategic interdependence situations, which means that first party's actions impact both its own and the second party's benefit, and conversely. Strategic interdependence is difficult to manage since parties must predict, act, and respond. Especially in this case, willful ignorance does not benefit any parties. The Prisoner's Dilemma is the earliest and therefore most discussed model in game theory, with a clear resolution.

Players

This model comprises 3 major interacting players:

1. Potential Buyer

Buyers of condominiums and houses may select green constructions in order to reduce energy consumption or delay climate change. When a buyer arranges and constructs their own house, they possess the most control. Most house purchasers, nevertheless, purchase units in multi-family compound structures and have no to little direct influence over their design and construction. Furthermore, since the market is a sellers' market, house buyer's impact in Turkey is more restricted. Furthermore, "greenness" is rarely a prominent criterion in apartment selection by generally being trumped by other variables such as pricing, service accessibility and quality, particularly school quality, and closeness to job location (Fundaminsky, 2007). The first payment is crucial. As per Turkey's Central Bank's (TCMB) annual assessment on the housing index, one of the severe property crises on record is faced. According to the TCMB, the median cost of a house in Istanbul is 1.6 million Turkish lira, which is approximately $110,000 in the year 2022, rising from 750,000 Turkish lira the year before (Data Governance And Statistics Headquarters Survey And Indices Directorate, 2022). According to the TCMB, property prices around Turkey rose an average of 96.4 % per year in February 2022, with Istanbul taking the lead at 106.3 %. Also, in the cities Diyarbakır and Şanlurfa, in the country's southeast, which are considered the least developed region of the country, the growth has reached 111%. To summarize, most Turkish purchasers have little authority or motivation in assessing if their house is environmentally friendly.

2. Construction Entrepreneur

Some Turkish businesses have lately begun to create green buildings or adapt existing structures for certification. In Turkey, there are now 779 certified buildings, 7 award-winning constructions, and 2 case studies (GBIG, 2022). Many constructors, however, remain cautious,

fearing that the expenditure of green building, particularly at a more demanding degree, would be more costly in terms of both time and money. While house purchasers may be unable to bear the additional expenditures, this skepticism appears to be more prevalent in the edge, among constructors, where buying power is smaller and profitability is more precarious. Individual financers are sometimes hesitant to take on the overall price of certification and by doing so suffer the "liability of newness", (Stinchcombe, 1965) even though green building is not a new nor uncommon approach in around the globe, supporting more of a "laissez-faire" policy.

3. Government

The government can participate in green building in a variety of ways, including research, management, legislation, and subsidization. As green construction standard in Turkey is currently voluntary at national scale, hence the government does not control its implementation. However, the government is already participating in supporting research and sponsoring initiatives through its ministries and may in the future implement obligatory measures. Governments, particularly those in the European Union, have provided subsidies for green building in order to comply with EU requirements (such as restrictions on nonrenewable energy usage) or to secure availability of subsidies and grants.

Player Strategies and Utilities

The Prisoner's Dilemma in this paper is a model wherein the 3 players face the following strategic quandaries at the same time.

- *Potential Buyer*: buying a greener apartment | buying a conventional apartment
- *Construction Entrepreneur*: building green | building conventionally
- *Government*: prioritizing green building | following a laissez-faire policy

The benefit that the player will acquire is determined by the following decisions:

In the case of the Potential Buyer:

Buying a house at a cheaper initial price.

If not, recovering money over time by cutting energy costs and achieving a greater unit monetary worth in the event of resale. Also, helping the environment recover from the on-going climate change.

In the case of the Construction Entrepreneurs:

Stronger profit potential.

If not, stronger monetary threat.

In the case of the Government:

Conserving energy and satisfying global expectations while demonstrating concern about citizen wellbeing and environmental concerns.

If not, exposed to subsidy expenses, consisting of the budgetary and administrative costs of management and implementation.

Parameters

Table 1. Parameters defined in the game.

Parameter	Definition
T_0	Conventional Unit Price
T_1	Moderate Level Green Unit Price
T_2	Certified Level Green Unit Price
α	Potential Buyer's eagerness for potential savings
pot	Potential savings
β	Potential Buyer's level of awareness and worry regarding climate change
env	Environmental return of the built building
D_0	Conventional Unit's Building Cost
D_1	Moderate Level Green Unit's Building Cost
D_2	Certified Level Green Unit's Building Cost
D_3	New Skill Acquirement Cost
S	Subsidy Cost
A	Governmental Acquisition - global benevolence, electoral support, and energy efficiency

In this model it is assumed that $T_0 < T_1 < T_2$ and $D_0 < D_1 < D_2$.

Accordingly, the benefit of the Potential Buyer is,

$$U_i = -P + \alpha * pot + \beta * env + S$$

$$\frac{\partial U_i}{\partial \alpha} = pot$$

The greater overall long-term reductions generated by greener construction technology, the greater the benefit to the wellbeing of unit purchasers. Likewise, for β:

$$\frac{\partial U_i}{\partial \beta} = env$$

The more value that unit purchasers place on the planet, the greater the impact of high-quality green buildings are to their wellbeing. If both α and β rise over time, enhancing the wellbeing of green building owners, the government will have the option to withdraw subsidies or, alternately, builders will be able to charge higher prices for green buildings, boosting their incentive to create such housing units.

The Game

The present status of the Turkish market may be represented as a concurrent 3-player game utilizing methods of game theory. The benefit of the Construction Entrepreneurs, Potential Buyers, and Government are represented by the first, second, and third expressions in each cell, sequentially. The colored cell in the first matrix represents the existing balance, while the colored cell in the second represents the intended outcome.

In the case that the Government provides no subsidies therefore no green buildings are constructed:

Table 2. The matrix for the case that the government does not provide subsidies.

Potential Buyer / **Construction Entrepreneur**	Conventional Building	Green Building
Conventional Building	$T_0 - D_0, -T_0, 0$	$T_0 - D_0, -T_0, 0$
Moderate Level Green Building	$T_0 - D_1 - D_3,$ $-T_0 + (T_1 - T_0), R$	$T_1 - D_1 - D_3,$ $-T_1 + \beta * env, R$

In the case that the Government provides subsidies therefore green buildings are constructed:

Table 3. The matrix for the case that the government provides subsidies.

Potential Buyer / **Construction Entrepreneur**	Conventional Building	Green Building
Conventional Building	$T_0 - D_0, -T_0, 0$	$T_0 - D_0, -T_0, 0$
Moderate Level Green Building	$T_0 - D_1 - D_3 + S,$ $-T_0 + (T_1 - T_0), R$	$T_1 - D_1 - D_3 + S,$ $-T_1 + \beta * env, R - S$

As demonstrated by the matrices, if a customer wants a green house but none are available, they will be required to compromise for a conventional house. In contrast, if a buyer inclines for a conventional unit however the construction entrepreneurs construct green, they will purchase a green unit, yet pay the cheaper option of a conventional one since they will only be spending P_0. Nevertheless, whenever they sell their house, it shall be worth the same as a green one. As a result, they will have a projected return (Luterbacher, 2021) of P_1-P_0. Moreover, because this buyer initially intended to purchase an average unit, they are unlikely to be concerned about the planet, and hence their β worth is 0. Ultimately, because the green units are on the moderate level, their efficiency gains are minimal, and so the parameter sav has a value of 0 (As labelling a unit as green increases its apparent worth and hence its value, even though it cuts little energy).

The Turkish market is currently in an equilibrium state in which construction entrepreneurs chose to construct conventional buildings or moderate green houses, whilst government avoids issuing subsidies and spending surveillance expenses, and purchasers avoid the extra cost of green buildings. These methods may be in equilibrium in the game, since:

$$T_0 - D_0 > T_0 - D_1 - D_3$$

The Turkish economy's objective is to achieve a new equilibrium wherein constructors and buyers prefer green housing, with the motivation of multiple factors explained through the paper. Nevertheless, such a shift is not likely to occur if the government retains a laissez-faire policy, owing to distrust among participants, similarly to the Prisoner's Dilemma phenomena. The benefit for each player is unquestionably greater when greener policies are used, as shown below.

For Construction Entrepreneurs:

$$T_1 - D_1 - D_3 + S > T_0 - D_0$$

For Potential Buyers:

$$-T_1 + \beta * env > -T_0$$

For Government:

$$R - S > 0$$

In order to reach an equilibrium achieved by countries such as England, Germany or France, this paper suggests that the government should acknowledge the higher gain of green building than conventional building, while two kinds of subsidies are brought in the game for a sway in parties' decision. To summarize, the government's incentive system would provide both builders and buyers - for certified green projects, either through direct subsidies or by granting lower interest to both buyers and builders of green buildings.

The Remodeled Game

After the establishment of the new incentive system, the two new variables are as shown:

Table 4. Newly defined parameters for the Remodeled Game.

Parameter	Definition
S_1	Buyers' Subsidy
B	Government's Electoral Advantage

The current matrix is as shown:

Table 5. The matrix for the case that the government provides subsidy also for the buyers.

Potential Buyer / **Construction Entrepreneur**	Conventional Building	Green Building
Conventional Building	$T_0 - D_0, -T_0, 0$	$T_0 - D_0, -T_0, 0$
Certified Level Green Building	$T_0 - D_2 - D_3 + S,$ $-T_0 + (T_1 - T_0) + \alpha * pot,$ $R - S$	$T_2 - D_2 - D_3 + S,$ $-T_2 + \alpha * env + S_1,$ $R + K - S - S_1$

Since this green building is certified, it conserves energy, therefore sav is included to the buyer's benefit model. If a buyer purchases a certified green apartment for the same price as a standard one, they will not obtain any governmental assistance.

The inequalities below compare each party's predicted benefit in the new equilibrium to the benefit they gained in the previous one.

For Construction Entrepreneurs:

$$T_2 - D_2 - D_3 + S > T_0 - D_0$$

For Potential Buyers:

$$-T_2 + \alpha * pot + \beta * env + S_1 > 0$$

For Government:

$$R + B - S - S_1 > 0$$

The proposed incentive could enable the market to shift to a better-for-all equilibrium for which constructors construct higher-level green buildings, buyers purchase them, and the government gives incentive both for buyers and constructors to promote the practice. Following this amelioration, the methods are in balance, as shown below:

For Construction Entrepreneurs:

$$T_2 - D_2 - D_3 + S > T_0 - D_0$$

For Potential Buyers:

$$-T_2 + \alpha * pot + \beta * env + S_1 > -T_0 + P_2 - P_0 + \alpha * pot$$

For Government:

$$R + B - S - S_1 > R$$

Conclusion

As the aftermath of many technological advancements, increased dependence on energy has brought up environmental destruction and uncontrolled consumption of natural resources. As excessive and wasteful consumption results in soil, air and water pollution problems, this has prompted organizations and states, and the concept of sustainability has gained importance.

With a big responsibility regarding this matter, construction industry has a major role in helping the globe recover from the ongoing pollution and climate change. When enough attention is given into what changes could be done in this sector, green buildings are one of the most promising reforms that fosters innovation.

For success in sustainability, it is necessary to set standards and monitor the process through measurement. Businesses are expected to care about both quality and the environment in their strategic planning and implementation processes. In this direction, criteria should be determined in terms of sustainability management and certification is required. Since the environmental, social and economic dimensions of each country are unique, it is thought that it would be appropriate for each of them to have their own certification system. However, it is generally seen that countries cannot always establish their own systems. Therefore, internationally certified frameworks are used to evaluate construction all over the world as well as a few more recent tools that are in use (such as the B.E.S.T. in Turkey).

Currently, Turkey's green building criteria may be inadequate to contribute significantly to greenhouse gas reduction and energy efficiency. A further development of the regulated green building standard is acknowledged as a necessity, which is likely to motivate those seeking to reduce GHG and save energy to function through some form of the green building regulation (Pamuk, 2016). Throughout this paper, it is believed that certified green construction standards can help achieve this purpose. It is also proposed that government incentives be used to encourage constructors and buyers to choose buildings with far higher levels of green construction standards.

Utilizing game theory, it has been demonstrated that supplying financial subsidies (while ensuring surveillance and implementation of the criteria) for certified green buildings might very well improve urban residents' wellbeing while enhancing government prestige, improving efficiency, and working the environmental issues. Finally, it is proposed that once such green building standards are implemented in a greater amount of construction, construction at that level will become increasingly more common, even if government subsidies are lowered or withdrawn, because the mistrust and uncertainty that leads to the Prisoner's Dilemma will be reduced.

Abstract

Several environmental uncertainties and dynamic nature of the construction industry render it one of the riskiest industries around the globe. Hence, occupational accidents are omnipresent in the industry, which requires a robust safety risk management plan to reduce the number and severity of construction accidents. This study develops a machine learning model to predict permanent disability status of construction workers. To achieve this objective, a dataset of construction accidents that occurred in Turkey was collected in the first step. Then several data preprocessing methods were adopted to prepare the data for prediction task. For the machine learning application, Support Vector Machine (SVM) was used. The findings show that the SVM yielded the recall values of 0.6988 for classifying permanent disabled workers. The results of the feature importance analysis also show that working days lost, type of injury, and daily wage were the most significant attributes in the model. The findings are expected to help construction professionals develop safety management strategies to minimize accidents that may result in permanent disability.

Keywords: *artificial intelligence, construction safety, machine learning, occupational accidents, support vector classifier.*

Introduction

Safety management is one of the most critical concerns in the construction industry (Koc et al., 2021). Adverse safety outcomes encapsulate accidents, injuries, disabilities, fatalities, along with the social and economic costs (Feng et al., 2015; Forteza et al., 2017). Therefore, strategies to improve safety performance of the industry are necessary to help construction workers increase their work and life conditions.

Occupational accidents resulting in permanent disability are regarded to be among catastrophic events in construction projects. This is a serious problem since more than 11% of all disabilities occur due to occupational accidents (Koc et al., 2021). After occupational accidents, early designation of disability status of construction workers may help construction professionals plan their workflows, construction workers consider permanent disability

application, institutions use it as a benchmark, and safety professionals understand in what conditions permanent disability occurs. Therefore, predicting permanent disability status of construction workers have diversity of advantages. In this vein, machine learning methods can be used effectively to detect the output variables.

This study aims to develop a prediction model to identify permanent disability status of construction workers. To achieve this objective, the dataset consisting of construction accidents experienced in Turkey was captured and several preprocessing steps have been performed. Then, a machine learning application was performed by means of support vector machine (SVM). Feature importance was also explored to increase the interpretability of the research findings. Overall, this study is expected to provide practitioners with valuable insights about the permanent disability conditions of construction workers.

Methodology

This study investigates the permanent disability status of construction workers using machine learning approach. The flowchart of the analysis procedure is presented in Figure 1. First, the dataset related to construction accidents occurred in Turkey was collected from the Republic of Turkey, Social Security Institution (SSI). Then the output variable was selected as permanent disability status of construction workers which include permanent disability (PD) and non-permanent disability (NPD).

In order to predict the output variable eight input attributes were selected through a diligent investigation of the dataset (Table 1). These include education level, working days lost, type of injury, injured body part, material used, type of construction, number of past accidents of workers, and daily wage. Then, missing values, inconsistencies, and duplicates were removed from the dataset, which ensured the size of the dataset as 47,938 (including 1,074 PD and 46,864 NPD). Then the categorical variables (i.e., education level, type of injury, injured body part, material used, type of construction) were subjected to label encoding to convert the categorical attributes into their numerical counterparts (Sarker et al., 2020a). The following step covers the data scaling to minimize effects of the range and magnitude of the attributes on the prediction output. Among several data scaling methods, standard scaler due to its wide applications was used (Sarker et al., 2020b; Swarna Priya et al., 2020; Thippa Reddy et al., 2020).

The dataset was divided into two major categories as training and testing sets. This was achieved by randomly taking the 70% and 30% of the dataset, respectively. This step was followed by the data resampling. Data resampling is necessary because there was an imbalance between minority (PD) and majority (NPD) classes. Hence, without data resampling, the model can predict all the cases as NPD with high but misleading accuracies. In this respect, random under-sampling (RUS) was used as one of the most widely adopted resampling strategies (Allah Bukhsh et al., 2020; Kang & Ryu, 2019) and considering the time efficiency into account (Liang et al., 2020). In the RUS algorithm, instances of the majority class are randomly removed from the dataset until the balance in the class distribution is achieved. It is important to note that data resampling strategies should be implemented only on the training set, since testing set, which is used to measure the model performance, should still be imbalanced similar to real-life applications.

As a major step of the analysis SVM method was used to predict output labels. The main principle of SVM relies on the statistical learning theory along with the structural risk minimization procedure (Cortes & Vapnik, 1995). Several classes of data points are identified in terms of a line, i.e., hyperplane in the SVM method (Koc et al., 2022). An optimal hyperplane is one that achieves the minimum of an error as well as maximum of the margin among all hyperplanes (Mahmoodzadeh et al., 2021). Kernel function used in the SVM method is significantly important for the model performance. Radial basis function (RBF) kernel covers a large function space compared to other kernels and has a flexible structure with generalization ability, while generating all relationships speedily (Yu et al., 2011). Therefore, we adopted RBF SVM to predict permanent disability status of construction workers. It is important to note that all the inertial parameters of SVM were determined by means of a trial-error.

After the developed models are fitted with the training sets, model performance is evaluated by blinded testing set. In this respect, recall and area under the receiver operating characteristic (AUROC) were used to examine the performance of the proposed model. Recall is determined by taking the rate of true positive instances to the sum of true positive and false negative instances (Buckland & Gey, 1994). In other words, it measures how well the label A is predicted as A. On the other hand, AUROC plots two metrics as true positive rate (TPR) and false positive rate (FPR). By taking the TPR at the vertical and FPR at the horizontal axes, area under the curve can be calculated (Dai et al., 2015). Despite the accuracy being another performance evaluation metric (Attal et al., 2015), AUROC is documented to be more robust metric when there is an imbalance between output labels (Choi et al., 2020). In addition, AUROC makes the interpretation and representation of the results easier, hence used in this study. After the performance of the model is evaluated, the random forest feature importance was used to identify the most influential attributes in the model.

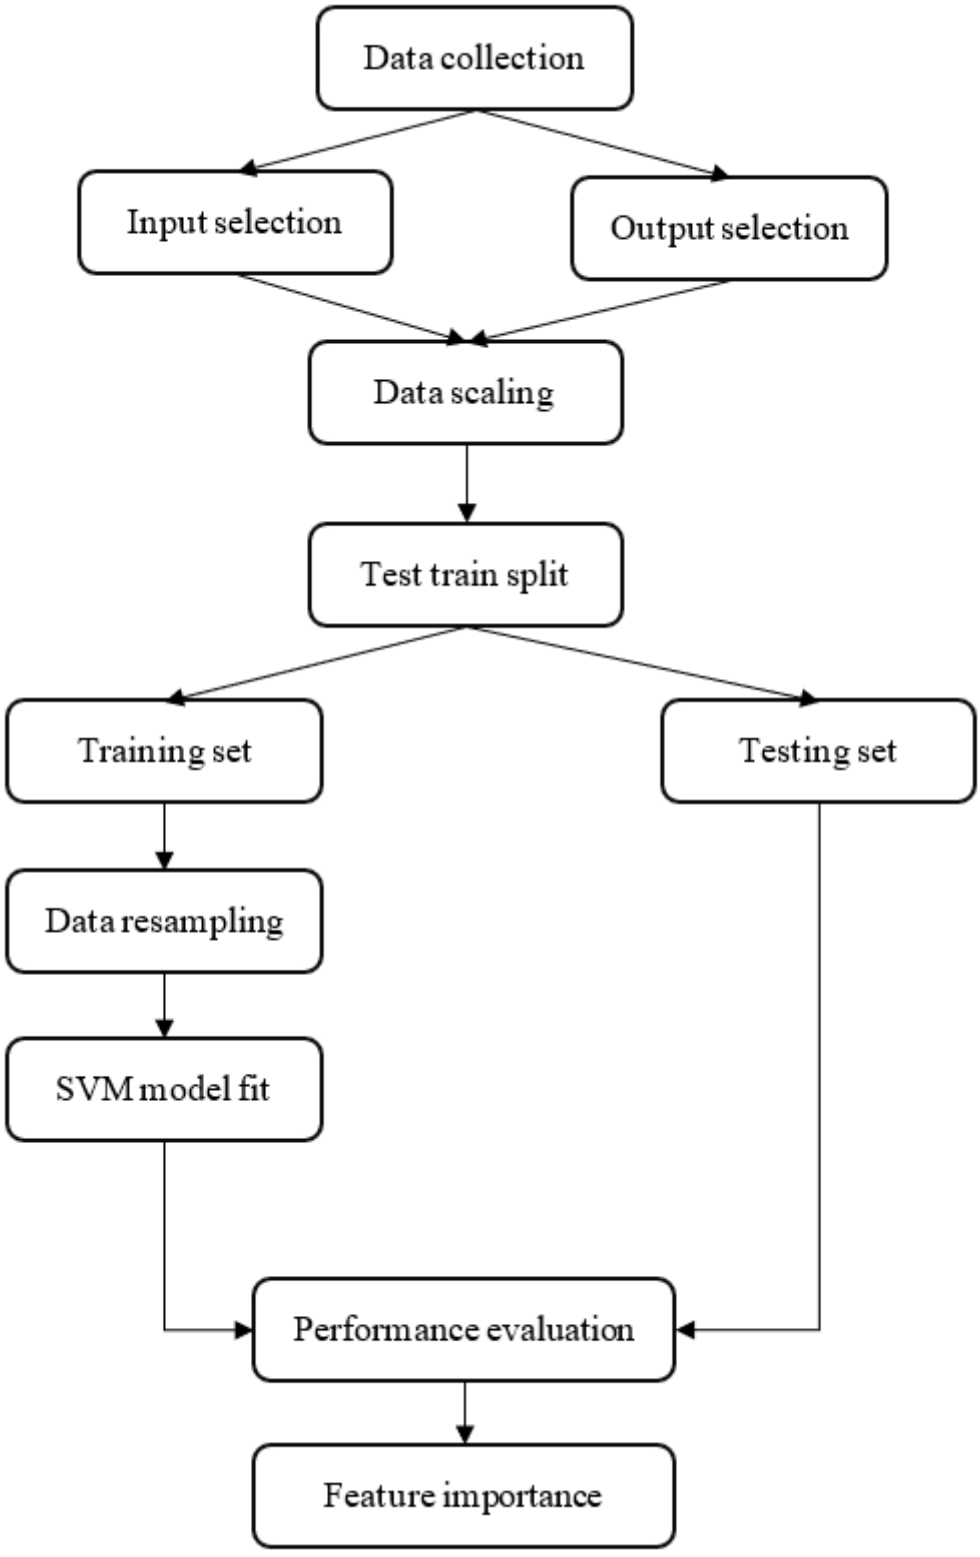

Figure 1: Flowchart of the study.

Table 1. Features used in the prediction model.

Features	Type	Descriptions
Education level	Categorical	This indicates the education level of worker including illiterate, only literate, elementary, secondary, high, graduate, Master, PhD.
Working days lost	Numerical	This indicates the number of days that the worker cannot work due to the accident.
Type of injury	Categorical	This indicates the type of injury of the worker including acute, chemical exposure, temperature exposure, fracture, shock, fluid effects etc.
Injured body part	Categorical	This indicates the part of the body of the worker injured due to occupational accident including, head, hand, leg, shoulder etc.
Material used	Categorical	This indicates the material used during the accident including construction machinery, construction materials, assembly kits, hand tools etc.
Type of construction	Categorical	This indicates the type of the construction that the accident is experienced including residential projects, road projects, water projects, etc.
Number of past accident	Numerical	This indicates the number of past accident of workers.
Daily wage	Numerical	This indicates the daily wage of the worker.
Permanent disability status	Binary	This indicates the output label including permanent disability and non-permanent disability.

Results

This study focuses on the permanent disability status of construction workers. First, the dataset (1,074 PD and 46,864 NPD) captured from the SSI was divided into testing and training sets, with 30% and 70% of the dataset. Hence, the size of the testing set become 332 PD and 14,050 NPD workers. On the other hand, the training set was subjected to RUS algorithm to equalize two output labels, i.e., PD and NPD. This process resulted in 742 PD and NPD instances, accounting the total number of 1,484 instances in the training set. In other words, balanced 1,484 cases were used for model training while imbalanced 14,382 cases were used for testing the model. Table 2 shows the changing size of the dataset regarding PD and NPD classes.

Table 2. Size of the datasets.

Dataset	Disabled (PD)	Non-disabled (NPD)	Total
Raw data	1,074	46,864	47,938
Test data	332	14,050	14,382
Train data	742	742	1,484

Testing performance regarding recall values are shown in Figure 2. The findings show that the SVM model achieved the prediction rate of 0.6988 for predicting PD class while it was 0.8797 for classifying NPD instances as NPD. In addition, Figure 3 shows the ROC curve of

the model performance. The findings show that the model achieved the prediction power of 0.84 of AUC, which indicates a good model performance (Choi et al., 2020).

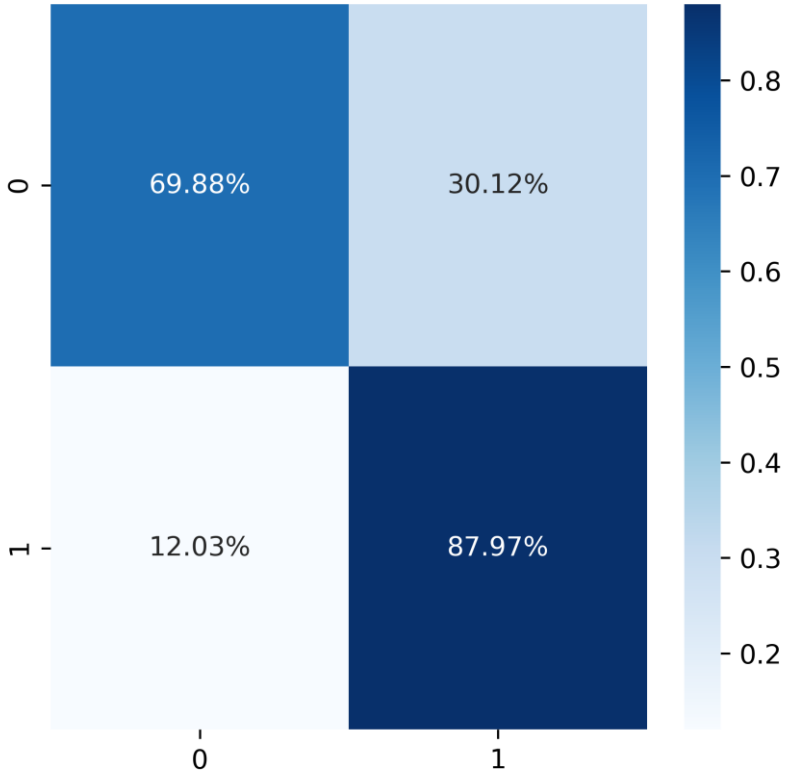

Figure 2: Confusion matrix of the model.

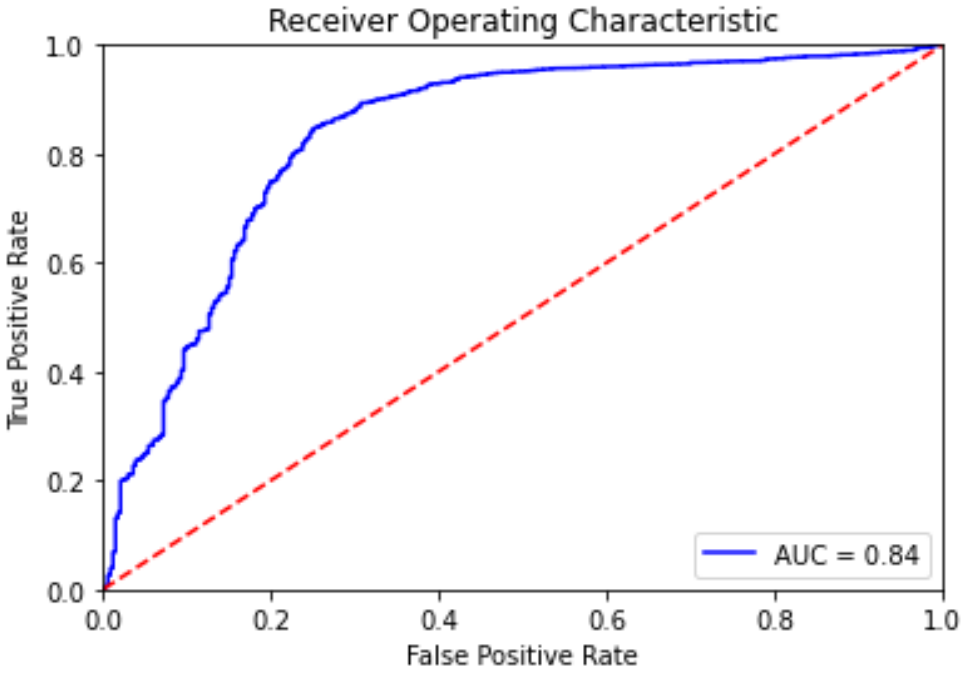

Figure 3: Receiver operating characteristic curve of the model.

This study further explored the impact of features on the predictions. Figure 4 shows the random forest feature importance results. The findings show that working days lost, type of injury, daily wage, and injured body parts were significant attributes. Working days lost can address the severity of injuries, thus can be related to permanent disability, which support its high effect on the prediction. On the other hand, some injury types can be related to specific outcomes on the workers' bodies, which can be associated with the severity and type of disabilities. Similarly, some body parts such as arm can be related to disability status of workers (Koc et al., 2021), while some body parts are affected only by minor injuries. This can also be related to the job of the workers, and daily wage can be influential in this regard since daily wage can provide some means to identify the job of the worker as well. Overall, this study shows that the characteristics that define the injury and severity of workers are highly effective in understanding the permanent disability of construction workers.

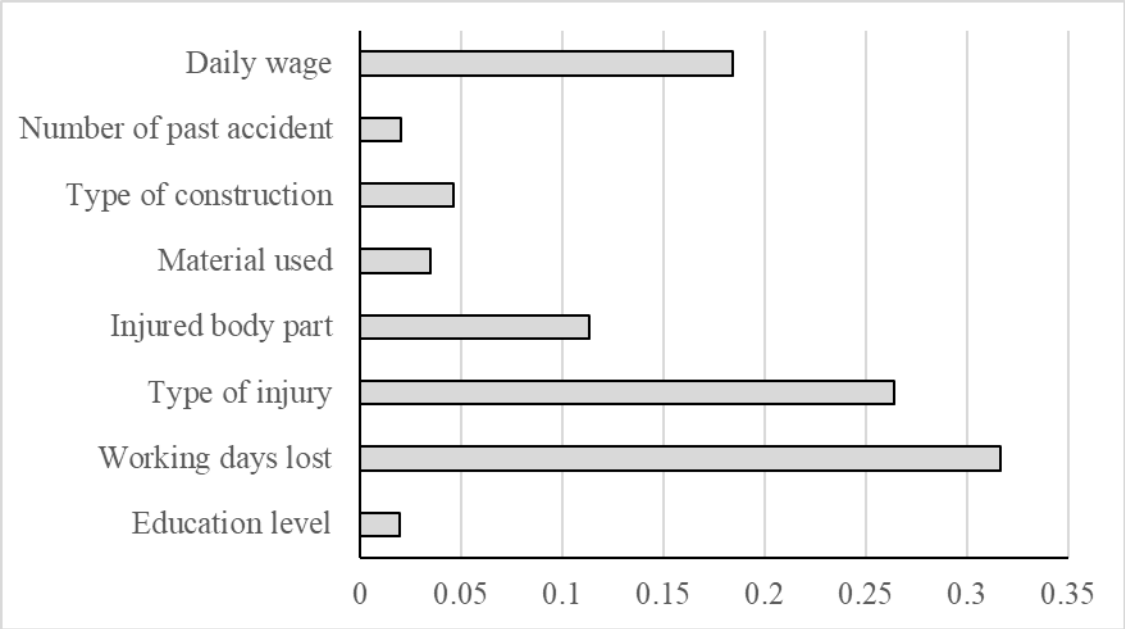

Figure 4: Feature importance.

Conclusion

This research investigates the permanent disability of construction workers in a binary classification problem. In this regard, machine learning-based solution provides significant means to understand and explore in what conditions permanent disability occurs. After several preprocessing elements, this study adopted the SVM method for detecting permanent disability status of construction workers. The findings show satisfactory model performances. In addition, attributes that define the type of injury, the affected body part, the severity of accident, and job of the worker were found to be influential attributes. This study presents some limitations similar to many studies. First, parameter optimization techniques can provide higher accuracies with improved model configuration. Besides, permanent disability status can also be predicted with only pre-accident attributes with a cost of accuracy. Still, it can provide significant insights for professionals to prevent accidents that might result in permanent disabilities. With methodological and practical improvements, we believe that the accidents that lead to permanent disability can be prevented with proactive safety risk management.

Abstract

In Turkey, the construction industry is almost always among industries with poor health safety records. In this respect, a broader evaluation of past studies may reveal the current health and safety performance of the construction industry and provide a useful framework for future efforts. The aim of the study is to conduct a systematic literature review of health and safety studies carried out in Turkey. To this aim, past studies from 2009 to 2021 were evaluated regarding topic, method(s), and findings in order to present a review of these studies. Overall, the results obtained may help to identify the current health and safety performance in the construction industry and to guide researchers for future studies about health and safety issues in Turkey.

Keywords: *construction industry, health and safety, review, Turkey.*

Introduction

The construction industry can be regarded as one of the most dangerous industries in terms of occupational incidents (Carter & Smith, 2001). Occupational accidents in construction cause human tragedy and huge economic losses (Kartam, 1997). Expenses of occupational accidents and illnesses may cause 6% of the total construction turnover (HSE, 1997). Each 1 US Dollar investment in health and safety precautions will save 2.27 US Dollars (Tang et al., 2004). Risk potential of a fatal accident in the construction industry is five times more likely than in a manufacturing-based industry (Davis & Tomasin, 1990). The main causes of construction accidents can be listed as: (i) lack of proper training, (ii) deficient enforcement of safety, (iii) lack of safety equipment, (iv) unsafe methods or sequencing, (v) unsafe site conditions, (vi) not using provided personal safety equipment, (vii) poor attitude toward safety, and (viii) isolated, sudden deviation from prescribed behaviour (Toole, 2002). According to Arslan and Kivrak (2009), lack of safety training was found as one of the important factors that can cause construction accidents in Turkey. Larsson et al. (2008) stated that key point to safety lies within the management (Larsson et al., 2008). Lack of training can be attributed to poor safety and health management by the companies. Therefore, occupational health and safety (OHS) issues of the construction industry have great potential to be investigated in academic studies. The aim of the study is to conduct a systematic literature review of OHS studies carried out in

Turkey. To this aim, past studies from 2009 to 2019 were evaluated regarding topic, method(s), and findings in order to present a review of these studies.

Literature Review

The literature on safety issues is vast due to the continuous interest of researchers. ‘There are numerous studies in the literature on OHS. Based on the language of the paper, the exclusion of duplicates, the inclusion of peer-reviewed journal articles alone, and the inclusion of publications based on the subject in Scopus and Web of Science, thirteen papers were obtained. The selected studies for this research were listed in Table 1. Table 1 categorizes the studies based on aim of the study, the used method in the study, utilized data and obtained results.

Table 1. Past studies from 2009 to 2019.

Reference	Aim	Method	Data	Result
Gürcanlı (2009)	To investigate the characteristics of accidents and to draw the attention of safety professionals.	956 expert reports submitted to criminal and labour courts were investigated.	956 expert reports and 971 fatal and non-fatal injury reports submitted to criminal and labour courts were examined in detail.	The negligence of basic safety rules in accidents caused by non-employee or third parties.
Gürcanlı and Müngen (2013)	This study was carried out to better understand the new laws and regulations among academicians as well as employees.	By examining the expert reports, the result of the incident, the date and time, the main causes of the accident, the type of the construction site, the profession, the responsible parties.	Expert reports on work accidents.	Inappropriate and unsatisfactory conditions, and the parties responsible for occupational injuries and an in-depth analysis of each type of accident.
Ulubeyli et al. (2014)	To view general information about OHS conditions in the Turkish construction industry from the perspective of construction workers.	A survey was conducted with 800 workers employed in 32 construction projects in Turkey.	Survey results were analysed in accordance with statistical methods.	Uninsured workers in the Turkish construction sector industry. Lack of unionization.

Table 1. Past studies from 2009 to 2019 (continued).

Gürcanlı et al. (2015a)	The purpose of this study is to combine construction project planning, risk assessment activities, and construction cost estimation into the cost of security of value and its distribution throughout a project.	Cost analysis was performed, and the results were analysed comparatively	Drawings, technical specifications, and invoices of 25 concrete residential buildings in the province of Istanbul were collected, construction sites were visited and information on OHS practices was collected from field engineers.	As a result of this study, it has been determined that the ratio of security cost to total cost is 1.92%, and according to 2013 prices, 0.85 USD should be spent per man-hour.
Gürcanlı et al. (2015b)	To determine the risk perception of construction equipment operators in Turkey.	Statistical methods such as t-test, ANOVA analysis, Kruskal Wallis one-way analysis of variance and ManneWhitney U test	Survey study with 198 heavy equipment operators in 51 construction projects	Pointed out that the type of construction project has an impact on the risk perception of the operators, and this is reflected in both severity and probability scores.
Ulubeyli et al. (2015)	To reveal cultural differences and understandings of OHS applications in several countries.	Semiotic Analysis	Cartoons from an International Occupational Health and Safety Cartoon Contest	Cartoons can be a good material for better understanding and retention of OHS practices.
Ulutaşdemir et al. (2015)	The aim of this study is to evaluate the effect of OHS practices on healthy lifestyle behaviours of workers.	Survey analysis	A survey was conducted with 400 construction workers.	Getting OHS training and using PPE is a healthy lifestyle affect their behaviour positively.

Table 1. Past studies from 2009 to 2019 (continued).

Arslan et al. (2016)	Identifying the problems of occupational safety experts and producing suggestions for the solution of these problems	A survey was conducted with 110 occupational safety experts.	Survey analysis	(i) Employer intervention, (ii) feeling of not being able to work independently, (iii) insufficient working and consulting time, and (iv) paying experts by the companies they consult
Birgönül et al. (2016)	A literature search was conducted in the construction industry, the causes of the accidents and the results of the lawsuits were analysed.	84 inspection reports were examined, and a method (DsSafe) was developed to determine the causes of construction accidents in Turkey.	Case reports.	DsSafe performed extremely well in 13 of 30 real cases studied and tested. Error rates are estimated to be 100%.
Gündüz and Laitinen (2017)	A 10-stage occupational health and safety management system (OHS MS) has been developed to help SMEs improve their working conditions.	The OHS MS rating system contains 50 items and each item is ranked on a 3-point scale where 0 means poor, 1 means average, 2 means good.	Performance data of 15 firms were utilized.	OHS MS provides a measurable performance monitoring tool to help develop and maintain a positive behavioural change towards better working conditions.
Yılmaz and Kanıt (2018)	The aim is to estimate the security costs of residential construction projects.	Adding a new software module to a computer program	All work items defined in the existing data modules of the computer program of the Turkish Ministry of Environment and Urbanization	To reduce the loss of life and to reduce safety costs resulting from serious injuries, deaths, administrative procedures, legal liabilities and litigation costs.

Table 1. Past studies from 2009 to 2019 (continued).

Baradan et al. (2019)	To investigate the relationship between HDI and mortality rates in the construction industry, as well as the parameters that make up HDI.	Curve fitting and correlation analysis (R2) is used to find the best fit line/curve for a set of data points.	Gross national income, life expectancy, average years of education, expected years of education	The higher level of development has a positive effect on reducing mortality rates in construction.
Yılmaz and Uğur (2019)	Calculating and budgeting prevention costs at the start of repair and maintenance projects	Estimation of the overall mandatory OSH costs, including all expenses incurred during the implementation of the measures.	Comparing the estimated OHS costs at the pre-tender stage with the actual OHS costs	Tender preparation process has been simplified by providing an accurate enough estimation of OHS costs.

These studies reveal different perspective of OHS research conducted in Turkey. Considering their themes, past studies were grouped under six topics; (i) legal litigation analysis, (ii) OHS and welfare level relation, (iii) workers working conditions, (iv) international comparison of OHS concept, (v) cost of OHS, and (vi) OHS performance evaluation.

Legal Litigation Analysis

Gürcanlı (2009), Gürcanlı and Müngen (2013), and Birgönül et al. (2016) analysed expert reports to conclude the reasons of occupational accidents and results of legal litigations of these accidents.

OHS and Welfare Level Relation

Baradan et al. (2019) concentrated on Human Development Index and studied the relation between OHS and gross national income, life expectancy, average years of education, expected years of education of countries.

Working conditions of workers

Ulubeyli et al. (2014) conducted a survey with 800 workers employed that is a massive number, in order to reflect general information about HS conditions in the Turkish construction industry from the perspective of construction workers. Moreover, Ulutaşdemir et al. (2015) evaluated the effect of OHS practices on healthy lifestyle behaviours of workers and they surveyed 400 construction workers. Gürcanlı et al. (2015b) aimed to determine the risk perception of construction equipment operators in Turkey and 198 heavy equipment operators were surveyed in the study. Arslan et al. (2016) interviewed 110 OHS experts in order to reveal current problems of them.

International Comparison of OHS Concept

Ulubeyli et al. (2015) presented a unique approach to OHS of construction industry. In their study, several cartoons on OHS applications were analysed utilizing Semiotic Analysis Method to reveal cultural differences or similarities of countries on this topic. There are also studies which concerns OHS costs for Turkish construction firms.

Cost of OHS

Gürcanlı et al. (2015a) focused on the cost of security, Yılmaz and Uğur (2018) researched security costs of residential construction projects, and Yılmaz and Uğur (2019) calculated prevention costs for maintenance projects from the perspective of OHS.

OHS Performance Evaluation

Gündüz and Laitinen (2017) developed a computer program to improve small and medium enterprises' performance concerning OHS applications.

Discussion and Conclusion

The construction industry has high safety hazards for workers at sites due to the complex and confined working environment. Construction workers face a lot of struggles and difficulties in the workplace due to the improper balance between work and their safety. Regarding to official numbers of occupational incidents, construction industry is one of the most dangerous industries in Turkey. From this point of view, researches on OHS have a significant role to sustain a safer and better conditions for construction workers.

Legal litigation results and expert reports reveal that most of the occupational incidents arises due to improper working environment, negligence of basic safety rules, and lack of safety awareness. Moreover, type of construction project has an impact on the risk perception of workers and operators in the construction site. Therefore, an effective OHS training system and using PPE may positively affect workers' behaviour. From the perspective of construction workers, their most significant problems are lack of insurance and unionization. These problems should be considered and solved in order to maintain job security. Regarding to costwise approach, OHS applications have not a devastating effect on project budget. Moreover, cost of precautions relatively lower than cost of occupational accidents recovery.

Considering the past studies in Turkey (Table 1), it can be asserted that lack of OHS culture and negligence of basic OHS rules cause most of the occupational incidents in Turkish construction industry. In addition, low unionization of workers and existence of uninsured workers result with poor OHS records for construction companies and workers. Therefore, there is a need of studies which concentrate on creating an OHS culture in Turkish construction industry. Regarding the cost of OHS practices, most of the construction companies, especially small and medium companies, should have better understanding of the importance to reduce safety costs resulting from serious injuries, deaths, administrative procedures, legal liabilities and litigation costs and expenses. In that case, more studies should be conducted in collaboration with construction companies to reveal the importance of cost of OHS precautions.

The limitation of the study is that the selection of articles for review is considered as only peer-reviewed articles, and publication from 2009 to 2019. Other sources of relevant articles such as book parts, chapters, conference proceedings, and Ph. D. theses were not considered. For future studies, a bibliometric analysis of OHS studies of Turkey can be carried out in order to reveal a better perspective for Turkish construction industry.

Awareness of Occupational Health and Safety in Architectural Office Workers: Kayseri Example

Z. Ö. P. Biçer and G. L. Gümüş
Erciyes University, Department of Architecture, Kayseri, Turkey
parlako@erciyes.edu.tr, gamzegumus38@hotmail.com

Abstract

Academic and practical studies on occupational health and safety in the field of construction are carried out with seriousness. However, the occupational health and safety issue for the works in architectural offices where the design phase of the sector takes place is ignored. While the job classification is very dangerous in construction sites, it is evaluated in the less dangerous class in offices. This causes the ergonomics problems faced by architectural office workers to be ignored. However, the ergonomics problems brought by long desk jobs put employee health at risk. In this study, it was tried to measure the awareness of occupational health and safety of architectural office workers. It is expected that the study carried out on the scale of Kayseri will contribute to the studies to be carried out throughout the country.

Keywords: *architectural offices, ergonomics, occupational health and safety.*

Introduction

The importance of the concept of Occupational Health and Safety (OHS) increases with the injury, death or damage of many employees as a result of occupational accidents each year, due to occupational diseases. The purpose of OHS activities; to identify dangerous situations that threaten the life of the employee, to protect them from these dangers, to minimize the damage of risky situations, in other words to create a healthy and safe working environment. OHS studies also include all activities and measures to ensure labor productivity. The importance of occupational health and safety has increased rapidly in business lines that contain risk factors. With OHS, it is possible to identify risky situations that threaten the health of employees, to protect employees against these situations and to reduce the impact of the damage to be encountered.

Fulfilling the requirements of ergonomics in office working conditions is of great importance in ensuring OHS. Employees working in the same position for a long time in intense work tempo in architectural offices have various risks in terms of OHS and ergonomics. Dangerous situations can be prevented with various arrangements to be made in order to work in conditions suitable for ergonomics. In this context, this study was needed to measure the awareness of OHS in architectural offices in Kayseri. The fact that Kayseri has important potentials in the field of architecture and that no relevant studies have been carried out in the province have been a factor in the selection of Kayseri. In the study, the number of samples was decided with

statistical analyses and a field study was carried out in 56 offices with the aim of reaching more participants. Responses were received from 141 office workers.

Although there are extensive studies on OHS related to office workers in Turkey, the absence of any study on architectural offices has led to the formation of this study. Within the scope of the research, it is aimed to draw attention to the importance, applicability, necessity and awareness of OHS in the works in architectural offices. The problems related to the subject were identified and the findings for the architectural office workers were included, and it was aimed to raise awareness for everyone and to increase the importance given to OHS. The main objective was to increase the level of knowledge about OHS by ensuring that the results revealed in the architectural offices in Kayseri, which were selected as the field in the study, were disseminated. Within the scope of the study, the universe of the application consists of the employees of the architectural offices registered with the Kayseri Chamber of Architects. While deciding on the sample selection, room registration information of the Chamber of Architects was obtained, and the number of offices and surveyed offices was decided by using the Statistical Page Program for Social Science (SPSS) 22.0 Program and the Power Analysis method. It is aimed that this study will be a guide for other architectural office workers in Turkey, and that the study conducted in Kayseri will set an example for the country in general and to increase awareness and correct practices on the subject.

Occupational Health and Safety in Architectural Offices

Occupational health and safety is the set of measures necessary to prevent employees from experiencing accidents and occupational diseases, and to provide a physically and mentally peaceful working environment (Çelik, 2016). OHS activities include the activities carried out to protect workers and other individuals in the workplace from adverse conditions. OHS is defined as a branch of science that works to eliminate risks before dangerous situations occur (Turan, 2016). With the development of technology in the world and in Turkey, along with industrialization, important problems have emerged regarding the health and safety of employees. Due to changing working conditions, diversified business lines bring many dangerous and risky situations. Adverse conditions reduce productivity by causing an increase in work accidents and occupational diseases. OHS practices are of great importance as they include activities aimed at eliminating or minimizing such adverse conditions. Negative conditions in the working environment harm the right of employees to live and work in a healthy environment. Due to such reasons, it is necessary to give the necessary importance to the issue of OHS and to take the necessary precautions (Çelik, 2016).

Since the OHS activities did not develop at the same pace with the realization of the industrial revolution, the losses in business life were seen as a natural part of the production process. Most of the time, the employee himself was held responsible for the accidents, not the employer. Heavy and risky working conditions, which continued until the 19th century, were turned into a scientific issue by industrial countries such as England and Italy. Until this period, treatment methods for employee health have been adopted. Until the 1900s, preventive practices on OHS were not included. In the 1980s, scientists' research on topics such as workload, psychological risks, work stress, psycho-sociology and work organization was realized as a result of targeting preventive activities. With the scientific studies in the following periods, the necessary importance was given to OHS and its transformation into today's state was ensured.

Architectural offices are busy working areas where design activities are carried out in a coordinated manner, usually at the computer. Since it is known that most of the life is spent in offices, taking into account the occupational health and safety conditions in the offices provides important contributions to both the employer and the employees (Demirci & Armağan, 2002). In terms of occupational health and safety, as in other offices, criteria such as lighting, ventilation, noise, temperature, humidity, color, decoration, cleanliness, ergonomics are among the issues to be considered in architectural offices. As in every office environment, the quality and performance of the architectural offices increase by increasing the productivity with the employees working in conditions suitable for OHS. In this context, the appropriate physical environmental conditions are important in terms of providing OHS.

It is important for the office workers who work in front of the computer for a long time in architectural offices to pay attention to ergonomics in ensuring OHS. Ergonomics; it is a part of OHS studies aimed at reducing and eliminating the risks foreseen to prevent occupational diseases and work accidents. Being aware of the relationship between ergonomics and OHS and working accordingly is another important issue. In this context, it is necessary to be aware of the importance of ergonomics in OHS. Taking short breaks in busy work schedules and doing exercises during breaks are essential for ensuring employee health and OHS structure in offices. In this study, it is aimed to observe the awareness of OHS in architectural offices in Kayseri.

Method

As a result of the literature studies, some calculations are included in order to determine how much office field work should be done in the study. While deciding on the sample selection, room registration information of the Chamber of Architects was obtained, and the number of offices and surveyed offices was decided by using the Statistical Page Program for Social Science (SPSS) 22.0 Program and the Power Analysis method. Then, the conditions to be examined in the field study were determined. Questionnaire questions were created to measure the knowledge level of employers and employees about OHS and awareness of OHS in architectural offices in Kayseri. The questionnaire was applied to architects, civil engineers and technicians working in architectural offices. In the study, data entry and analysis with SPSS, sample selection with statistical analysis, and analysis with Chi Square test were deemed appropriate. While deciding on the sample size created to define the study universe; concepts such as population size, confidence interval, margin of error have become important. In this context, the formula used in selecting the sample is as follows:

$$\boldsymbol{n = \frac{Z^2 . \sigma^2 . N}{e^2 . (N - 1) + Z^2 . \sigma^2}} \quad (1)$$

N = the size of the total universe.
σ = represents the standard deviation of the population. If this data is unknown, 0.5 is assumed.
e= 5% (taken as 0.5)
Z = 95%, which is necessary for the study to be considered reliable, is the minimum value (95%–Z-Score = 1.96).

If $p \leq 0.05$, it is concluded that there is a significant difference in the results of employers and employees. If $p > 0.05$, it is concluded that there is no significant difference in the findings of employers and employees.

$$\mathbf{38} = \frac{(\mathbf{1,96})^{\mathbf{2}} \,.\, (\mathbf{0,5})^{\mathbf{2}} . \mathbf{139}}{(\mathbf{0,5})^{\mathbf{2}} . (\mathbf{139} - \mathbf{1}) + (\mathbf{1,96})^{\mathbf{2}} \,.\, (\mathbf{0,5})^{\mathbf{2}}} \quad (2)$$

According to the formula, it was determined that fieldwork should be done in 139 offices, with a confidence interval of 95%, with a standard deviation of 0.5 and approximately 38 offices. A field study was organized for 56 bureaus, aiming to increase the authenticity of the results by reaching more samples. While choosing the office; project approval rates were checked from the chamber of architects in Kayseri. As a result of the survey, responses were received from 141 office workers.

Examining OHS Awareness in Kayseri Architecture Offices

It was aimed to determine the knowledge level of office workers by creating a multiple-choice question in the survey study created within the scope of the study. In this question, the definition of the concept of OHS was asked. In the question in which the definition of the concept of OHS was asked in line with the answers received from 141 employees in architectural offices; it was determined that 92.9% (131 people) of the participants could fully define the definition of OHS, while 7.1% (10 people) had an idea about the definition of OHS, but defined the concept incompletely. 88.7% (55 people) of the employers who answered the questionnaire gave the most correct answer knowing the definition of OHS exactly, and 11.3% (7 people) interpreted the definition incompletely due to their incomplete approach to the subject despite knowing the definition of OHS (Figure 1). 96.2% (76 people) of the employees who participated in the survey were seen as having a good grasp of the definition of OHS, and 3.8% (3 people) as those who knew the definition of OHS but misinterpreted them (Figure 2). According to the results, it has been seen that the employees' knowledge of the definition of OHS is higher than that of the employers. The majority of the participants are fully familiar with the definition of OHS.

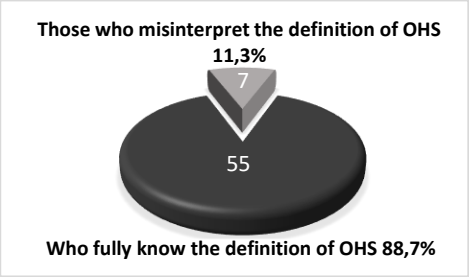

Figure 1: OHS approaches of employers.

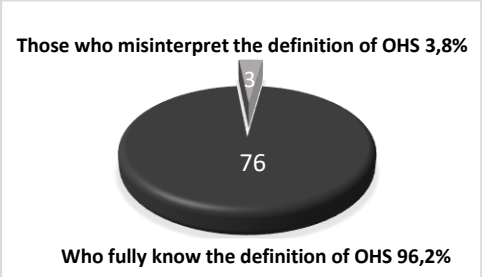

Figure 2: OHS approaches of workers.

In the case of receiving OHS training, 61.7% (87 people) of the participants stated that they received OHS training, of which 27% (38 people) were employers and 34.7% (49 people) were employees. It was observed that 25.6% (36 people) did not receive OHS training, of which 11.4% (16 people) were employers and 14.2% (20 people) were employees. 12.8% (18 people) of the participants expressed their indecision on this issue. 5.7% (8 people) of the undecided participants were observed as employers and 7.1% (10 people) as employees. Considering the level of OHS training of the participants working in architectural offices, it was seen that 61.7% of them stated that they received training (Table 1). It has been observed that employees receive OHS training at a higher rate than employers. However, this rate was not considered sufficient for the employees of architectural offices.

It is important for health to take short breaks between works in ensuring OHS. Resting the tired office worker at regular intervals creates a healthier working environment in terms of both ergonomics and OHS. In this context, in the question asked about the situation of taking short breaks in office work; 90.8% of the participants (128 people) stated that they work by taking breaks. 38.3% (54 people) of those who gave this answer were identified as employers and 52.4% (74 people) as employees. Of the participants, 2.1% (3 people) were employers, 1.4% (2 people) were employees, and 3.5% (5 people) stated that they worked at the computer for a long time without taking short breaks. 3.5% (5 people) of the participants were employers, 2.1% (3 people) were employees, and 5.7% (8 people) expressed their indecision on this issue (Table 1). When the rates of working by taking a break were examined, it was observed that the majority of the participants took breaks from their studies. This shows that employers and employees are aware of the importance of working by taking breaks in providing OHS.

It is also important to do exercises during breaks from office work. Therefore, in another question, the participants were asked whether they did exercises during the breaks. Of the participants, 16.3% (23 people) were employers and 20.6% (29 people) were employees, 36.9% (52 people) stated that they worked by doing exercises. Of the participants, 20.5% (29 people) were employers, 24.8% (35 people) were employees, and 45.4% (64 people) stated that they continued their work all day long without exercising. 17.7% of the participants (25 people) stated that they were undecided on this issue. 7.1% (10 people) of those who gave this answer were observed as employers and 10.6% (15 people) as employees. When the rates of exercise during the breaks were evaluated, it was observed that only 36.9% of the participants exercised (Table 1). It has been observed that this rate is higher in employees. However, the rate of exercise of architectural office workers who continue their activities in an intense work tempo was found to be low.

When asked about the awareness of the importance of ergonomics in providing OHS; 29.8% (42 people) of the participants were employers, 36.2% (51 people) were employees, and 66% (93 people) stated that they were aware of the relationship between OHS and ergonomics and that they worked under appropriate conditions. 0.7% (1 person) of the participants were employers and 1.4% (2 people) were employees, and 2.1% (3 people) stated that they were not aware of the link between OHS and ergonomics. Of the respondents, 13.5% (19 people) were employers and 18.4% (26 people) were employees, 31.9% (45 people) stated that they were undecided about the awareness of the relationship between OHS and ergonomics. The rate of participants who have awareness of OHS and ergonomics was determined as 66% (Table 1). It was observed that this rate was higher in employees (36.2%). Although the definitions of OHS and ergonomics are known, it is not enough to have 66% awareness of the relationship between the two concepts. It is thought that it is important to organize training for office workers in order to eliminate this deficiency.

Table 1. Analysis results for OHS awareness in Kayseri architecture offices.

		Absolutely I agree	**I agree**	**I'm undecided**	**I do not agree**	**I strongly disagree**	**p**
Obtaining OHS training	employer % (n)/ worker % (n)	12,1%(17)/ 19,1%(27)	14,9%(21)/ 15,6%(22)	5,7%(8)/ 7,1%(10)	5%(7)/ 7,1%(10)	6,4%(9)/ 7,1%(10)	**0,900**
	Total	**31,2% (44)**	**30,5%(43)**	**12,8% (18)**	**12,1%(17)**	**13,5% (19)**	
	employer % (n)/ worker % (n)	17%(24)/ 26,2%(37)	21,3%(30)/ 26,2%(37)	3,5%(5)/ 2,1%(3)	2,1%(3)/ 0,7%(1)	0%(0)/ 0,7%(1)	**0,405**

Taking short breaks in office work	**Total**	**43,3% (61)**	**47,5% (67)**	**5,7% (8)**	**2,8% (4)**	**0,7% (1)**	
Exercise during short breaks at the office	employer % (n)/ worker % (n)	7,1% (10)/ 12,8% (18)	9,2% (13)/ 7,8% (11)	7,1% (10)/ 10,6% (15)	17% (24)/ 16,3% (23)	3,5% (5)/ 8,5% (12)	**0,358**
	Total	**19,9% (28)**	**17% (24)**	**17,7% (25)**	**33,3% (47)**	**12,1% (17)**	
Awareness of the importance of ergonomics in OHS	employer % (n)/ worker % (n)	14,2% (20)/ 14,9% (21)	15,6% (22)/ 21,3% (30)	13,5% (19)/ 18,4% (26)	0% (0)/ 0% (0)	0,7% (1)/ 1,4% (2)	**0,888**
	Total	**29,1% (41)**	**36,9% (52)**	**31,9% (45)**	**0% (0)**	**2,1% (3)**	

($P \leq 0.05$ indicates that there is a significant difference between employers and employees.)

As a result of the questions asked to measure the OHS awareness of architectural office employees; it has been seen that the participants have knowledge about OHS but are not fully aware of the relationship between them and other disciplines. It has been observed that the employees of architectural offices that know OHS do not fully fulfill the requirements of working in conditions suitable for OHS, and this is due to the lack of knowledge on the subject.

Results

With the developing technology conditions, important transformations have taken place in working life as in every field. This situation has both positive and negative effects. In terms of OHS, experiencing negativities is one of the main problems. Occupational diseases and occupational accidents have also diversified with the emergence of different business lines that have increased with the industrial revolution. This situation necessitated taking measures for OHS. The purpose of OHS is to protect the health of employees and ensure that they work at high efficiency. Working in conditions suitable for OHS is of great importance in office work areas. The results of the fieldwork carried out in the architectural offices in Kayseri are discussed in this section.

Discussion

There have been significant changes in office work with the new working styles brought by the changing living standards with the developing time conditions in the world and in Turkey. Especially with the widespread use of computers, most of the studies started to be carried out at the desk in front of the screen. As a result of this situation, various dangers to ergonomics arise. Working in conditions suitable for OHS and ergonomics for office workers, who are in the working environment for a long time, minimizes dangerous situations and ensures a healthy work environment. For this reason, the concepts of OHS and ergonomics maintain their importance with the intense office activities today. These concepts also show their effect in studies conducted in the world and in Turkey. In the studies conducted, it was seen that the risks related to ergonomics in terms of OHS were evaluated. In the studies, it has been observed that the common purpose is to improve the working conditions such as increasing the performance and productivity and providing OHS.

Results

Employees working in the same position for a long time in intense work tempo in architectural offices have various risks in terms of OHS and ergonomics. Dangerous situations can be

prevented with various arrangements to be made in order to work in conditions suitable for ergonomics. In this context, this study was needed to measure the awareness of OHS in architectural offices in Kayseri. The fact that Kayseri has important potentials in the field of architecture and that no studies related to the subject have been made in the province have been a factor in the selection of Kayseri. In the study, the number of samples was decided with statistical analyzes and a field study was carried out in 56 offices with the aim of reaching more participants. Responses were received from 141 office workers.

Using a five-point Likert scale, a questionnaire study was created that aimed to rank the opinions of the participants and to provide easy answers. The survey data were analyzed with the Chi Square test in the SPSS (22) program. It was examined whether the status of being an employer and an employee made a significant difference in the results. Since $p>0.05$, it was concluded that there was no significant difference between employers and employees in all of the data. When the findings of employers and employees in architectural offices in Kayseri are examined, it has been determined that employers have more information about OHS than employees. In general, this rate was found to be close to employers among employees. Therefore, it was observed that there was no significant difference in the results.

The responsibility of providing OHS in architectural offices belongs to the employer. Working in a healthy environment, ensuring high performance and efficiency is an important issue in architectural offices as in every business activity. For this reason, employers have a great responsibility to ensure that employees work in conditions suitable for OHS and produce quality products. Since office activities are in the less dangerous class, the seriousness of the employees about OHS may decrease. For this reason, the issue is not given due attention. In order to prevent this situation, employers should inform their employees, organize trainings, monitor working conditions under appropriate conditions and ensure the continuation of the necessary regulations. Employees should be encouraged to work in accordance with OHS. It has been observed that there are deficiencies in the level of education since some employers do not hold themselves responsible for receiving OHS and ergonomics training. This is a misconception. The education level of all employees, both employers and employees, must be sufficient and in a suitable condition to work. It is recommended that employers be more aware of this issue and eliminate their deficiencies. It will be important that the level of knowledge is sufficient in order to ensure that the employees work in conditions suitable for OHS and ergonomics. It is recommended that employers organize seminars and trainings for their employees at regular intervals. It has been observed that exercises are not done during short breaks in offices and they work in the same position for a long time. Although this issue is seen as unimportant by office workers, it causes serious health problems if not taken care of. For employers, this situation causes loss of performance and workforce in their employees. For this reason, it is necessary to raise awareness of employees especially about doing exercises by employers.

Academic researches on the working environment in architectural offices are considered important due to the limited number of studies in the field. Considering the architectural office workers in architectural offices throughout Turkey, the importance of guiding studies on the subject increases. It is foreseen that this study, which is thought to have an important contribution to the literature, will form the basis for other studies to be carried out. It is thought that the missing aspects of the work station examined within the scope of the research will be eliminated with other studies to be done and it will have an important place in the literature.

Construction Safety Hazard Recommendation using Graph Representation Learning

F. Mostofi and V. Toğan
Karadeniz Technical University, Department of Civil Engineering, Trabzon, Turkey
fatemee.mostofi@gmail.com, togan@ktu.edu.tr

Abstract

Construction safety possesses a considerable challenge to the construction industry. Factual risk assessment (RA) is vital for the effective identification of construction hazards and controlling the associated risks. In this regard, a wide range of machine learning (ML) methods are used over the construction safety records, for achieving a better representative RA. This study first depicts the accident records in form of graph-structured datasets and then utilizes graph representation learning (GRL) *methods for obtaining the node embeddings and optimizing a neighborhood-preserving. To this end, a technique is used to learn the hazard by embedding an unbiased random walk in the neighborhood space of construction accidents. As a result, the developed system is beneficial for the construction site managers to receive recommendations of possible site safety hazards based on the existing hazard scenario.*

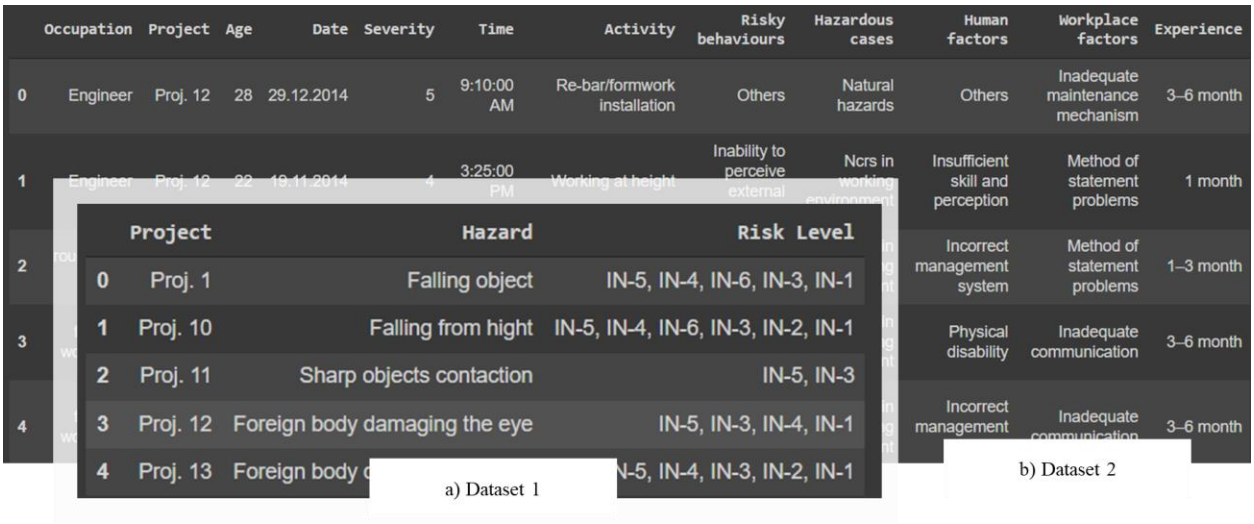
Keywords: *construction risk assessment, graph representation learning (GRL), hazard recommendation, machine learning, semi-supervised learning.*

Introduction

Site occupational safety poses a considerable challenge to the construction Industry. Before any intervention for improving the site safety status, the risk assessment (RA) procedure is conducted, comprising the identification, analysis, and evaluation of safety risks. The first stage of risk identification is to identify any item with the capacity of causing negative health outcomes. In this respect, hazard identification involves gathering job-specific information and site inspection. Considering the complexity of the construction site, identification of all the hazard items is difficult and time-consuming. Despite its essential role in RA procedure, there exists no international regulation for hazard identification (Chartres et al., 2019). Collecting the hazard items using experience, research and brainstorming is prone to human error and negligence and thus reduces the confidence level of RA procedure and affects the risk-informed decision-making outcome. Unless a hazard item is identified, an appropriate RA procedure cannot be conducted. This in turn hinders effective implementation of the risk countermeasures and reduces the site safety status.

To increase confidence in hazard identification utilization of the past accident records and experience gathered from the previous projects is vital. Utilization of the past construction accidents enhances the breadth of the hazard item lists. The collected accident records contain rich information about the accident, associated causations, and embedded hazard items. One way to effectively utilize the past event dataset is to train the Machine Learning (ML) algorithms for the specific task. In the existing body of knowledge, the ML methods are well developed over the past decades in a wide range of construction safety applications (Cheng et al., 2020; Comberti et al., 2018; Koc et al., 2021; Yang & Kim, 2020; Yang et al., 2022). For example, ML approaches are used for predicting construction falls (Mistikoglu et al. 2015; Piao et al. 2021; Yang et al. 2016), traffic (Almamlook et al. 2019; Chong et al., 2005; Lee et al. 2020; Sohn & Lee 2003; Wang et al. 2019) and workplace (Matías et al. 2008) accidents. Likewise different Natural language Processing (NLP) are used to retrieve textural safety information (Cheng et al., 2020; Tixier et al. 2016). However, amongst different ML and NLP methods, there have found no literature for developing a hazard remuneration system to assist the RA procedure.

Recommendation engines are providing useful information to end-users and hence improve the quality of their decision-making process. These recommendation engines offered practical solutions to information retrieval platforms LinkedIn, YouTube, Facebook, Netflix, and Amazon and thus lately have attracted the attention of researchers (Awan et al., 2021). Considering the usefulness of the recommendation engines for information retrieval from the dataset, this study develops a novel recommendation engine based on graph representation learning (GRL) (Hamilton, 2020) to facilitate hazard identification as well as to improve the comprehensiveness of the hazard list. As one of the most promising and fast-growing sub-areas of ML, GRL has shown great potential in deriving knowledge embedded in different kinds of graphs. Specifically, many GRL techniques, such as random walk and graph neural networks, have been developed to learn the particular type of relations modeled by graphs, and have been demonstrated to be quite effective (Wu, 2021; Wu et al. 2021).



In addition, GRL understands the embedded nodal and link information of the construction accident features. These mandate learning the representative features themselves, with all the associated diverse connection patterns, perceived within the established network (Grover & Leskovec, 2016). Identifying influential features in maximizing the odds of preserving the nodes within a neighborhood, allows for mapping them in low-dimensional space with the project information in each node (Grover & Leskovec, 2016). Here, the node2vec algorithm can continuously learn the embedded mapping between the nodes and feature representation in a network of construction projects linked with their associated safety indicators. For effective exploration within diverse patterns of all neighborhoods, a biased random walk procedure is implemented by the node2vec algorithm. This secures flexible neighborhood exploration and facilitates learning a richer feature representation, whereby generalizing the notion of network neighborhood (Grover & Leskovec, 2016). Therefore, the GRL-based recommender advances the hazard recommendations for three reasons; firstly, GRL illustrates the relationship between the characteristics of different accident data collection across various projects while considering the project similarities in terms of the shared hazard items; secondly, a relation-aware representation (RAR) datasets is structured while assigning each hazard item to both project and its accident features and also to the different construction occupations; thirdly, a hazard recommender engine is developed which is capable of suggesting the relevant hazard items considering the accident

features shared amongst different projects and construction occupations. Compared with the literature this study is innovative in sense of its first time developing a safety/hazard recommender engine while combining the NLP algorithm with the optimization method.

Construction Safety Network

The construction safety network is developed, as the input data of the proposed hazard recommender engine, within the five steps as follows.

Step 1. Create a graph-structured dataset, placing project information at nodes, while connecting the projects based on the shared hazard items, referred to as edges. For this, two datasets are generated where dataset 1 shows graph-structured dependency information (Figure 1a) while dataset 2 details the safety features associated with each project node (Figure 1b).

	Occupation	Project	Age	Date	Severity	Time	Activity	Risky behaviours	Hazardous cases	Human factors	Workplace factors	Experience
0	Engineer	Proj. 12	28	29.12.2014	5	9:10:00 AM	Re-bar/formwork installation	Others	Natural hazards	Others	Inadequate maintenance mechanism	3–6 month
1	Engineer	Proj. 12	22	19.11.2014	4	3:25:00 PM	Working at height	Inability to perceive external	Ncrs in working	Insufficient skill and perception	Method of statement problems	1 month
2										Incorrect management system	Method of statement problems	1–3 month
3										Physical disability	Inadequate communication	3–6 month
4										Incorrect management	Inadequate communication	3–6 month

a) Dataset 1

	Project	Hazard	Risk Level
0	Proj. 1	Falling object	IN-5, IN-4, IN-6, IN-3, IN-1
1	Proj. 10	Falling from hight	IN-5, IN-4, IN-6, IN-3, IN-2, IN-1
2	Proj. 11	Sharp objects contaction	IN-5, IN-3
3	Proj. 12	Foreign body damaging the eye	IN-5, IN-3, IN-4, IN-1
4	Proj. 13	Foreign body c	N-5, IN-4, IN-3, IN-2, IN-1

b) Dataset 2

Figure 1: a) Dependency information and, b) accident features in the safety network.

Step 2. Weights are added to the hazard connectivity information based on the age of construction workers. For this the positive mutual information method is used between project node X and project node Y. Thus, the hazard connectivity will be defined as stated in Eq. (1).

$$log(XY) - log(X) - log(Y) + log(D) \quad (1)$$

Where, XY shows the number of workers' ages shared, while X and Y are the hazard-based worker's ages at node X, and node Y. The outcome of Eq. (1) quantifies the discrepancy between the probability of node X adjacent to node Y, under the assumption of having independent joint and individual hazard connectivity edges. Additionally, D show the total number of workers' age-based hazards. Besides, the proposed system accommodates the flexibility of excluding irrelevant hazard features. Also, to demonstrate this, the hazard connectivity information related to workers older than 60 years old is removed from the created network. The generated safety network

comprised 73 project nodes, and 2394 hazard edges, while the weight between the edges shows the age of the construction workers (Figure 2). In Figure 2b, the node ranking shows the importance of the node degrees (Figure 2c) based on their number of hazard connections. Also, the number of hazard-based connections within the dataset collected across different projects is shown by the node density.

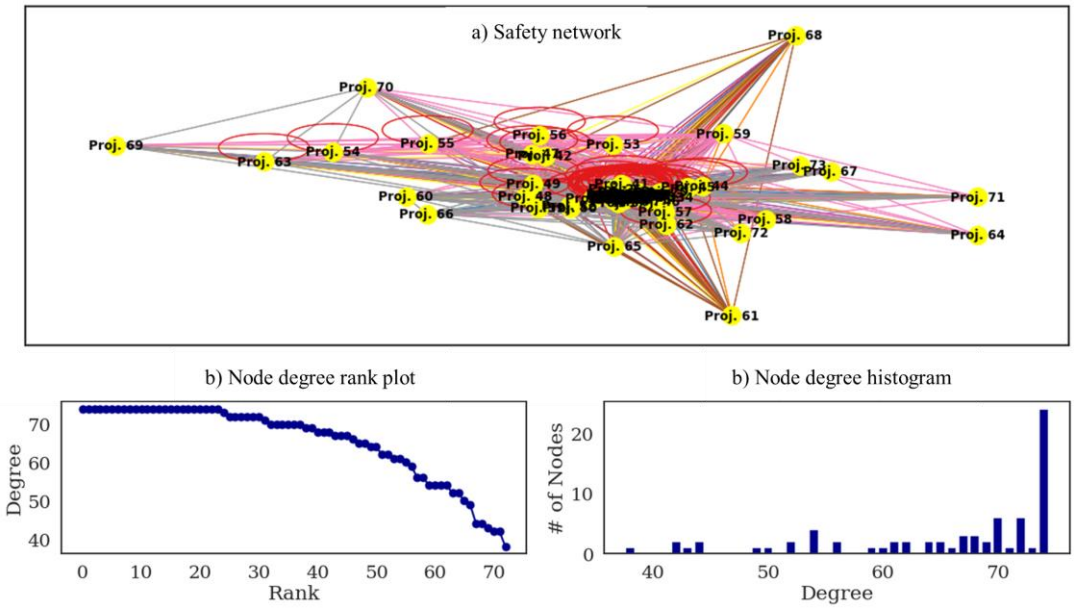


Figure 2: Safety network.

In the node degree in Figure 2c, more than 30 projects are sharing 70-75 hazard items. This further emphasizes the importance of using past accident records for achieving an all-inclusive hazard item list. To illustrate the application of node degree in information retravel from construction accident records, the highest degree node was identified from the created hazard network (Figure 3).

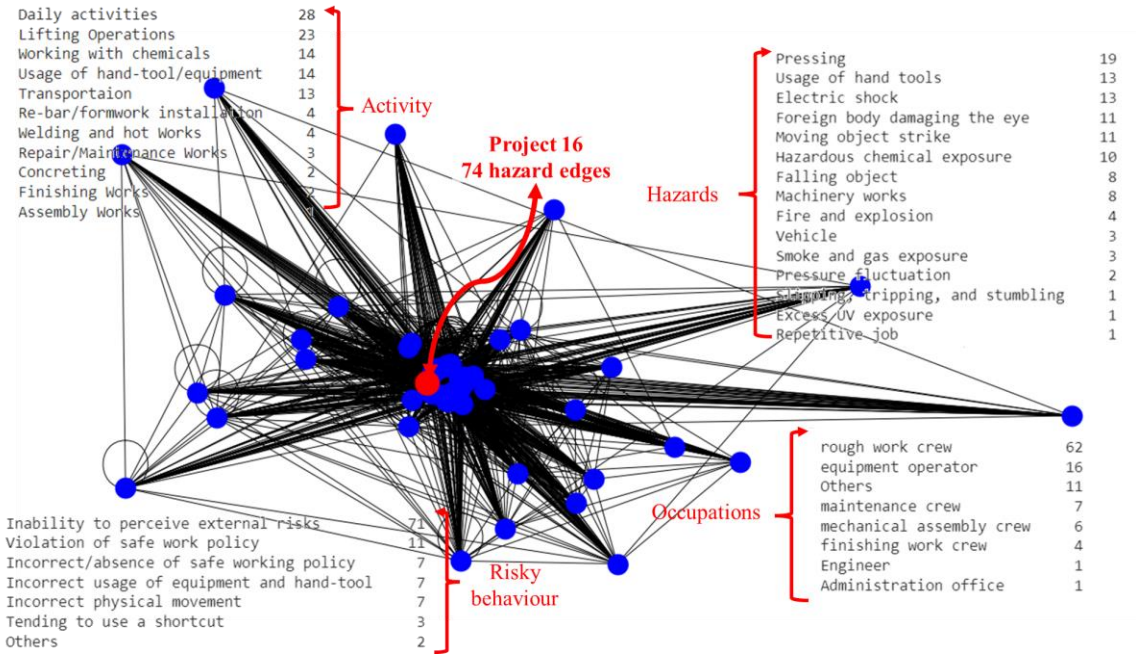

Figure 3: Retroviral of the project safety information with the highest hazard connectivity.

Besides, the centrality (closeness) of the network is measured, showing the reciprocal summation of the shortest connections amongst the nodes. In this respect, the project node with higher centrality is closer related to other projects in terms of the shared hazard items (Figure 4a). Besides, betweenness shows the degree that which project nodes are standing between each other, and thus represents their higher influence on the overall safety network (Figure 4b).

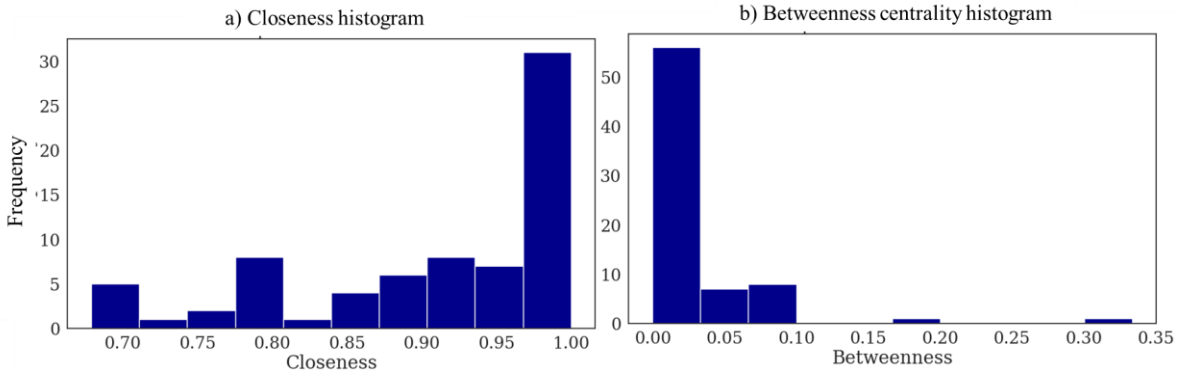

Figure 4: a) Closeness and b) centrality betweenness within construction safety network.

Based on Figure 4, the most critical information can be retrieved through careful investigation of the accident dataset in central projects.

Step 3. A vocabulary of projects concerning different construction occupations is created while mapping the project IDs into the associated integers.

Step 4. The generated GRL is utilized to learn embedded hazard information at the safety network. For this Node2vec (Awan et al., 2021) is used for learning the low-dimensional embeddings from the project nodes and optimizing the received safety information from neighborhood project nodes. Here, a biased random walk is initiated from a certain node, while the next neighborhood is randomly selected based on probabilistically the age weights within the hazard edges. The number of steps taken in each of the random walks is based on the generated sequence of the related project nodes. The adopted random walk is advantageous compared to either visiting just local project nodes (breadth-first sampling) or visiting the distance nodes (depth-first sampling) (Awan et al., 2021). Here, setting high or low likelihood values encourages moderate exploration or local walk, respectively. Besides, the in-out parameter is set as one, showing the inward or outward search allowance. Setting a higher in-out parameter biases the random walk towards the neighborhood nodes, while its lower parameter biases the for visiting distant nodes. In this study, the likelihood of immediate revisiting of a node during a random walk is set as 10 while taking the in-out parameter as one. Besides, five walks, each taking 10 steps arranged.

Step 5. Create positive and negative examples through these walks from one project node to another, while the age of the worker (weight) shows the frequency of hazard items between the nodes within a sequence of a random walk. This resulted in 4260 nodes, labels, and weight matrixes.

Modeling the Hazard Recommendation Engine

Recommending the related hazard items over the construction accident network necessitates feature engineering before the recommendation task. The adopted methods are summarized within four steps as follows. It is also to be noted that the developed safety network, as well as the hazard recommendation engines, are scripted within a Python environment using the Google Colab web-based integrated environment while using a GPU hardware accelerator.

Step 1. Training the skip-gram model.

Training a continuous skip-gram model for prediction of the before and after words. To learn the word embedding, this study adopted a natural language processing (NLP) method named as Word2Vec: a family of ML models which perform both ML and optimization that learns embedding from a large dataset. Subsequently, the dot products amongst node embeddings are sent to the sigmoid activation function, while using a binary Crossentropy loss. Hence, the architecture of the described skip-gram model is presented in Figure 5.

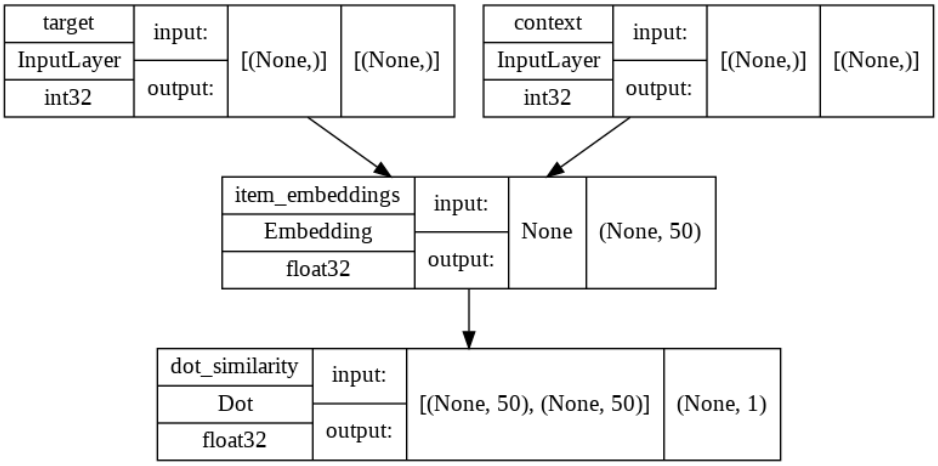

Figure 5: The architecture of the skip-gram model.

According to Figure 5, the learning rate, embedding dimension, number of epochs, and epoch size for training the skip-gram models are set as 0.1, 50, 250, and 1024, respectively.

Step 2. Embedding the hazard information.

To find the embeddings from the entered hazard item, its cosine similarity with other hazard items is calculated, and accordingly, the top five similar hazard items are presented.

Step 3. Evaluating the skip-gram model.

The training loss of the skip-gram model is illustrated in Figure 6 while using the 13.8s CPU time.

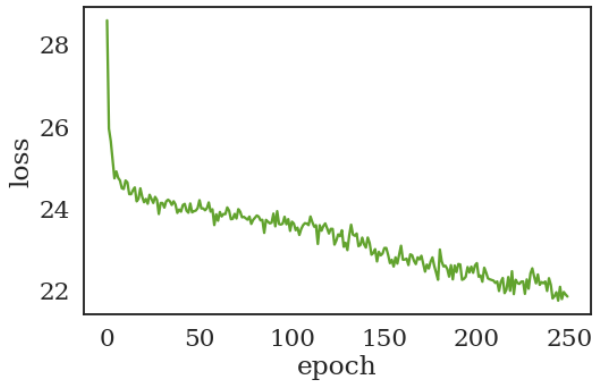

Figure 6: Training loss of skip-gram model.

Step 4. Recommending similar hazard items.

The hazard word vectors visualization was evaluated to better interpret the implementation of the proposed hazard recommendation engine. Accordingly, the analyzed embedding is illustrated in

three-dimensional space of the 1st, 2nd, and 3rd principal components, with 16.9%, 4.1%, and 2.8% variance within the whole hazard space (Figure 7).

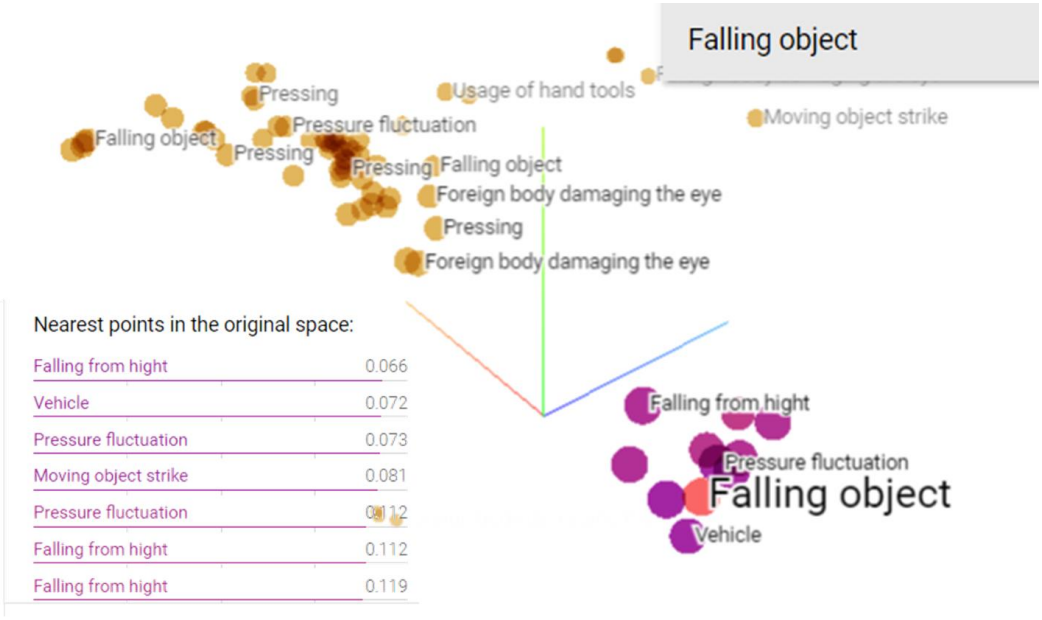

Figure 7: Illustration of the falling embeddings.

As it is shown in Figure 7, the hazard recommendation engine recommends similar hazard items using the cosine distance amongst the project safety nodes. In this study, there exist multiple records of a hazard item, that each defines a single neighborhood.

To illustrate the application of the developed hazard recommendation engine, different hazard items are processed while the system recommendation in terms of similar hazards is presented in Figure 8.

Figure 8: Sample hazard recommendation using the proposed recommender engine.

To recommend the most related hazard item, the developed model searches through the hazard information within the embedding space and selects the nearest cosine nodal information as the first recommendation. Accordingly, the further distant nodes are to be listed as the next hazard items.

Overall, the developed recommender system enhances the hazard identification procedure and thus facilitates the risk-informed decision-making for accident prevention in construction sites. Besides, the system can be further improved by integrating the identical hazard recommendation to select the best recommendation items. In practice, the model can be integrated with Microsft Excel to suggest a similar hazard item to what is entered by the user. Since the system is trained over the past accident records, its accuracy increases with the accumulation of the accident dataset.

Conclusion

To effectively utilize the accident records for hazard identification, this study develops a construction accident safety network for the use of a hazard recommendation system. The developed recommendation engine utilizes the node2vec algorithm as a semi-supervised ML technique that learns the represented hazard information at nodes of the created construction safety network. The system also adopts a biased random walk for exploration of different project neighborhoods within the created safety network, whereby offers a richer learning experience to the developed system in terms of flexibility in feature learning before obtaining the mapped information from the low-dimensional space. The model enhances the comprehensiveness of the hazard list during the RA procedure by recommending similar hazard items based on past accident records. This recommendation engine facilitates hazard identification tasks and thus improves the comprehensiveness of the construction RA. The created safety network provided rich information about the construction hazards shared amongst the accidents across different construction sites.

A Framework for Management of Welfare Facilities in Construction Projects

I. M. Uzun
Isik University, Occupational Health and Safety Program, Istanbul, Turkey
mert.uzun@isikun.edu.tr

Construction projects involve many manual or physical activities, and the construction sites have a challenging working environment. These harsh working conditions negatively affect workers physically and mentally. Welfare facilities such as living accommodations, sanitary facilities, washing facilities, drinking water, changing rooms, rest facilities, and canteens all help reduce fatigue and improve worker health. Deficiencies in the management of welfare facilities cause employees to be unable to meet their vital needs, weakening their commitment to health and safety practices, loss of motivation and productivity, and legal sanctions. On the other hand, the provision of welfare facilities in construction projects is a legal requirement in many countries as part of health and safety regulations and more stringent requirements may vary according to contract terms. Additionally, employee well-being is also a matter of sustainability. Therefore, it is important to ensure welfare of employees in construction projects. This study discusses the management of welfare facilities in construction projects from the perspective of construction management. In addition, it presents a framework on how to determine the criteria to be considered for the design and operation of welfare facilities and how the requirements should be addressed at different stages of construction projects.

Keywords: *construction management, occupational health and safety, sustainability, welfare facilities.*

Introduction

According to Cambridge Dictionary (2022), welfare means physical and mental health and happiness, especially for a person. People have a set of needs to be healthy and happy. Maslow's (1943) theory can provide a perspective for a fundamental approach to this issue. According to Maslow's hierarchy of needs, physiological needs (breathing, food, food, water, sexuality, sleep, healthy metabolism, excretion) and safety needs (body, work, resources, morals, family, health, and property security) come first. Considering that most people spend a third of a day at work, it will be better understood why these basic needs must be met. In addition, in some construction projects, migrant workers spend all their working days at the construction site. For this reason, it is necessary to meet the basic vital needs of workers, even for temporary periods.

The construction industry is one of the riskiest industries in terms of accident frequency and accident results. Improving the health and safety conditions of workers in construction is one of the most important issues (Gurcanli et al., 2015). The working environment in the construction industry is challenging because the operations require intensive labor and are

easily affected by climatic conditions. Also, construction projects involve a lot of manual or physical activity. These harsh working conditions negatively affect employees physically and mentally.

Ensuring well-being of employees in the construction industry is generally considered a part of occupational health and safety practices. Studies show that a problem experienced by the construction industry in occupational health and safety also ensures welfare of workers. In addition, meeting welfare needs of workers reduces workforce absenteeism and increases employee productivity. In other words, ensuring well-being of employees is not only a matter of occupational health and safety but is also directly related to productivity (Gyamfi, 2021; Aravamudhan et al., 2019; Chandrasekaran & Ganeshprabhu, 2020).

Employee well-being is directly related to sustainability. In the early years when the concept was first introduced, it focused mostly on environmental and economic issues. However, in recent years, the International Labour Organization (ILO) (2015) has also included social sustainability in its contributions to the sustainable development goals published by the United Nations (UN) (2015). In summary, social sustainability has subheadings that include ethical, legal, and moral needs of employees (See Figure 1).

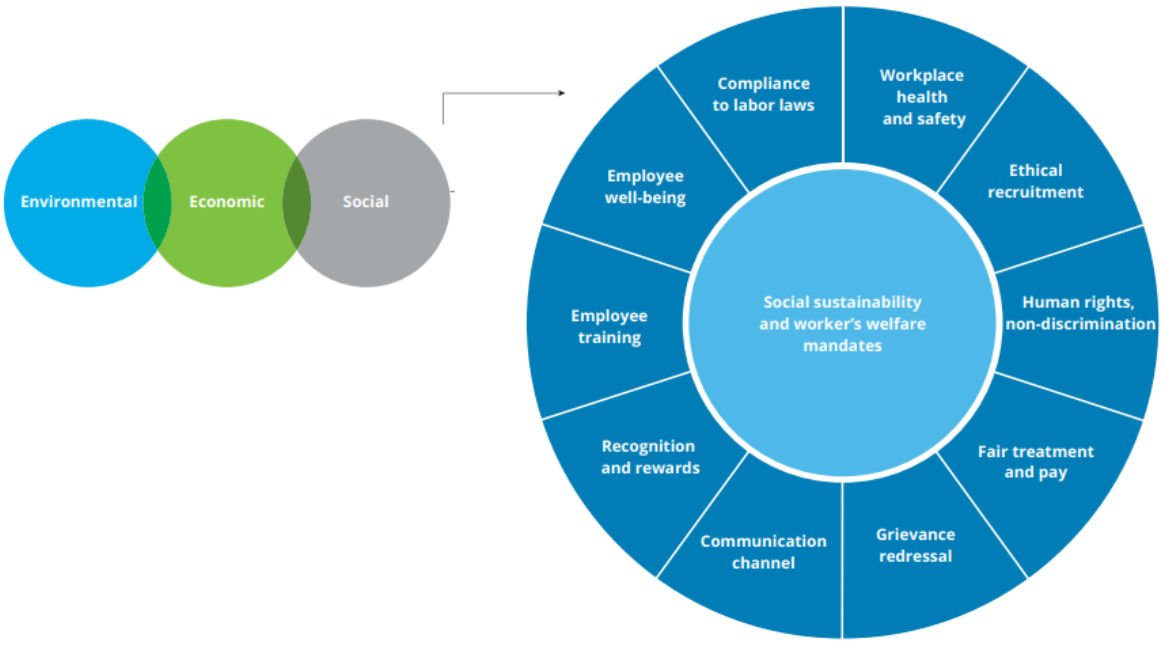

Figure 1: Three pillars of sustainability and relation with welfare (Deloitte, 2019).

Although there are legal regulations in many countries of the world to ensure welfare of employees, there are certain criteria for the management of environmental and social risks in the financing processes of investment projects (International Finance Corporation (IFC), 2012; European Bank of Reconstruction and Development (EBRD), 2019). In this context, providing welfare opportunities to employees has turned into a financial and ethical responsibility of organizations besides their legal responsibilities. As seen in Figure 1, worker welfare mandates include numerous topics, such as occupational health and safety, worker welfare, training, grievances, etc. To increase welfare of the workers, these issues should be linked and a holistic approach should be developed.

If the subject is discussed from the perspective of the construction industry, first, it is necessary to describe the industrial specifications. The main features that distinguish the construction industry from other industries are construction site organization, product, project stakeholders, business, and process. A construction site is established for each new product (building), and it is dismantled after the building is completed. The type of construction and the conditions of the production(construction) site differ for each project. The topographical structure of the construction site, ground type, transportation conditions, climatic conditions, workers, materials, and equipment possibilities vary according to project types. Social facilities are needed in all construction projects. These are site offices for technical staff, warehouses, welfare facilities, etc. All the construction site facilities have a temporary character. At the end of the work, they are completely dismantled. In other words, to construct a building, temporary facilities need to be built to meet the administrative and social needs of employees. Some studies have stated that construction contractors hesitate to make the necessary investments due to this characteristic feature of the facilities (Hatem et al., 2019). To manage a successful construction project, it is important to design these facilities considering various parameters (legal/contractual) during the preparation phase of construction projects so that worker welfare is conflict-free throughout the project (Nuhu et al., 2015).

The aim of this study is to present a practical approach to determining the basic requirements for welfare facilities management in construction projects and handling them in project management. The basic requirements are stated by reviewing the literature and international standards/guidelines. A flowchart has been developed to address these requirements during the preparation phase of the projects.

Construction Welfare Facilities and Basic Requirements

The ILO has broadly defined what constitutes welfare facilities for workers. According to the ILO, there are eight categories of social assistance facilities, which are sanitary facilities, washing facilities, catering, eating facilities, changing, storage and drying facilities, recreation/accommodation rooms and childcare facilities (ILO, 1961, 1992, 1999). In addition, first aid and fire precautions are also included in these facilities. Although the ILO defines welfare facilities in a general context, they need to be adapted according to industrial specifications. Directive 92/57/EEC published by the European Union on construction works has defined general rules in this regard (EU, 1992).

Ensuring the well-being of workers on construction projects is regulated in many countries. In most countries, ensuring the well-being of workers is covered in occupational health and safety law and construction work regulations. Policies and implementation guides have been published by international financial institutions to meet the accommodation and other basic needs of workers, apart from the national legislation regulations in the countries (IFC, 2012; EBRD; 2019; IFC & EBRD, 2009). In addition, some companies and autonomous institutions have published various specifications to avoid worker welfare issues by creating a detailed compliance framework regarding worker welfare requirements. These specifications describe various norms as part of the tender/contracts for the construction project (Expo Dubai 2020; QF, 2013)

There are similar expressions about welfare facilities in the ILO and EU regulations and national legislation accepted by the countries. The common emphasis in the regulations is that

an employer is responsible for ensuring the well-being of workers. In this context, the employer should ensure the welfare of the workers by allocating sufficient resources and making adequate planning. In addition, these regulations contain general descriptions of the minimum conditions required to ensure the welfare of the workers. However, general definitions do not include specific measures of minimum welfare requirements (e.g., accommodation rooms must have $4m^2$ of space per worker, etc.). Expressions such as "adequate or appropriate" describe that the employer must manage the welfare facilities in a way to meet the requirements in the legislation.

In IFC and EBRD's performance standards, there are defined dimensions (size, count, etc.) in some titles (accommodation and sanitary facilities). Similarly, some construction organizations have definitions of minimum requirements (CIDB, 2018). In summary, there are not any internationally standardized norms to describe the minimum requirements for welfare facilities in construction projects in detail. Nevertheless, the specified legislation regulations and guides provide sufficient information on the subject. The highlights of international guidelines and things to be considered in welfare facilities are summarized in the following sections.

Accommodations

It is difficult to provide home comfort for employees in a temporary facility. For this reason, if possible, it should be considered to provide the workforce by making use of local opportunities and to ensure that workers do not stay in a temporary accommodation facility. This can eliminate many accommodation-related risks in terms of the risk control hierarchy. However, workers may need to stay on camp for many reasons, such as insufficient local labor supply or the location of the construction site far from residential areas. In these cases, building type or conventional containers for the accommodation of workers should be preferred depending on the specificity of the project. Where accommodations are provided for single workers or those who are separated from their families, additional housing standards should be considered (IFC & EBRD, 2009):

- a separate bed for each worker
- gender-specific accommodation
- adequate sanitary conveniences
- common dining rooms, canteens, rest and
- recreation rooms and health facilities, where not otherwise available in the community.

Accommodation facilities should be located at a reasonable distance from the construction site to be protected from wind, dust, floods, fires and other disasters. These facilities must have sufficient structural strength and adequate dimensions. In these areas, adequate measures should be taken against the risk of fire (fire detection devices and alarm, fire-fighting equipment, etc.). It is also the employers' responsibility to take adequate measures for the workers' transportation from the accommodation area to the construction site.

The area where workers live should have adequate thermal comfort. For this, the dimensions of rooms and some other requirements, such as air conditioning, must be at acceptable levels. The recommended dimensions in the guidance published by IFC and EBRD (2019) are as follows: "Density standards are expressed as minimum volume or minimum floor area per resident, ranging from 10 to 12.5 cubic meters (volume) or 4 to 5.5m² (surface). Other

restrictions that can affect the design of temporary facilities should include a minimum ceiling height of 2.10 meters. In minimized collective rooms, only a reasonable number of workers are allowed to share the same room to give workers some privacy, ranging from two to eight as a standard. When using a double deck, there should be sufficient free space (0.7 to 1.10 meters) between the bottom and top bunks of the bed". "Ensuring good standards in living facilities helps to avoid safety hazards and to protect workers from diseases and illness resulting from humidity, the spread of the fungus, proliferation of insects or rodents, as well as to maintain a good level of morale".

Sanitary and Toilet Facilities

Sanitary and toilet facilities include water closets, portable chemical toilets and urinals (HSE, 2010). There should always be an adequate number of sanitary and toilet facilities in the construction. Adequate facilities mean making sure there are enough toilets, so people do not have to queue for long periods to go to the toilet. In addition, adequate hygienic conditions should be ensured in these facilities. Toilet arrangements are necessary in construction projects to prevent any contamination caused by biological risks and to prevent the spread of infectious diseases.

The COVID-19 pandemic has revealed the importance of occupational hygiene. The cleaning frequency should be determined according to the number of utilizations. Daily cleaning may not be sufficient; thus, there should be a cleaning plan for these facilities.

The recommended practices for sanitary and toilet facilities in the guidance published by IFC and EBRD (2009) are as follows: "Standards range from one unit per 15 persons to one unit per six persons. For urinals, the usual standards are one unit per 15 persons. Toilet facilities are conveniently located and easily accessible, with standards ranging from 30 to 60 meters from rooms/dormitories. Toilet rooms shall be located to be accessible without any individual passing through any sleeping room. In addition, all toilet rooms should be well lit, have good ventilation or external windows, have sufficient hand washbasins, and be conveniently located. Toilets and other sanitary facilities should be ("must be" in cold climates) in the same building as rooms and dormitories. An adequate number of handwash facilities are provided to workers, with standards ranging from one unit per 15 persons to one unit per six workers. Handwash facilities should consist of a tap and a basin, soap, and hygienic means of drying hands. An adequate number of shower/bathroom facilities are provided to workers, with standards ranging from one unit per 15 persons to one unit per six persons". The BS6465 code (2006) recommends a ratio of one toilet per seven persons where portable toilets are emptied once a week.

Washing and Laundry Facilities

Activities in the construction industry often take place in a dusty and dirty work environment. Activities include the handling and use of chemicals and other hazardous materials. For this reason, an adequate number of washing facilities should always be available in construction areas as a hygiene measure. Washing facilities include basins or sinks that allow people to

wash their hands, face, and forearms (HSE, 2007). In addition to running water (hot and cold), sufficient soap and other personal cleaning materials should be provided. Washing or shower facilities are provided for particular dirty work or work exposing workers to a hazardous substance such as concrete pouring (HSE, 2007). These facilities must be kept in good working condition, cleaned frequently, and always ensure that there is sufficient ventilation and lighting (HSE, 2010). The recommended practices for washing facilities are as follows: "An adequate number of handwash facilities are provided to workers. Standards range from one unit per 15 persons to one unit per six workers. Handwash facilities should consist of a tap and a basin, soap and hygienic means of drying hands" (IFC & EBRD, 2009). Employers should provide the necessary facilities for the workers to wash their dirty clothes. When work clothes are used in contact with a dangerous substance (for example, the application of pesticide), special laundry facilities (washing machines) should be provided (IFC & EBRD, 2009).

In case of special chemical risks such as asbestos in demolition and renovation activities, the number, location, and adequacy of these facilities should be specially evaluated.

Drinking Water

Construction workers take part in strenuous activities. They can face many risks from dehydration on a routine day. To prevent this, workers should always be encouraged to consume enough water, and accordingly sufficient clean water should be easily accessible at the construction site. A healthy source of drinking water should preferably be readily available from the mains. If this is not possible, potable water tanks and bottles can be considered. In all cases, containers that contain drinking water must be protected from contamination. The source of drinking water should be marked to distinguish between potable and non-potable water, such as hazardous liquids and non-potable water (HSE, 2007).

Canteen/Dining Halls/Cooking Facilities

These facilities must be kept in clean and sanitary conditions. The canteen, kitchen, cooking floors, ceilings and walls should be made of easily cleanable materials. The canteen and dining hall should be adequately furnished. Tables, benches, individual glasses and plates, and other necessary materials should be available in sufficient numbers and suitable conditions in these areas. These areas should be designed in sufficient size so that workers do not wait in line at mealtime sanitation.

Hygiene while cooking for workers and food safety is important. Places for food preparation should be designed to permit good food hygiene practices, including protection against contamination between and during food preparation (IFC & EBRD, 2009).

Adequate precautions should be taken against fire in kitchens. For this, sufficient fire/gas detection sensors and the right type of fire extinguisher should be available. Wall surfaces adjacent to cooking areas in kitchens should be made of fire-resistant material.

Changing Rooms and Lockers

Changing rooms and lockers are essential for workers to store their belongings and change their daily clothes with the necessary protective clothing. Work clothes should be kept away from personal clothes. Because work clothes can be contaminated with dangerous substances, clothes can become dirty due to the working environment.

Changing rooms should have such a design that workers can dress comfortably and there should be a separate locker for each worker. Standards vary from providing an individual cupboard for each worker to providing 475-liter large lockers and one meter of shelf unit (IFC & EBRD, 2009). The cabinet lock must be personal. The safety of personal belonging in locker rooms should be ensured by facility security personnel.

Rest Facilities

Activities carried out in construction projects are labor intensive. In a routine working day, it is inevitable for workers to take breaks at certain times. Breaks are important to reduce the mental and physical fatigue of workers. For this reason, suitable and adequate resting facilities should be provided so that workers can easily access during break times. Rest areas can also be in working areas only if they are clean enough (for eating). However, these areas should not be used to store equipment or supplies. Rest areas should be designed in a way that is less affected by seasonal conditions (wind, rain, etc.).

The size of the remaining facilities is proportional to the workforce in the project. If there is an accommodation facility in the project, special areas should be created for the workers in these areas apart from the working areas. Adequate seating groups and tables should be provided in rest facilities, as well as equipment and materials to enable workers to consume hot drinks and meals.

Medical Facilities

Providing adequate first aid training can save lives and prevent minor injuries from becoming major injuries. The availability or level of medical facilities provided in workers' accommodations is likely to depend on the number of workers living on the site, the medical facilities already existing in the neighboring communities and the availability of transport (IFC & EBRD, 2009).

Other Social Facilities and Requirements

To improve workers' well-being, it is important to provide workers with basic recreational and social facilities. The building contractor should consider providing basic public social areas (e.g. prayer rooms, libraries, multipurpose halls, TV rooms, etc.) and additional leisure/sports facilities. Communication systems, such as an Internet connection, should be provided conveniently or free of charge.

Management of Construction Welfare Facilities

Every construction project needs different sizes and types of welfare facilities to ensure the well-being of workers. The size and variety of the facilities may vary depending on the legislation in the country of the construction, company policy, client/investor expectations/contract conditions, project type and workforce. Therefore, before starting any project, the welfare requirements in the project should be analyzed in detail. If these requirements are not understood and the necessary planning is not done, in most cases, it is not possible to expand and diversify these facilities during the construction phase. In addition, analyzing the construction welfare facilities can also help define the cost analysis and the resources to be allocated during the project.

Welfare facilities planning in construction projects should be considered during the planning and preparation phases of each construction project before construction work begins. HSE (2010) proposes to consider the following when planning outreach to constructions:

- "the nature of the work to be performed and the associated health risks (physical, chemical and biological risk factors)
- duration of work and number of different locations
- the number of people who will use them
- are relocated during the construction phase."

Multiple parameters affect the size and location of welfare facility types. The association made by the ILO (n.d) regarding the types of welfare facilities in constructions and the factors affecting them has been updated by the author in Figure 2.

Considering the parameters and relations specified in Figure 2, the type, size, and location of welfare facilities should be determined. The site layout should be prepared after evaluating the location of welfare facilities and their relationship according to the emergency planning and site access roads (Elbeltagi et al., 2004). Another work to be done during the preparation phase of the project is to plan the management of these facilities. It is recommended to prepare a written Construction Welfare Facilities Management Plan (CWFMP) for this. This plan should be linked to other plans and procedures as a component of the project's health and safety management system. The CWFMP should contain, as a minimum, the followings:

- A policy that meets workers' welfare needs
- Identification of facilities (types, sizes, location, and minimum requirements)
- Identification of key personnel and their responsibilities for the maintenance and management of the facilities (site manager, accommodation manager, security guard, HSE team, etc.)
- Methods for risk reduction in facilities (including relocation of facilities)
- Routine checks and drills
- Regular maintenance activities
- Relationships with the communities and grievances
- Facility security

Facility/Factors	Factors affecting sizing of facility							Factors affecting locating of facility						
	Statutory requirement	Company policy	Past experience	Size of workforce	No. of workers	Site location/Type	Phase of project	Statutory requirement	Company policy	Past experience	Size of workforce	No. of workers	Site location/Type	Phase of project

Accommodation		•	•	•		•		•	•	•	•	•		•
Sanitary and toilet	•	•	•	•				•	•	•	•	•	•	•
Washing and laundry	•	•	•	•				•	•	•	•	•	•	•
Canteen/Dining hall	•	•	•	•			•	•	•	•	•	•	•	•
Changing rooms and lockers	•	•	•	•			•	•	•	•	•	•	•	•
Rest facilities	•	•	•	•				•	•	•	•	•		•
Medical facilities	•	•	•	•		•		•	•	•	•	•	•	•

Figure 2: Affecting factors and welfare facility type (adapted from ILO, n.d).

The CWFMP should be completed during the preparation phase of the project; if needed, it can be revised later. Mobilization planning should be carried out using the CWFMP. According to the CWFMP, installed/assembled facilities should be inspected and regularly maintained throughout the construction period.

Employees should be informed about the rules for the use of facilities. In addition, emergency drills need to be conducted. The condition of the facilities should always be reviewed as part of the emergency planning in the project, especially fire.

If it is necessary to relocate welfare facilities at various stages of the project, this should be done by observing the minimum criteria previously described in the CWFMP. The optimum positioning of welfare facilities is important, particularly in projects with insufficient construction areas. For this, modular systems can be rented or purchased. In light of the factors affecting the type of facility and the above information, the association made by the ILO (n.d) for the design and management of welfare facilities in construction projects has been developed and updated by the author as shown in Appendix 1.

It should be reminded that the temporary facilities mentioned in this study are related to the basic vital needs to ensure welfare of the workers. Workers' holistic needs for health and well-being require more than just building and operating these facilities. It should also be reminded that ensuring well-being in the workplace also covers issues such as recognition and rewards, communication channels, grievances, fair treatment and pay, human rights, and nondiscrimination.

Conclusion

Ensuring the well-being of employees has become a practical necessity in terms of sustainability in addition to being a legal obligation. If welfare of the workers is not ensured sufficiently in constructions, there is a risk of worsening their health, an increased loss of working days, loss of motivation in the workers regarding occupational health and safety

practices and loss in productivity. For this reason, although welfare management is considered a component of the occupational health and safety activities conducted in the project, this should be considered as a title of project risk management. For construction projects to be more efficient, healthy and safe, project managers can acquire deeper knowledge of the needs of health, safety, and wellbeing. They can also consider international best practice recommendations in the design of facilities and ensure that workers are fully provided with welfare facilities during construction.

This study has defined the steps to be followed for the management of welfare facilities from the preparation phase of the project to the end of the construction phase. It is recommended to implement a plan called CWFMP for the management of welfare facilities in construction projects. The criteria specified in this study are limited to the norms specified in the references. As mentioned earlier, welfare requirements in construction projects may differ according to the type of projects, the legislation of the countries in which they are carried out, and other requirements of commercial contracts. These variables can change the depth of information that may be required for the CWFMP and other related documents.

A Review Study for Real-time Monitoring in Construction Health and Safety

T. Altınkaynak Akıncı, O. H. Türkakın and Ö. Giran
İstanbul University-Cerrahpaşa, Department of Civil Engineering, İstanbul, Turkey
tugce.altinkaynak@iuc.edu.tr, turkakın@iuc.edu.tr, ogiran@iuc.edu.tr

Abstract

The construction industry has one of the highest accident ratios according to international occupational safety statistics. Construction safety monitoring is mostly done by manual supervision in present applications. It is challenging for safety inspectors to continuously monitor and manually determine all events that have potential health and safety risks. To deal with this matter, real-time monitoring of construction sites is necessary to detect and remove possible dangers on time. Therefore, both the hazardous status of environments and the risky behavior of workers must be monitored in real-time to protect workers from injuries and fatal accidents. Monitoring systems can include a variety of components and methods, can be applied to different kinds of environments and activities, and satisfy the needs of the safety inspection. This study aims to review the previous works and present the current research status on this subject. Literature research and interpretation in construction monitoring are presented in this review. The results show the advantages of monitoring in real-time, system components, effects of monitoring on safety, and limitations of the system. In a conclusion, real-time monitoring system elements can be chosen according to site conditions, and they are more powerful in safety the contrast to manual inspection.

Keywords: *construction site safety, real-time monitoring, sensors.*

Introduction

Sensor and monitoring technologies have been in a rapid development process in recent years. The production of more sensitive, fast data transfer, affordable and suppliable products is increasing. With these products, control and monitoring of large areas can be realized. In order to meet the increasing population and needs, the size of the structures to be built is also increasing. As a result, construction sites also cover large areas, and monitoring of these sites becomes essential for occupational safety and worker health. Monitoring of construction sites is essential for internal and external stakeholders as well as employees. The right time and regular flow of information are crucial for the success of the project (Naticchia et al., 2013; Teizer et al., 2007). Many fatal accidents are common on construction sites. Visual control and monitoring become more and more difficult in construction sites where many employees work together (Xiong et al., 2022).

The construction industry strictly depends on monitoring the construction area as well as taking precautions against occupational accidents. And taking precautions depends on

monitoring the construction field. Various tools are developed such as RFID, UAV, and Computer Vision. And besides, the outcomes of these tools are investigated in various research studies (e.g., Rao et al., 2022). This study focuses on safety issues and solving them by using emerging technological devices and methods. Besides this, a scientometric study is applied to see the trends and current developments of sensor applications on safety issues in construction management.

Studies about IoT and Sensors on Construction Monitoring

The Internet of things (IoT) represents a group of interconnected sensors and devices that work simultaneously to process specific tasks. In industry, IoT can be applied for tracking of safety management in warehousing systems (Zhao et al., 2021). And in the construction sector, IoT is used for detecting the unsafe behavior of construction workers. There are several initial studies about monitoring the construction field to provide occupational safety (Chi et al., 2008; Lee et al., 2009). Khan et al. (2022) designed a safety hook monitoring system using smart safety hooks at high working places. A similar study is conducted on falling from scaffolds by using computer vision techniques (Khan et al., 2022). By using these technologies, a significant decrease in falling from heights appears. Kim et al. (2019) developed a Zigbee-based IoT alarming system that is triggered when a worker reached a hazardous zone. Early warning systems can be built by using IoT technologies. Kanan et al. (2018) develop an IoT-based system to warn workers of the risk of occupational accidents. Zhou and Ding (2017) developed a safety barrier warning system for underground workers. Zhang et al. (2019) used an IoT-based system to detect nonuse of hard hats in the construction area.

By using IoT technologies, a worker can be spotted by using low-energy Bluetooth sensors in the construction zone (Lim et al., 2016). As a result of the spotting ability of IoT techniques, BIM technologies can practically cooperate along with IoT technology. Especially for facility management, IoT can be easily applied for monitoring the facility and labeling BIM data. Su and Kensek (2021) detect anomalies (e.g., inconsistencies with ASHRAE 55 comfort standards) and display anomalies in 3D BIM models. Cheung et al. (2018) developed an early warning system for hazardous gases which employs both BIM and a wireless sensor network. Zhang et al. (2021) used an AI-based IoT technology to monitor tunnel construction and estimate construction-based settlements using the random forest algorithm. Tang et al. (2019) provide a literature review for BIM and IoT-related publications. Besides, IoT and 5G technologies are used for recycling construction wastes (Sartipi, 2020).

Studies about Wearable Devices

Wearable devices include several kinds of technologies that enable tracking workers' situations such as locations, working speed, and health situations. In recent years, various studies are conducted on the benefits of wearable devices. By using these devices, projects can be monitored in more detail and more frequently. Monitoring could be done before adopting these devices. Such as, Teizer and Vela (2009) used video cameras to track construction personnel. By using wearable technologies, personnel's physical condition can be tracked alongside their locations (Al Jassmi et al., 2021). The basic challenge is to transform the acquired data from the devices into a more structured form to be more useful to project managers (Rebolj et al., 2008).

Studies about Construction Monitoring

Scientometric studies are conducted for obtaining new trends in the literature. There are various software packages developed for generating network graphs that show connections between authors, keywords, or other various fields. In this study, VOS viewer is used for analyzing the literature field. A detailed literature review was performed to obtain a complete overview of real-time monitoring studies in terms of construction health and safety. The focus of this review is giving scientometric background on the related articles that were published between 2006 and 2022. For the purpose of finding relevant papers, the following academic databases were used: ASCE, Emerald Insight, ICONDA CIB Library, ITcon, MDPI, Science Direct, and Taylor&Francis. 85 studies were obtained to be more pertinent as a consequence of the search. Journal articles and conference proceedings are the two types of acquired studies. Totally, seven conference proceedings and 78 journal articles were obtained. The scientometric analysis is conducted for these documents.

Figure 1 shows the percentages of databases in a pie chart. The ScienceDirect database holds the largest number of studies with 52 papers, 61% of all publications. ASCE database includes 16 papers and 19% of the total publications. . These 16 studies include 10 journal articles and 6 conference proceedings. The rest of twenty percent of publications were found from these databases: 6% (5 articles) from the ITcon database, 5% (4 articles) from the MDPI database, 5% (4 articles) from the Taylor&Francis database, 3% (3 articles) from Emerald Insight database, and 1% (1 conference proceeding) from ICONDA CIB Library database.

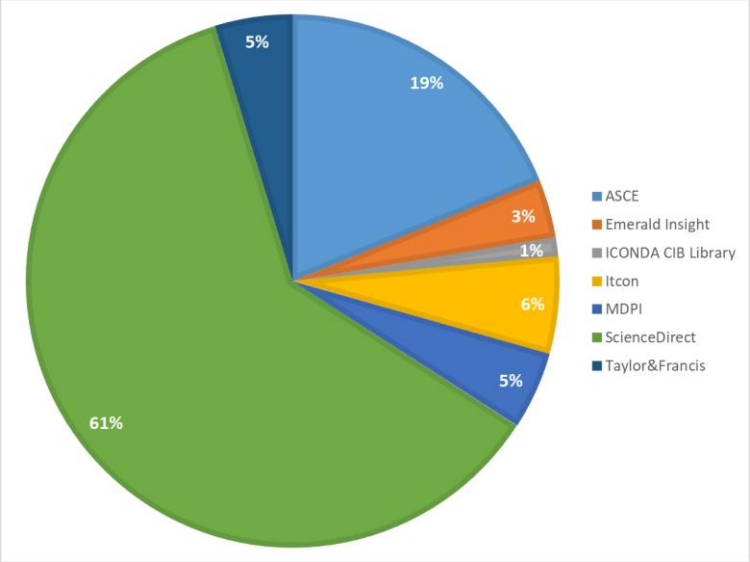

Figure 1: Distribution of databases used to find relevant studies.

Figure 2 illustrates the quantity of journal papers in different journals. A total of 78 journal articles are published in 23 distinct resources. The Automation in Construction journal has the most articles, 32 total, accounting for 41% of all publications. 7 articles (9%) published in Safety Science, 6 articles (8%) published in Journal of Construction Engineering and Management, and 5 articles (6%) published in Advanced Engineering Informatics. There are three articles (4%) for each of the following journals: Journal of Civil Engineering and Management, Journal of Computing in Civil Engineering, Journal of Information Technology

in Construction, and Sensors. Electronic Journal of Information Technology in Construction has 2 articles, accounting for 3%. 14 other journals, each with one publication, account for the remaining 14%.

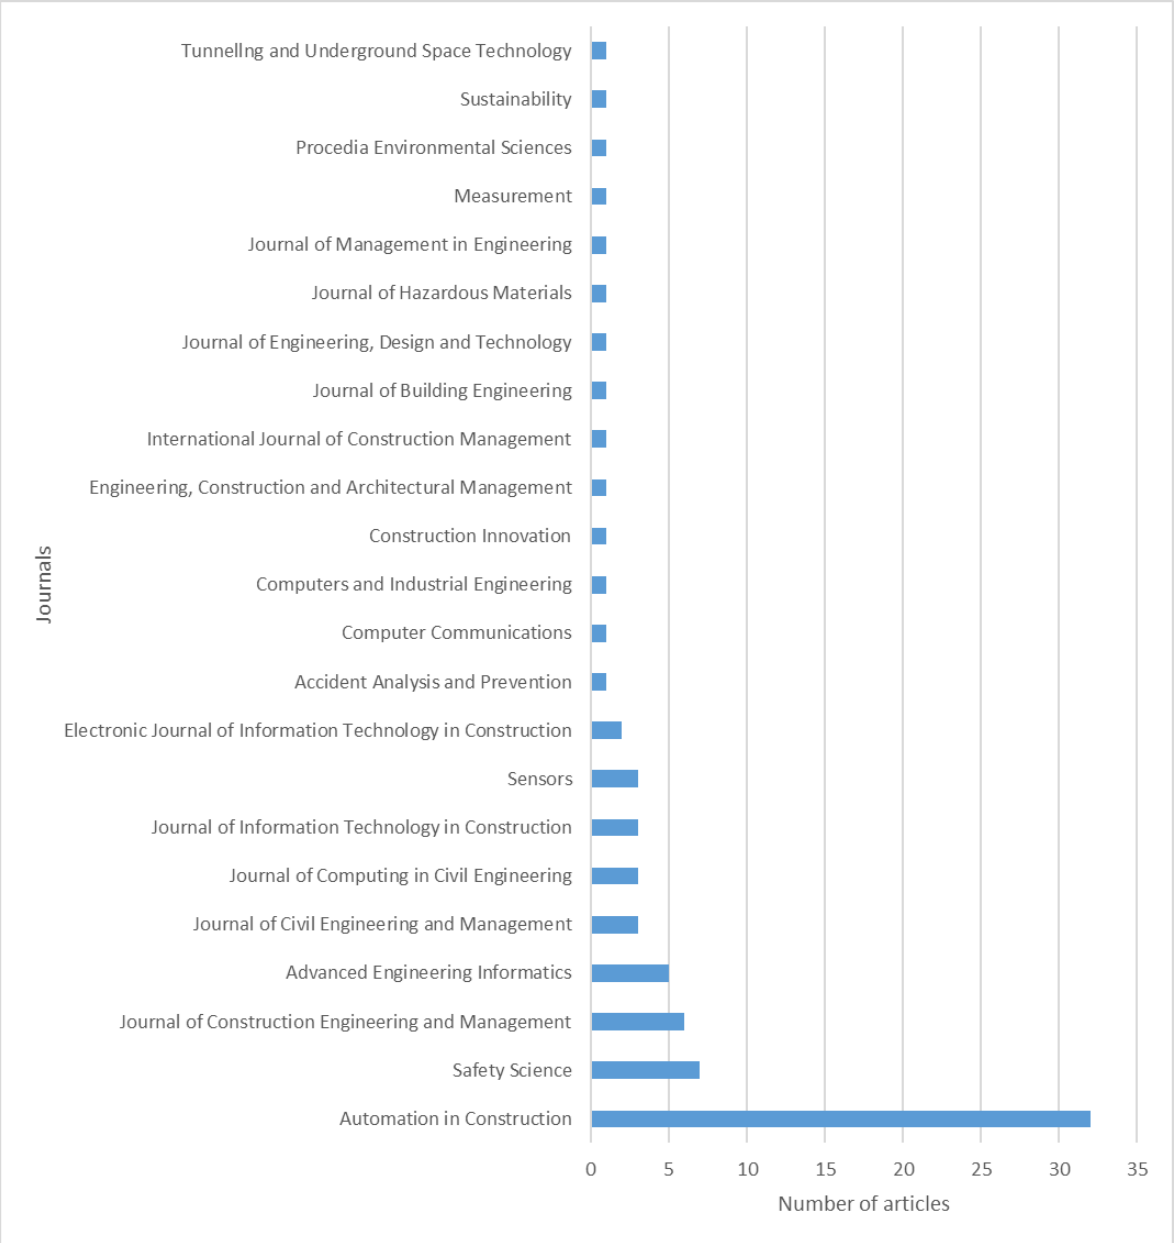

Figure 2: Number of articles published in various journals.

The geographical distribution of research on the topic of real-time monitoring in construction health and safety is visualized in Figure 3. Whole publications are submitted from 17 different countries. In the case of multiple authors, the country of the corresponding author was taken into account while generating the geographical distribution of the articles. The majority of studies are from the United States. There are 30 studies (35%) from the United States, 24 studies (28%) from China, 6 studies (7%) from South Korea, 5 studies (6%) from Germany, 3 studies (4%) from Australia, 3 studies (4%) from Italy, 3 studies (4%) from the United Kingdom, 2 (2%) studies from Israel and 9 (10%) from other countries. Additionally, just one

publication was discovered on the following 9 countries: Brazil, Japan, Pakistan, Poland, Singapore, Spain, Taiwan, Turkey, and United Arab Emirates.

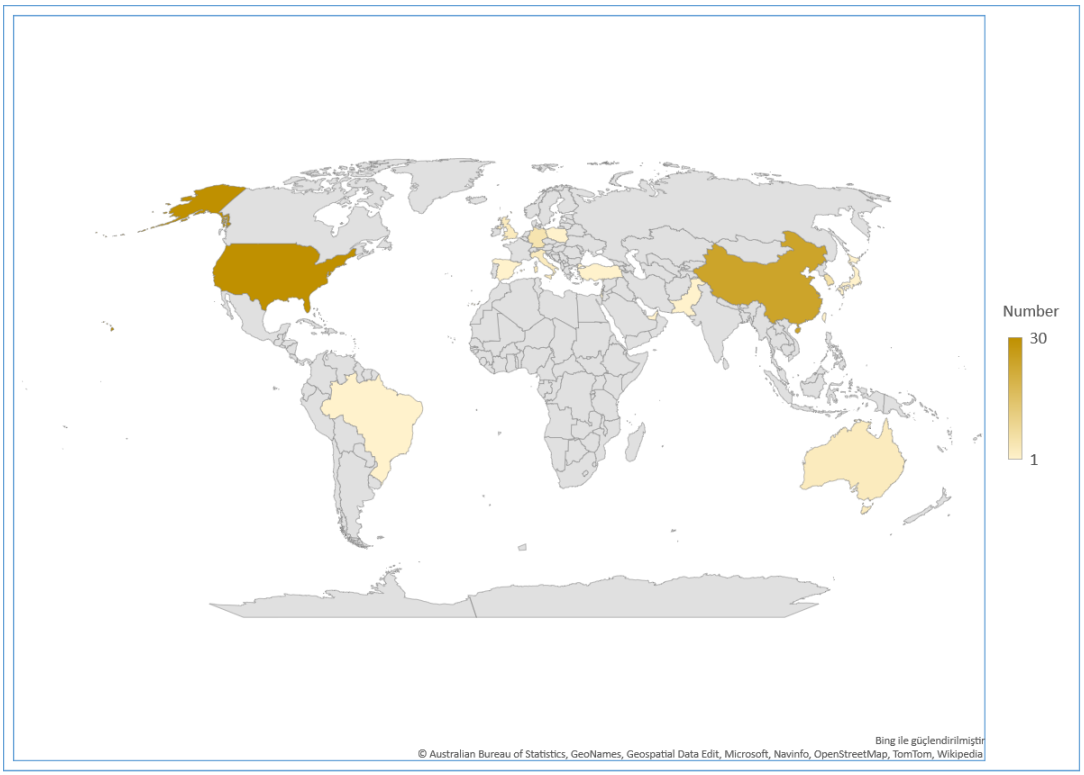

Figure 3: Geographical distribution of articles about real-time monitoring in construction site safety.

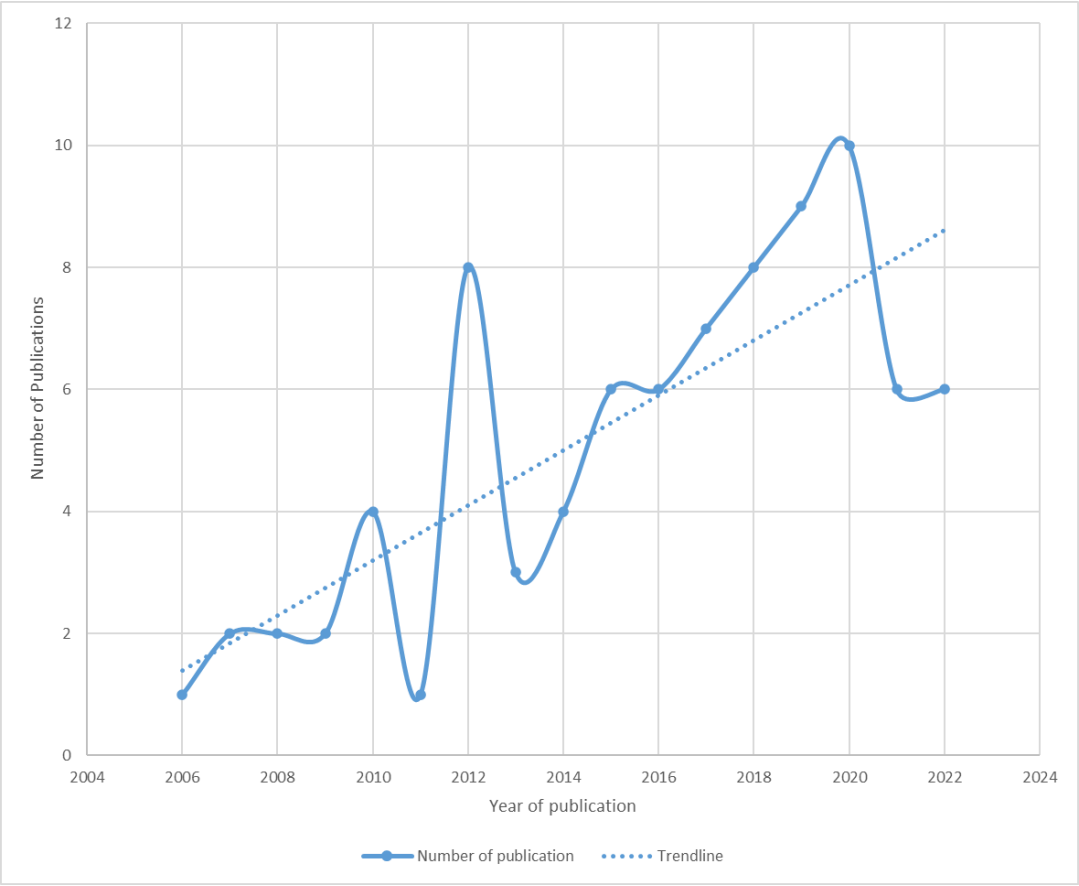
Figure 4 shows the chronological distribution of publications on real-time construction safety monitoring between the years 2006 and 2022. The trendline, a line that closely passes the data points, is plotted on this graph. The plot shows that the number of studies about construction safety monitoring has been increasing over the years, and that means the trend in the area is increasing.



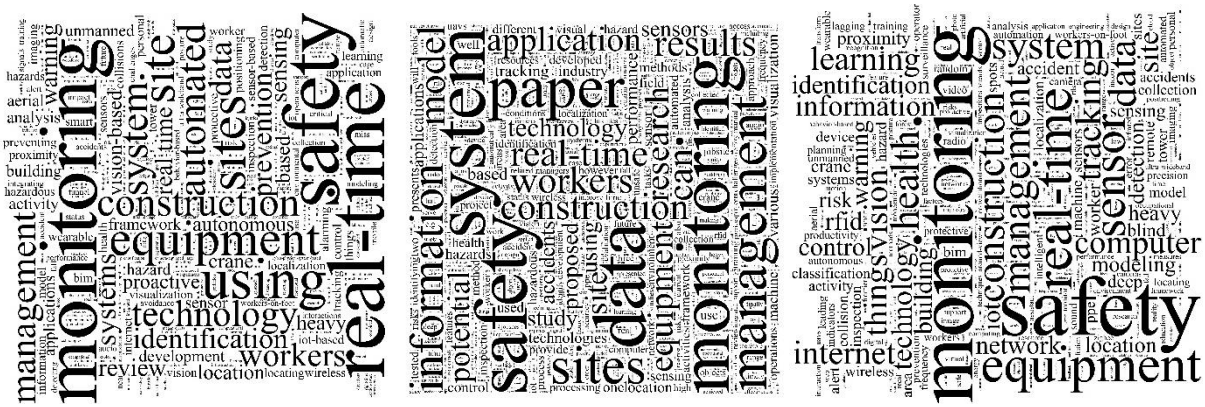


Figure 4: Number of studies about real-time construction safety monitoring per year.

Figure 5 shows the frequency of words used in studies analyzed using the word clouds. Word clouds for the keywords, abstracts, and titles were all generated separately.

(a) Title (b) Abstract (c) Keywords

Figure 5: Distribution of terms depending on how frequently they appear in the title, abstract, and keywords of the papers under analysis.

Another type of textual analysis that was carried out with the use of the VosViewer software tool was similarity analysis. The relations between terms are demonstrated by similarity analysis. The Vosviewer software tool supports a variety of data sources for creating maps, including bibliographic database files from Web of Science, Scopus, Dimensions, Lens, and

PubMed, reference manager files from RIS, EndNote, and RefWorks, and data through API from Crossref, OpenAlex, Europe PMC, Semantic Scholar, OCC, COCI, and Wikidata. Firstly, the publications in Mendeley, a kind of reference manager, were exported as a RIS file and then imported into Vosviewer to perform similarity analysis. After the analysis and counting methods were chosen, the maps were generated.

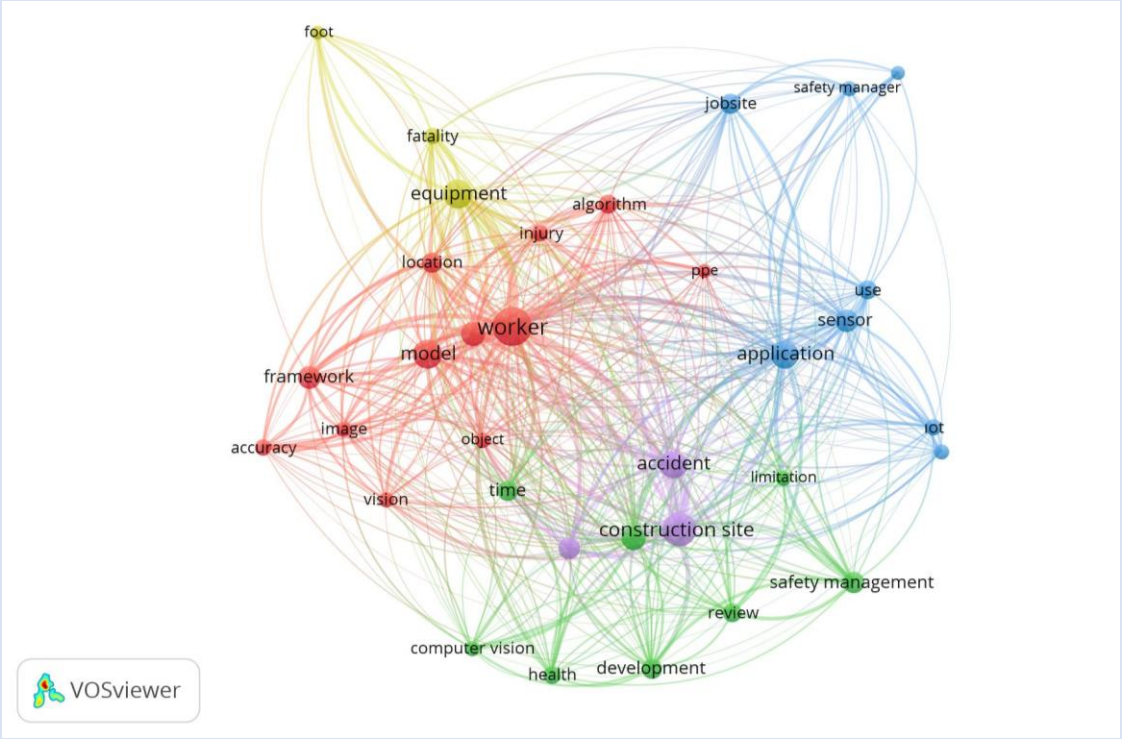

Figure 6: Term similarity analysis within the corpus of texts.

The similarity analysis using a graph is demonstrated in Figure 6. According to the proportion of co-occurrence, the graph in Figure 6 displays the connection between the terms in the abstracts. Larger words appeared more frequently in the abstracts than smaller ones, and more lines imply higher co-occurrence. Figure 7 shows the co-authorship network map which also indicates the year of studies that the author contributes by the color of circles. And each line represents the co-authorship between authors.

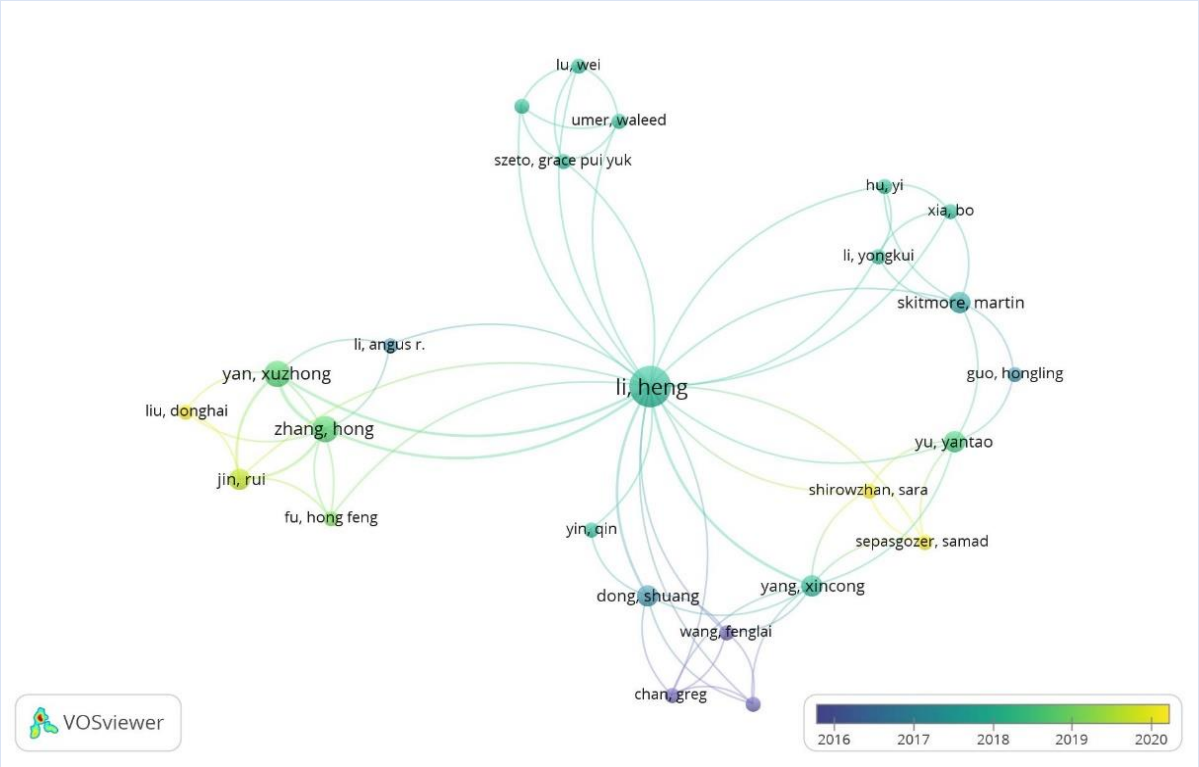

Figure 7: Co-authorship network visualization of analyzed studies.

Conclusion

Various kinds of research are conducted to increase measure levels of occupational safety. In recent years, various novel technologies such as IoT, BIM, and RFID accompanied occupational safety research studies. The difficulty of monitoring construction sites with complex structures is emphasized, and automation is recommended to overcome this difficulty. However, high investment costs and adaptation processes can be considered obstacles to the widespread use of real-time sensing and monitoring technologies in construction projects. In the construction management discipline, IoT and different types of sensors are starting to be used more frequently for safety issues. There is a need of conducting scientometric analysis for the related works. This study shows the increased interest in dealing with safety-related problems by using these kinds of devices.

Assessment of Occupational Health and Safety Problems in the Construction Sector in the World and in Turkey

S. Demirkol Kurkcuoglu and E. Bostancioglu
Istanbul Kultur University, Institute of Graduate Education, Istanbul, Turkey
sukrandemirkol@hotmail.com, ebostancioglu@iku.edu.tr

Abstract

The construction sector is one of the leading sectors of the Turkish economy, as in all other countries. Due to the large number of employees, difficult working conditions and a dynamic structure of the construction sector; occupational accidents, injuries and acquired diseases have reached serious numbers over time. They have caused damage to human life, the sector and the economy. According to the data of the Social Security Institution in Turkey, 281.191 people have had work accidents for the last five years and 2,432 people died in the work accidents. Occupational health and safety aims to provide necessary controls and to minimize accidents with the measures to be taken in line with these factors. In this study, the literature about the occupational health and safety in the construction sector will be scanned, and the problems of occupational health and safety on the basis of countries will be evaluated with content analysis method. Content analysis method is an appropriate method that can be used in scanning the texts in the literature in order to express and classify the problems with certain words. The problems and the weights of the problems for occupational health and safety in the construction sector will be determined on the basis of countries with content analysis method. The problems identified in the world will be evaluated and compared with those in Turkey.

Keywords: *construction sector, content analysis, occupational safety.*

Introduction

The construction sector is a dynamic sector that communicates and interacts with almost every sector in the country and includes many sub-sectors. The construction industry in Turkey is the locomotive industry. The construction sector has undertaken important functions such as providing resources to the economy, creating employment, activating other sectors, influencing the natural and social environment, adding value and creating competition. For this reason, positive and negative developments in the country's economy directly affect the construction sector. Positive and negative developments arising from the sector directly affect the country's economy.

The construction industry has become a sector that has many risks and dangers due to the large number of employees, difficult working conditions and active structure. Due to the structure of the sector; accidents, injuries and acquired diseases have reached serious numbers

and have caused material and moral damage to human life, the sector and the country's economy.

According to the definition of the World Health Organization (WHO), “Occupational accident; It is an unplanned event that often leads to personal injury, damage to machinery, tools and equipment, and production stoppage for a while”. (WHO). According to the definition of the International Labor Organization (ILO); “An unexpected and unplanned event that causes specific harm or injury” (ILO).

When the distribution statistics of the within the scope of article 4-1/a of the Social Security Institution (SGK) Law No. 5510, who had a Work Accident, had a fatal work accident or got an Occupational Disease, according to Economic Activity; it has been determined that the construction industry in Turkey inflicts thousands of material and moral losses every year between the years 2016-2021.In the last five years, a total of 281.191 people in the construction sector have had work accidents and have become incapable of work for a certain number of days. However, a total of 2,432 people lost their lives due to work accidents. In addition to production technology, production tools, environmental conditions, many sociological, psychological and physiological factors play a role in the occurrence of occupational accidents. However, all the factors that cause occupational accidents can be reduced to two main factors. These are the unsafe situations in the workplace and the unsafe behaviors of the employees (MMO, 2012). The measures taken to prevent these unsafe situations and unsafe behaviors of employees, and which are legally obligatory to be taken are called "Occupational Health and Safety Precautions".

Within the scope of this study, national and international literature in the field of occupational health and safety in the construction sector has been reviewed. Theses covering the terms "Construction", "Occupational health" and "Occupational safety" have been scanned from YÖK Thesis Center.

The fact that there have been many publications in the field of occupational health and safety in every sector up to now, especially in sectors where occupational accidents and occupational diseases have been frequently encountered, shows the importance of the subject.
In this study, as a result of the literature review, National and International publications in the field of occupational health and safety in the construction sector were evaluated by content analysis method and the publications were classified according to the determined categories. It is aimed to determine the category weights and to compare these weights in Turkey and in the world.

Method

The flow chart of the method of the study is shown in Figure 1. Studies in the field of occupational health and safety in the construction sector have been compiled. The related sources were scanned by content analysis method and their repetition frequency was determined by classifying them according to the determined categories.

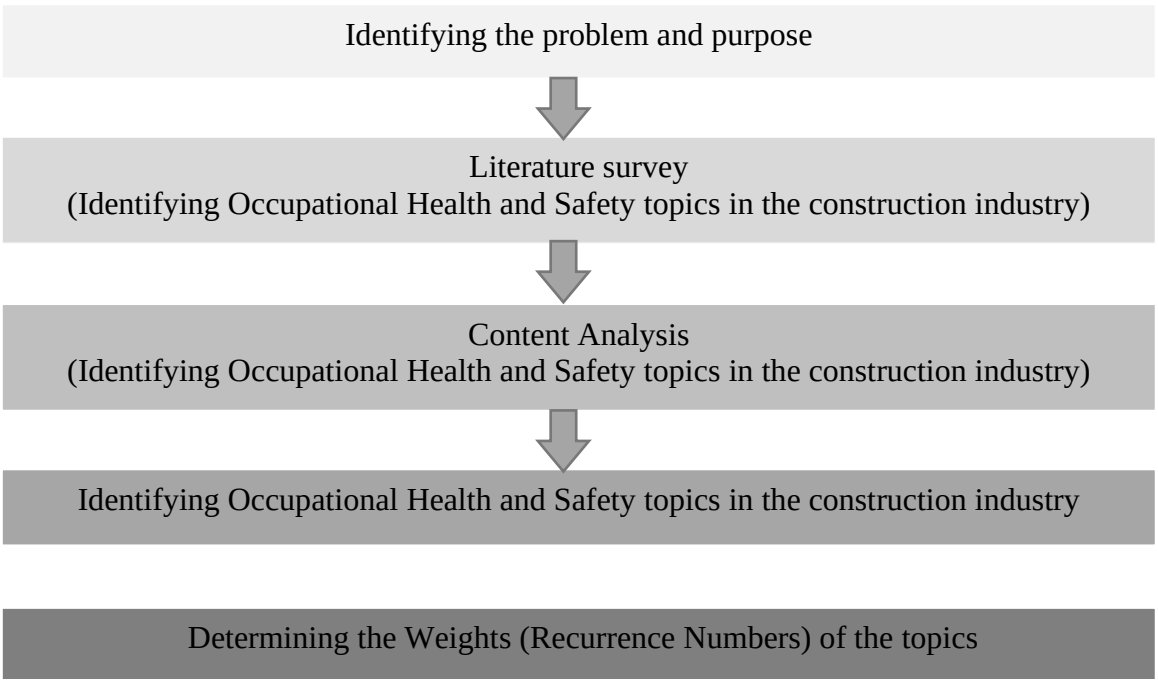

Figure 1: Method flow chart.

Literature Research

When the studies in the literature have been examined, many studies have been found in the fields of Health, Industry, Education-Training, Law, Business Administration, Architecture and Engineering, including the terms "Construction sector", "Occupational health and safety", "Worker". Theses published in the fields of Architecture and Engineering have been examined and a total of 76 theses have been reached in this field. According to the literature review made on Web of Science, a total of 126 resources were reached, including 83 articles, 32 Papers, 6 Review articles, 5 Article-Book sections. The publications reached in the literature will be scanned with the content analysis method in the next stage of the study. Categories will be determined as a result of the content analysis.

Content Analysis

Content analysis is a method of analyzing written, oral or visual communication messages. (Cole, 1988) It allows the researcher to test theoretical issues to enhance understanding of the data. Through content analysis, it is possible to distil words into fewer content related categories. It is assumed that when classified into the same categories, words, phrases and the like share the same meaning (Cavanagh, 1997) It is the systematic examination of text and field notes by identifying and grouping themes and coding, classifying and developing categories (Jonge et al., 2007) In qualitative content analysis, the results are presented in the form of categories and/or themes. (Graneheim et al., 2017).

Determination of the Sample

A total of 126 publications, including articles, papers and book chapters containing the terms "Construction sector", "Occupational health" and "Occupational safety", published in the Web of Science between 2010-2022 were scanned.

Determination of the Categories

Within the scope of the study, the topics in the International Occupational Safety and Employee Health Congress and the International Occupational Health and Safety Congress have been scanned (Table 1). At the end of the assessment of national and international publications with the topics of both congresses (Table 1), "Occupational and Worker Safety", "Occupational Health and Accidents", "Design", "Occupational Safety Management System", "Accident Risks", "Occupational Health and Safety Culture", "Occupational Health and Safety", "Safety practices", "Legislation", "Occupational safety training", "Audit" and "Cost" have been determined as categories.

Table 1. Topics of international occupational health and safety congresses.

INTERNATIONAL OCCUPATIONAL SAFETY AND EMPLOYEE HEALTH CONGRESS (http://www.isguvenligivecalisansagligikongresi.org/)	**INTERNATIONAL OCCUPATIONAL HEALTH AND SAFETY CONGRESS** (http://www.iohsc2017.org/)
Emergency Management	Behavioral Sciences and OHS
Employee Safety	Chemical Industry and OHS
Employee Health	Emergency Management and OHS
Nutrition in Employees	Incentive Mechanisms in OHS
Motivation and Performance in Employees	Ergonomics and OHS
Security Engineering Applications	Good Practices in OHS
OHS Security	Inspection and Audit Practices
OHS Emergency Communication	Occupational Hygiene
Risk Analysis in OHS	Maintenance, Repair and Periodic Controls of Work Equipment
Risk Management in OHS	Metal Sector and OHS
OHS Training	Accidents at work
OHS Cost Analysis	Occupational Health and Occupational Diseases
OHS Legislation	Occupational Health and Safety Services

OHS Database	OHS and Law
OHS Statistics	OHS in Public Institutions and Organizations
OHS Management Systems	OHS Culture
Industrial Products in OHS	OHS Regional Cooperations and Networks
Accident Analysis	OHS organization in the workplace
Controls and Documents to be Issued (Documentation)	OHS in the Agriculture Sector
OHS in mines	OHS in the Construction Sector
Health Informatics	OHS in the Mining Industry
Social Security System	OHS in the Use of Chemicals
Hazardous Substances and Waste Management	OHS Management Systems
Technology Management and Use	Personal Protective Equipment
Fire Response Techniques	OHS in Planning and Project Design
Structural Health and Safety	Process Safety and Management Systems
OHS in Construction Works	Risk management
Occupational Hygiene	Scientific and Technological Developments
Labor Law Employee Rights	Sectoral OHS Practices
Work health	Education and OHS
Business and Quality Management	Working at Height
Equipment Maintenance and Repair in Businesses	
Health Management in the Workplace	

Data Analysis

Identified categories have been assessed on the basis of the 126 publications. Abstracts of the 126 publications have been reviewed and the categories identified have been analyzed based on the words in the abstracts. The countries of publications have been assessed, too. (Table 2). "Occupational and Worker Safety", "Occupational Health and Accidents", "Design", "Occupational Safety Management System", "Risk Analysis", "Occupational Health and Safety Culture", "Occupational Health and Safety Practices", "Legislation and Legislation

appropriate work", "Occupational safety training", "Inspection", "Cost" categories have been assessed in terms of countries. Identified categories have been assessed for Turkey, too.

Table 2. Category classification in terms of countries (https://access.clarivate.com/).

COUNTRY	**CATEGORY**	**PUBLICATION (AUTHORS AND YEARS)**
USA	Work and Worker safety	Hinze et al. (2013), Gatti & Schneider (2014), Park et al. (2015), Bhoir & Esmaeili (2015), Choi et al. (2017), Yang et al. (2017), Hindman et al. (2017), Lee et al. Determination of the Counting System

"Occupational and Worker Safety", "Occupational Health and Accidents", "Design", "Occupational Safety Management System", "Accident Risks", "Occupational Health and Safety Culture", "Occupational Health and Safety Practices", "Legislation", "Occupational safety training", "Audit", "Cost" categories have been analyzed on the contents and abstracts of the publications, and the frequency of categories have been determined. Frequency of the data has been considered as counting system for the assessment of data

Evaluation of the Findings

In the research conducted on Web of Science between 2010-2022, publications of 27 countries in the field of occupational health and safety have been found. USA 34 in this regard; China 19; Malaysia 14; Spain 10; Australia 6, Lithuania 4; Turkey 3; Portugal 3; South Africa 3; Indonesia 2; Iran 2; India 2; South Korea 1; Pakistan 1; Nigeria 1; Taiwan 1; Ghana 1; Iraq 1; Syria 1; England 1; Norway 1; Germany 1; Slovakia 1; Bangladesh 1; Uzbekistan 1; Singapore has 1 publication. Nine of the studies are general studies, not country-based. It is seen that the countries with the highest number of studies are the USA, China and Malaysia, respectively. Turkey is in 8th place.

The frequency of categories in the world and in Turkey is shown in Figure 2. In 126 publications in the literature; 30 in the “Occupational and Worker Safety” category, 19 in the “Occupational health and accidents” category, 16 in the “Design” category, 15 in the “Occupational safety management system” category, 15 in the “Risk analysis” category, 12 in the “Occupational health and safety culture” category, There were 8 publications in the "Occupational health and safety practices" category, 3 publications in the "Legislation" category, 3 publications in the "Occupational safety training" category, 2 publications in the "Audit" category, and 1 publication in the "Cost" category (Figure 2).

In 76 graduate theses published in Turkey; 3 in the "Occupational health and accidents" category, 2 in the "Design" category, 9 in the "Occupational safety management system" category, 16 in the "Accident Risks" category, and 16 in the "Occupational health and safety culture" category. 7, 15 studies were found in the "Occupational health and safety practices" category, 2 in the "Legislation" category, 11 in the "Occupational safety training" category, 2 in the "Audit" category, and 9 in the "Cost" category. There hasn’t been a graduate thesis on "Occupational and Worker Safety" category.

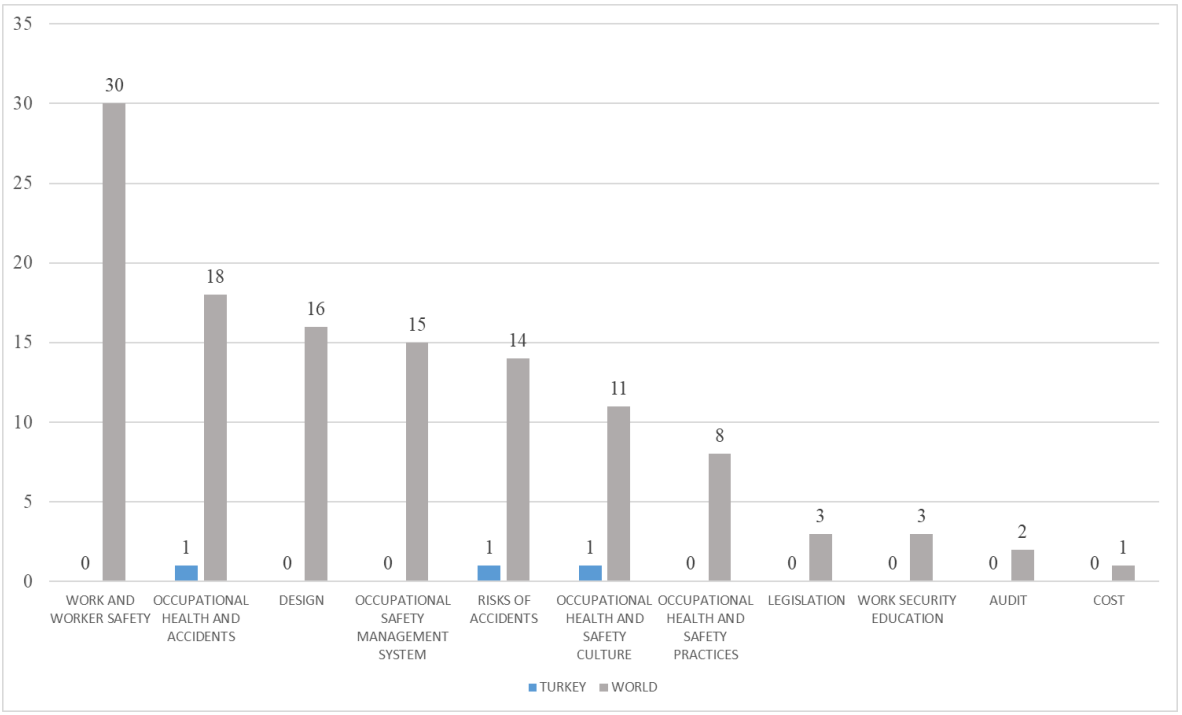

Figure 2: Frequency of categories in the world and in Turkey.

Most of the studies done in the world belong to America, China, Malaysia and Spain. Most of the American publications are on "Occupational and Worker Safety". China has made most of its publications on "Occupational health and accidents", "Occupational health and safety" and "Accident risks" (Figure 3).

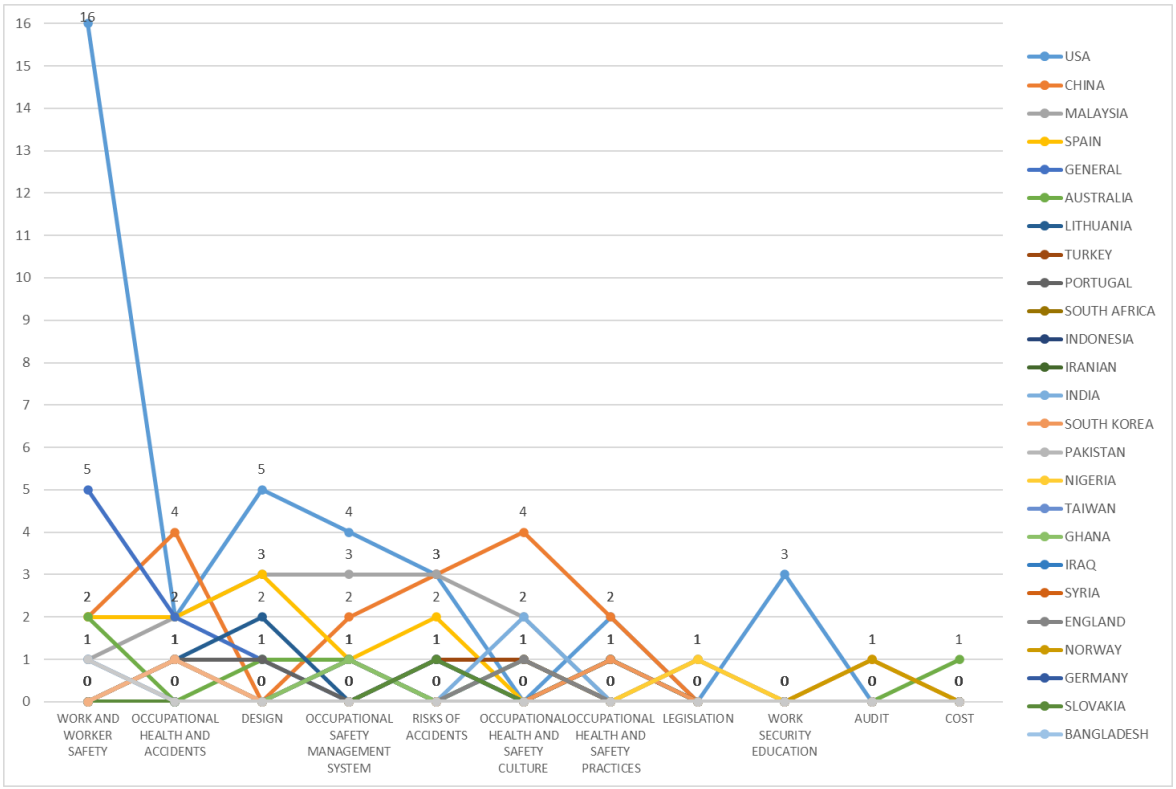

Figure 3: Distribution of studies conducted in the world by categories.

Results and Conclusion

As a result of the content analysis, there are many studies on the "Work and Worker Safety" category in the world, but there is no study in Turkey. However, while there are many studies on "Occupational health and accidents" and "Design" categories in the world, there are very few studies in Turkey. The frequency of the studies carried out in the world and in Turkey in the categories of "occupational safety management system", "accident risks" and "occupational health and safety culture" is almost the same. The studies conducted in Turkey in the categories of "Occupational health and safety practices", "Occupational safety training" and "Cost" are much more numerous than the studies conducted in the world. Very few studies have been conducted in Turkey and in the world on "Legislation" and "Control" categories.

The limited number of studies in the fields of "Occupational and Worker Safety", "Occupational Health and Accidents" and "Design" in Turkey may be a topic suggestion for future studies. The fact that these subjects have been studied in few numbers in Turkey is a major disadvantage for the prevention of occupational accidents.

Occupational Safety Specialist, employer, and worker; need information resources to train themselves and others in the field of Occupational Health and Safety. In this context, the lack of knowledge resources in the current situation is one of the inadequacies in preventing accidents.

As a result of the study, compared to countries such as the USA, China and Malaysia, it is seen that the number of studies conducted in Turkey is quite low in all categories. The small number of studies conducted is a negative situation that coincides with high accident rates. According to SGK statistics between 2016-2021 in Turkey; In the fields of Building Construction, Non-building constructions, Special construction activities, Architecture and Engineering activities, technical inspection and analysis, 281.191 people had work accidents and 2,432 people had fatal work accidents. (SGK,2021). These occupational accidents were mostly caused by falling from a height, falling from roof cavities, being electrocuted. (SGK,2021) For this reason, studies in the fields of Occupational Health and Safety Culture, Design and Risk Analysis in our country will play a major role in preventing occupational accidents and increasing public awareness. It is anticipated that this study will be a guide for future studies in the field of Occupational Health and Safety.

Abstract

Construction industry (CI) experiences adverse effects of accidents and near misses. Occupational health and safety standards (OHSS) can play guiding role in enhancing Occupational Health and Safety (OHS) performance in CI. Standards need to be and are kept updated in line with the changing needs, technologies and requirements with respect to the OHS in the CI. This research aims to rethink and examine OHSS from the integration of the industry 4.0 technologies (I4T) into the OHS in the CI. With this aim, 10 international OHSS have been examined. Furthermore, an online questionnaire survey has been applied to the sample consisting of professionals who have experience and/or publications in the relavant field in the CI and academics who have academic publications in this research related field. This study reveals potential of the examined 10 standards to adopt the I4T to the OHS in the CI and provides recommendations. This study may be beneficial to academics and professionals in the relevant field as well as to the workers and professionals in the CI.

Keywords: *construction industry 4.0, industry 4.0 technologies, occupational health and safety standards 4.0.*

Introduction

Adverse consequences of accidents in the construction industry (CI) can be reduced through occupational health and safety standards (OHSS) in CI. CI is an inherently dangerous industry (Taylor, 2015). While construction continues to be a leading industry with respect to annual injuries and deaths, various institutions and organizations work dedicatedly to ensure that injuries and deaths are minimized (Chokor et al., 2016). According to the OSH law, employers are responsible for providing safe workplace which does not contain OHS hazards (Breitbarth, 2021). OSHA's mission is to determine working conditions and standards, and to provide training, social assistance, etc. for the implementation of standards, and to ensure that employees work in a safe and healthy environment (OSHA website, n.d.). Before the OHS law came into force, the number of deaths due to work-related accidents was very high and it was not possible to know the actual number (360trainingwebsite, 2022). The numbers obtained did not even take into account non-fatal injuries, illnesses, and workplace risks (e.g.,

from prolonged exposure to the cancer-causing chemicals) (360trainingwebsite, 2022). Responsibility conscious companies can be willing to take part in environment, OHS applications enable workers to work in a safe environment and to establish appropriate mechanisms for cases such as injury and illness cases (compliance quest website, 2022). Regulatory interventions such as standards and regulations are among the most effective factors in prevention of occupational safety related problems in the CI (Choe et al., 2016). Complying with OHSS can provide many benefits to the employers (e.g., reducing the costs of insurance) (Paoletta, 2019). Even if implemention of OSHA standards (OSHAS) may seem to be costly in the short term, employers who comply with the standards can save from various factors (e.g., workers' compensation and other insurance costs, enabling workers to create a safer workplace and making workers feel productive) in the long term (Graphic products website, 2022). For example, U.S. worker employment has been doubled since OSHA's founding in 1970, whereas workplace death, illness, and injury rates have been dropped by approximately two thirds (Graphic products website, 2022). OHS measures to be taken by experts/specialists in accordance with the changing conditions with Industry 4.0 should be in line with new standards and the legislation need to be updated so that they cover related issues (Tepe, 2021). As industry 4.0 technologies (I4T) are gaining importance depending on the development in technologies, it is necessary to ensure the adaptation of that OHSS in CI are adapted to these changes covering use of I4T in OHS in CI. This study focuses on rethinking and examining OHSS from the perspective of the integration of I4T into OHS in the CI.

Relationship Among OSHAS, CI and Industry 4.0

OSHA (Occupational Safety and Health Administration) was established in the early 1970s as a result of the OSH Act (360trainingwebsite, 2022). Even if the OSH Law was not the first workplace safety law in the country, it was the most comprehensive one (360trainingwebsite, 2022). As part of the US Department of Labor, it is the government agency that sets rules about workplace safety (Woodson, 2012). OSHAS are rules that define the methods which employers should use to protect their employees from hazards (Shrm website, 2022). OSHAS are a set of guidelines and requirements implemented by the OSHA to minimize OHS risks/hazards in US based workplaces (safetyculture website, 2022). These standards encourage employees to be active in establishment of these policies (Safetysign website, 2022). OSHAS are developed to support workplace OHS for all employees (safeopedia website, 2018). OSHA's primary rule is that employers are responsible for maintaining a safe workplace (safeopedia website, 2018). Even if depending on the industry, there may be many OSHA safety regulations for which employers are responsible in their workplaces, these regulations have common points as they were created to protect workers (Safetysign website, 2022).

There are four main groups of OSHAS (i.e., General Industry, Construction, Marine and Agriculture General Industry, Construction, Maritime, and Agriculture) (OSHA, 2019). Some OSHAS are detailed with specifications that vary from industry to industry (360trainingwebsite, 2022). Some standards are industry specific whereas others apply to all industries (Creative safety supply website, 2022). CI standards set specific requirements for all CI employers (Keller, 2010). CI employers are legally required to comply with these standards and all relevant 29 CFR Part 1910 General Industry standards (Keller, 2010). All businesses, regardless of their size and industry, must adhere to OSHAS (Breitbarth, 2021). There are following five main and basic clauses that all employers must comply with:

providing a safe and hazard-free workplace; posting OSHA's healthy and safe workplace advertisements and posters where employees can see them; keeping records for work-related injuries and illnesses, and written emergency action; creating a plan, giving regular training to employees about all risks in the workplace (Breitbarth, 2021). Employees have the right to file their complaint to OSHA and request inspection of their workplace (Paoletta, 2019). Before OSHA can issue a standard, it must go through an extensive and lengthy process involving significant public engagement (compliance quest website, 2022). OSHA can enforce its regulations by conducting scheduled inspections after a serious injury or death in the workplace (Creative safety supply website, 2022). Violated regulations can result in penalties ranging from fines to six months imprisonment (Creative safety supply website, 2022). Many rules, regulations and standards have been developed over the years to minimize the risks faced by employees (Graphic products website, 2022).

Industry 4.0 refers to the intelligent use of data and digital technologies to improve business processes and production systems in the manufacturing industry (i4amf website, 2022). Real-time communication, human–machine cooperation, etc. are becoming increasingly important in industry (Badri et al., 2018). As I4T's effects on daily life increase, new paradigm changes can occur and OHS management can be affected (Badri et al., 2018). Furthermore, it is important to raise awareness of the integration of OHS into I4T, and it is necessary for a smooth transition that field experts and industrialists collaborate (Badri et al., 2018). I4T is a new production paradigm which has a strong impact on work and employees (Zorzenon, 2022). Effects of I4T on OHS are uncertain (Zorzenon, 2022). I4T refers to new developments in automation and data exchange in production technologies (e.g., big data, additive manufacturing, cloud computing, artificial intelligence) (Iavicoli et al., 2022). I4T may lead to new OHS risks and necesitate appropriate risk assessment (Iavicoli et al., 2022). I4T have the potential to help create a sustainable environment as they can provide perspectives regarding future innovation and business growth (Javaid et al., 2022). In the age of Industry 4.0, production is linked with information and communication systems (Javaid et al., 2022). This I4T revolution has been designed to enhance efficiency, flexibility and quality of industrial production, and it can affect the way work is organized and performed as well as employees' OHS (Leso et al., 2018). Standards are an integral part of the transition to industry 4.0 (I4amf website, 2022). There is a growing awareness of the need for standards to strengthen Industry 4.0 (i4amf website, 2022).

OSHAS Related Studies

Literature on OSHAS and the relationship of these studies to I4T can be executively summarized as follows: Based on data obtained from the Bureau of Labor Statistics, Choe et al. (2016) provided evidences for the effectiveness of the revised OSHA 29 CFR 1926 standard in preventing general occupational injuries in structural iron and steel industry in the US CI. With the aim of providing information that can help prevent future recurrences and help policymakers identify inadequate safety standards, Al-Bayati et al. (2021) has conducted a study on evaluation of OSHA's death and disaster investigation summaries. Koshy et al. (2021) conducted a study on future worksite biohazards and infectious diseases. Grant and Hinze (2014) conducted an analysis of the OSHA death and catastrophic event database to better understand the risks associated with truss installation. Malaby (2016) aimed to examine the history of OSHA's laboratory standard. Chokor et al. (2016) focused on analyzing OSHA report data using Unsupervised Machine Learning. Woodson (2012) focused on providing information and general requirements so that employers do not fail OSHA audits and

encounter expensive consequences. Taylor (2015) focused on the benefits of OSHA's 10 hours safety training and developed recommendations for keeping records of accidents and injuries. Biller (2016) worked on the current version of OSHA's Eye and Face protection standard. Keller (2010) focused on the OSHA Subpart regulations for electric safety. Tepe (2021) discussed in detail the views on how the OHS in CI can be affected by Industry 4.0, and on new risks that may cause various occupational diseases and accidents.

OSHA's Standards

A brief description of the 10 OSHAS examined within the scope of this study can be provided as follows:

- *Fall Protection, construction (29 CFR 1926.501):* It describes employers' action to be taken regarding the risks of falls that workers may face. It contains information on issues such as unprotected edges, railings, wall openings, and structural integrity that may cause fall risks.
- *Hazard Communication Standard, general industry (29 CFR 1910.1200):* It indicates that the potential hazards of all chemicals produced or imported must be examined and classified by employers. It explains the information and details (e.g., labels and forms) that should be made by the employer about the hazards to which the employees may be exposed.
- *Respiratory Protection, general industry (29 CFR 1910.134):* It is a standard in which the precautions that employers should take under the situations that may cause various occupational diseases (e.g., harmful dusts, mists, fumes) are provided.
- *Scaffolding, general requirements, construction (29 CFR 1926.451):* It is a standard that deals with the precautions that employers should take against the risks related to the subject starting from the fact that the scaffolds should be designed and constructed by experts professionally to ensure safety of workers on the scaffolds.
- *Ladders, construction (29 CFR 1926.1053):* It contains details of actions (e.g., related with load amount, clearance information) to be taken to address the risks related with fixed ladders or portable ladders.
- *Control of Hazardous Energy (lockout/tagout), general industry (29 CFR 1910.147):* It covers the details for controlling the energy that may endanger workers, and controlling the related machinery.
- *Powered Industrial Trucks, general industry (29 CFR 1910.178):* This standard contains details on the safe use (e.g., fire protection, maintenance and design) of special industrial trucks in workplaces.
- *Fall Protection–Training Requirements (29 CFR 1926.503):* It includes details about the employers' obligation to inform all employees about the risk of falling, and to provide various trainings.
- *Eye and Face Protection (29 CFR 1926.102):* It includes the details of employers' obligation to provide eye and face protection against various substances that may harm employees.
- *Machinery and Machine Guarding, general requirements (29 CFR 1910.212):* It contains several details on employers' obligation to protect operators and other workers working with machinery from various hazards such as rotating parts and sparks.

Research Method

Within the scope of the literature review, relevant previous studies, importance of OHS standards and Industry 4.0 in CI, OSHA's top 10 most frequently cited standards (OSHA web site, 2021) were examined. Following the literature review, a questionnaire survey was applied to a sample consisting of professionals who have experience and/or publications in the relavant field in the CI and academics who have academic publications in this research related field. This survey was prepared to evaluate the potential of the relevant standards to be integrated with I4T. The survey was created through the veti system of Istanbul Technical University and contained questions on respondents' profile and background, and assessment of the standards based on the 5 point Likert scale. The 5 point Likert scale assessment of the standards (where 1 indicates "the lowest potential for integration" whereas 5 indicates "the highest potential for integration") aimed at evaluation of the potential of the 10 OHS standards to be integrated with I4T. Questionnaire survey was applied online to the sample. Respondents were informed that participation to the survey was totally voluntary. None of the questions was obligatory. In total, 58 participants answered the questionnaire. Data obtained through the questionnaire survey have been analysed, mean values, standard deviation and rankings have been provided.

Results

The survey data were analyzed via the SPSS program. Reliability analyzes were performed for each standard separately and for all standards. The Cronbach's Alpha value for the answers given to all questions is 0.870 which indicates reliability. In the following step, the number of participants who answered the questions about the relevant standards, the mean values of each standard, and the standard deviations were calculated and listed. These findings are given in the Table 1.

According to the respondents, the standard with the highest potential (mean=4,4310) to be integrated with/cover I4T is the FPT, whereas the standard with the lowest potential (mean=4.00) is the EFP. 57 participants answered the question asked about the potential of CHE to be integrated with I4T, and it was seen that this standard, with an average value of 4,2105, was in the 2nd rank. 57 participants answered the question about the potential of MMG and RP to be integrated with I4T, and the average value of the answers was 4.1930, and it was seen that they were both equal and in the 3rd rank. 58 participants answered the question about the potential of HC to be integrated with I4T, and it was seen that this standard, with an average value of 4.1724, was in the 4th rank. 58 participants answered the question about the potential of FP and PIT to be integrated with I4T, and it was seen that the average values of the answers given were 4,1552 for both standards, and they were in the 5th rank. 58 participants answered the question about the potential of L and S to be integrated with I4T, and it was seen that the average values of the answers given were 4,1034 for both standards, and they were in the 6th rank. As even the lowest average value is 4.00, based on respondents' assessment in the 5-point Likert scale, indicates that all standards have been indicated by the respondents as capable of being integrated with I4T.

Table 1. Descriptive statistics.

OSHA's Top 10 Most Frequently Cited Standards	Mean	Std. deviation	N	Rank
Fall Protection Training, construction (29 CFR	4.4310	.75189	58	1

1926.503) FPT				
Control of Hazardous Energy (lockout/tagout), general industry (29 CFR 1910.147) CHE	4.2105	.86058	57	2
Machinery and Machine Guarding, general industry (29 CFR 1910.212) MMG	4.1930	.93424	57	3
Respiratory Protection, general industry (29 CFR 1910.134) RP	4.1930	.93424	57	3
Hazard Communication, general industry (29 CFR 1910.1200) HC	4.1724	.88135	58	4
Fall Protection, construction (29 CFR 1926.501) FP	4.1552	.98767	58	5
Powered Industrial Trucks, general industry (29 CFR 1910.178) PIT	4.1552	.98767	58	5
Ladders, construction (29 CFR 1926.1053) L	4.1034	.98568	58	6
Scaffolding, construction (29 CFR 1926.451) S	4.1034	.98568	58	6
Eye and Face Protection, construction (29 CFR 1926.102) EFP	4.0000	1.11803	57	7

*Items in the right columns refer to the OSHAS names

Discussion

When the literature on studies on OSHAS is evaluated, it is seen that publications generally focus on a single standard or the content of the standards (e.g., Choe et al. 2016; Malaby, 2016). Chokor et al. (2016), however, investigated OSHAS and I4T and stated that the analysis of accident reports, which are stated to be mandatory in OSHAS, can be done through machine learning. Chokor et al. (2016) evaluated one OSHAS and I4T together in this respect. Many studies (e.g., Choe et al., 2016; Biller, 2016) examined in the literature specifically examined one or more of the OSHA standards, but did not evaluate them holistically in terms of integration with I4T. There is lack of studies discussing each I4T in detail and how the I4T can be integrated more specifically and effectively into each of the standards. It was stated that even if it was indicated in the literature that changing conditions due to industry 4.0 can cause new and various accidents and occupational diseases (e.g., Tepe, 2021) and the standards should be handled comprehensively (e.g., Tepe, 2021), there is lack of studies specifically focusing on OSHAS from this aspect.

According to the survey participants' evaluation of the potential of 10 OSHAS to be integrated with/to cover I4T, the highest average value receiving standard obtained 4.43 whereas the lowest average value receiving standard received 4.00. This reveals that even the lowest average value receiving standard received relatively high value regarding its integration potential.

The CI has developed solutions related to OSHAS to get rid of the adverse effects of accidents and near misses. OSHAS is developing day by day both procedurally and sectorally, as it can be seen as a result of this literature review. Complying with the developments in I4T and changing needs, there is need to consider the OSHAS for minimizing and eliminating OHS problems together with I4T in CI. Figure 1 highlights that OSHAS, I4T, and CI need to be considered and rethought in an integrated and holistic way.

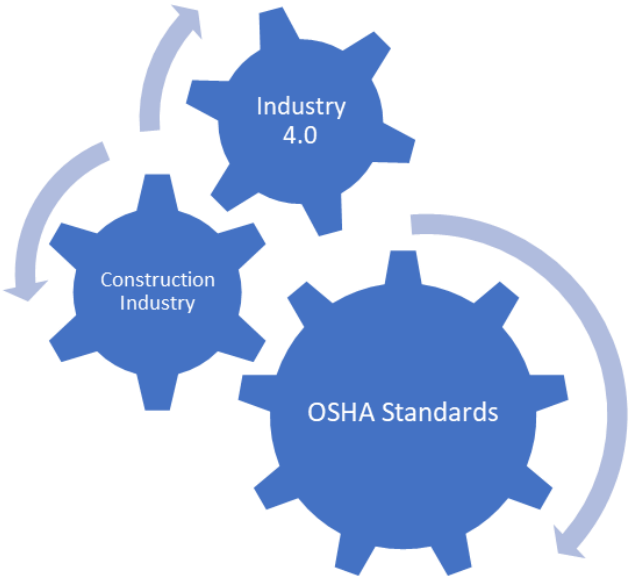

Figure 1: Relationship among OSHAS, I4T and CI.

OSHAS integrated with I4T in CI can have the potential to contribute to sustainability in the CI. For example, OSHAS integrated with I4T can contribute to the reduction in/elimination of worker death and injury and relevant compensations; and to the reduction in accidents and near misses. Considering CI's significance in development in nearly all countries, highlights the significance of the potential support of I4T integrated and covering OSHAS' effectiveness in CI and sustainable development. Even if compliance with OSHAS integrated with I4T in CI may seem to be perceived as costly due to many potential reasons (e.g., initial investment and training costs), it can have potential to provide an economic advantage in the long run enabling the companies to catche up with the era and to adapt themselves to the current situation in CI. Lean management in the CI can have potential to be supported through the integration of I4T and OHSS as accidents and near misses can be expected to be further eliminated/minimized (Erusta & Sertyesilisik, 2019).

Conclusion

As CI is being significantly affected by the consequences of accidents, it is necessary to carry out studies to minimize or completely eliminate the effects and causes of these accidents and near misses. Effectiveness in the OHS management and performance can be supported by OSHAS in CI as OSHAS imposes certain responsibilities on employers and requires them to provide a safe working environment for all CI stakeholders. OSHAS' potential for being a solution to the OHS problems has been indicated in the literature (e.g., Choe et al., 2016; Paoletta, 2019; 360trainingwebsite, 2022; Compliance quest website, 2022). Changing needs of OHS in compliance with development in technologies and requirements require the need for keeping OSHAS up-to-date. The holistic handling of ever-developing I4T with OHS and their adaptation to OSHAS can positively affect the solution of OHS problems in CI. As OHS standards can play an effective role in enhancing OHS performance in CI, integration of I4T into the OSHAS may be important.

OSHAS integrated with I4T in CI can support sustainability in CI especially to this integration's potential contribution to reduction in accidents, deadths, illness, injuries and relevant costs and compensations as well as to the image of CI and companies regarding their OHS performance and record. Furthermore, effective integration of OSHAS with I4T in CI can further support sustainable development.

Within the scope of this study, following the literature review, an online questionnaire survey was applied to get an understanding on the potential of the relevant OSHAS to be integrated with/to cover I4T. According to the respondents, FPT is in the 1st rank as the standard, which is considered to have potential to be integrated with I4T in CI whereas the EFP standard ranked in the last rank having mean value of 4.00 in a 5-point Likert scale assessment indicating EFP being considered by the respondents as capable of integrating I4T in CI. According to the participants, all relevant standards have high potential to be integrated with/to cover the I4T in CI. Future researches can focus on more studies on each OSHAS' integration with I4T in CI and how each updated OSHAS can contribute to sustainability in CI.

This study emphasised importance of and need for rethinking and updating the OSHAS through the integration of I4T into OHS in the CI. This study can be beneficial for academics and professionals working in the relevant field, as well as for workers and professionals working in CI.

Abstract

To protect the health and safety of employees, the law in force in Turkey is the Act No. 6331 on Occupational Health and Safety. Within the scope of this law, the measures to be taken by the workplace begin with collective protection measures. However, due to the diversity of work items and the difficulty of applicability on construction sites, employees often have to work individually in different regions and dispersed settlement. For this reason, the necessity of protecting employees with the use of personal protective equipment arises. Legally, in order to protect the employees from possible disasters in hazardous construction areas, helmet which is the one of the personal protective equipment have to be used by the employees. Similarly, according to this law, the employer is obliged to observe whether the helmets given to the employees are worn or not. Also, the employer is obliged to warn the employees who do not wear the helmet, too. But, the wide and dispersed construction sites make it difficult to observe employees. Today, thanks to the developing technology, these obligations can be easily observed with automation systems. In this direction, in this study, detection of helmet usage of construction workers was carried out by using the segmentation method based on deep learning. The study was diversified with different analyses and the outputs were evaluated comparatively.

Keywords: *deep learning, helmet detection, image segmentation.*

Introduction

The concept of Occupational Health and Safety (OHS) is deal with making the working environment safe by considering the interests of both the employer and the employees, and thus protecting and maintaining the health of the workers. In Turkey, Occupational Health and Safety is carried out within the scope of the Act No 6331 on Occupational Health and Safety Law. It is extra important that this law is applied meticulously in dangerous business lines such as the construction sector, where construction works are carried out. Within the scope of this law, collective protection measures are primarily used to protect employees from dangers. However, collective protection measures in the construction industry are often insufficient, as employees often work independently and dispersedly on construction sites. At this point, personal protective equipment is used, which aims to protect workers individually in order to protect and maintain worker health. Personal protective equipment is the collection of items used or worn by the worker to protect the worker from hazards. In this study, the helmet which is one of the PPEs, is only emphasized. It should also be noted that within the scope of

this law, the use of PPEs must be supervised by employers and OHS specialists. Considering this control requirement, in this study, the helmet usage status of the workers was examined by using image segmentation method based on deep learning in order to provide an automatic solution. Deep learning, a subtype of machine learning, emerged with the development of artificial neural networks over time. In data processing, it follows the functioning of the human brain (Önün, 2019). It has features such as natural language processing, speech recognition, image recognition and processing, video and audio processing. Thus, recently, it has been preferred for problem solving in different fields such as medical medicine applications, translation linguistics, security and defense industry, robotics industry, computer vision and economy etc. (Doğan & Türkoğlu, 2019; Khallaf & Khallaf, 2021). Object detection, image classification and image segmentation are the three main application forms of deep learning. When the studies on helmet detection with deep learning are examined, it is seen that all the studies can be reached in the literature are carried out with the object detection method. These studies are briefly summarized. While detecting the workers with helmets using the deep learning method, Xie et al. (2018) also examined whether the helmets were properly worn. Fang et al. (2018), presents a method for estimating helmeted workers, focusing only on workers who do not wear helmets. Sağın (2019) and Mneymneh et al. (2019) created algorithms that first identify the workers and then determine whether the determined workers are in helmets. Bo et al. (2019), Wang et al. (2020) and Huang et al. (2021) conducted studies focusing on the heads of workers while examining the use of helmets. In addition to these studies, there are studies that detect protective vests while detecting helmets in workers (Wang et al., 2020; Nath et al., 2020; Torres, 2021). Saudi et al. (2020) detected protective boots in addition to hard hats and protective vests for workers. Önal and Dandıl (2021) suggested a comprehensive study in which the use of various PPE components such as vests, masks, goggles, and gloves was supervised, not just hard hats. There are also studies in the literature enriched with algorithms that are sensitive to helmet colors (Wu et al., 2019; Casuat et al., 2020) and more sensitive to detect small objects (Xu et al., 2019; Zhang et al., 2021; Tan et al., 2021) in order to perform helmet detection more accurately. In this study, image segmentation method based on deep learning was used in order to automatically detect the use of helmets at the construction site. The reason for choosing image segmentation as the automatic method is that when previous studies were examined, the studies were carried out only with the object detection and it was desired to offer a new automatic solution to the helmet detection by using the image segmentation method. For this purpose, U-Net algorithm was used for the image segmentation method. In addition, various analyses were executed according to different analysis combinations in order to evaluate how the model training could be more performant. The most determinative factor among the analyses is that the helmet detection is carried out with reference to either the whole body integrity of the workers or only their heads.

Methodology

In this study, helmet usage was determined by making use of the image segmentation method based on deep learning. The methodology of the study, which consists of data collection, image masking, data augmentation, model training and model testing, is given in Figure 1.

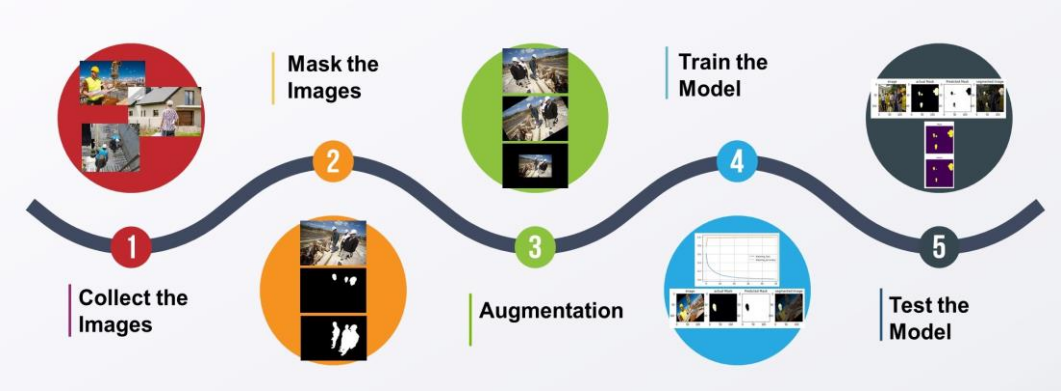

Figure 1: The methodology of the study.

Data Sources

A total of 164 images were brought together to create a dataset to be used in the training of the model. In 124 of these images, only helmeted workers were present, while in 40 of them there were workers with and without helmets together. In order to achieve high success in model training, it is requested that the dataset consists of images with different characteristics as much as possible. Accordingly, the dataset images were diversified according to features such as different angles, distances, and light etc. The 164 images that make up the dataset are images taken personally by the author at the construction sites or accessed from the internet.

Mask the Images

Figure 2: Examples of original images and masked images of helmeted workers with reference to their entire body integrity and only their heads.

The training dataset was created from the original images and masked images. Masked images were obtained by identifying and painting the helmet areas in the original images. In this direction, the areas of the workers with helmets, which were selected with reference to the whole body integrity of the workers and only their heads, respectively, were painted white and the other areas were painted black. Figure 2 illustrates the original images with masked images by reference regions.

Augmentation

The masking process is a time-consuming and laborious process. Within the scope of the study, masking of the images took place in 22 hours and 16 hours, respectively, with reference to the whole body integrity of the workers and only their heads. For this reason, instead of increasing the number of inputs in order to increase the number of images in the dataset, the data augmentation method was applied to the existing inputs. Data augmentation was performed by applying brightness, 30^0 rotation, mirror reflection, -30^0 rotation and zooming operations to each of the original images and masked images that make up the data set. In Table 1, the processes performed for data augmentation over an image are shown with reference on the entire body integrity of the workers and only their heads.

Table 1. An example of the augmented form of the images.

Original	Brightness	Rotation (30^0)	Vertical Flip	Rotation (-30^0)	Zoom Out
					

Accuracy Assessment

The measurement metrics used to evaluate the performance of the model in the study are accuracy, loss and intersection over union (IoU). The metric that expresses the ratio of the cases correctly determined by the algorithm to all cases is called accuracy. It can take values between 0 and 1. In models with high predictive ability, this value is expected to be as high as possible. The metric that gives the difference between the true value and the value predicted by the model is called loss. It can take values between 0 and 1. In models with high predictive ability, this value is expected to be as low as possible. The ratio of the intersections of to combination of the class space determined by the algorithm and the class space that is actually true represents the IoU metric. In models with high predictive ability, the IoU value should be as close to 1 as possible (Semercioğlu, 2022).

Results and Discussion

Model Training

Google Colab Notebook with virtual GPU, a free cloud service, was used for the training of the model. Colab was powered by Intel Xeon Processor with two cores @ 2.20 GHz and 13GB RAM. The dataset was trained under 6 different analyses detailed in Table 2. Analyses were diversified according to the reference region, inclusion/exclusion of helmetless workers, and data augmentation. In the study, the epoch was determined as 50 and the particle size was determined as 16. While Analysis 1, 2, 3 and 4 were trained in 1 minute, Analysis 5 and 6 were trained in 3.5 minutes.

Table 2. Detailing of different analysis combinations.

	Reference of the Images	Group of the Images	Number of Images
Analysis 1	Entire body integrity	All images	164
Analysis 2	Entire body integrity	Only helmeted workers	124
Analysis 3	Only head	All images	164
Analysis 4	Only head	Only helmeted workers	124
Analysis 5	Entire body integrity	All images (with data augmentation)	984
Analysis 6	Only head	All images (with data augmentation)	984

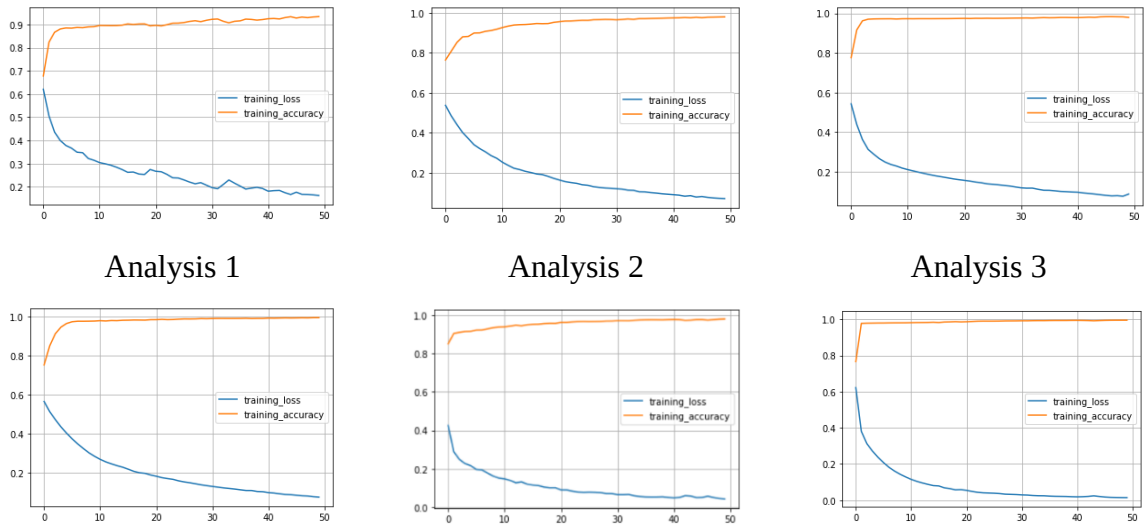

Figure 3: Loss and accuracy graphs of analyses.

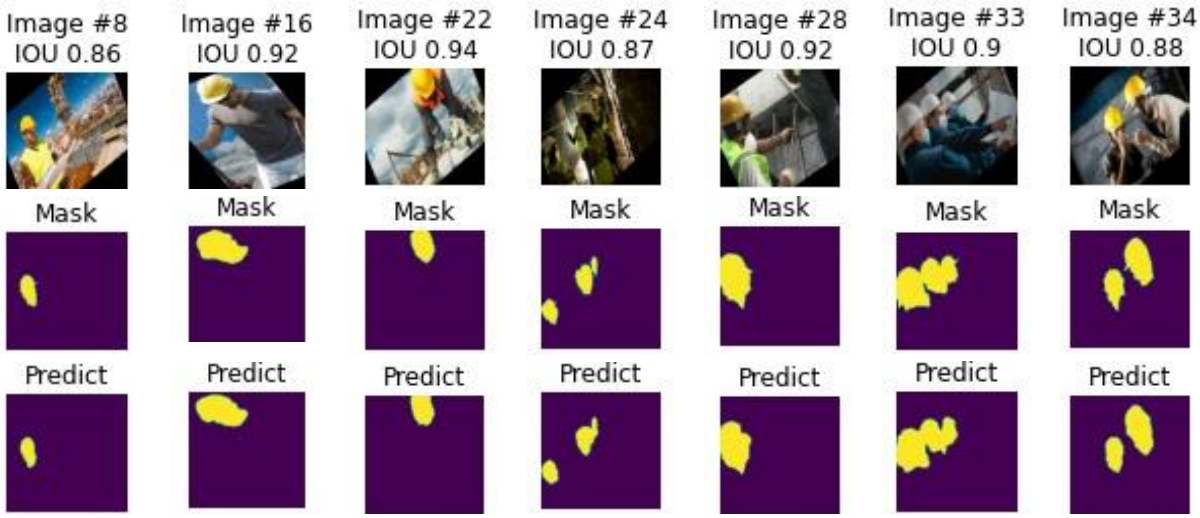
Figure 3 shows the accuracy-loss graphs achieved by each analyses as a result of model training. In these graphs, the curve representing the training accuracy is the orange curve, while the curve representing the training loss rate is the blue curve. Table 3 presents the loss-accuracy values reached by each analyses as a result of model training. As a result of model training, when the accuracy-loss values acquired by the analyses were interpreted, it was seen that the model predictive ability was high. Analyses that give the most efficient results in

terms of accuracy-loss values are Analysis 5 and 6, in which the number of inputs is increased by data augmentation. When these two analyses were evaluated in themselves, Analysis 6, which only referenced the heads of the workers, was found to be more successful than Analysis 5, which referenced the entire body integrity of the workers. When the loss-accuracy values of all analyses are compared, example images of the training data of Analysis 6, which were seen to reach the most successful results, are given in Figure 4 by comparing their masked and predicted images. Images are selected from images with different IoU values. The average IoU values of the training datasets for each of the analyses were calculated as 0.45, 0.40, 0.23, 0.34, 0.72 and 0.60, respectively. When the IoU values reached by the analyses were examined, it was seen that the values varied. In models with high predictive ability, the IoU value is expected to be close to 1. Most of the analyses were below 0.5, indicating that the predictive ability of the model remained weak in general.

Table 3. Loss and accuracy values of analyses.

	Analysis 1	Analysis 2	Analysis 3	Analysis 4	Analysis 5	Analysis 6
Loss	0.1628	0.0718	0.0862	0.0773	0.0422	0.0137
Accuracy	0.9338	0.9803	0.9797	0.9938	0.9810	0.9950



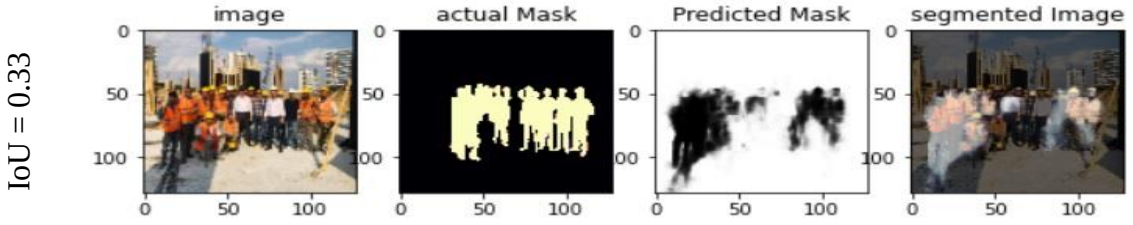


Figure 4: Masked and predicted image examples of analysis 6.

Model Testing

In order to evaluate the performance of the trained model, the model was tested for each analyses with a test dataset consists of 7 images. For achieve the performance evaluation in an objective manner, test dataset was created from images not seen before by the model.

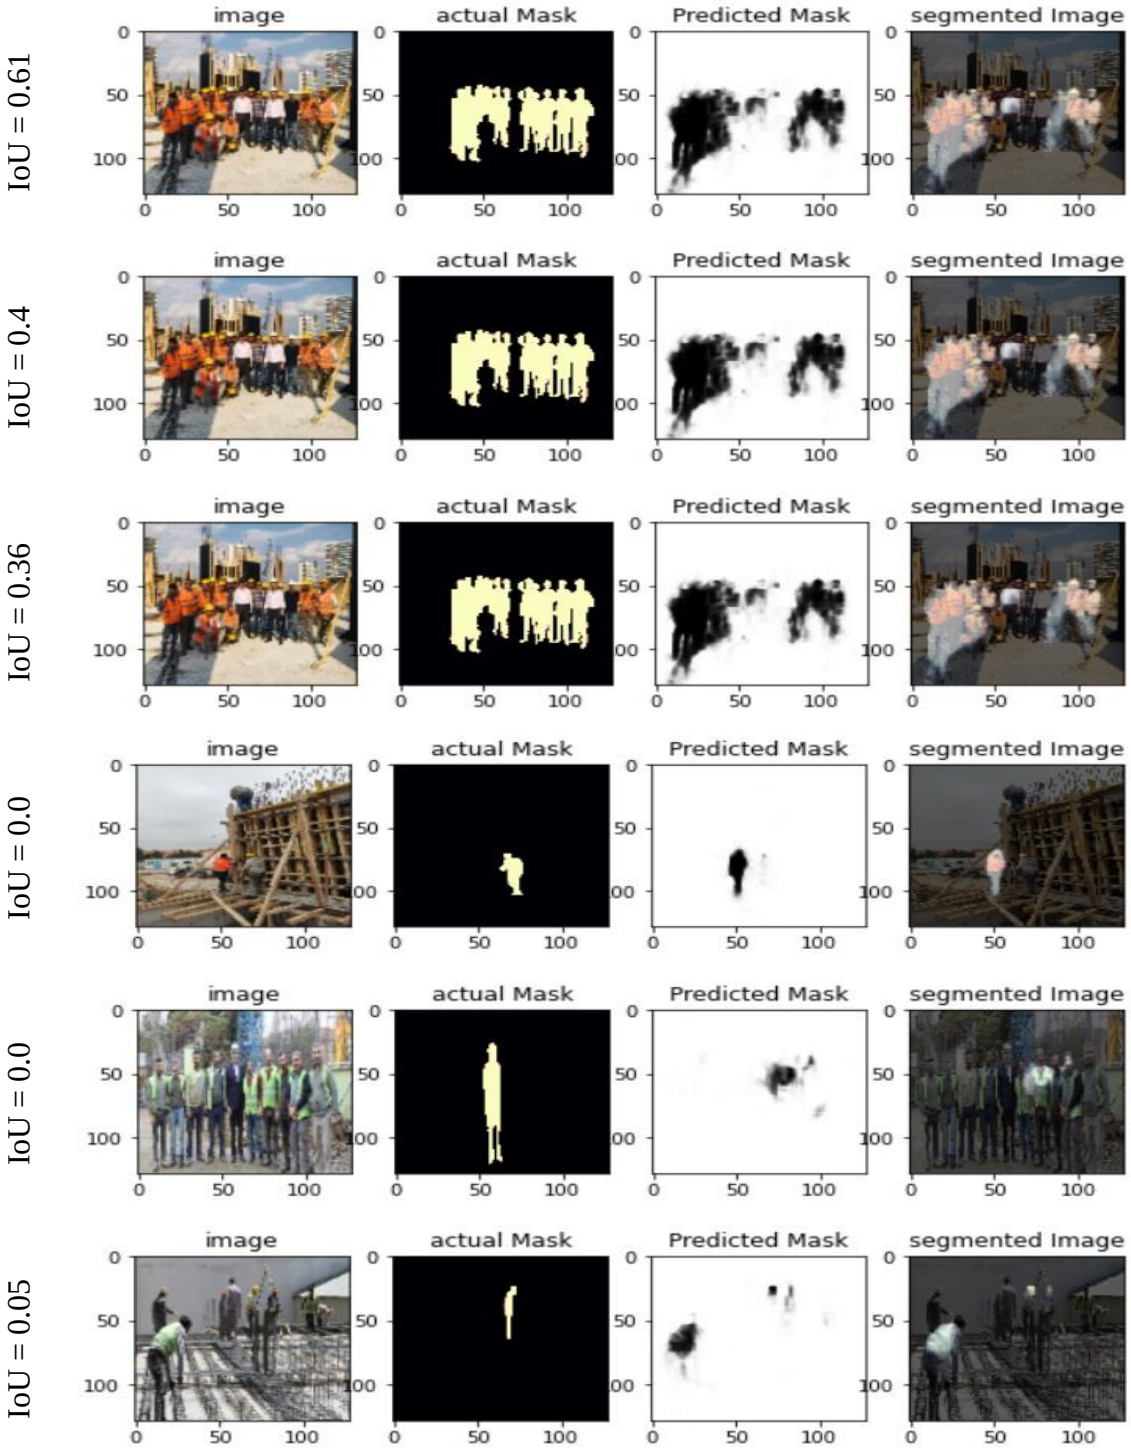

Figure 5: Results of test images for analysis 5.

Test evaluations are based on the average validate IoU measurement metric. The test average validation IoU values of analyses 1-6 were 0.21, 0.08, 0.13, 0.03, 0.25, and 0.23, respectively. When the predictive ability of the model was interpreted according to the test average validate IoU values reached by all analyzes as a result of the model test, it was observed that the results were far below the desired ones. It was thought that the insufficient number of data in the test dataset caused this situation. Analyses that give the most efficient results in terms of training and test average validate IoU values are Analysis 5 and 6, in which the number of

inputs is increased by data augmentation. When these two analyses were evaluated in themselves, Analysis 5, which referenced the entire body integrity of the workers, was found to be more successful than Analysis 6, which only referenced the heads of the workers. Figure 5 shows the results of the test images for Analysis 5.

Conclusions

In this study, the detection of the helmet usage situations of the workers working in the construction sites was carried out within the scope of the segmentation method based on deep learning. For this purpose, U-Net architecture was used. The study was diversified by presenting different analysis options.

As a result of 6 different analyses performed, it was observed that the analyses showed high performance in terms of loss and accuracy values, but remained underperformed in terms of training and test average validation IoU values. According to the loss and accuracy values, Analysis 3, 4 and 6, which reference only to the heads of the workers, were interpreted to be more performant than the others. Among these three analyses, the analysis that achieved the highest model performance was determined as Analysis 6 with data augmentation. Considering all evaluation metrics, it was determined that Analysis 5 and 6 were the most successful analyses. These analyses, in which data augmentation was performed, came to the fore with the increase in both the number and variety of input data. The missing and validation values of the two analyses strongly support the model performance. While the training average validation IoU values were high, the reason for the low test average validation IoU values was interpreted as the test group data being composed of a small number of images. Also, when compared to reference regions, no significant difference was observed between Analysis 6, which referenced only the heads of workers, and Analysis 5, which referenced entire body integrity of workers.

Abstract

Because each construction project has a unique process, various problems may arise during the implementation. Work accidents come first among these problems. Work accidents in the construction industry can result in death, serious injury, or long-term incapacity. Other problems such as stopping the construction after a work accident, punishing the employer or the responsible persons, and loss of motivation in the employees after a work accident may occur. Therefore, it is extremely important to re-motivate the employees when they return to work after a work accident. For this study, survey statements were created. As a result of this study, the factors that are important when returning to work after an accident that may occur in the construction sector have been revealed.

Keywords: *construction project, motivation, work accidents.*

Introduction

In this period of increasing industrialization, one of the important problems regardless of the sector is work accidents. The construction sector is one of the sectors with the highest number of work accidents. Accidents in the construction industry can result in death or serious injury. Although we tried to take precautions, we have not been able to reduce the work accidents to the numbers we want yet. The main reason for these measures is the completion of the construction activities without harming any employees. In addition to this main reason, it becomes extremely important to minimize the damage to construction companies.

Various problems will occur after a work accident that may occur. Employees are directly or indirectly affected by work accidents. In a fatal or severe work accident, other employees are also indirectly affected. These indirectly affected employees may think that they may be affected in a similar work accident that may occur. Or the employee who has been exposed to a work accident may be his own relative or acquaintance. Therefore, an emotional impact will occur. As a result, there will be a loss of motivation. Therefore, it will be important for employees to continue to work without losing their motivation when returning to work. Continuing to work with low motivation of employees after a work accident may result in a

repeat work accident due to insufficient concentration, and delays in construction activities may occur because they work with low productivity. For this, it will be necessary to mention the motivation after a work accident in the occupational health and safety (OHS) culture or climate. The aim of this study is to reveal the factors affecting motivation after a work accident and the scale expressions related to these factors.

Occupational Health and Safety Culture

There are various studies on Occupational Health and Safety (OHS) culture (Yeong & Shah Rollah, 2016; Jin et al., 2019; van Nunen et al., 2018; Kalteh et al., 2021; Kim et al., 2019; Newaz et al., 2019a). In these studies, they mentioned the importance of an effective OHS culture from different perspectives so that there are fewer work accidents. Comprehensive studies have been carried out from communication to human factors, from management approach to incentives. For example, a study identified 13 main factors affecting OHS performance in construction projects. These are motivation, rules and regulation, competence, OHS investment and costs, financial aspects and efficiency, resources and equipment, work pressure, working condition, culture and climate, attitude and behavior, lessons learned from accidents, management systems, organization, and OHS programs (Mohammadi et al., 2018). In a study by Ghasemi et al. (2015), it was found that incentives proved to improve employee safety performance in the short term.

In an effective OHS system, new studies are constantly emerging. Within the framework of OHS culture, attention is drawn to different aspects. It is also important to restore motivation after a work accident in an effective OHS culture. There were not many studies on this subject in the studies. This is the reason for this study. Because after a work accident, the productivity and well-being of workers drop significantly (Ling et al., 2019). It is expected that the motivation of the employees in enterprises with a good OHS culture will return to normal quickly and effectively after a work accident. This is also extremely important for businesses in terms of productivity. If the welfare, peace, and confidence of the employees are in place, their productivity will also be good. Because there is a positive relationship between the well-being of employees and their productivity (Ling et al., 2019). In this context, factors related to post-work accident motivation are tried to be brought together.

Methodology

Since there is no ready-made survey about motivation after a work accident, the survey was created by using the literature. For this, studies using various keywords (such as construction sector, motivation after a work accident, productivity) were examined. From these studies, 28 motivational factors and 28 survey statements related to these factors were obtained. The survey is administered to construction workers. The survey statements are asked to be answered according to a 5-point Likert scale (1=affects very negatively; 5=affects very positively). Since the application of the survey has not been completed yet, this study is limited to how the motivation factors after a work accident survey is developed. When the survey is finished, different statistical analyzes will be made, especially regarding the reliability of the survey.

Results

Motivation factors after a work accident were obtained with the help of literature. Motivation factors after a work accident are shown in Table 1 below. The scale expressions based on these factors are also shown in Table 1. Motivation survey after a work accident consists of 28 statements. Different analyses will be made in future studies by revealing a motivational survey after a work accident. The implementation of the survey continues. When the desired sample size is reached, various analyses are made and it is aimed to be published in different places. Since enough samples were not reached, this study was limited to how to reveal motivational factors and scale expressions.

Ling et al., 2019	Psychological support	It is important for employees to receive psychological support after a work accident.

Conclusions

This study aims to reveal the scale expressions of factors affecting motivation after a work accident. When the desired sample size of the survey is reached, different analyses will be made. The productivity of the employees needs to work without losing their motivation after a work accident. The main goal after a work accident is to try to keep employees away from work accidents by re-creating their motivation. In addition, it is an important problem in productivity. Because construction projects are expensive projects and are made within a certain plan. Any delay caused by the performance of the employees will cause direct or indirect costs. This will increase the construction cost. Therefore, motivating after a work accident is important not only for workers but also for employers. Factors and scale expressions obtained with the help of the literature are expected to be a source for future studies.

Work Conditions and Psychological Stressors among the Construction Workforce in South Africa

M. T. Raliile, T. C. Haupt and K. Kajimo-Shakantu
University of the Free State, Department of Quantity Surveying and Construction Management, Bloemfontein, South Africa
mohlomiraliile@gmail.com, pinnacle.haupt@gmail.com, KajimoShakantuK@ufs.ac.za

Abstract

This study investigates organizational stressors among the construction workforce in South Africa. The study focuses on the working conditions and interpersonal relationships among the workforce. Work conditions, workplace relationships, and pressures from groups can result in adverse health conditions among the workforce. A combination of these factors results in occupational stress affecting employees 'work-life balance and worker's well-being. This quantitative study forms part of ongoing empirical research. A snap survey was conducted and the questionnaires were distributed among 40 conveniently sampled contractors in the Kwa-Zulu Natal province. The study achieved an 80% response rate and the internal reliability was 0.725 and deemed acceptable. Convenience sampling was favored due to the respondent's proxy to the researcher and also, to speed up the data collection process due to COVID-19 challenges. The self-completion data were analyzed using descriptive statistics methods on IBM SPSS v25. The, findings of the study revealed that working at night and during weekends as a result of work overload; job insecurity, and unfair reward were the most prevalent issues among the workforce. However, homogeneity among the groups of respondents was not achieved and the findings of the study may not be generalized due to the small sample size.

Keywords: *construction industry, construction workforce, occupational stress, work conditions, work relationships.*

Introduction

Construction fatalities emanate from a number of known and unknown factors. Predominantly, causes of fatalities and accidents in construction have been classified as faulty equipment accidents; falls from heights; slips, trips and falls on the same level; repetitive stress injuries; inhalation, absorption or ingestion accidents; trench accidents; elevator shaft accidents; electrocution; motor vehicle accidents; struck by accidents; caught in between; and gas leaks, fires and explosive (OSHA, 2021; FEMA, 2021) with no mention of occupational stressors as mental health problems under the classifications. Although the construction industry is regarded as one of the most stressful occupations, more attention has been placed on preventing physical injuries with little focus on mental health issues such as stress, depression, anxiety, suicide, and substance abuse (Leung et al., 2005; Ng et al., 2005; Liang et al., 2021). It is therefore, essential to monitor and to address the issues of mental health among the construction workforce in order

to better understand their effects and to subsequently prevent occupational injuries and increase productivity (Boschman et al. 2013).

Psychological stress can be defined as the physical processes created by conditions exerting psychological demands on an individual (Selye, 1976). These demands exerted on the body are called stressors (McGrath, 1982). Occupational stress is defined as the individuals 'perception of the discrepancy between the environmental demands (stressors) and individuals 'abilities to satisfy these demands (Topper, 2007; Vermunt & Steensma, 2005; Varca, 1999; Randall & Ross, 1994; Beehr, 1995). Occupational stress is a dangerous illness for industrialized economies and hinders development, threatens production as it affects the physical and mental health of the workers (ILO, 2014). In addition, WHO (2019) contents that recently, occupational stress has become a major public health concern with negative effects on human health. Moreover, psychosocial risks and occupational stress are increasingly among the most challenging issues in occupational health and safety (EU-OSHA, 2021). The EU-OSHA reported that about half of the general European workforce regarded stress as the main contributing factor for about half of all lost workdays. Similarly, ILO (2014) indicated that stress is the second most prevalent work-related health problem and it is believed that the number of workers suffering from occupational stress-related illnesses is likely to increase.

A considerable amount of literature has been published on the causes of occupational stress among the construction workforce and the issues have remained somewhat similar throughout the studies (Goldenhar, 2003; Molen, 2000; Boschaman et al., 2013; Bowen et al., 2013, 2014, 2018; CIOB, 2006; Leung et al., 2016; Ng et al, 2005; Hamid et al, 2014; Lingard et al., 2009, Love, 2010; Sheratte, 2018; Jepson, 2017; Langdon & Sawang, 2018; Bryson & Duncan, 2018; Tijani et al., 2020). Researchers have shown that the adverse working conditions in construction can contribute to stress. The workforce in construction experiences long hours working under pressure with tight deadlines, high levels of conflicts, low job control, lack of managerial support, job insecurity, and lack of work-life balance (Bowen et al., 2013, 2018; Langdon & Sawang, 2018; Panahi et al., 2017; Love et al., 2010; Cattell et al., 2016, Sherratt, 2018).

Furthermore, most workers in construction commute long distances to work and some travel far away from their homes to work which could result in loneliness and be a significant factor contributing to stress, depression and anxiety (Christodoulou, 2021). Construction projects take place over a short period of time leading to job insecurity which in itself is another major stressor (ibid). Over and above dangerous working conditions and strict deadlines, workers must adhere to safe working procedures which can be extremely difficult when working under pressure. As a result, workers worry about their wellbeing and become increasingly anxious where they believe exposure to work hazards may result in diseases or injury and this often causes distress (negative stress) (ibid).

This study seeks to investigate the impacts of working conditions and psychological stress among the South African workforce and how these impacts affect the worker's mental wellbeing in relation to occupational stress. It has been reported that most studies on occupational stress in the construction industry have been conducted in developed countries especially in the UK, USA, Australia and New Zealand with little focus on African countries (Bowen et al., 2013). Developing countries are characterized by extreme socio-economic issues, such as inequality and crime (Bowen et al., 2013). It has also been reported that in South Africa specifically, the nature of mental health issues requires a uniquely South African solution (SACAP, 2019). Furthermore, there exists both a population and a knowledge gap within the

South African context on the causal effects of occupational stress among the general workforce and not only on construction professionals as with other previous studies.

Methods

An extensive literature review on the topic was done and questionnaires were formulated from the literature to conduct a snap survey. Structured questionnaires were distributed to contractors in the Kwa-Zulu Natal province to explore the constructs underlying the research topic. The sample was selected using convenience sampling, and the respondents were sampled based on proximity and familiarity. This form of sampling maximized the response rate as the study was conducted over a short period. Some respondents were referrals recommended by other participants – a variant of snowballing sampling technique. Self-administered questionnaires with a series of close-ended questions were emailed. A total of 40 questionnaires were emailed and the study achieved a response rate of 80%. The study employs a quantitative research approach and data were analyzed using IBS SPSS v25. The exploratory study forms part of ongoing empirical research.

Results

This section presents the analysis of the data collected and discusses the findings. Data were analyzed using IBM Statistical Package for Social Sciences (SPSS) version 25. Descriptive statistics was adopted for the data analysis and further interpreted using inferential statistics. Tables were used to present data and key findings.

Profile of the Respondents

The participants in the study were the general construction workforce working for contractors. The respondents were artisans, construction professionals and construction laborers. Table 1 outlines the demographics/profile of the respondents.

Table 1. Profile of the respondents.

Age and number of years of experience			
	Median	Minimum	Maximum
Age of Employee	33	25	52
Years of Experience	10	2	32
Gender of Respondents			
	Frequency		Percent
Male	20		62.5
Female	12		37.5

Total	32	100.0
Highest formal qualification		
	Frequency	Percent
Secondary or high school	4	12.5
Technical or Vocational College	4	12.5
University Degree	24	75.0
Total	32	100.0
Position in Organization		
	Frequency	Percent
Construction Manager	4	12.5
Health and Safety Officer/Manager	2	6.3
Quantity Surveying	9	28.1
Civil Engineering	6	18.8
Foreman/Supervisor	2	6.3
Artisan	3	9.4
Construction Workers/Labourer	4	12.5
Other (Specify)	2	6.3
Total	32	100.0

The results in Table 1 indicated that the median age of the respondents was 33 years ranging from 25 years minimum to 52 years' maximum. The median years of experience were 10 years ranging from a minimum of 2 years to a maximum of 32 years. The majority of the respondents were male at 62.5%. Most respondents had obtained a University Degree (75%) followed by both technical/vocational schools (12.5) and secondary/high school qualifications (12.5%). Furthermore, most respondents were Quantity Surveyors (28.1%); followed by Civil Engineers (18.8%); both Construction Workers Construction Managers (12.5%); Artisans (9.4%) and Health and Safety Officers/Managers and others (6.3%). Therefore, most respondents were construction professionals (65.7%) followed by Construction Labors (18.8%) and Artisans (15.7).

It is apparent from the findings in Table 1 that majority of the respondents were well within the acceptable working ages although not a true representation of the entire workforce which usually ranges from 18 to 65 in the South African construction industry. The same may be implied for work experience. Further, majority of the respondents were construction professionals. This may be attributed to the fact the study was conducted during the pandemic and mostly data collection was by means of emailed questionnaires and google forms.

Therefore, the results of the current preliminary study should be interpreted with caution because usually, the construction industry has more artisans and laborers than construction professionals.

Data Interpretation

Table 2 presents the data range interpretation based on the 5-point Likert scales used in the study. The group interval coefficient value for the 5-point Likert scale was calculated as (5) /3 = 1.67. The range interpretations for the 5-point Likert scale were used in Table 4-5. For further ease of interpretation, the mean values for the 5-point Likert scale were interpreted as; high, medium and low.

Table 2. Data interpretation ranges.

Range	**5-Point Likert Scale**	
	Agreement Scale	Ease of interpretation
5.00 - 3.34	Strongly Agree	High (H)
	Agree	
3.33 – 1.68	Neutral/Unsure	Medium (M)
≤1.67	Disagree	Low (L)
	Strongly Disagree	

Reliability

Cronbach's Alpha reliability test was conducted in IBM SPSS v25 to determine the reliability and internal consistency of the scales that had been used to analyze compliance and impact of legislative changes on construction workers' wellbeing. The reliability test was done for each construct, as indicated in Table 3. The Cronbach's Alpha coefficients between $0.70 \leq \alpha \geq 0.80$ are 'acceptable' while between $0.80 \leq \alpha \geq 0.90$ are considered 'good' and coefficients $0.9 \leq \alpha$ are 'excellent' (Tavakol & Dennick, 2011). Therefore, the internal consistency of the various scales was deemed acceptable for further interpretation.

Table 3. Cronbach's Alpha reliability test.

Cronbach's Alpha	Reliability
.725	Good

Reliability was acceptable across all the scales used, and further analysis of the results was conducted.

Organisational Stressors among the Workforce

Table 4 indicates the average number of working hours in their organizations.

Table 4. Average working hours per week.

No. of Hours	Frequency	Percent
Between 0-40 hours	8	25.0
Between 41-49 hours	18	56.3
Between 50-59 hours	6	18.8
Total	32	100.0

The findings from Table 4 revealed that 56.3% of the respondents work anywhere between 41-49 hours a week while only 25% work 0-40 hours per week and the rest work for 50-59 hours. According to the Basic Conditions of Employment Act in South Africa, workers are permitted to work for 45 hours per week under normal circumstances. The majority of the respondents had indicated working hours between 41-49 hours. Therefore, based on the findings, the exact number of hours worked is unclear and this calls for further investigation. However, worth notice is that 18.8% of the respondents worked for more than 50 hours per week. This suggests working overtime which is in line with several literature findings (Tijani et al., 2020).

Working Conditions and Psychological Stressors among the Workforce

In Table 5 the respondents were presented with 17 statements based on literature about the most prevalent working conditions that lead to psychological stress. Although several working conditions lead to distress, only 17 statements were selected because they were the most prevalent in most studies (Christodoulou, 2021; Tijani et al., 2020; Chan et al., 2021). Therefore, the respondents were requested to indicate their level of agreement on working conditions leading to psychological stressors based on a 5-point Likert scale where 1=Strongly Disagree, 2=Disagree, 3=Neutral, 4=Agree and 5=Strongly Agree.

Table 5. Working conditions.

Statements	Mean	SD	Int.	Rank
I sometimes work at night	3.94	.948	H	1
There is too much workload	3.91	.928	H	2
I sometimes work on weekends	3.84	1.019	H	3
I worry about my job security	3.84	1.221	H	4
I am not happy with my salary/wage	3.81	1.176	H	5

I get support from my boss when I have problems with my work	3.53	.879	H	6
I am not told about change at work	3.47	1.270	H	7
I always get my work done on time	3.47	1.016	H	8
I travel/commute long distance to work	3.44	1.268	H	9
My work is dangerous	3.34	1.285	H	10
I do not get enough training	3.28	1.023	M	11
I have limited decision making at work	3.13	1.129	M	12
My personal values and those of my company are very different	3.03	1.150	M	13
I want to leave my company	2.94	1.045	M	14
I am not satisfied with my company	2.84	1.194	M	15
I do not understand my duties and responsibilities at work	2.13	1.008	M	16
I am bored because there is not enough work	1.91	1.118	M	17

The findings in Table 5 revealed high levels of agreement for unpredictable working hours such as working at night (mean=3.94) and working on weekends (mean=3.84). Workers also indicated that there was too much workload (mean=3.91). Therefore, it may be inferred that workers work on weekends and at night due to workload demands. Workers also reported a high level of concern for their job security (mean=3.84) and their salaries (mean=3.81). Respondents further revealed that their bosses were supporting when they needed help (mean=3.53) although they had also highly agreed that they were not told about changes in the workplace (mean=3.47). Further, most respondents had indicated getting their job done on time (mean=3.47). The respondents also had a high level of agreement regarding long travel time (mean=3.44) to work and the danger of their jobs (mean=3.34). There was however a medium level of response in relation to decision latitude, role demands, career stress and underworking. Workers responded moderately to insufficiency of training (mean=3.28); limited decision making (3.13); role demands (mean=3.03); leaving their current companies (mean=2.94); satisfaction with organization (mean=2.84); role ambiguity (mean=2.13) and boredom at work (mean=1.91).

Discussion

The findings of this study are consistent with the finding from a systematic review conducted by Tijani et al. (2020) (from 1997 to 2020) and Chan et al. (2021) (from 1992 to 2020) about the causes of occupational stress in construction. Work demands such as working at night, working on weekends and work overload which is attributed to tight deadlines were the most prevalent causes of occupational stress among the respondents. It may be inferred from these findings that this leads to home-work conflict which is in line with the findings from Tijani et

al. (2020) where home-work conflicts ranked highest among the causes of occupational stress in construction. Not being able to separate personal life from work and working on site is stressful due to poor working conditions and could also disrupt an individuals' circadian rhythms leading to sleeping and eating disorders and subsequently psychological stress (ILO, 2020).

Furthermore, job insecurity and poor remuneration which have been linked to financial stress ranked high and this is also in line with the systematic review findings. Most construction workers in South Africa are bread winners. Financial stress which has been linked to suicide among the workers (Martin et al., 2016) occurs when these individuals are unable to meet their financial obligations. This has also been cited by Hobfall (1989) in relation to the Conservation of Resources (COR) theory which assumes that stress occurs in any of three situations identified as when people experiences loss of resources, when resources are threatened and when individuals invest their resources without subsequent gain. Therefore, the premise of COR theory maintains that individuals are in constant pursuit to acquire, preserve, nurture, and safeguard the things they value (Hobfoll et al., 2018; Hobfoll, 1996).

Poor working conditions lead to workers' worry about their wellbeing and become increasingly anxious where they believe exposure to work hazards may result in diseases or injury and this often results in depression, anxiety, boredom, frustration, and other negative emotions. Stress and unhealthy working conditions are known to manifest as psychosomatic symptoms such as headaches, low energy, insomnia, back pain or chest pain. Furthermore, increased job demands can lead to unintentional blindness as too much focus on complex tasks often leads to low levels of concentration. It is evident that as mental and physical fatigue mount during prolonged work activities such as working at night, on weekends or work overload workers are most likely to conduct unsafe behaviors.

However, contrary to previous studies on the lack of support by management, this study revealed that they did receive support from their superiors although not fully. Nevertheless, this inconsistency may be attributed to the low sample collected in the study as the respondents further indicated that there was poor communication especially relating to changes in the workplace.

Other issues emerging from the findings of the study revealed dangerous working conditions and traveling long distances to work. These findings are also in line with the finding from previous studies (Tijani et al., 2020; Chan et al., 2021). There was, however, a moderate response level relation to career stressors, role demands and boredom at work. Therefore, the findings of this study while preliminary, are suggestive that unrealistic timeframes (working at night and during weekends) as a result of work overload, job insecurity and unfair reward are the most prevalent issues among the workforce.

Conclusion

This study has investigated the prevalence of work stress emanating from work conditions among workers in the South African construction industry. The research confirms previous findings and contributes to an understanding of how the workforce is affected by occupational stress in a developing country. However, a number of limitations need to be acknowledged. This is a preliminary study that forms part of ongoing empirical research. Therefore, a snap survey was conducted over a short period of time in order to help reveal the common causes of

occupational stress in the South African context among the general workgroups such as artisans, construction workers and construction professionals. Homogeneity among the groups of respondents was not achieved and therefore, it was not easy to distinctly look at how each construct affects each working group as CPPs may not be exposed to similar job conditions as artisans and laborers. Also, the sample size of the study was low due to time constraints. As a result, it is imperative to conduct a study with a large sample size in order to make generalized conclusions.

Abstract

Construction projects include highly complex and risky processes, documents, and approval stages due to the complex structure of the Architecture, Engineering, and Construction (AEC) industry. These processes are traditionally carried out with contract standards such as FIDIC and KIK, and these standards contain various dilemmas within themselves. As an alternative to these, the development of Web 3.0 and the blockchain-based smart contracts included in the AEC industry contain suitable solutions for the aforementioned dilemmas. Therefore, this study aims to determine how blockchain-based smart contracts provide solutions to the problems of traditional contract standards with a systematic literature review. Within this aim, scientific articles which were published between 2018-2022 years were reviewed, and a total of 46 articles closely related to the subject were analyzed. This qualitative synthesis of the research was used to identify the advantages of smart contract implementation in the AEC industry over traditional contract standards. The findings of the study list the contributions, difficulties, and threats to validity and implications of blockchain-based smart contracts, which have features for solving the problems caused by standard contracts, to the process.

Keywords: *AEC industry, blockchain-based smart contracts, construction, meta-synthesis, qualitative study.*

Introduction

One definition of the construction industry treats it as “complex product systems” (Winch, 1998). This complex structure tries to keep up with technological developments with its subsets. The latest developments experienced by the Architecture, Engineering, and Construction (AEC) industry are changing due to both the change in technology and the disruptions imposed by the coronavirus pandemic. For this reason, smart contracts included in the AEC industry can benefit many integrations, especially the supply chain (Hamledari & Fischer, 2021a). With the inclusion of the latest developments in information technologies in the AEC industry, project management and contracts in the industry are also affected and digitally renewed (Pradeep et. al., 2021). Blockchain technology, which is revolutionary for many industries, is a pioneering technology for digital transformation while defining business

processes from the ground up for many industries (Pattini et al., 2021). Large-scale construction projects and process management are very complex, so there is an increasing desire for the industry to adopt emerging technologies and integrate (Hargaden et al., 2019).

Smart contracts are a self-executing program used for the execution of automated transactions, usually determined by parties, when working with a blockchain-based system (Chatterjee et al., 2018; Governatori et al., 2018). This technology is considered by many experts as one of the most effective solutions in the AEC industry (Construction Economy Newspaper, 2018). On the other hand, construction projects contain some uncertainties according to their types. Technologies in construction projects also have their own uncertainties. These uncertainties cause conflicts between stakeholders (Çevikbaş & Köksal, 2018). At the same time, there are various abuses in the system. With this integration, changing project data in construction projects automatically creates inconsistencies that can be detected. In this way, common frauds in the AEC industry can be detected and prevented (Le et. al., 2014). As a solution to voluminous, complex, and incomprehensible construction contracts; smart contracts are an effective and alternative option (Gurgun & Koc, 2021). Blockchain is an internet version that can be traced and authenticated as it is recorded in a distributed database and has features such as transparency and reliability (Lima, 2018). Some pilot applications are carried out with blockchain technology all over the world. Blockchain technology can be used in matters such as custody of judicial files, financing of state structures, money tracking, marital status, voting system, business licenses, criminal records (Ølnes et al., 2017). The integration of blockchain technology and smart contracts has attracted the attention of the AEC industry around the world due to its potential to increase the transparency, traceability, and immutability of construction data (Lu et. al., 2021a). With these developments, blockchain-based smart contracts become a remarkable alternative to traditional contracts that single-handedly govern their terms and obligations (Koç & Gürgün, 2020). While this technology is relatively new, it commonly carries solutions to many business problems. Many institutions, organizations and even governments incorporate this technology into their business processes (Yang et. al., 2020).

Within these backgrounds, this study identifies the contributions of smart contracts to the AEC industry by using meta-synthesis method. It is anticipated that the findings obtained from the study will form a basis for further studies by presenting a summary that brings together the literature deficiencies, main topics mentioned in the literature, problem determinations and development options related to blockchain technology-based smart contracts that will work in integration with the AEC industry. Through meta-synthesis analysis, potential barriers to incorporation into the AEC industry, such as the inability to understand or adopt blockchain-based smart contracts, have been identified. These determinations are important for the determination and selection of the topics that should be focused on in future studies. It is also important to be able to understand the nature of smart contracts in the construction industry as they are incorporated into the project management process.

Research Methodology

The meta-synthesis method is used to determine what the subjects proved by the results of scientific studies want to express or whether there are contradictory results in the scientific literature. In other words, it is a relatively new research synthesis that combines quantitative and qualitative meta-analysis. By using these syntheses, the validity or deficiencies of

previous studies are determined (Sandelowski, 2006; Cooper, 2009). In this way, an integrated result of the information belonging to previous studies is obtained (Sandelowski, 2006). While a systematic literature review is based on empirical evidence and answers research questions by collecting and summarizing all empirical evidence, meta-synthesis uses a qualitative research design and attempts to integrate results from several different but interrelated qualitative studies. A systematic literature review provides us with qualitative data whereas handling the obtained data with meta-synthesis also provides us with quantitative data. Meta-synthesis produces synthesis findings in which quantitative data are combined with qualitative data. Therefore, this study adopts meta-synthesis method since the aim of the study is reviewing, analyzing, and examining the literature and thus establishing the relationship between existing studies to obtain a framework for the possibilities that the application of smart contracts in the AEC sector can provide. As the output of meta-synthesis analysis, a result table (Table 1) was obtained in which the deficiencies, gaps in the literature or the issues that need to be developed for the future work were expressed. The meta-synthesis method contains two main steps which are 1) determining the research questions and 2) inclusion/exclusion criteria necessary for performing the meta-synthesis.

Identification of the research questions. At this stage, research questions that need to be addressed were determined. Questions addressed in this study can be summarized as below:

- How are smart contracts used in the AEC industry?
- What are the benefits of using smart contracts in the AEC industry?
- What are the difficulties and threats to validity of smart contract usage in the AEC industry?

Inclusion/exclusion criteria. To find answers to these research questions, publications related to the subject were examined. Due to the topicality of the subject, it is important to follow the latest developments. For this reason, the studies carried out in the last 5 years covering the years between 2018 and 2022 will be examined. The publications within the scope of the study are selected among the publications in the American Society of Civil Engineers (ASCE), ScienceDirect and IEEE Xplore Digital Library database. To conduct the meta-synthesis analysis, keywords such as smart contracts, block-chain, and Architecture, Engineering, and Construction (AEC) industry were chosen. In this case, there is a special case that can create complexity in the data as a problem. The word "Architecture" is used as a means of expressing the logic of many other subjects, as well as expressing the field of architecture within the construction industry. For example, "domain architecture". Therefore, even if they are not included in the exclusion criteria, studies that are not related to the subject although they provide the keywords are excluded. As a result, 501 article was found suitable for review. In addition, although "supply chain" is a concept used in the AEC industry in general, only those that cover the "construction supply chain" sub-title of the publications on this subject are discussed. Although block-chain technology and smart contracts are often used interchangeably, first, the effects of smart contracts on the AEC industry were examined in terms of the subject of the study. After all the eliminations were completed, a literature review was made on the contributions of block-chain-based smart contracts to the AEC industry over the remaining 46 articles. Figure 1 shows the literature search strategy, and the selected studies and summary findings of selected articles are shown in Table 1.

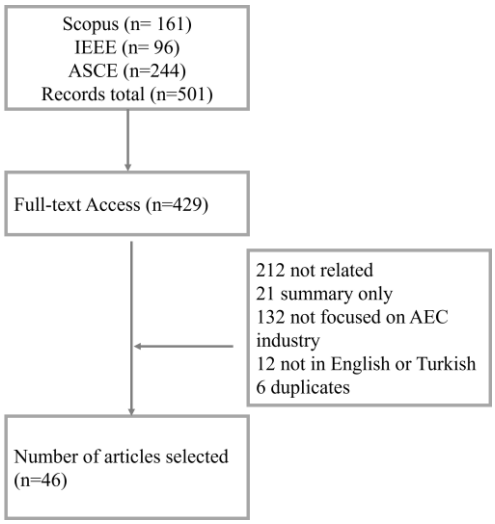

Figure 1: Literature search strategy.

Table 1. Summary findings of selected articles.

#	Title of Publication		
	Author/s - Year of Publication	**Benefits**	**Difficulties and Threats to Validity and Implications**
1	**A Semantic Differential Transaction Approach to Minimizing Information Redundancy for BIM and blockchain Integration**		
	Xue et al., 2020	Intermediary payments are eliminated, and a transparent payment system has established.	This system, which can work in small-scale projects, will create limitations in large-scale construction projects. The instability of the value of cryptocurrencies against each other.
2	**Understanding Stakeholders Needs for Using Blockchain Based Smart Contracts in Construction Industry of Thailand: Extended TAM Framework**		
	Chaveesuk et al., 2020	It has been stated that smart contracts can provide a better allocation of risks in the contract, thanks to their self-executing feature.	The difficulties in implementing smart contracts are serious. Contracts are irrevocable and unchangeable and are prone to human error.
3	**Intelligent Contract Adoption in The Construction Industry: Concept Development**		
	McNamara et al., 2021	In the construction sector, the smart contracts would help eliminate the slow, expensive, and brittle transactions, associated with integrity and transparency issues due to potential records manipulation of the traditional contracts.	Adoption and transition of smart contract intent in the construction industry requires a paradigm shift in perception, formulation, decoupling, and contract management philosophies and guidelines.
4	**Do You Need A Blockchain In Construction? Use Case Categories and Decision Framework for DLT Design Options**		
	Hunhevicz et al., 2020	The increased reliability and traceability of validated information flows on the blockchain makes it possible to use tools to backtrack the construction process at any time.	(-)
5	**Construction Payment Automation Using Blockchain-Enabled Smart Contracts and Robotic Reality Capture Technologies**		
	Hamledari et al., 2021a	Smart contracts provide benefits for the automatic, transparent, and secure process of interim payments made in projects. With smart contracts storage and management costs are reduced.	(-)
6	**Digital Building Twins and Blockchain for Performance-Based (Smart) Contracts**		
	Hunhevicz et al., 2022	Record integrity and data integrity are ensured in construction documents.	Although it facilitates document management for AEC projects, it creates certain security vulnerabilities while taking advantage of blockchain security due to smart contract logic.
7	**BIM Integrated Smart Contract for Construction Project Progress Payment Administration**		
	Sonmez et al., 2022	Fair and accessible storage is provided.	Prototypes need to be tested in realistic environments.
8	**Blockchain in the AEC industry: Current Status, Key Topics, and Future Research Agenda**		
	Xu et al., 2020	It records construction progress in distributed ledgers, facilitating inspections and payments.	A poorly designed smart contract will cause irreversible financial losses. Payments and applications via smart contracts are still in the early stages of development and are far from mass acceptance for now.
9	**Blockchain and Smart Contracts: A Solution for Payment Issues in Construction Supply Chains**		
	Nanayakkara et al., 2021	Integration of blockchain and supply chain provides traceability and real-time information	(-)

		access.	
10	**Digitalization in Construction: Blockchain Applicability in The Industry**		
	Pattini et al., 2021	By using real cases to eliminate information asymmetries and to investigate the legal consequences of contracts, solutions to improve trust and conflict between stakeholders can be produced.	(-)
11	**Public and Private Blockchain in Construction Business Process and Information Integration**		
	Yang et al., 2020	Blockchain-based payment automation has benefits for dispute resolution and construction law informatics.	(-)
12	**Integration of Blockchains and Smart Contracts into Construction Information Flows: Proof-Of-Concept**		
	Ciotta et al., 2021	The article provides insight into the feasibility of potential adoption smart contracts with BIM.	It is thought that this integration will take time.
13	**Blockchain-Based Framework for Improving Supply Chain Traceability and Information Sharing in Precast Construction**		
	Wang et al., 2020	Construction projects potentially generate revenue using the distributed ledger.	Distributed database research in the AEC sector remains at the theoretical level.
14	**Blockchain-Based BIM Digital Project Management Mechanism Research**		
	Ni et al., 2021	Payment system becomes easy and transparent with the use of digital building twins to handle digital payments.	(-)
15	**Blockchain in Construction Management: Applications, Advantages, and Limitations**		
	Mahmudnia et al., 2022	Confidentiality in the industrial environment is protected through smart contracts.	(-)
16	**Construction Quality Information Management with Blockchains**		
	Sheng et al., 2020	Supply chain is protected against malicious data.	(-)
17	**The Role of Blockchain in Improving the Processes and Workflows in Construction Projects**		
	Hargaden et al., 2019	Because smart contracts are decentralized, unnecessary bureaucracies are reduced and communication problems are resolved, while conflicts arising from incorrect documentation and payment issues are avoided.	The challenges of smart contracts are lack of professional training, lack of regulatory clarity, and lack of trust.
18	**Exploring Smart Construction Objects as Blockchain Oracles in Construction Supply Chain Management**		
	Lu et al., 2021a	Functional for supply chain management.	Adoption of new technologies is complex in the construction industry, where expected value is immediately met and short-term views on innovation investments are adopted.
19	**Smart Contracts and Supply Chain Management Using Blockchain**		
	Singh et al., 2022	Blockchain technologies have the potential to make the construction industry more efficient, inexpensive, or completely automated.	The technological state of the industry, skills, resistance to change, readiness for adoption, power, malicious attacks, coding of smart contracts, interoperability, legal, connectivity, and bandwidth are the challenges of blockchain technologies in the construction industry.
20	**Towards Adoption of Smart Contract in Construction Industry in Malaysia**		
	Bolhassan, et al. 2022	The processes in which technological developments are included will provide better service to their customers and in this way, they will gain a competitive advantage.	(-)
21	**The Application of Blockchain-Based Crypto Assets for Integrating the Physical and Financial Supply Chains in The Construction & Engineering Industry**		
	Hamledari et al., 2021b	The fusion of BIM and Blockchain technology creates a process that ensures balance of interests, non-destructive transmission of building information, accountability traceability and customer satisfaction.	(-)
22	**Measuring the Impact of Blockchain and Smart Contracts on Construction Supply Chain Visibility Hesam**		
	Hamledari et al., 2021c	Provides benefits in terms of information management and cash flow management.	Blockchain, as a distributed ledger technology, could disrupt the traditional hierarchy way in which information is shared and processes are developed in the construction industry.
23	**Blockchain-Aided Information Exchange Records for Design Liability Control and Improved Security**		
	Pradeep et al., 2021	A transparent and reliable environment is ensured when quality files are stored with a blockchain-based smart contract.	Issues such as initial development cost need to be resolved.
24	**Securing Interim Payments in Construction Projects Through a Blockchain- Based Framework**		
	Das et al., 2020	Applications of blockchain technology, a reliable, distributed data storage mechanism combined with smart contracts, focus on solutions for complex inter-organizational processes for payment related issues.	(-)
25	**A Smart Contract System for Security of Payment of Construction Contracts**		

	Ahmadisheykhsarmast, & Sonmez, 2020	Construction processes speed up conflicts between stakeholders are reduced payments made easy.	Since the system does not allow price updates, some survey participants hesitated to switch to unit price projects.
26	**Role of Blockchain-Enabled Smart Contracts in Automating Construction Progress Payments**		
	Hamledari et al., 2021d	Construction project management platform based on blockchain, and smart contract technologies can enable peer-to-peer collaboration between construction parties, which improves information flow to reduce cost and time expenditures while increasing quality in construction.	(-)
27	**Building Applications for Smart and Safe Construction with the DECENTER Fog Computing and Brokerage Platform**		
	Kochovski et al., 2021	It is stated that the two projects carried out with smart contracts can increase the integration of crypto assets in cash and product flow.	Risks exist in regulatory environments, security, and price volatility. With the involvement of crypto assets there are risks associated with regulations, security and volatility of cryptocurrencies in projects.
28	**The Role of Blockchain Technologies in Construction Engineering Project Management**		
	Hargaden et al., 2019	With smart contracts, management costs are reduced, service costs are saved, and the efficiency of business processes is increased.	(-)
29	**A blockchain-based Integrated Document Management Framework for Construction Applications**		
	Das et al., 2022	Building trust among stakeholders.	Technological barriers brought by information redundancy.
30	**Designing a Collaborative Construction-Project Platform on Blockchain Technology for Transparency, Traceability, and Information Symmetry**		
	Udokwu et al., 2021	It has the potential to improve the transparency and traceability of materials supply chains.	(-)
31	**A Systematic Analysis of the Application of Blockchain in the Field of Construction Engineering**		
	Fu et al., 2021	New technologies such as blockchain-based technologies are beneficial for the development of the industry.	(-)
32	**A Blockchain Information Management Framework for Construction Safety**		
	Morteza et al., 2021	With blockchain integration, construction workers and the public are protected by providing reliable and complete information at the right time to organizations in projects.	(-)
33	**BIM Fork: Are Smart Contracts in Construction More Likely to Prosper with or without BIM?**		
	Mason et al., 2019	Thanks to digitalization, transaction costs and times are reduced. Stakeholders do not have to deal with internal affairs, thus ensuring risk allocation.	(-)
34	**Blockchain Technology for Governmental Supervision of Construction Work: Learning from Digital Currency Electronic Payment Systems**		
	Lu et al., 2021b	It is recommended for government supervision of construction works because of blockchain technology's traceability, immutability, and transparency advantages.	Even if there is one-way anonymity in the proposed system, authorized institutions can monitor the transactions. For this reason, there would be privacy concerns if it was used for international business transactions.
35	**Blockchain-Enabled IoT-BIM Platform for Supply Chain Management in Modular Construction**		
	Li et al., 2022	Using blockchain for supply chain can save storage costs in BIM and avoid a single point of failure for IoT networks with privacy and security protection mechanisms.	It is unclear how data can be used in an adaptive way as existing smart contracts are almost deterministic.
36	**Construction E-Inspection 2.0 in the COVID-19 Pandemic Era: A Blockchain-Based Technical Solution**		
	Lu et al., 2022	A blockchain-based solution proposal has been presented in the e-audit system proposed for the measurement of construction quality under pandemic conditions.	(-)
37	**Insights into Blockchain Implementation in Construction: Models for Supply Chain Management**		
	Tezel et al., 2021	Blockchain implementations in payment arrangements has been shown to be simpler than traditional methods in terms of workflow in tender management.	Legal reforms are needed to confirm the rights to data held in smart contracts and the immutability of data stored in the blockchain. Besides, a loss of employment in the industry due to automation processes facilitated by blockchain is a general concern.
38	**On-Site Construction Quality Inspection Using Blockchain and Smart Contracts**		
	Wu et al., 2021	The risk of document and data loss and data manipulation will be solved thanks to the immutable and transparent recordability feature of the blockchain.	Integration of blockchain with IoT can work together in a viable and efficient way is a major challenge.
39	**Rationale for the Integration of BIM and Blockchain for the Construction Supply Chain Data Delivery: A Systematic Literature Review and Validation through Focus Group**		
	Hijazi et al., 2021	The lack of resolution of disputes between stakeholders involved in BIM is resolved with a	(-)

		blockchain-based system.	
40	**State-of-the-Art Review of Blockchain-Enabled Construction Supply Chain**		
	Yoon & Pishdad-Bozorgi, 2022	A supply chain management system combined with blockchain technology is proposed to improve sustainability in the supply chain, encourage cooperation and facilitate information sharing.	(-)
41	**Using Blockchain to Improve Information Sharing Accuracy in the Onsite Assembly of Modular Construction**		
	Wu et al., 2022a	Owing to its decentralized consensus mechanism, blockchain has the potential to improve information-sharing accuracy on construction sites.	(-)
42	**Blockchain Technology in the Construction Industry: Current Status, Challenges, and Future Directions**		
	Wu et al., 2022b	Blockchain has a potential from the whole lifecycle of building projects, in the design stage, construction stage and the operation stage.	Immutability challenge of smart contracts, lack of examinations on blockchain-based cooperation and workflows, lack of supporting policies on blockchain adoption, reluctance to change current systems; considered as the problems of the blockchain.
43	**A Turn to Smart Contracts and Future Applications towards Construction Innovation: A Hybrid-Metric Review**		
	Owusu et al., 2020	The feasibility of smart contracts was demonstrated during the planning, purchasing, execution and management of the processes related to the construction project.	(-)
44	**Blockchain: A Theoretical Framework for Better Application of Carbon Credit Acquisition to the Building Sector**		
	Woo et al., 2020	With the blockchain, the sustainability of the construction industry in terms of the carbon market will be ensured.	(-)
45	**Facilitating Smart Contract in Project Scheduling under Uncertainty—A Choquet Integral Approach**		
	He et al., 2022	Smart contracts will help project managers speed up the manpower and scheduling management required in their use of resources.	(-)
46	**Leveraging Blockchain Technology in AEC Industry during Design Development Phase**		
	Singh & Ashuri, 2019	With the incorporation of smart contracts into the AEC industry, a framework will be created to monitor and record design commands and events in a secure, transparent, and collaborative platform.	This technology is in early development as the construction industry is resistant to adapting to new technologies. These technologies are difficult to verify as there are no similar techniques for comparison.

Studies are generally on the integration, potentials, and opportunities of new technology. Although the negative aspects of the use of blockchain are not expressed in all studies, various problems are mentioned as a limitation in most of them. Some studies have focused on the application of the use of blockchain in civil engineering. For example, Fu et al. (2021) used only the construction engineering context in their study. Hijazi et al. (2021) solves a specific problem involving BIM integration; Owusu et al. (2020) on the other hand, conducted a literature review on smart contracts studies until 2018. Although a similar study was conducted with Mahmudnia et al. (2022), this study deals with the benefits and challenges of integration rather than a detailed content analysis. Moreover, more recent studies were examined as a supplement to the reviewed literature. Detailed explanations related to identified 46 reviewed articles is included in the "Implementation of Smart Contracts in the AEC Industry" section.

Implementation of Smart Contracts in the AEC Industry

Blockchain, one of the latest developments in technology, has recently produced an alternative way for the AEC industry to potentially achieve reliable collaboration, especially in construction processes (Risius & Spohrer, 2017). Blockchain and other distributed ledgers hold great potential for the AEC industry to integrate governance and contracting methods that increase trust and collaboration (Hunhevicz & Hall, 2020).

Distrust in construction contracts has become a natural situation. For this reason, it can be said that the blockchain has potential with its cryptographic and verifiable transactions stored in a decentralized ledger, with a system that can ensure trust among construction stakeholders (Xue & Lu, 2020). With the inclusion of the blockchain in the system, the payment security in the construction sector is ensured, while the burden of other payments such as administrative costs, attorney costs, and intermediary bank payments is alleviated (Ahmadisheykhsarmast & Sonmez, 2020). Resource management platform developed by Kochovski and Stankovsk (2020), offers a blockchain-based system to oversee broad categories of construction such as occupational safety, site management, and resource and waste management. In Das et al.'s (2022) study, the use of blockchain-based smart contracts was proposed due to the security concerns that lie in the collection and management of these documents since the documents and their management of AEC projects require record integrity and data integrity. Hamledari and Fischer (2021b) proposed a blockchain-integrated smart contract system in their work that senses construction progress, captures it with machine intelligence and BIM, and analyzes and documents it. With the prototype proposed by Pradeep et al. (2021) individual design inputs are added to the project design in the construction industry, images are recorded, and long-term records of key exchange transactions can be taken. In this case, the design responsibility and control of all stakeholders will be changed. In addition, the evidence in this system is stored independently of a third party. This way, the information's existence, integrity, and authenticity can be verified. Therefore, this integration supports existing information exchange systems. Sheng et al. (2020) presented a system that can be used for the management of quality information in construction with the support of blockchain to enable quality management in the AEC industry. The work by Hunhevicz et al. (2022) proposed a blockchain-based smart contract link that calculates the costs of the devices to be used in the construction project, thus allowing performance evaluation and routing digital payments. In the study of Hamledari and Fischer (2021a), it was stated that two projects carried out with smart contracts can increase the integration of crypto assets in cash and product flow. Yang et al. (2020) presented the process, benefits, and challenges of adopting private and public blockchain technologies by examining two cases to find out the effects of smart contracts in the construction industry. Ciott et al.'s (2021) work aim to reduce human error in the process and increase the reliability and transparency of structural system decision-making processes on construction sites by providing common data environments to support document management of blockchains and smart contracts. By integrating smart contracts into the construction sector, payment security in the construction sector is ensured, while the burden of other payments such as administrative costs, attorney costs, and intermediary bank payments is relieved (Risius & Spohrer, 2017; Ciott et. al., 2021). A survey of construction experts in Sonmez et al.'s (2022) study showed that blockchain has the potential to speed up all construction processes, streamline progress payments, reduce disputes, and improve traditional payment procedures.

Benefits of Smart Contract Applications

It was suggested that blockchain technology can contribute to building trust among construction stakeholders (Xue & Lu, 2020). It is mentioned that the effect-based trust in traditional contracts will be replaced by systems-based trust. As the cooperation between stakeholders increases, so does the trust of users. In this way, stakeholders are gained on the quality of the construction done (Pradeep et al. 2021; Yang et al., 2020). With the idea of a smart contract to be used in the interim payment stages of construction projects, security measures such as the privacy of data and users are taken, while storage and management costs

are reduced (Das et. al., 2020). With the use of smart contracts, performance-based contracts are reliably digitized, performance-based uses are scaled in the embedded environment, and new business models are possible by stimulating project lifecycle-related markets (Hunhevicz et al., 2022). Tezel et al.'s study revealed that using the implementation of blockchain in payment arrangements in construction is simpler than traditional methods in terms of workflow in tender management (Tezel et al., 2021). Lu et al. (2022) proposed a system that provides remote control for conditions such as pandemics. In this case, a blockchain-based solution proposal is presented in the proposed e-audit system for the measurement of construction quality. Thus, this control will be made more secure with rigorous technological analysis. With Hamledari and Fischer's (2021b) proposal to integrate smart contracts with construction progress, construction progress data is stored in distributed ledgers, making payment management easier. Thanks to digitalization, transaction costs and times are reduced. Stakeholders do not have to deal with internal affairs, thus ensuring risk allocation (Mason et al., 2019).

Through the smart contract, data sharing is encouraged. Approval processes are facilitated, operating costs are reduced, collaborative efficiency is increased, a reliable infrastructure is obtained for the digitalization of the construction industry, and labor and cost savings are achieved (Ni et al., 2021). The use of smart contracts in contracts allows for reliable and unalterable archiving of every document in the process, such as drawings, models, datasheets (Pattini et al., 2021). Transparency and traceability of the supply chain are improved in the business process where the blockchain is included. Records cannot be changed and can be viewed retrospectively. In this way, transparency is ensured, and quality fraud issues are alleviated (Yang et. al., 2020). Because smart contracts are decentralized, unnecessary bureaucracies are reduced and communication problems are resolved, while conflicts arising from incorrect documentation and payment issues are avoided (Mahmudnia et al., 2022). Smart contracts ensure that payments are made automatically, eliminating the need for third parties, and saving time and money in case of any dispute involving third parties (Pattini et al., 2021).

In Woo et al.'s (2020) study, with the blockchain, the sustainability of the construction industry in terms of the carbon market will be ensured. Yoon and Pishdad-Bozorgi (2022) points out that the use of blockchain in the supply chain will be beneficial for sustainability.

Difficulties and Threats of Smart Contract Applications to Validity and Implications

The integration of BIM and blockchain and see it as a great potential for achieving more efficient applications, it may face many technological hurdles due to information redundancy (Xue & Lu, 2020). On the other hand, currency fluctuations are the biggest obstacle to the proposed system. Financial risks cannot be fully protected since the relationship of cryptocurrencies with each other will not always progress with a positive correlation. In addition, the current market value of cryptocurrencies creates limitations for large-scale construction projects (Ahmadisheykhsarmast & Sonmez, 2020; Hamledari & Fischer, 2021a).

The current market value of cryptocurrencies creates limitations for large-scale construction projects. Financial risks cannot be fully protected due to currency fluctuations (Ahmadiseykhsarmast & Sonmez, 2020). Due to the continuous development of the use of blockchain in areas such as finance, pilot applications are very few, which limits studies and applications (Wang et. al., 2020). Since distributed database research in the AEC sector

remains theoretical, there are very few applied cases today (Hunhevicz & Hall, 2020). Moreover, payments and applications via smart contracts are still in the early stages of development and are far from mass acceptance now (Hamledari & Fischer, 2021b). Progress payment system proposed by Sönmez et al. since the system does not allow price updates, some survey participants hesitated to switch to unit price projects (Sonmez et al., 2022).

Although the document management system consisting of blockchain-based smart contracts proposed by Das et al. facilitates document management for AEC projects, it may suffer from certain security vulnerabilities while benefiting from blockchain security due to smart contract logic (Das et al., 2022). Moreover, by using real cases to eliminate information asymmetries and to investigate the legal consequences of contracts, solutions to improve trust and conflict between stakeholders can be produced (Hamledari & Fischer, 2021c). Legal reforms are required to confirm the rights of data held in smart contracts and the immutability of data stored in the blockchain (Tezel et al., 2021). According to Pradeep et al.'s (2021) research, smart contracts have theoretical advantages in improving the relationship between stakeholders, but it is recommended for future work to test prototypes in realistic environments. It is doubtful whether the agreement will be reached between the parties in the proposed framework on smart contracts and quality management in construction, and issues such as initial development cost need to be resolved (Sheng et. al., 2020). There is a lack of experience using smart contracts and it is unclear whether this will be beneficial for some stakeholders (Mohammed et al., 2021).

The technological state of the industry, skills, resistance to change, readiness for adoption, power, malicious attacks, coding of smart contracts, interoperability, legal, connectivity, and bandwidth are the challenges of blockchain technologies in the construction industry (Mohammed et al., 2021). The blockchain-based model proposed by Lu et al., authorized institutions can monitor transactions even if there is one-way anonymity in the system, and this will raise privacy concerns for international commercial transactions (Lu et al., 2021b).

A change of mindset and specific training are required so that blockchain-based smart contracts can be used in the AEC industry and integration can be accelerated (Pattini et al., 2021). Although useful, a comprehensive paradigm shift is required in terms of contract management philosophies and guidelines in the transition to smart contracts in the construction industry (Chaveesuk et al., 2020). Despite gaining benefits in theory, the construction industry, which is accustomed to traditional practices, cannot easily trust and adapt to innovations (Pattini et al., 2021). The construction industry has many stakeholders who use the traditional system and are stubborn in using it, so coordination between units is difficult (Nanayakkara et al., 2021). AEC industry lags in the adoption of process-based technologies (Hargaden et al., 2019; Mohammed et al., 2021). In addition, a loss of employment in the sector due to automation processes facilitated by blockchain is a general concern (Tezel et al., 2021)

Discussion and Conclusion

Smart contracts are seen as one of the newest technological developments in the AEC industry. The main purpose is to carry out the construction works, which are quite complicated compared to all other sectors and carried out with many procedures among multiple stakeholders, in a more reliable, transparent, fair, and auditable manner. While

production companies are trying to incorporate smart contracts into their systems as soon as possible, this integration needs to be investigated more through real-life applications. With this meta-integrating qualitative study, the relationship of the project management process of the construction industry with blockchain-based smart contracts and the emerging integration threats are revealed, contributing to knowledge. When the literature review is made, the fact that the current studies focus on the last years shows that the research in this field have increased as we approach the present day, that is, this research topic has gained popularity.

Study findings agree that smart contracts have many benefits for the AEC industry, including resolution of disputes, ensuring record integrity, equality between stakeholders, removing unnecessary bureaucracy, reliability, removal of agents, ensuring cooperation, reducing costs, auditability, providing convenience and transparency. Although all studies have positive thoughts about the integration of smart contracts into the industry, they state that this integration process will be difficult, especially due to the conservative and non-changeable nature of the construction industry. In addition to these difficulties, the risks that the blockchain in the structure of smart contracts will face during the implementation phase are also mentioned due to various features such as irreversibility, immutability, and deficiencies in legal regulations. All but one of the studies discussed focused on the benefits of the mentioned integration, while negative opinions were also mentioned in 23 studies. Studies have focused on the difficulties and threats to validity and implications that may arise with the integration of smart contracts into the AEC industry. When the benefits of smart contract application highlighted in the articles were examined it can be stated that the most intense studies focus on the benefits of "transparency". This is followed by the technology facilitating processes and auditability, which are two features obtained with the inclusion of blockchain technology. There are statements that this integration provides to reduce the costs in the project management processes and beyond that, it improves the relations between the stakeholders. In addition, reliability, the elimination of intermediary institutions and organizations, followed by the end of unnecessary bureaucracy processes are among the benefits. With this integration, while ensuring equality and balance between the stakeholders, the reliability of the records is proven by retrospectively auditing the transactions. Finally, there are benefits of smart contracts for dispute resolution. When the data obtained about the difficulties and threats of smart contract applications were scanned; it was seen that majority of the articles focused on the working of cryptocurrencies depending on the blockchain and the problems arising from the blockchain technology itself. As examples of these difficulties and threats, problems such as not being able to take back the contract clauses, the rules that need to be restructured according to the scale of the project, security vulnerabilities, and the lack of necessary legal regulations can be listed. It has been stated that more real-life examples are needed for the integration mentioned in the 7 articles. In addition, the concern was expressed that the necessary training should be obtained for the adoption and acceptance of blockchain technology by the stakeholders. In 3 articles, the size of the initial development cost of integrating this technology is also considered a problem.

According to the literature, although the integration of blockchain-based smart contracts into the AEC industry has some risks and uncertainties, it is claimed that the mentioned combination is quite facilitating in terms of costs, disputes, payment periods, project completion time, and project management in the industry. However, the literature is insufficient in the solution of the identified risks and negativities. The primary reason for this is that smart contract applications are not widespread and yet have very few experts. In this regard, the findings of this study will be useful for the AEC industries to understand, adopt and list the opportunities and threats they may encounter during the implementation phase of

blockchain-based smart contracts. For this reason, our recommendation for future studies is to expand the studies to be carried out on the benefits of smart contracts to the construction industry, as well as on the improvement of the acquired risks and negativities. Finally, this study reemphasizes the necessity of producing new scientific studies through real-life application examples of the mentioned integration.

Change Management in Construction: A Systematic Review

A. Ergin and E. Acar
Istanbul Technical University, Department of Architecture, İstanbul, Turkey
ergin20@itu.edu.tr, acare@itu.edu.tr

Abstract

Change management is a strategic act that supports organizations in achieving their goals in the global marketplace. Construction firms as project-based entities need to manage change in different settings for survival and competitiveness. Managing change efficiently has become a central concern for construction firms in terms of sustaining and improving their position in a fluctuating environment by rapidly adapting and responding to external changes in a flexible manner. Over the years, a considerable amount of study has been conducted relating change management which revealed various causes of change, the implications of change, the factors relating to resistance to change, the change management models, and the relevant systems in the construction industry from different perspectives. While a significant number of research papers relied on case-based approaches, only a few presented a systematic review of the existing body of knowledge. The main objective of this paper is to conduct a systematic review of the existing scholarly work to clarify gaps and highlight possible paths as inputs for in-depth empirical research. Paper presents the classification of methods and outcomes from the change management studies in construction.

Keywords: *Change, change management, construction firms, systematic review.*

Introduction

Increasing global competition, growing scarcity of resources as well as technological developments put great pressure on all organizations to adapt and survive by responding to constant change (Al-Sedairy, 2001). In a global marketplace characterized by ever-increasing competitiveness and customer expectations, change management has emerged as a strategic function that supports organizations in staying ahead of the competition (Erdogan et al., 2005). The unique and dynamic nature of the construction industry necessitates change management in all phases of the construction projects (Mohammed & Karri, 2020), since scope changes are inevitable over their lifecycles (Padala et al., 2020). Accordingly, a systematic change management system during the construction process is essential to minimize the impact of changes on project targets (Bitamba & An, 2020).

Over the years, a considerable amount of research studies have been conducted relating change management which revealed various causes of change (Wu et al., 2005; Sun & Meng, 2009; Andersen et al., 2011; Oyewobi et al., 2016; Yap et al., 2017; Bitamba & An, 2020; Padala et al., 2020), the factors relating to resistance to change (Davis & Songer, 2003; Davis & Songer, 2009; Lines et al., 2015), the change management models (Price & Chahal, 2006; Ibbs & Chen,

2015; Saoud et al., 2017; Jaaron et al., 2022), the best practices (Zou & Lee, 2009), in addition to various change management systems from different perspectives such as technology adaptation (Maali et al., 2020; Jaaron et al., 2022), and sustainable systems adaptation (Lim et al., 2016). While a significant number of research papers relied on case-based approaches, only a few presented a systematic review of the existing body of knowledge. These studies are mainly based on reviews of change management practices at the project and organizational levels (Erdogan et al., 2005) and the causes and effects of change in construction projects (Sun & Meng, 2009; Padala et al., 2020). Such studies can be seen as a roadmap to review, evaluate and manage changes in projects (Sun & Meng, 2009). However, available literature mostly focused on specific aspects of change management in the construction industry, which indicates the need for a systematic investigation to review the current change management practices and trends in the construction industry.

As a part of an ongoing research study, authors aim to conduct a systematic review of the existing scholarly work on change management. Paper presents the classification of the methods of and outcomes from the change management studies in construction, based on the analysis of publications which shows patterns of changes within a discipline, thus enabling the assessment of the impact of contributions, detecting existing topics related to the research scope, and setting research gaps for future search.

Change Management in Construction Industry

Any extensions, deletions, or alterations to project objective and scope are regarded as change that result in increase or decrease of schedule or cost of a project (Ibbs et al., 2001). For construction firms to achieve a desirable status in the future, there is a need for a structured approach to change. According to Managing Change in Organizations: A Practice Guide (Project Management Institute, 2013), change management refers to *"a comprehensive, cyclic, and structured approach for transitioning individuals, groups, and organizations from a current state to a future state with intended business benefits."* Change management contributes organizations to incorporate stakeholders, structures, processes, business strategy as well as culture (Project Management Institute, 2013). To sustain organizational growth according to business needs, construction organizations should adapt to change in the market (Ozorhon & Demirkesen, 2014). According to Project Management Institute (PMI) (2021), changes may arise from a consequence of project risks or environmental factors, the need for a deeper understanding of project needs, or client requirements. Shipton et al. (2014) argued that changes in construction occur due to the needs of clients, while the availability of construction material or unpredictable ground conditions also lead to various changes. According to Padala et al. (2020), the maximum number of changes occur in the execution stage of the projects which result in time and cost overruns. Bitamba and An (2020) classified causes of changes in construction under various categories: design-related, contractor-related, owner-related, organizational and management-related, project-related, changes related to environment and site conditions, changes related to materials and equipment, changes related to economy and governmental regulations.

Change management in construction requires the consideration of not only the causes of change but also the critical change effects that have critical impact on project outputs in a positive or negative way. Ibbs et al. (2001) argued that change actions cover two significant typologies including beneficial and detrimental ones, while the former should be encouraged, the latter should be avoided, authors argued. Beneficial changes are the output of value management

operations, which help to reduce the degree of difficulty, schedule as well as the cost of the project. Detrimental changes, in contrast, have negative influence on project so they should be minimized carefully (Ibbs et al., 2001). Bitamba and An (2020) argued that detrimental changes can cause uncertainties as well as interfaces which lead to production of non-viable movements. Hwang and Low (2012) pointed out the criticality of the timely description and understanding of project changes' impacts to minimize their adverse effects. Some primary adverse effects of changes were identified by Hwang and Low (2012) as the increase in project cost, recruitment of new professionals, increase in overhead expenses, quality degradation, decrease in labor productivity, delay in procurement process, rework and demolition, safety conditions, and delay in completion schedule.

Construction management literature has focused on both the causes and effects of change (Sun & Meng, 2009; Padala et al., 2020). Sun and Meng (2009) proposed three levels of classification for the construction projects. Level 1 consists of three dimensions including external, organizational and project internal causes. External causes cover environmental, political, social, economic and technological factors. Organizational causes consist of process, people and technology related factors. Lastly, project internal causes are identified as generated by client, design consultant, contractor/subcontractor, and other (such as poor communication, instability of project team and unsuitable organizational structure). Taxonomy for the effects consists of three different levels. Level 1 includes time, cost, and relationship and people effects. Time effects consist of time extension, loss of productivity, and increased risk. Cost effects cover direct and indirect cost increases. Also, relationship, working conditions, staff, as well as quality related factors include the dimensions of relationships and people effects. In a similar vein, Padala et al. (2020) identified 85 causes and 45 effects of change from the literature, and they investigated 3951 changes from 19 projects to define causes and effects in construction projects. Padala et al. (2020)'s taxonomy covers three levels. Level 1 consists of client-related, design, interfere, construction, external, and performance dimensions related to *causes of change.* The identified Level 1 for the *effects of the change* covers time, cost, and others (including site conditions, quality, delays in procurement, and relationships among the project team).

Change management typically arises in construction at two levels including the *project* and *organization* (Erdogan et al., 2005). Project level covers mostly design changes and those prior to the execution stage. Changes in technology, culture, stakeholders, management (Erdogan et al., 2005), politics and economy (Padala et al., 2020) are the examples of organizational level changes. Table 1 summarizes different types of changes in construction at both levels. It is critical to introduce change to the organization since any misunderstanding, fear for the future, the lack of awareness, and the speed of change implementation can be seen as a threat to stakeholders, thereby causing resistance. The latter is seen as a main challenge to organizational change actions which requires the consideration of project scope, size and duration of change event, organizational expectations of change implementation speed, the establishment of formal change agents, and the level of change agent involvement with implementation activities (Lines et al., 2015).

Table 1. The classification of different types of changes (Taken from Erdogan et al., 2005).

According to	**Project Changes (PCs)**	
Type of Impact (Construction Industry Institute (CII), 1994)	*Beneficial Changes*	*Detrimental Changes*
	Reduce cost, schedule or degree of difficulty.	Reduce owner value, have negative impact on the project.
Need for Change (CII, 1994)	*Required Changes*	*Elective Changes*
	Implemented to meet the objectives or regulatory/ legal/ safety/ engineering requirements/standards.	Enhance the project, but are not required to meet the original objectives.
Initiation Nature/Responsiveness of change (Burnes, 1996)	*Emergent/ Reactive Changes*	*Anticipated/ Proactive Changes*
	Unplanned, unexpected. The response is after the occurrence.	Expected before it occurs, therefore necessary actions are taken.
According to	**Organizational Changes (OCs)**	
The difference in the organization due to change (Tichy, 1982)	*Strategic Changes*	*Non-strategic Changes*
	Nonroutine, nonincremental and discontinuous, alter the overall orientation of the organization.	Do not affect the overall orientation of the company, do not result in a drastic difference.
Speed of the transformation in the organization (Cao et al 2000; Cummings and Worley, 1997)	*Incremental/ Gradual/ Fine Tuning*	*Radical/ Quantum Changes*
	Routinely necessary for any organization to adapt to its environment.	Necessitates a thoroughgoing reexamination of all facets of an organization
Initiation Nature (Burnes, 1996)	*Emergent Changes*	*Planned Changes*
	Driven from bottom up and is an open-ended and continuous process of adaptation to changing conditions.	Result of an action research& an analysis of the social and organizational problems in question.
Initiation Nature (Burnes, 1996)	*Emergent Changes*	*Anticipated Changes*
	Same as above.	Not planned by the organization but it's happening is expected.

According to the PMI's PMBOK 7th Edition, the ability to implement new strategic initiatives and change has rapidly become a key differentiator (Project Management Institute, 2021). Effective and efficient management of change supports the achievement of desired project goals, improve the construction firm reputation, and reduce the cost, and schedule of the project. Change management in construction firms requires strong leadership skills, an effective change management plan that establishes the change control board (Project Management Institute, 2017), the involvement of proper project stakeholders (Lines et al., 2015), adapting the speed of change, and benefits and impacts of change communicated to all levels of the organization (Project Management Institute, 2021).

Change Management Models

Numerous change management models have been proposed in the literature which considers the technical (e.g., procedures) and non-technical (e.g., culture and habits) aspects of change. Table 2 shows the commonly cited change management models, in depth explanation of which is beyond the scope of this paper due to space limitations.

Table 2. The classification of change management models (Adapted from Project Management Institute, 2021).

Change Management Models	*Steps*	*Consideration*	*References*
Lewin's Three Step Model	Unfreeze Moving Refreezing	One of the most influential approaches in the change management discipline that indicate the stages of organizational change.	(Lewin, 1947)
William Bridge's Transition Model	Endings Neutral zone New beginnings	Provides an understanding of what occurs to individuals psychologically when an organizational change takes place.	(Bridges, 1991)
Virginia Satir Change Model	Late status quo The foreign element Chaos The transforming idea Practice and integration New status quo	Mainly based on how people experience and cope with change.	(Satir et al., 1991)
Principles of Effective Change Management	Promote a balanced change culture Recognize change (when it occurs) Evaluate change Implement change Continuously improve from lessons learned	Assist project managers to manage change more effectively.	(CII,1994)
The 8-Step Process for Leading Change	Create urgency Form a powerful coalition Create a vision for change Communicate the vision Remove obstacles. Create short-term wins Build on the change. Anchor the changes in corporate culture	Outlines how to systematically and effectively implement change in an organization.	(Kotter, 1996)
ADKAR Model	Awareness Desire Knowledge Ability Reinforcement	Provides a tool for change that is effective on an individual level.	(Hiatt, 2006)
Managing Change in Organizations: A Practice Guide	Formulate change Plan change Implement change Manage transition Sustain change	It is a complementary document to Project Management Institute's (PMI) foundational standard and provides guidance on implementing change management.	(PMI, 2013)

Various change management models or frameworks have also been proposed for construction firms. Ibbis et al. (2001) proposed an efficient system for managing change in projects which covers respectively: promoting a balanced change culture, recognizing change, evaluating change, implementing change, as well as improving from lessons learned. Hao et al. (2008) developed a model for change processes containing identify, evaluate and propose, approve, implement and review phases for construction. Sun et al. (2004) described a toolkit for change management for construction projects, supporting the project team related to the prediction and reaction of change with knowledge and procedural perspectives. Gibson et al. (2012) developed

an organizational change model that includes the forces for change, performance outcomes, diagnosis of the problem, selection of appropriate intervention, limiting conditions, implementation of the method, and evaluation of the method. Al-Sedairy (2001) offered a change management model specific to Saudi construction industry that consists of four stages of action plans each catering to the seriousness or depth of the perceived organizational problem. Jaaron et al. (2021) proposed a model that identified two main phases and ADKAR steps for various project team members to execute an accomplished change management process regarding the BIM adaptation by using the ADKAR model.

Method

A systematic and structured literature review was conducted by focusing on selected scholarly works on change management. Data were obtained from the Web of Science (WoS) database (Web of Science, 2022) and Scopus database (Scopus, 2022), since these databases cover inclusive, interdisciplinary (Scopus, 2022) as well as the high-impact publications (Web of Science, 2022). Considering the scope of the study, the search keywords were identified as "change management," "construction industry," and also, "construction sector." The search was conducted with various combinations of these keywords. The selection criteria were limited in that each publication should address either change issues or change management, or both. The searches were done in the topic field (covering title-abstract-author keywords- keywords plus®) in WoS and in the title-abs-key field (covering title-abstract- keywords) in Scopus. The research was limited to a 22-year time span from 2000 to 2022. The language type was limited to English for the selected documents.

As a result, 110 publications from the WoS database and 201 publications from the Scopus database were identified, totalling 311 documents which includes journal articles, conference proceeding papers, book chapters, book reviews, reviews, and early access. Some of the documents selected for this study included at least one of the keywords defined for this study in their titles, abstracts, or keywords. Publications were arranged in alphabetical order and those with the same title were removed and identified as 189 documents. The title, abstracts, and keywords of 189 documents were investigated to reach relevant studies thus after the investigation 177 documents were included. Lastly, the full texts of 177 documents were assessed in terms of their relevance to change management and construction industry and 75 publications were included to this study. Figure 1 shows the selection processes of total publications identified through WoS and Scopus.

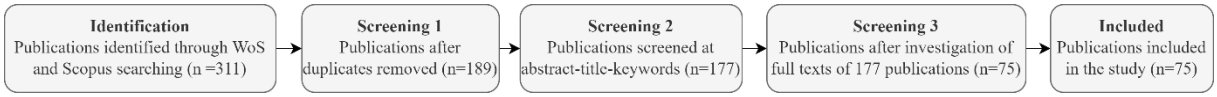

Figure 1: The selection processes of publications for analysis (Search date 22.03.2022).

The second step of the study was a bibliometric analysis by using the VOSviewer software tool (version 1.6.18.) (VOSviewer, 2022) to visualize and create maps by using the network data. The network data consists of 75 scholarly works identified from WoS and Scopus database searches. These 75 publications were added to the reference manager program Zotero, and reference manager files were converted to the RIS format for VOSviewer analysis.

VOSviewer was used to analyze keyword co-occurrence and create network model based on keywords of the identified publications. All duplicating keywords in the network data were

eliminated from the visualization maps using by VOSviewer thesaurus file. The keywords included in VOSviewer were limited to 3 times of repetition.

Findings

Having clarified the need for a systematic investigation of the current change management issues in construction, following parts present the current status, point out the future gaps, and highlight possible paths as inputs for in-depth empirical research, according to the systematic literature review. This section represents the descriptive analysis of selected 75 publications and VOSviewer analysis.

Firstly, the 75 relevant publications were analysed according to the distribution over 22 years period (Figure 2). The maximum number of scholarly works was published in 2009, followed by 2020 and 2017, respectively. Except for the years 2000, 2004, and 2010, at least one study was conducted each year relating change management. Notably, distribution of publications over the years indicates a revival in the field.

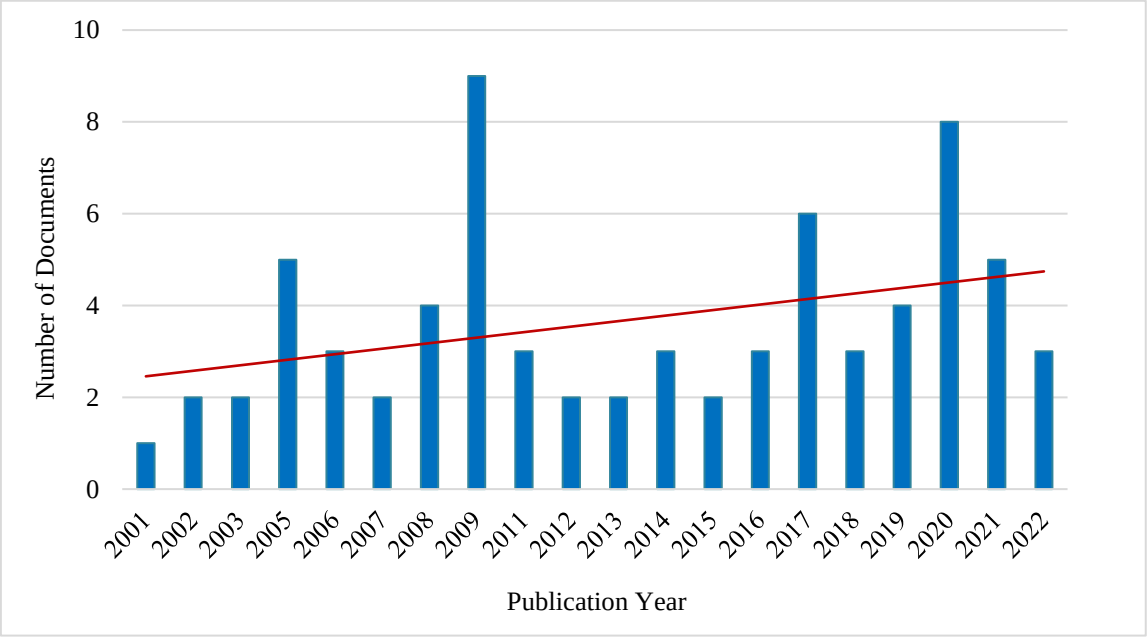

Figure 2: Distribution of publications between 2001 and 2022.

Next, the distribution of publications was analyzed geographically (Figure 3). The USA has the most scholarly works with 15 followed by the UK with 14, demonstrating that change management studies in the construction industry during the period of interest concentrated in these two countries. Figure 3 also shows that research interest in change management has been growing in the Australia and China.

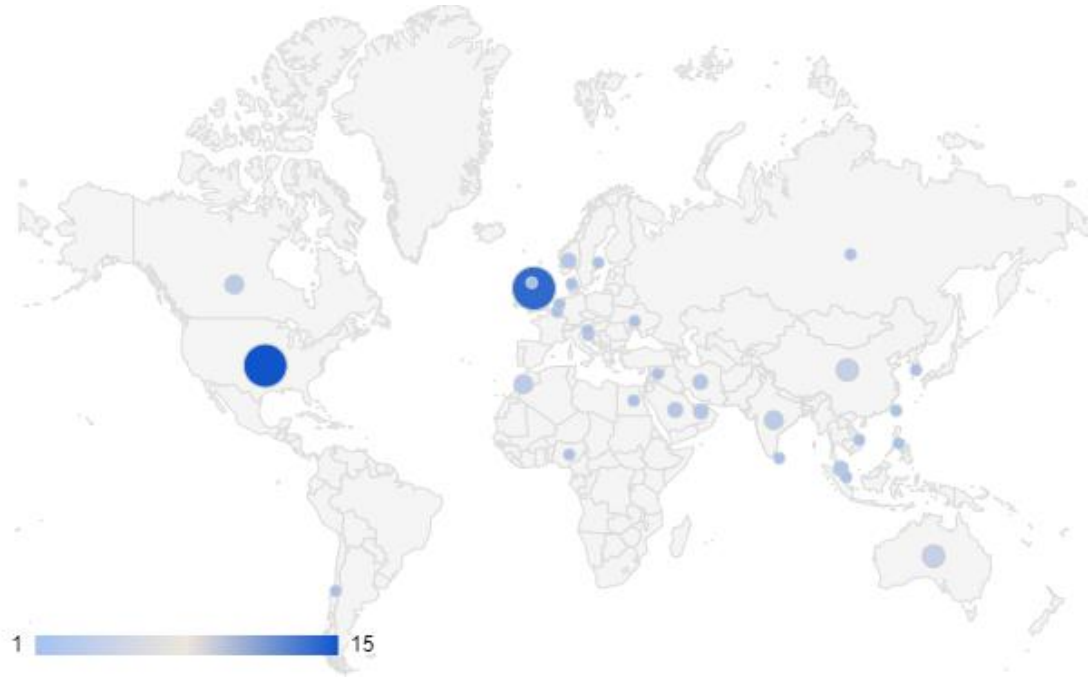

Figure 3: Distribution of publications according to countries (2000-2022).

Selected studies were analysed by considering the main objectives of the studies to summarize the prominent change management themes (Figure 4). In a 22-year period, technological changes like Building Information Modeling (BIM) or sustainability and their adoption into construction organizations and projects were the predominant themes in the construction management field. The management of such technological changes can have positive or negative impacts on project success. In terms of negative influence, resistance to technological change is one of the prominent considerations among technological change, as construction firms face high resistance to change due to lack of communication (Jafari et al., 2020; Maali et al., 2020), lack of understanding of new technology solutions (Maali et al., 2020), lack of establishment of a realistic timeframe for change adoption (Maali et al., 2020), lack of knowledge management and learning (Senaratne & Sexton, 2009), lack of effective change agents and lack of setting clear milestones for change implementation (Maali et al., 2020). Accordingly, the number of publications and citations relating technological change, innovation, BIM and adoption has been growing steadily.

Developing and proposing “change management systems or models or frameworks” were the other prominent themes in the construction management field. To achieve project and company goals and gain a competitive advantage in the industry, proposing roadmaps for effective and efficient change management was a central theme for many scholars. The investigation and classification of “causes or impacts of change management” in construction firms was another area of concentration, since the proper understanding of causes and impacts assist project participants in managing changes proactively (Padala et al., 2020).

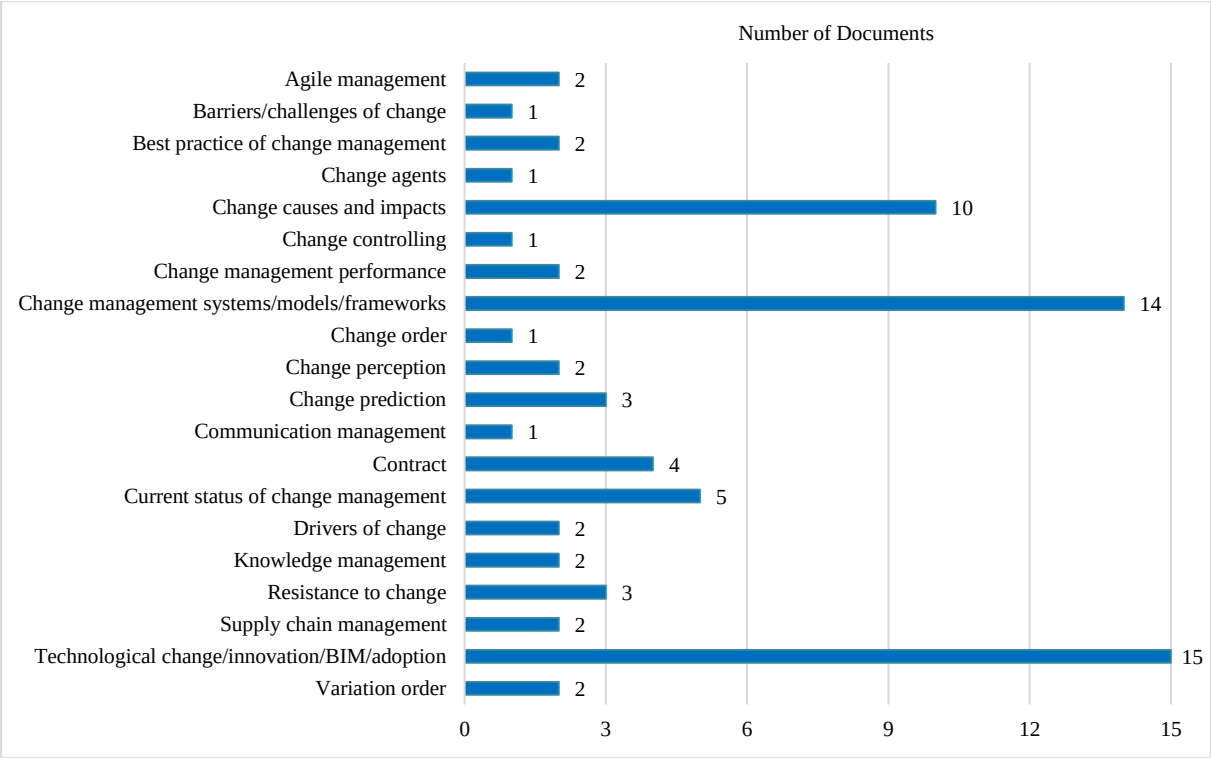

Figure 4: Change management themes in construction management research (2000-2022).

Lastly, to clarify relationships and tendencies based on "change management" and "construction industry" keywords over the period of interest, a network model was created by using VOSviewer. According to VOSviewer analysis, 275 of 1380 keywords meet the threshold. The network maps include various colorful groups known as clusters (McAllister et al., 2021) and each colour represents different clusters. Notably, the clusters in the network map consists of node, labels and links. The nodes are connected with each other by links. The co-occurrence of keywords and the strongness of links impact the size of the nodes and labels (McAllister et al., 2021). Keyword co-occurrence analysis shows that "project management," "change models," "construction management," "management," "knowledge management," "construction," "BIM," "cost management" and "innovation," have larger labels and circles. The aforementioned keywords demonstrate the most preferred research themes under the "change management in the construction industry." Notably, the closer the keywords are to each other, the stronger the relationship between them (Van Eck & Waltman, 2022). The keywords *innovation*, *adoption*, *organizational change*, *communication*, and *information technologies* are located to each other, indicating their strong relatedness. The co-occurrence of knowledge management as a keyword in the publications is high in the VOSviewer, which indicates that knowledge management and organizational learning are seen as essential elements of managing change. However, according to visualization, there is no critical link between "organizational learning" and "change management in the construction industry," this is seen as a possible path for future research.

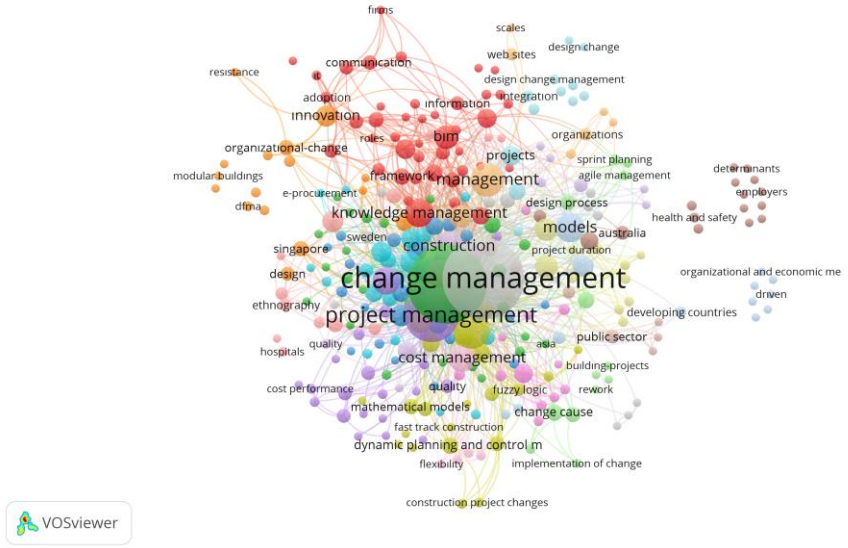

Figure 5: Network visualization of publications keywords.

According to the years, a color scale was created by VOSviewer from the oldest to the newest. The blue color shows the themes considered in previous years, while the yellow color shows the themes that have been considered in recent years. Overlay visualization shows that "agile management," "construction project changes," "information technologies," "adoption of new technologies," "implementation of change" and "BIM" are seen as recent research trends related to change management in the construction industry.

Furthermore, the findings of the systematic review and VOSviewer analysis show that studies with agile management perspectives are limited but agility is a critical consideration in change management since it assists the change in terms of rapid and flexible change reactions. Recent studies in the literature focusing on agile management show that the research gap on the topic has been recognized, although the number of relevant studies is yet limited, and further research effort is needed to address the issues of change and agile management approaches.

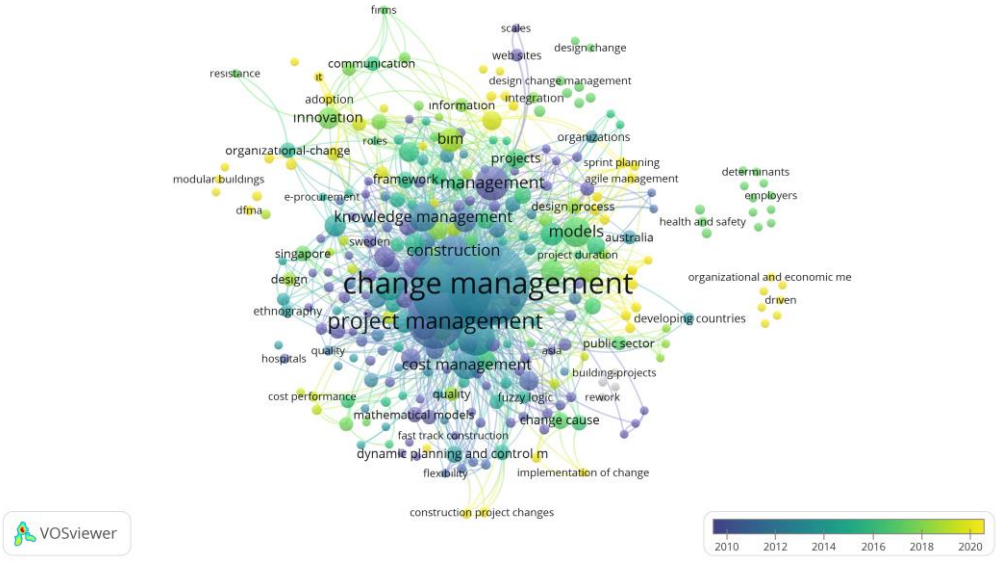

Figure 6: Overlay visualization of publication keywords according to year wise.

Conclusion

Managing change is a strategic competence for construction firms, not only because each project is subject to various changes over its life cycle, but also translating lessons learnt from different projects into company level actions require change management skills to respond to environmental turbulence. Findings of the systematic literature review reveal that the most productive countries identified as USA and UK which have change management studies in construction industry. Outputs of the systematic literature review also indicate that while *technological change/ innovation/ BIM/ adoption, change management systems/ models/ frameworks* and *change causes and impacts* were the predominant focus of interest over the period of interest, there are yet significant research gaps in the construction management literature regarding the implementation of proposed change management systems/models/frameworks and the investigation of the methodological approaches for a better understanding of change management practices in construction. Keyword co-occurrence map signifies that change management in the construction industry is highly related the *management issues (project, construction, knowledge, and cost), change models*, *BIM*, and *innovation.* Overlay visualization indicates that *agile management, construction project changes, information technologies, adoption of new technologies, implementation of change,* and *BIM* have a critical influence and attention over the last years. Overview of the VOSviewer analysis and the systematic literature review show, for example, that further research efforts are needed to explore the potential of agile management approaches to develop rapid and flexible responses to change, as well as the linkage between knowledge management, organizational learning and change. In particular, approaching change management from a learning perspective might be quite fruitful considering that each change is a learning experience for any organization.

Evaluating Readability Risks in Construction Contracts Using Fuzzy TOPSIS Method

H. Kunkcu

kerimkoc@ yildiz.edu.tr, apelin@yildiz.edu.tr

Abstract

Construction contracts play a significant role in the success of a project. Multiple interpretation of contract clauses in construction contracts may cause adverse outcomes between contracting parties. Therefore, an analysis of risks influencing readability of construction contracts is essential. In this study, fuzzy technique for order of preference by the similarity to ideal solution (TOPSIS) is proposed to assess the readability risks judged by construction professionals who have experience in the construction sector. The findings indicated that unnecessary complexity in noun phrases and improper use of referents, lack of visual representations, and unnecessary length in the clauses, sentences, and words were the most significant risks; while inclusion of matters which are more effectively covered in the technical specification, paraphrasing existing law, and lack of flowcharts between clauses were the least significant risks. The findings are expected to help construction professionals improve readability of construction contracts, aiding to reduce conflicts.

Keywords: *construction project, contract, dispute, fuzzy TOPSIS, readability risk.*

Introduction

Construction contracts, which are written and signed documents that the contracting parties have agreed upon, are important in the successful achievement of project objectives and preventing adverse outcomes such as serious disagreements, conflicts and claims in the project (Chan et al., 2021; Lee et al., 2020). Due to ambiguous and conflicting statements in construction contracts, multiple interpretation of contract clauses may cause negative consequences between contracting parties (Abdul-Malak & Hamie, 2019). Therefore, it is necessary to identify the contractual risks (Lee et al., 2020) and ensure that the readability of the clauses in the contract is clarity, accurate and in precise detail (Rameezdeen & Rodrigo, 2014; Sertyesilisik, 2010).

This research aims at assessing readability risks in terms of project cost, time and quality impacts in the construction projects. Therefore, the readability risks identified by Koc and Gurgun (2021) for more effective contract management were further examined with the fuzzy

TOPSIS method based on construction professionals' opinions. The combination of fuzzy set theory with the simple and easy to understand TOPSIS method (Jang et al., 2017) is expected to provide more accurate solutions to minimize risks influencing the readability of construction contracts.

Methodology

Risk factors affecting the readability of construction contracts were investigated through a comprehensive literature review by Koc and Gurgun (2021) and 18 readability risks were identified as shown in Table 1. 18 predetermined readability risks were assessed using the fuzzy TOPSIS method. Due to the fact that it is related to the performance of the projects, the project time, cost and schedule were determined as criteria to assess the readability risks in this study.

Table 1. Readability risks.

Risk	Definitions
Risk 1	Unnecessary length in the clauses, sentences, and words
Risk 2	Unnecessary complexity in noun phrases and improper use of referents
Risk 3	Excessive use of passive voices
Risk 4	Repetition of words and provisions
Risk 5	Use of negative style of language
Risk 6	Controversial uses of legal terms
Risk 7	Abstractness and ambiguity in word or sentence causing more than one meaning
Risk 8	Use of specialized vocabulary, legal terms, and legal jargon
Risk 9	Using engineering terminology not common to all disciplines
Risk 10	Reader unfriendly layout and the structure of the whole contract document
Risk 11	Lack of visual representations
Risk 12	Paraphrasing existing law
Risk 13	Inclusion of matters which are more effectively covered in the technical specification
Risk 14	Cross-referencing between clauses
Risk 15	Lack of flowcharts between clauses
Risk 16	Placing similar provisions or clauses arbitrarily
Risk 17	Poor grammar use
Risk 18	Unnecessary use of abbreviations

After that focusing on time, cost and quality criteria, the effects of these risks were asked to 20 industry professionals. 65% of the participants had more than 20 years of experience in the industry. Participants were requested to evaluate the effects of readability risks on each other using the linguistic variables used in the fuzzy TOPSIS method given in Table 2.

Table 2. Linguistic scales and fuzzy numbers used in the method.

Linguistic variables	Fuzzy number	Linguistic variables	Fuzzy number
Criteria weights		Alternatives	
Very low	(0, 0, 0.1)	Very poor	(0, 0, 1)
Low	(0, 0.1, 0.3)	Poor	(0, 1, 3)
Medium low	(0.1, 0.3, 0.5)	Medium poor	(1, 3, 5)
Medium	(0.3, 0.5, 0.7)	Fair	(3, 5, 7)
Medium high	(0.5, 0.7, 0.9)	Medium good	(5, 7, 9)
High	(0.7, 0.9, 1.0)	Good	(7, 9, 10)
Very high	(0.9, 1.0, 1.0)	Very good	(9, 10, 10)

The collected data were analyzed using the fuzzy TOPSIS method, which is convenient for solving the group decision making problem in a fuzzy environment (Chen, 2000). The steps of the fuzzy TOPSIS method are as follows (Chen, 2000; Wang & Chang, 2007):

1. Step: A decision matrix as a result of the assessment of the decision makers is developed.
2. Step: A fuzzy normalized decision matrix is constructed.
3. Step: The weighted normalized decision matrix is calculated by multiplying the normalized fuzzy decision matrix with the weight of each criterion.
4. Step: The fuzzy positive ideal distance (A^*) and the fuzzy negative ideal distance (A^-) of each alternative are calculated.
5. Step: The ranking order for each alternatives is defined by a closeness coefficient (CC). The closeness coefficient is computed by taking the distance of the alternatives from A^- divided by the sum of distance of alternatives from A^- and A^*.

$$CC_i = \frac{d_i^-}{d_i^+ + d_i^-} \quad (1)$$

Here, d_i^+ is the distance between the fuzzy positive ideal point and alternative *i*, and d_i^- is the distance between the fuzzy negative ideal point and alternative *i*. A high value of the CC_i index of an alternative indicates a high degree of risk for this study.

Results

This study assessed the risks affecting the readability of construction contracts by focusing on time, cost, and quality effects. Initially, the fuzzy TOPSIS method was applied by considering only the cost, time and quality criteria and the ranking results of the risks are shown in Table 3. Risk 2 was found to be the most significant factor in terms of cost and time criteria, while Risk 11 was the most significant factor in terms of quality criteria. In addition, when only the quality criterion was applied, Risk 2 was one of the significant factors, similar to the ranking results of the factors for other criteria (Table 3).

The readability risks that may be encountered in construction contracts have been evaluated by focusing on the cost, time and quality effects of the project. The overall findings for all criteria are presented in Table 4.

Table 3. The results of fuzzy TOPSIS method based on criteria.

Risk	Criteria 1: Cost				Criteria 2: Time				Criteria 3: Quality			
	d_i^+	d_i^-	CC_i	R	d_i^+	d_i^-	CC_i	R	d_i^+	d_i^-	CC_i	R
Risk 1	0.531	0.534	0.501	5	0.488	0.577	0.542	2	0.602	0.490	0.449	5

Risk 18	0.672	0.395	0.370	10	0.625	0.442	0.414	10	0.672	0.412	0.380	9

Note: R denotes Rank.

Table 4. The results of fuzzy TOPSIS method.

Risk	d_i^+	d_i^-	CC_i	Rank
Risk 1	1.621	1.601	0.497	3
Risk 2	1.294	2.002	0.608	1
Risk 3	1.968	1.238	0.386	11
Risk 4	1.941	1.269	0.395	9
Risk 5	1.931	1.279	0.398	8
Risk 6	1.724	1.489	0.464	5
Risk 7	1.659	1.598	0.491	4
Risk 8	1.861	1.344	0.419	7
Risk 9	2.082	1.092	0.344	15
Risk 10	2.073	1.092	0.345	14
Risk 11	1.607	1.610	0.500	2
Risk 12	2.150	1.028	0.324	17
Risk 13	2.155	1.023	0.322	18
Risk 14	2.078	1.116	0.350	13
Risk 15	2.110	1.078	0.338	16
Risk 16	2.066	1.125	0.352	12
Risk 17	1.772	1.436	0.448	6
Risk 18	1.969	1.249	0.388	10

The results show that “unnecessary complexity in noun phrases and improper use of referents (Risk 2)”, “lack of visual representations (Risk 11)”, and “unnecessary length in the clauses, sentences, and words (Risk 1)” were found to be the top three most impactful readability risks with closeness coefficients of 0.608, 0.500, and 0.497, respectively. While, “inclusion of matters which are more effectively covered in the technical specification (Risk 13)”, “paraphrasing existing law (Risk 12)”, and “lack of flowcharts between clauses (Risk 15)” were the least significant readability risks with closeness coefficients of 0.322, 0.324, and 0.338, respectively.

Conclusion

This study aims to determine the risk factors affecting the readability of construction contracts. To achieve the study objective, fuzzy TOPSIS method was used to assess predetermined readability risks through literature review. 18 readability risk factors and 3 criteria as cost, time and quality were determined. Then, the top three readability risks were found as follows: (1) unnecessary complexity in noun phrases and improper use of referents, (2) lack of visual representations, (3) unnecessary length in the clauses, sentences, and words. Analyzing key risks influencing quality of construction contract could improve risk management practices in projects. Further, the results of this study will be beneficial to construction project professionals to minimize the inconsistency of contract clauses and to reduce disputes and conflicts.

Smart Contracts and Construction Industry: A Systematic Literature Review

A. Tanrıaşıkı and E. F. Taş
Istanbul Technical University, Department of Architecture, İstanbul, Turkey
tanriasiki@itu.edu.tr, taselcin@itu.edu.tr

Abstract

In the globalizing world with the development of technology, industries try to survive in a wide and increasing competition. Industries adopting technological developments continue developing by utilizing technologies' opportunities and producing solutions to their problems. Blockchain, one of these new technologies, has considerably influenced the whole world. It is thought that smart contracts technology, which is the product of blockchain technology, may provide new perspectives to the sectors and offer new opportunities. While the construction industry currently benefits from technologies such as Building Information Modelling (BIM), drones, and 3D printing, it has not paid much attention to the digitization of construction contracts. However, it is thought that this situation may begin to change with smart contracts. This study aims to review the topics of the studies which focus on smart contracts and construction industry and determine potential research areas related to smart contracts and construction industry. This research consists of two-stage systematic literature: bibliometric search and scientometric analysis respectively. Findings of the bibliometric search within the scope were reviewed to present a holistic map of smart contracts and construction industry interaction by using the VOSviewer tool.

Keywords: *bibliometric search, blockchain, construction, construction management, scientometric analysis, smart contracts, VOSviewer.*

Introduction

Although there are many definitions of smart contracts, first mentioned by Nick Szabo in 1994, there is no universally accepted definition (Szabo, 1994; Mason, 2017; Mik, 2017; Cardeira, 2015; Meitinger, 2017). Szabo, a cryptographer, with the idea of placing smart contracts on physical objects, which he defined as smart properties, defined smart contracts as "the computerized transaction protocols that execute the terms of a contract" (Szabo, 1994; Cardeira, 2015).

In the literature, smart contracts are defined as digital programs based on the blockchain consensus system, self-executing, tamper-proof due to their agentless and decentralized nature, and self-executing when contract conditions are met (Christidis & Devetsikiotis, 2016). Smart contracts are digital protocols that would facilitate, verify, or enforce the negotiation or performance of a contract, or that prevent the need for a contractual clause (Fox, 2016).

It is important to know the definition, and understanding of a blockchain to understand how smart contracts work since smart contracts are based on the blockchain consensus mechanism and they are one of the important uses of blockchain technology (Christidis & Devetsikiotis, 2016; Efanov & Roschin, 2018). The "Bitcoin: A Peer-to-Peer Electronic Cash System" article published by Satoshi Nakamoto in 2008 introduced blockchain technology. In this article, it was mentioned that blockchain provides interoperability and interchangeability to its users as a solution to centralization despite classical database technologies (Nakamoto, 2008). Blockchain can be defined as a distributed and decentralized data recording system or a chain of blocks, in which blocks containing encrypted transactions are cryptographically chained to each other (Meitinger, 2017; Vandermerwe & Rada, 1988). The fact that blockchain technology operates without being connected to a center means that there is no third party between the users who request the service and the users who provide the service. The blockchain is a distributed data recording system, it means keeping blocks with the same transaction history as all nodes in the blockchain network. It would not be correct to call the blockchain a database because, in addition to adding data, data updating and deletion can be done in classical database technologies, while the data saved in the blockchain can never be changed or deleted again (Ataşen, 2019; Bodó et al., 2018; Rodrigues et al., 2018). It is thought that smart contracts and blockchain technologies may make significant contributions to various sectors such as the health sector, banking sector, and construction sector due to the characteristics of these technologies (Ekblaw et al., 2016). This study focused on the relationship between smart contracts and construction industry in literature. The main topics and research areas in the academic studies conducted were reviewed through bibliometric search and scientometric analysis.

Methodology

This study consisted of two-stage systematic literature: bibliometric search and scientometric analysis respectively.

Stage 1: Bibliometric Search

1. The "Smart Contract" and "Construction" keywords were searched together in the abstracts, titles, and (or) keywords of publications indexed in Scopus.
2. Selection of all documents.
3. Analyzing the search result.
4. Export the bibliographical data as a CSV file.

The first step of the systematic literature review was the bibliometric search. This bibliometric search, carried out on 17 June 2022, was conducted in the Scopus database. This database consists of a high amount of publications, including scientific journals, books, and conference proceedings. The access strategy used in Scopus was "smart contract" and "construction". Any time limit was not applied to reach all the data in the literature. Likewise, to reach all the data, the Scopus study searched all document types including articles, conference papers, conference reviews, and book chapters. The study only focused on documents written in the English language. A total of 296 documents were obtained. The results were selected to be exported in CVS file format for bibliometric analysis.

Stage 2: Scientometric Analysis

5. Implementing co-occurrence keyword analysis using bibliographic data in VOSviewer.

6. Creating the Thesaurus file to correct typos in the keywords list obtained from VOSviewer.
7. Second implement co-occurrence keyword analysis using bibliographic data with the created Thesaurus file in VOSviewer.

The second step of the review was scientometric analysis, and the studies resulting from the bibliometric search were analyzed using VOSviewer (version 1.6.18) software. The co-occurrence keyword link analysis was performed in the VOSviewer program. This analysis was studied two times to obtain compact data since the keywords can be written in different styles by authors. In addition, the keywords contained typos, so all the keywords were reviewed, and the document was created to help correct errors in the analysis.

Results

From 2015, the publication of the first document, to June 2022, almost 300 documents (the exact number of documents 296) had been published in Scopus. The analysis of the studies was collected in 3 main titles: documents by year, country, and type.

Bibliometric Graphs from Scopus

A bibliometric search provides sufficient information on the necessary records (Bankar & Lihitkar, 2019). It has been used to trace relationships amongst abstract, article, and title citations.

Documents by Year

As mentioned above, blockchain technology started to develop in 2008, and the concept of smart contracts was included in the second generation of blockchain in 2015. In parallel with the development of blockchain, the basis of publications in the field of smart contracts dates back to 2015. According to Figure 1, the number of publications in the smart contracts field has shown an increasing trend since 2017. The published documents reach the highest level in 2021 with 114 publications. Considering the available data at the time of this research, the current number of published documents in 2022 is almost 50, and it can be expected that the total number of publications may increase at the end of the year.

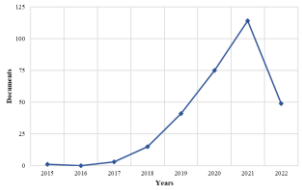

Figure 1: Documents distribution by year (2022).

Documents by Country

Figure 2 shows the top 10 countries listed in the international arena. According to Figure 2, China is at the top of the list with 102 studies, among 54 countries where researchers have

published studies on the theme of the smart contract. With 30 studies, the United States is in the 2nd place and the United Kingdom with 28 studies is in the 3rd place in the list, respectively. Hong Kong ranked fourth and published 19 studies, after which countries such as Italy, Australia, Germany, India, Russia, and Greece complete the list. Greece is located in the last place on this list with 10 publications. Turkey, with a small number 6 of studies, is not located in the top 10 countries list.

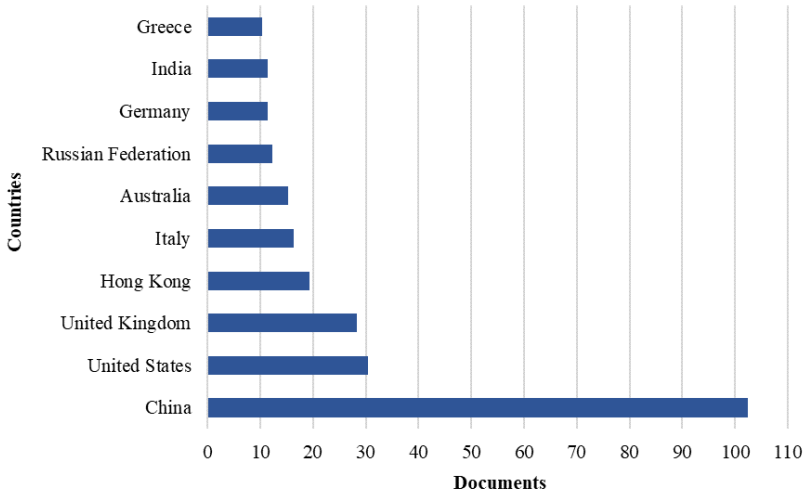

Figure 2: Documents distribution by country or territory (2022).

Documents by Type

According to Figure 3, among the 296 documents on the subject of Smart Contracts in the Construction Industry, conference papers are the most common with approximately 50 percent (146 documents). Then, the subject of smart contracts and the construction industry are discussed in the articles with approximately 35 percent (103 documents). In the third place, the relationship between smart contracts and the construction industry is examined in conference review documents with 8 (24 documents).

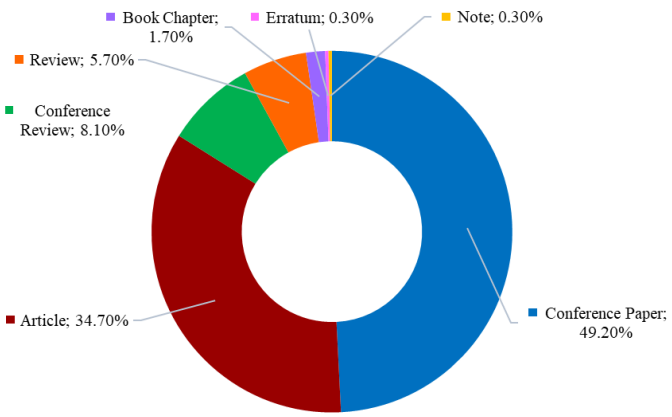

Figure 3: Document distribution by type (2022).

Holistic Maps from VOSViewer Scientometric Analysis

Co-occurrence Keywords

VOSviewer, a scientometric analysis software tool is chosen to construct and analyze the bibliometric network of science due to its unique mining and visualization feature for large amounts of textual data (Eck & Waltman, 2016). Keyword co-occurrence analysis was applied by using VOSviewer and the keywords co-occurrence analysis shows the recent research trends and the core of research. The co-occurrence keyword analysis was performed twice to present a more explanatory and summative result. As a result of this analysis, a holistic map was obtained. The holistic map consisted of nodes of different sizes, links of different thicknesses, and keywords with different font sizes. As the number of times, keywords were repeated, the node sizes and font sizes increased. Also, as the number of keywords used together increases, the link thickness between them increases. Thanks to the holistic map, the most studied and trending study topics in the researched field were displayed.

In the first analysis, bibliometric data from Scopus, unedited raw data, was used in VOSviewer. The ordinary full counting methodology was chosen in the analysis. The minimum number of co-occurrence keywords was selected 1 time to not lose any keywords because there could be typos in the bibliographic data list. Then, the keywords used in this analysis were exported and arranged in an Excel file. A standardization approach was adopted to merge variant terms (e.g. “blockchain”, “block chain”, and “blockchain technology” were merged into “blockchain”). Moreover, some keywords were grouped. (e.g. “cryptocurrency”, “crypto token”, and “central bank digital currency” were merged into “cryptocurrency”) This edited file was used as the Thesaurus file in VOSviewer, that is, it acted as a dictionary file that assists the bibliometric data file to obtain more compact results. After the editing process, the second co-occurrence keyword analysis was applied in VOSviewer using the thesaurus file. As in the first analysis, the ordinary full counting methodology was chosen in the second analysis. To clarify the most trending topics and links, in the second study, the minimum number of co-occurrence keywords was selected 3, 42 out of 646 keywords matched the threshold. The normalization method was selected as Lin/Log Modularity. In VOSviewer, the groups of keywords called clusters are formed according to keywords and their frequency of together usage. In the second analysis, cluster size was selected as 3. As a result of this analysis, 42 keywords created four clusters colored differently in Figure 4. These clusters showed the main study areas of smart contracts and construction.

As can be seen in Figure 4, the clusters were expressed with different colors. The first cluster was represented in red, the second cluster in green, the third cluster in blue, and the fourth cluster in yellow. The first cluster consisted of access control, blockchain, business process management, cloud platform, construction management, cryptocurrency, cyber-physical systems, decentralized applications, decentralized environment, Ethereum, information technology, IoT (Internet of Things), payments, smart contracts, and supply chain management keywords. The second cluster consisted of automated construction, bibliometric analysis, BIM, collaborative process, construction contracts, Distributed Ledger Technology, information trust, lean process, and trust keywords. The third cluster consisted of consensus mechanisms, construction document management, construction quality information, digital contract management, information sharing, privacy protection, security, smart city, and zero-knowledge proofs keywords. The last cluster consisted of Big Data, construction industry, data analysis and management, digitalization, and Industry 4.0 keywords.

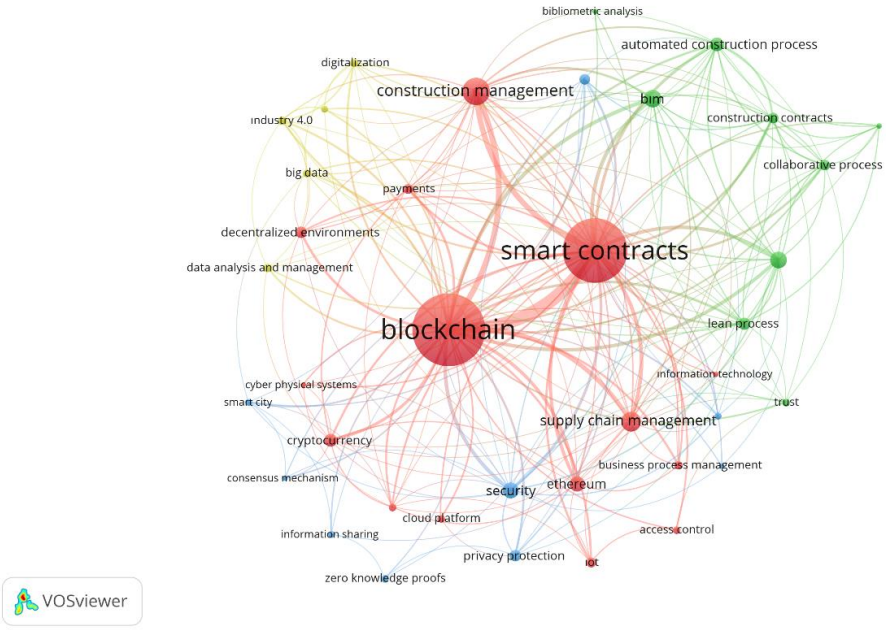

Figure 4: The holistic map as a result of co-occurrence analysis in VOSviewer (2022).

In the holistic map, the main terms smart contract, construction management, and blockchain which were the main topics appeared to be the most repetitive words. Supply chain management was the most pointed out keyword after the main keywords. According to the literature, it mentioned that smart contracts may be beneficial in the supply chain of the construction industry. BIM, which provides great changes and useful opportunities in the construction industry, was one of the prominent keywords. BIM is used actively today and its usage areas in the construction industry continue to be developed. The application of BIM in construction projects together with smart contracts, which are the products of developing technology, has been examined in the literature. The Distributed Ledger Technology keyword was used frequently since the smart contracts are one of the applications of this technology. Another outstanding keyword was security. Smart contracts are based on blockchain technology which provides to secure network for their users. Therefore, the security was a topic frequently included in literature. Ethereum is the platform where smart contracts are created; thus, it is mentioned more frequently in documents. The automated construction process stood out relatively. In literature, it is indicated that the construction processes may progress automatically in projects where smart contracts are combined with other information technologies. The lean process was another pronounced keyword since it referred to that smart contracts provide trustability, transparency, and traceability features to their users in literature. Privacy protection was frequently mentioned in the literature as one of the benefits of the contracts. Decentralized environments are related to the structure of smart contracts, so this was frequently mentioned in the documents. According to documents, the information technologies like the Internet of Things (IoT), Big Data, and Cloud Systems can support smart contracts; however, IoT has been researched more than others currently. Therefore, the IoT node size was bigger in the holistic map.

Conclusion

This study aims to visualize the research topics and gaps in smart contracts and construction industry with a holistic map using the VOSviewer application and to show the current research status on smart contracts and construction industry with graphs from Scopus. The co-occurrence keywords analysis conducted within the scope of this study can help to clarify the topics in the context of smart contracts and construction industry. This analysis also helps to detect areas of interest that have not been touched upon by researchers.

The context of smart contracts and construction industry still needs to be studied and explored considering the publication numbers and types.

According to the holistic map obtained in this study, most current documents focus on the blockchain, Distributed Ledger Technology, and decentralized environments sub-headings which describe the structure of the smart contracts. In addition to these sub-headings, Ethereum, the platform on which smart contracts are created, was mentioned regularly. Moreover, the security, automated construction process, lean process, and privacy protection topics, which are the potential advantages of smart contracts due to their features, were generally discussed. The supply chain management sub-headings, which is the area where smart contracts can be advantageous, were also discussed in the current studies. There is also research that addresses supporting information technologies such as BIM, IoT, Big Data, and Cloud Systems.

azsozen@medipol.edu.tr

Abstract

Scope is one of the Project constraints and the scope of the contractor's work is defined under contract documents. Yet almost all contracts contain a changes/variations clause that empowers the employer to increase, decrease or omit any part of the work. The cardinal change doctrine developed in the US Court of Federal Claims as a response to change orders fundamentally altering the original contract scope and has recently been introduced into Variations and Adjustments clause of the 2017 editions of FIDIC. As FIDIC forms are frequently used for internationally funded public construction projects in Turkey with Turkish law as the governing law, the mechanisms provided by the law for dealing with changes outside the scope of the contract may have a significant effect on the interpretation of the terms of the agreement. The first section traces the historical background of the cardinal change doctrine. The second section reviews courts' treatment of changes beyond contract scope in the US and UK and the introduction of the concept into the new FIDIC editions. The Public Procurement Law's perspective on limitations to variations is covered in the third section. A critical comparison of the two approaches is presented as the paper's conclusion.

Keywords: *cardinal change, FIDIC, Turkish public procurement law, variations.*

Introduction

Almost all construction contracts have a changes or variations clause that unilaterally allows the employer to modify work defined in the contract documents. A fully developed changes mechanism in a contract describes the types of changes allowed, authority to issue change orders, formal procedures for issuing change orders, time and cost impacts and occasionally the relationship of changes with the critical path through a time extension clause.

There is certainly a deadline for issuing change orders. This is the stage of substantial completion (unless the parties have agreed otherwise), when the contractual conditions for completion of the works have been met and the employer is able to take possession or occupancy of the project. The contractor has to rectify outstanding items and rectify defects during the defect liability period.

Are there other restrictions on the power to issue variations? This issue has been subject to discussion for a long time. The second edition of FIDIC Conditions of Contract, released in 2017, has introduced several adjustments, including a variation mechanism, which entitles the

contractor to object to a variation if the varied work is “unforeseeable” with respect to the scope of work described in the contract. The amendment has been interpreted as “the introduction of the cardinal change doctrine” (The Society of Construction Claims Specialists International, 2017) which limits the employer’s powers to issue variations beyond scope.

FIDIC forms are widely used for internationally funded public construction projects in Turkey where Turkish law generally governs. The choice of law can have a considerable impact on the interpretation of the contract and control the parties’ rights and obligations. Therefore, the mechanisms provided by Turkish law for dealing with changes outside the scope of the contract may have a significant effect on the interpretation of the terms of the agreement.

The present paper shall address the limits to the scope of the work described in the contract documents under Turkish legislation to explore the applicability of the new variation mechanism in FIDIC.

The Cardinal Change Doctrine

The Cardinal Change doctrine was initiated by the United States Federal Court of Claims in the 1960’s. Initially, there were two objectives in the development of the law in federal procurement. The first was to protect the contractors from being compelled to perform work beyond contractual requirements. The second was to prevent government agencies from “from circumventing the competitive procurement process by adopting drastic modifications beyond the original scope of a contract” (King, 2001, p. 119). The argument is that the employer could misuse the advantages of the bidding procedure by using its post-contract negotiation ability to completely alter the terms of the contract (Libor & Sandars, 2001, p. 65).

A key case in the evolution of the doctrine is Air-A-Plane Corporation v. the United States. Air-A-Plane Corporation undertook the production of 1100 smoke generators for the Army Chemical Corps, based on a fixed price agreement. During the execution of the contract, an excessive number of variations were issued by the government, including changes to the design of the product. The court found that the sheer number of variation orders and the transformation of the fixed price production contract into a design and development agreement constituted a cardinal change (U.S. Department of the Army, 1983, p. 10-18). The court not only addressed the number of changes but also the total effect of the change orders, transforming the original project delivery system.

Another case that is frequently mentioned is Edward Marden Corporation v. the United States, in which Marden, the contractor, agreed to build an aviation hangar, which collapsed during the construction phase because the government's specifications were inadequate. Marden was instructed to clean up the debris and reconstruct the building, which, in turn, resulted in huge cost overruns. The court found that the reconstruction work was beyond what was originally bargained for by the parties and could not be rectified under the changes clause of the original contract (Enhada et. al., 2001).

Since then, the doctrine has been adopted by several state courts in the United States and recognized in private construction contracts (Silberman, 2017).

English courts have disallowed modifications that go beyond the terms of the contract as early as the 19th century. In Thorn v. London Corporation, Lord Cairns determined that additional work "so peculiar, so unexpected, and so different from what any person reckoned or calculated upon, that it is not within the contract at all," is to be considered outside of the scope of the variations clause (Davenport & Harris, 1998, p. 107). In Blue Circle Industries v. Holland Dredging Co. UK, the Employer's instruction to transform a dredging contract into an artificial bird island construction contract was considered to be beyond the scope of the original agreement (O'Reilly, 1999, p. 33-34).

Cardinal changes can be additive or deductive. Deductive changes that remove a major part of the original work (also known as *descoping*) upset the balance of the contractor's offer and may be interpreted as "abuse" of changing Powers (Costa, 2020). Reduction of a 99,000 USD nurses' quarters from a hospital contract worth 911,000 USD was held to be a cardinal change (Crowell & Johnson, 1967, p. 557-558).

In McMaster v. State of New York, the employer's removal of 5 of 15 buildings in a state hospital was found to be a cardinal change, entitling the contractor to damages (Callahan, 2005, p. 296).

The decisions generate basically two topics for discussion:

1. What is meant by "beyond the scope of the contract"?
2. What happens when variation orders are beyond the scope of the contract?

There seems to be no exhaustive definition of the scope of the contract. Relevant definitions include "scope of project" and "scope of work". PMBOK defines project scope as "The work that needs to be accomplished to deliver a product, service, or result with the specified features and functions." (Project Management Institute, 2017). "Scope of work", on the other hand, may be a portion of a project. The basic principle appears to be the parties' anticipations because court decisions regarding whether the specified task is inside or outside the scope largely depend on the specific circumstances (Burr, 2016, p.773). A fairer criterion may be "scope of original competition" for both additive and deductive changes, in other words, what all the bidders should have expected to be within the scope of the competition (Cibinic et al., 2006, p. 386).

Contractors' Rights and Remedies

What happens when variation orders are beyond the scope of the contract? Several judicial decisions in the U.S. have established principles (e.g. contract abandonment, breach of contract, cumulative impact) entitling the contractor to recover for material changes. When deciding whether a cardinal change has occurred, the courts have taken several factors into account, including the following: significant changes in the scope of the job, the quality, nature, and type of work envisioned by the original contract (Callahan, p. 53). It is beyond the scope of the present paper to discuss the various theories developed in the U.S. with regard to change orders beyond the scope of the original contract. The term "destruction of the contract" has been proposed as an embracing concept, covering cardinal change, abandonment and material breach theories (White, 2006). In general, the cardinal change and abandonment theories aim to offer redress to those who have been the targets of change-order abuse: the terms of the contract do not apply; hence the changes clause is no longer effective and the contractor is allowed to decline the change. Therefore, the contractors have two

choices if they think the change order is out of scope. The first is to follow the order and then request payment in quantum meruit as the contract's terms (the change order clause) are no longer relevant. The alternative is to reject the order and file a breach of contract lawsuit.

The contracting officer must decide whether the omitted work is a deductive change or a partial termination for convenience under federal contracts, which are controlled by the Federal Acquisition Regulations (Federal Acquisition Regulation, 2022). In order to decide the appropriate clause in the event that a contractor contests the contracting officer's decision, courts and boards will look at the nature of the modification. The contractor is free to negotiate whatever settlement amount where it is judged that the deletion should be handled as a "partial TFC," so long as it is reasonable and the total payments to the contractor won't go beyond the agreed-upon price for that work (Cch Incorporated, 2007).

Under English law, the contractor has rights of reasonable objection to variations beyond the scope of initial work. In Bush v Whitehaven Trustees (1888) 52 JP 392 even though the bid called for summer working, the contractor was still required to work during the winter. Because the court found that the contractor had entered into a distinct contract as a result of the winter working, the contractor was entitled to payment on a *quantum meruit* basis. (Lift & Escalator Industry Association, n.d.) In Costain Civil Engineering Ltd v Zanen Dredging & Contracting Co (1997), the subcontractor was entitled to quantum meruit damages for instructions to turning a casting basin into a marina Project (Moloney, n.d).

The current editions of the FIDIC Rainbow suite include the contractor's rights of reasonable objection. The new clauses provide for the contractor to object to a variation order if “the varied work is Unforeseeable having regard to the nature and scope of the work described in Specification (FIDIC Red Book, 2017, Sub-Clause 13.1a) / the Employer’s Requirements” (FIDIC Yellow Book, 2017; FIDIC Silver Book 2017, Sub-Clause 13.1a).

The introduction of the subclause has been interpreted as a reference to the cardinal change doctrine: “Cardinal change has arrived (sort of!)” (Corbett, 2018). The consequences of objection and potential rejection, however, remain unclear. If the consequences are to be interpreted in terms of governing law, the position of Turkish law is worth considering.

How Turkish Public Procurement Law Deals with Excessive Changes

The Public Procurement Law (Law No. 4734) outlines the rules and guidelines that must be followed in any procurement undertaken in Turkey by institutions and public authorities subject to public supervision, public law, or both.

“General Conditions for Building Works” is the only model contract used in Turkey, establishing the general principles for public construction works regulated by the Public Procurement Law (Law no. 4734). Public Procurement Contract Law (Law no. 4735) governs the legal relationships of public authorities in carrying out public procurement contracts. Both laws came into effect in 2003, following a reform process in public procurement intended to comply with European Union and worldwide procurement practices. However, the original version of the Public Procurement Law prohibited increases or decreases in work. This approach was found to be impractical and both laws were revised by Law No. 4964 to allow for additive changes within reasonable limits (Public Procurement Law, 2003; Public Procurement Contract Law, 2003).

Article 24 of the aforementioned law restricts the employer's flexibility in issuing changes:

ARTICLE 24.- (Amendment: 4964/ Article 46) In case any work increase is inevitable due to unforeseen reasons, provided that;

a) work increase is kept within the project subject to the contract,
b) it is not technically and economically possible to separate additional work from the main contract without burdening the contracting entity,
the contracting entity may have the same contractor perform the work increase up to the amount of 10 % of the main contract's price in turn-key lump-sum works contracts and up to the amount of 20 % of the main contract's price in unit price goods, services and works contracts in accordance with the provisions specified in the original (main) contract and tender documents except the provisions on contract duration.
In case it is determined that the work can not be completed under these circumstances the accounts (of the contract) shall be wound up in accordance with general provisions without any increase. However, under such circumstances, it shall be compulsory that the entire work be fulfilled in accordance with provisions of tender documents and of contract.
(Translation http://www2.ihale.gov.tr/english/4734_English.pdf)

Article 24 describes different procedures for additive and deductive changes. The conditions for increases in work can be summarized as follows:
1. The increase should be unforeseeable (for example, insulation of a facade is not "unforeseeable").
2. The task that is subject to an increase must still be part of the agreed-upon project.
3. The additional work should be an inseparable part of the main contract.

As long as the new work conforms to the aforementioned conditions, the same contractor is permitted to perform it. Otherwise, the contractor and the employer cannot enter into a new contract and therefore, the current contract's accounts must be closed (wound up). The contract conditions are not applicable and the amount payable to the contractor shall be decided in accordance with general principles.

What is interesting is that unforeseeability is a precondition for additional work under Law no.4735, whereas it may be a ground of objection by the contractor in the new FIDIC editions. Two cases demonstrate the position taken by the Supreme Technical Board, a service unit of the Ministry of Environment, Urbanization and Climate Change on the permissible extent of variations. (Recently, the Board's authority was expanded to cover contract dispute resolution).

In the first case, the employer, a public authority applied to the Board for permission to order the construction of an additional warehouse during the execution of an ongoing project. The employer, a governmental entity, applied to the Board for approval to issue variations for an additional warehouse while the project was still being carried out. The Board cited the aforementioned article and determined that the building of a second warehouse could not be considered work "within the same Project" or an integral component of the primary contract. As a result, the Board held that additional work could not be performed by the same contractor (ÇŞB YFK Başkanlığı, 2020, decision 2012/27)

In the second case, when a hospital was being built, the employer, a public university sought to convert the warehouse in the original project to an oncology center and to add an 185 sq. m. radiotherapy unit. The employer's main defense was that an oncology center was required because the closest facility was 180 kilometers away from the city where cancer rates had surged. The Board, once more referred to Article 24 of Public Procurement Contract Law and held that neither the modification of the warehouse into a oncology center nor the addition of a radiotherapy unit was an unforeseeable condition at the tender stage, that the proposed modifications could not be completed without changes in the original design and technical documents in the original contract and that the required modification was not an integral part of the original contract (ÇŞB YFK Başkanlığı, 2020, decision 2010/59).

The same Article also outlines the process for work omissions. The contractor is required to complete the works when it is anticipated that less than 80% of the contract value will be spent on the project. If this is the case, the contractor receives 80% of the contract value in exchange for the actual costs incurred, the contractor's profit, and 5% of the difference between the contract price and the amount of work completed (expressed as a percentage), based on prices as of the provisional acceptance date. This is a problematic issue, particularly with lump sum agreements, where the contractor offers a total project price instead of bidding on each individual item. Thus, the calculation of the difference between the contract price and the amount of work completed may be impossible (İnan, n.d.).

Another issue emerges if the works are not finished despite less than 80% of the contract amount having been spent and there is a deductive change of less than 20% (e.g. in case of a force majeure event). The contractor loses the right to receive the 5 percent payment under these circumstances.

Discussion

The aforementioned rulings demonstrate that Turkish law places limitations on the employer's variation powers: changes that go beyond the terms of the agreement are restricted under the Public Procurement Contract Law and the “General Conditions for Building Works”. When changes exceed the permissible limits defined, the project has to be re-tendered.

With reference to what constitutes changes beyond scope, the first striking difference between FIDIC Conditions of Contract and Public Procurement Contract Law is the interpretation of the word “unforeseeability”. Under FIDIC Conditions, the contractor may object to a variation order if the varied work is unforeseeable in terms of scope and nature of the Works. “Unforeseeability” is now a defined term under the 2017 editions and is defined as meaning “not reasonably foreseeable by an experienced contractor by the Base Date”. The contractor’s right to object is “intended to limit the extent or scope of variations” (Godwin, p.132). Under Public Procurement Contract Law, unforeseeability is a precondition for a valid variation. Insulating the facade, for instance, is not unforeseen, but a latent condition or a change in the law would be considered unforeseeable. It has been found permissible to update the elevator design in order to reflect modifications to the relevant Disability Act, provided that the extent of the adjustments does not exceed 10% of the contract price (ÇŞB YFK Başkanlığı, 2020, decision 2012/30).

A second distinction is the strict application of Public Procurement Contract Law's definition of excessive alterations as a percentage of the contract value, regardless of the nature of the

change. The proportion of variation cost to contract value, expressed as a percentage, serves as the only measure for the degree of modifications. The only metric used to determine completion is the ratio between the amount actually spent (or anticipated to be spent) and the contract value. This approach does not allow for flexibility in evaluating variations that may alter the nature of the original agreement between the parties or impact other operations.

The stance toward negative variations or deductive change orders is the third key distinction. The 2017 editions feature two requirements for the omission of work: either the parties have consented to it, or the contractor has made excessive delays in correcting defects (Sub-Clause 11.4). In a similar vein, Sub-Clause 15.5 of the 1999 editions states that following a termination for convenience, the employer is not permitted to carry out the work itself or make arrangements for any portion of the work to be carried out by a different contractor. The 2017 editions restrict the employer's powers to do so until the contractor has received adequate compensation for its losses (including loss of profit). The question of whether a significant deductive change can count as a partial termination for convenience under FIDIC conditions is, however, uncertain.

It is not entirely clear how substantial deductions are handled under the Public Procurement Contract Law. First of all, there is debate over whether the remedies are equitable within the current method (Gündüz, 2018). The question of whether descoping may be understood as a partial termination for convenience needs to be addressed in light of the Turkish Code of Obligations, which does recognize termination for convenience, provided that the contractor is compensated for the work carried out before completion (Turkish Code of Obligations, 2011, Article 484).

Conclusions

The revised FIDIC variations mechanism has made an introduction to the cardinal change doctrine. However, the new mechanism is silent on the implications of the contractor's rights of objection and significant deductive changes. Are the gaps to be filled by referring to provisions of the applicable law, or to other agreements between the parties? As discussed above, assessing the contractor’s remedies for major deductive changes may prove to be a serious problem under FIDIC conditions.

We've also seen that the employer's ability to issue variations is restricted by the Public Procurement Contract Law in Turkey. Unforeseeability of conditions is a prerequisite for issuing variations under the law. In my opinion, the purpose here is to prevent discretionary variations by the employer. Under FIDIC conditions, on the other hand, unforeseeability of the varied work is a prerequisite for an objection ground by the contractor. Although the intent is essentially the same, there may be disagreements over the interpretation.

The Public Procurement Contract Law primarily has two issues: a confusing omissions mechanism and exclusive dependence on percentages to assess the degree of changes. The biggest challenge in drafting regulations for public procurement is the escalating complexity of construction disputes. It must be admitted that the Public Procurement Law and the Public Procurement Contract Law, both of which were passed in 2003 and only slightly modified by Law No. 4964, may not be able to address the many issues that arise in the administration of international contracts today.

The changes clause is known to be one of the most litigated clauses in public and private contracts. The new variations clause in the new FIDIC editions has unclear implications, and there may be significant differences of opinion over how Turkish law would apply to FIDIC contracts in the event that change orders exceed the scope of the contract.

Keyword-Based Risk Assessment for Construction Contracts

H. B. Altuntaş and H. B. Başağa
Karadeniz Technical University, Department of Civil Engineering, Trabzon, Turkey
hbyapim@gmail.com, hasanbb@ktu.edu.tr

Abstract

Risk assessment is essential in contract management because the clauses in the contract may cause claims and disputes in the application. This study aims to support engineers in the risk assessment of construction contracts. In order to achieve this aim, the titles of the clauses that cause disputes in the application were determined by 30 experts from the general conditions of the FIDIC 1999 Red Book. Keywords were extracted using Natural Language Processing (NLP), a branch of Artificial Intelligence (AI), from the sentences in 25 clause titles determined by the experts. Using statistical approaches in keyword extraction, word frequency, word collocations, and co-occurrence results were examined, and 45 keywords were extracted. The extracted keywords were scored by 7 experts using the probability-impact matrix used in risk assessment. As a result of this application, the total risk score was determined for each clause in the contract conditions. These values are expected to assist engineers in decision-making in the risk assessment process of construction contracts.

Keywords: *contract management, FIDIC, keyword extraction, risk matrix, statistical approaches*.

Introduction

Due to unforeseen risks in construction projects, various risks begin to emerge after the application of the project. For this reason, risk management should be done with a proactive approach before starting the application in construction projects (Bakr et al., 2012). However, since risk management requires expertise and knowledge, many employers and contractors cannot correctly manage risk before application. As part of risk management during the bidding of construction projects, the parties must thoroughly review the duties and obligations defined in the contract conditions (Murdoch & Hughes, 2008). In particular, contractors should examine the contract conditions and manage risk. However, due to the contract management teams' limited capabilities, the contract terms cannot be complete and comprehensively examined (Yiğit, 2009). Because the contract conditions are not examined comprehensively, various claims and disputes arise during the application of construction projects. Claims and disputes arising during the application can cause delays, cost overruns, and a decrease in the applications quality, negatively affecting the project's objectives. In addition, construction companies need to rely on the knowledge of the few contract management experts they have (Lee, 2018). Since the complete and comprehensive examination of contract terms in construction projects is open to individual differences or errors depending on the expertise and experience of the expert, the necessary information should be systematized for the review of contract conditions. This study

aims to provide a solution that will systematize the review of contract terms in the tender process, which is among the tasks of contracting and risk management and will support decision-making. For this purpose, it is aimed to calculate the total risk score value as output by making a risk assessment over the keywords determined as a result of the keyword extraction application by using the contract clause as input as given in the main structure in Figure 1.

Figure 1: Keyword-based risk assessment main structure.

Within the scope of this study, the general terms of the FIDIC 1999 Red Book contract were taken as input and used as text data. As an output, it is aimed to make a keyword-based risk assessment to determine the total risk score of the contract article. Although risk assessment is a rather tricky risk management process, it potentially yields valuable results. Therefore, this study examined and applied risk management standards for risk assessment. According to risk management standards (PMBOK, 2004), risk management planning typically proceeds by identifying risks, qualitative risk analysis, planning risk response, and monitoring and controlling risk.

There are various studies on the assessment of contractual risks. In the keyword-based risk assessment applied in this study, keyword extraction, a natural language processing application, was used in the risk assessment of contract clauses. This practice is integrated into the cycle of proactive risk management processes. The keyword-based risk assessment aims to determine the words and word groups that may be related to the risk and the total risk score for each sentence by using these keywords and word groups. With this application, it is foreseen that the contract engineer/manager can evaluate the total risk score values in the review process of the contract by focusing on the contractor during the tender process. Keyword-based risk assessment parameters applied within this study are given in Table 1.

Table 1. Keyword-based risk assessment parameters.

Keyword-Based Risk Assessment Parameters	
Input Data	General Conditions of Contract (FIDIC, 1999)
Tool	Keyword Extraction
Qulitative Risk Analysis	Probility-Impact Matrix
Output Data	Total Risk Score
Target	Contractor
Application User	Contract Engineer / Manager

Literature Review

There are various studies on risk assessment for construction contracts. In the past studies, it has been observed that the effect of the literal meaning of the contract clauses on contract management has been examined very little and mainly focused on the readability of the contract. (Youssef et al., 2018).

Since a keyword-based application is made in this study, keyword extraction applications on contrac management in the construction domain are reviewed in this section. There are few studies on contract management in the construction domain with keyword extraction. Choi et al. (2021) developed the Critical Risk Check (CRC) module, which was developed as an EPC (Engineering, Procurement, and Construction) contract risk analysis tool for contractors during the tender process, using artificial intelligence and text mining techniques. With the CRC module, previous tender documents are analyzed, and risky contract clauses are extracted through the rules developed by the user. It is the Technical Risk Extraction (TRE) module developed by Park et al. (2021) to extract and analyze the risks in the technical specifications of EPC projects based on machine learning algorithms. The TRE module automatically extracts design risk items by analyzing technical specifications. In the TRE module, technical risk keywords were collected and turned into a dictionary (Technical Risk Lexicon-TRL) and extracted through machine learning and natural language processing tecniques. In this study, Choi et al. (2021) conducted contract risk analysis in the tender process, and Park et al. (2021), the keyword extraction application used in modules that perform design risk analysis on technical specifications was made on the contract clauses in the general terms of the standard contract in the tender process.

Data and Methodology

The keyword-based risk assessment research methodology for construction contracts applied in this study is given in Figure 2.

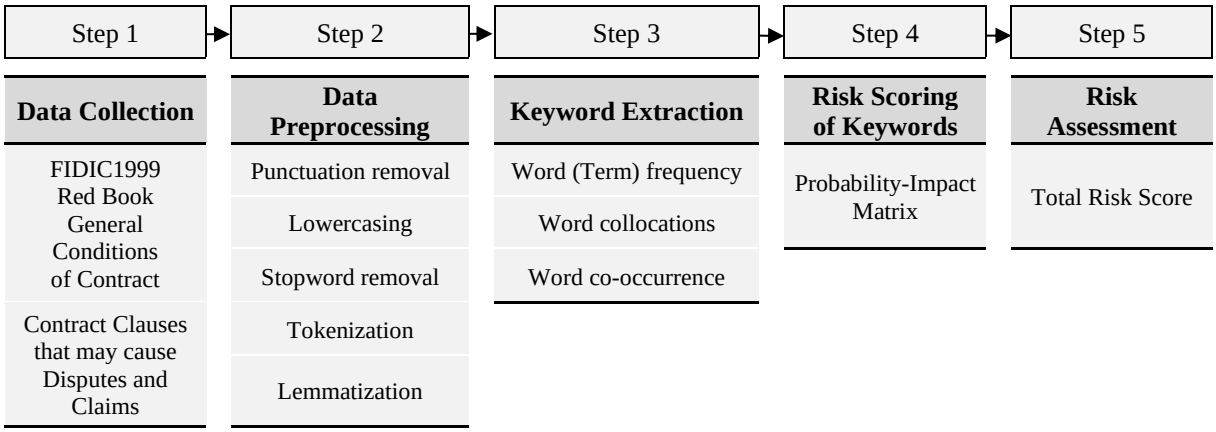

Figure 2: Research methodology.

In this study, FIDIC 1999 Red Book was used as a reference for contract data. All 20 chapters and 163 article titles in the standard contract general conditions for construction in the 1999 FIDIC Red Book have been used. The data set was created by manually separating the sentences in the general terms of the Red Book contract. Various cleanings and syntactic adjustments were made to the completed data set. As a result of the arrangements made, the data set was prepared as 987 sentences of contract clause sentences.

After the data set was created, a survey was conducted to determine which claims and disputes arose in the FIDIC 1999 Red Book applications before making a risk assessment. With the survey conducted, expert participants were asked to mark the titles of the 163 clauses in the Red Book that may cause claims and disputes in practice. A total of 30 responses were received to the survey from different experience levels. Evaluations were made out of 30 responses to

the survey study. After the assessment, it was decided to make a keyword extraction application on 15 markings and over-marking clause titles. For this purpose, according to the results of the survey, the data set, which was previously composed of 163 clause titles and 987 sentences, was narrowed for the keyword extraction application and a new data set consisting of 25 item titles and 178 sentences were created. As a result of the survey, 25 item titles with 15 markings (50%) or more and the number of markings are given in Table 2.

Table 2. Clauses that may cause claims and disputes in application.

Clause Title	Number of Markings
1.5 Priority of Documents	17
1.9 Delayed Drawings or Instructions	22
2.1 Right of Access to the Site	15
3.3 Instructions of the Engineer	16
3.5 Determinations	23
4.12 Unforeseeable Physical Conditions	21
5.3 Payments to nominated Subcontractors	16
8.2 Time for Completion	18
8.3 Programme	19
8.4 Extension of Time for Completion	23
8.5 Delays Caused by Authorities	23
8.6 Rate of Progress	15
8.7 Delay Damages	15
8.8 Suspension of Work	21
8.9 Consequences of Suspension	16
9.2 Delayed Tests	17
10.2 Taking Over of Parts of the Works	16
11.1 Completion of Outstanding Work and Remedying Defects	15
12.3 Evaluation	15
13.1 Right to Vary	15
13.3 Variation Procedure	18
14.8 Delayed Payment	24
14.9 Payment of Retention Money	15
17.3 Employer’s Risks	15
20.1 Contractor’s Claims	19

According to the results of the survey, 15 (50%) and more marked 25 clauses and 178 sentences were used as text data, and keyword extraction was performed. For the keyword extraction application, it was aimed to determine the words and word groups related to the potential risk with the data set narrowed by selecting the clause titles with high marks as a result of the survey. For this purpose, before the keyword extraction application, data preprocessing steps were applied to the text data.

The data preprocessing step was carried out using the Python programming language and the NLTK (Natural Language Toolkit) library. The basic natural language processing data preprocessing steps of the data preprocessing application are the removal of punctuation marks, upper and lower case conversion, separation of the sentence into meaningful units

(Tokenization), removal of ineffective words (Stopword), finding the roots of words that cannot be broken down and are the smallest meaningful form (Lemmatization) steps were applied. The steps applied as an example and the text data are given in Table 3.

Table 3. Example of text data pre-processing.

Pre-processing Step	Text Data
Contract Clause [Raw Data]	Contractor means the person(s) named as contractor in the Letter of Tender accepted by the Employer and the legal successors in title to this person(s).
Punctuation Removal	Contractor means the persons named as contractor in the Letter of Tender accepted by the Employer and the legal successors in title to this persons
Lowercasing	contractor means the persons named as contractor in the letter of tender accepted by the employer and the legal successors in title to this persons
Tokenization	['contractor', 'means', 'the', 'persons', 'named', 'as', 'contractor', 'in', 'the', 'letter', 'of', 'tender', 'accepted', 'by', 'the', 'employer', 'and', 'the', 'legal', 'successors', 'in', 'title', 'to', 'this', 'persons']
Stopword Removal	[contractor, means, persons, named, contractor, letter, tender, accepted, employer, legal, successors, title, persons]
Lemmatization	['contractor', 'mean', 'person', 'named', 'contractor', 'letter', 'tender', 'accepted', 'employer', 'legal', 'successor', 'title', 'person']

The word cloud formed from the words in the data set with the visualization study after the data preprocessing step is given in Figure 3. The sizes of the words in the word cloud are visualized in proportion to the frequency values of the words in the data set.

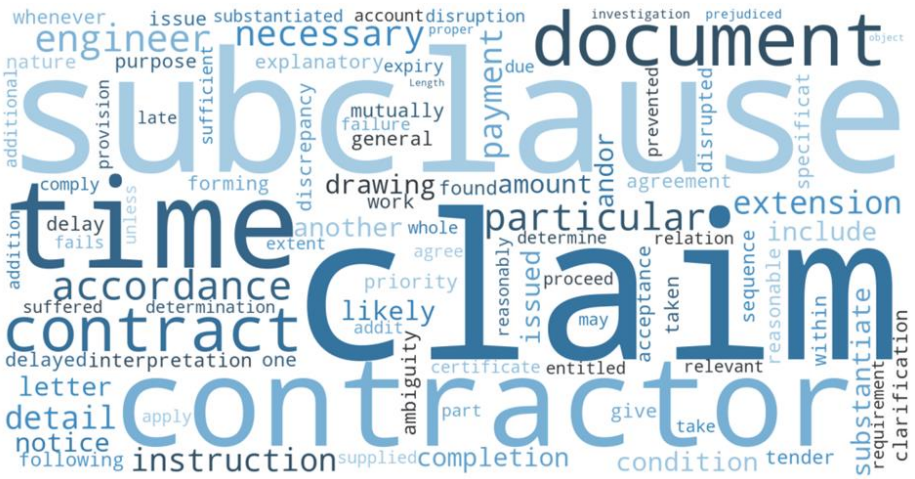

Figure 3: Keyword word cloud.

Keyword extraction is a text mining application that extracts essential words and phrases from a text document (Chang et al., 2022). Generating labeled datasets for keyword extraction is time- and cost-intensive. The unsupervised learning approach, which does not require a labeled data set and is mainly domain-independent, is used more in keyword extraction applications (Vajjala et al., 2020). This study used an unsupervised learning approach for keyword extraction applications. Statistical methods were used in this study, which was conducted using an unsupervised keyword extraction technique. Statistical methods are one of the simplest methods of identifying keywords in text data.

There are different statistical methods, including word frequency, word collocations, and co-occurrence of words, TF-IDF (Term Frequency–Inverse Document Frequency), and RAKE (Rapid Automatic Keyword Extraction) (Sun et al., 2020). In this study, word frequencies, word collocations, and coexistence values of words were used in keyword extraction applications.

In the keyword extraction application, the frequency values of the words in the data set were determined after the data preprocessing step. The CountVectorizer function of the scikit-learn library, also used in the feature extraction step of the model, is used to determine the frequency values, which are the frequency values of the words in the text data. With this function, 178 sentence data in the data set were analyzed, and keyword extraction results were obtained using frequency values. With this application, the data set was analyzed, and the keyword and keyphrase extraction results were obtained by determining the 2-word (bigram) and 3-word (trigram) in the data set.

The keywords extracted from the application were sorted from high to low according to their frequency values before the final evaluation. As a result of the final assessment, 45 words and word groups were determined as keywords with the keyword extraction application. The determined 45 keywords are ranked according to their frequency values. The words and word groups extracted as a result of the keyword extraction application and ordered according to their frequency values are given in Table 4 as unigrams (n=1 words), bigrams (n=2 words), and trigrams (n=3 words).

As a result of the keyword extraction application, the co-occurrence of the determined keywords was examined. An example word network of keywords is given in Figure 4.

Figure 4: Example of word network.

The distribution of the 45 keywords determined by the keyword extraction application in the data set consisting of 163 item titles and 987 sentences is given in Figure 5 with the lexical dispersion plot. Accordingly, 45 keywords extracted from 178 sentences in 25 article titles were distributed over the entire data set, consisting of 163 article titles and 987 sentences.

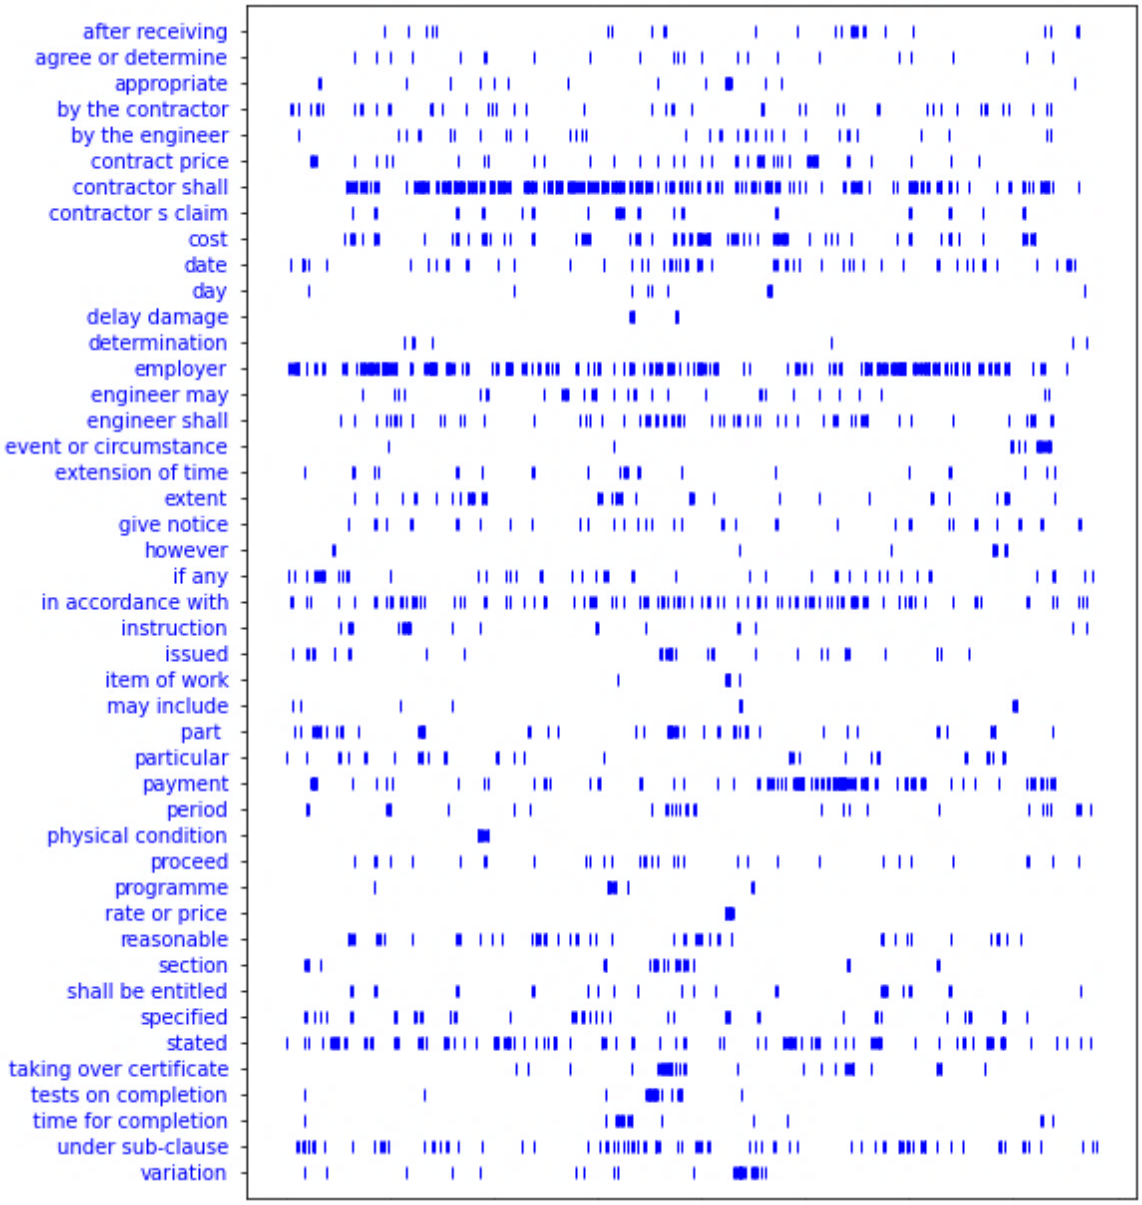

Figure 5: Lexical distribution plot of keywords.

The 45 keywords determined as a result of the keyword extraction application were scored by the experts using the risk assessment matrix with the second survey. The survey was answered by 7 experts with at least 5 years of experience. In the survey, experts were asked to determine a probability and impact value for each keyword using the probability-impact matrix used in risk assessment and given in Figure 6 in the application of Red Book contracts.

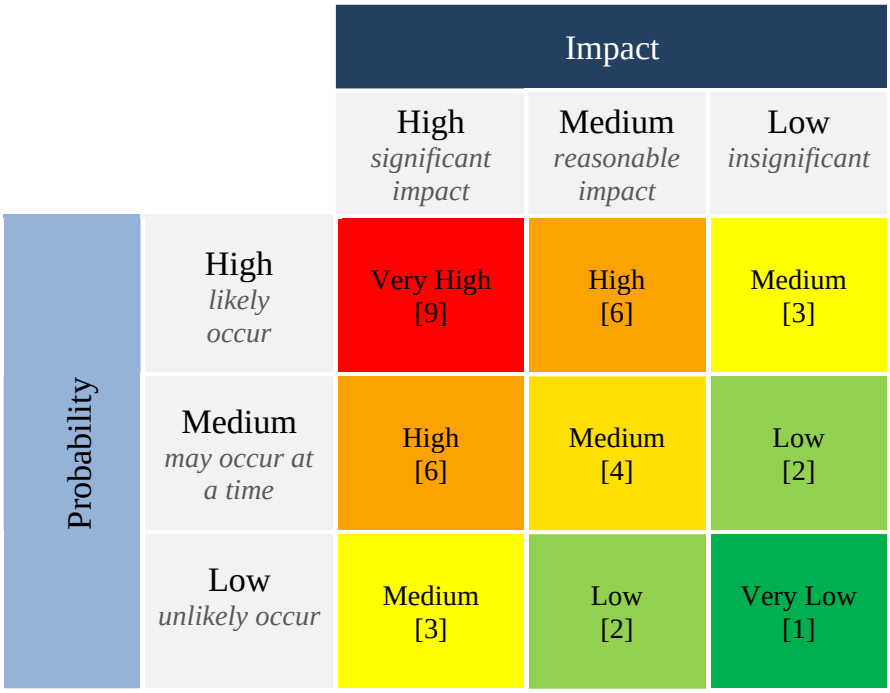

Figure 6: Probability-Impact matrix for scoring keywords.

The probability-impact matrix, which the surveyed experts were asked to use, is one of the widely used qualitative methods for risk assessment. Risk assessment is made by considering specific scales of probability and impact variables of an event. There is a special two-dimensional approach to the assessment of the risk of the event in terms of the probability (probability) of occurrence on the one hand and the effect (impact) of the outcome on the other (Dumbrava & Iacon, 2013). In the survey, experts were asked to determine the probability and impact value for Red Book applications for keywords with this two-dimensional approach.

During the evaluation of the answers to the survey, the average values of the probability and impact values determined by the experts for the keywords were taken and rounded to the nearest integer value. The risk score was calculated for each keyword using the probability and impact values obtained for the keywords as a result of the survey study.

Findings

Based on the first survey conducted for keyword-based risk assessment for construction contracts, 45 keywords related to risk were determined by keyword extraction. A risk score value was calculated with the second survey study conducted for each of the determined keywords. Probability-impact values and risk scores of keywords are given in Table 5.

Tablo 5. Risk matrix results of keywords.

After the scoring process on the survey results, the total risk score was calculated by summing the keyword scores in the sentence for each sentence data in the data set. The calculation of the total risk score of the sample sentence data selected from the sentence data set based on the contract conditions is given in Table 6.

Table 6. Example of total risk score calculation.

Contract Clause	Keywords	Total Risk Score
The Contractor shall promptly give notice to the Engineer of specific probable future events or circumstances which may adversely affect the work, increase the Contract Price or delay the execution of the Works.	contractor shall [9] give notice [9] contract price [6]	24
The Employer shall supply, free of charge, the free-issue materials (if any) in accordance with the details stated in the Specification.	employer [4] if any [2] in accordance with [4] stated [4]	14

Keyword-based risk assessment and total risk score results were obtained as an Excel file. For each contract clause sentence, the total risk score values obtained based on the risk score results of the keywords were evaluated. As a result of the evaluation, the total risk score histogram, the number of contract clause sentences, the maximum score, and the average score is summarized in Figure 7.

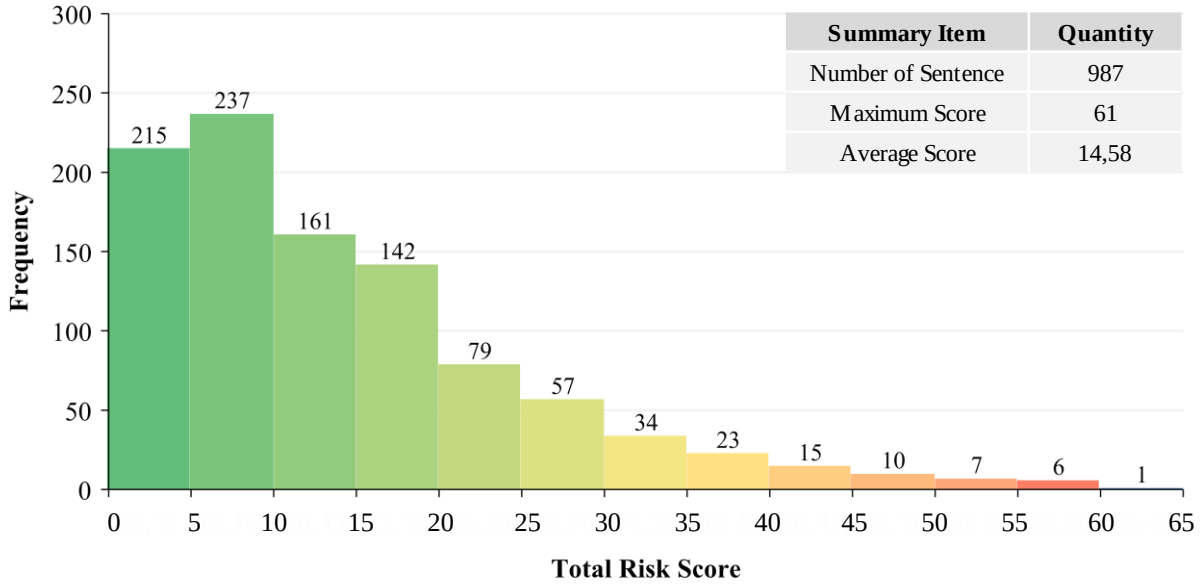

Figure 7: Total risk score result summary.

As a result of the evaluations, more than half of the total risk score value is between 0-15 points. The frequency value decreases as the total risk score value increases to 10 and above.

Results and Discussion

This study it is aimed to provide a technique and solution that can support the risk management task in the contract with a keyword-based risk assessment for construction contracts.

- For this purpose, the first survey study was conducted in order to determine the titles of clauses that have a claim and disputes in the application of the FIDIC 1999 Red Book contract conditinos, which were first selected for the research. By evaluating the results of the survey study, 25 cluse titles in the general conditions of the FIDIC 1999 Red Book were determined.
- It was tried to find the keywords and key phrases that may be related to the risk with the keyword extraction study on the data set consisting of the contract conditions in the specified clause titles. At the end of the keyword extraction application, 45 keywords that may be related to risk were determined.
- A second survey was conducted using the probability-impact risk assessment matrix to determine a risk score for each of the 45 identified keywords. A risk score was calculated for each keyword by evaluating the results of the survey.
- Using the risk scores calculated for the keywords, a risk assessment was made for each sentence data in the data set formed from the clauses in the Red Book general conditions. As a result of the evaluation, the total risk score value was calculated for each sentence of data.

It is expected that the total risk score calculated as a result of the study will be informative to the contract engineer/manager as a qualitative assessment output and supportive in decision making about the risks in the contract. However, this study needs to be expanded considering its limitations in various aspects.

As the output of the keyword-based risk assessment application made in this study, the total risk score value was calculated for each sentence of the contract clause. For this application, high-frequency words were determined as keywords with statistical methods in the extraction of keywords. However, the prevalence of the determined keywords in the contracts caused the probability values to be high. Depending on this situation, the total risk scores determined for the keywords as a result of the survey study using the probability-impact risk assessment matrix were higher than expected. In addition, the general conditions of the FIDIC 1999 Red Book, which is used as text data in this study, are modified according to the needs of the parties by negotiating and negotiating on the terms of the contract. Therefore, the results obtained from this study do not cover all standard contracting applications and risks. To solve this problems and get more accurate results:

- More quality and meaningful keywords and phrases that may be associated with risk can be extracted by examining more contract data.
- In addition, more balanced risk scores for keywords can be obtained by increasing the number of experts participating in the surveys.

A more comprehensive risk assessment can be made with quality keywords to be extracted and balanced risk scores. However, it should not be forgotten that the risk assessment may vary according to the experience of the parties to the contract and their attitudes during the applications process.

Abstract

Construction industry is prone to disputes resulting in the Extension of Time (EOT). Numerous studies were conducted to improve delay analysis methods; however, the construction industry still suffers from the dispute stemming from EOT. Unresolved dispute concerning EOT ends up in time and cost overrun in projects as well as deteriorate the relationships of the contracting parties. Therefore, resolution of EOT issues in a timely fashion is very crucial. Thus, this study intends to detect the major problems stemming from delay analysis methods. The unstructured interview was conducted with 7 experts and their opinions were evaluated via content analysis to detect the common theme of the experts' views. This study is unique in that it reveals the drawbacks of the existing delay analysis which were not detected by the existing studies. Therefore, it is highly believed that study will pave the way for future study improving delay analysis methods.

Keywords: *construction, delay, delay analysis, delay claim, extension of time.*

Introduction

Claim is an inevitable part of construction projects due to its complex nature. As for the delay in the construction projects, it is considered to be one of the major causes of claims and also one of the most challenging issues to overcome in the construction industry (Bilgin et al., 2018; Kim et al., 2005). For a delay to be settled and equitably segregated as per project parties, the most appropriate delay analysis method considering the characteristics of the project environment is to be adopted. Researchers have made tremendous efforts for developing delay analysis techniques and documents of good practice to guide practitioners instrumentally. Despite the availability of these delay analyses, the projects mostly fail to apportion the project delays to the responsibilities of the project parties due to the disadvantages of current delay analyses and their limited recognition (Asim et al., 2017).

According to a survey conducted with construction consulting organizations in the UK, most practitioners lack recognition of delay analysis methods despite their importance (Braimah & Ndekugri, 2009). The fact that the projects suffer from the catastrophic results of the delays has attracted the attention of researchers and paved the way for the improvement of delay analysis concerning construction projects. In this study, unstructured interviews were conducted with 7 experts experienced in the delay analysis domain in the construction industry to detect the major problems concerning delay analyses. Following the unstructured interviews, content analysis was conducted to release the common themes of the participants' views. In conclusion, it is detected that none of them can detect any improvements or further delays made by the contractor for the delays caused by the employer and force majeure. Additionally, it is detected that existing delay analysis methods necessitate overwhelming number of requirements of the delay analyses. Furthermore, lack of numerical procedure concerning delay analysis result in inconsistent applications in the construction industry.

Delay Analysis

The construction industry is recognized for its notoriety in terms of frequent and costly delays. Delays in projects occur when a delay in an activity surpasses its total float. While distributing the delays to the responsible parties, float ownership comes into prominence. Unless otherwise specified in the contract, the project float is owned by the project parties (AACE International, 2007). Board decisions have confirmed that a party using the float first gains the benefits of float (de la Garza et al., 2007; Wickwire et al., 1988) and most of the delay analyses are based on this approach.

Delays can be categorized as compensatory delays (CD) caused by the owner, non-excusable delays (ND) caused by contractors and excusable delays (ED) which represent other kinds of delays caused by acts of God or a third party (Kraiem & Diekmann, 1988). While non-excusable delays may arise from slow progress, compensatory delays may result from change order, site instruction, disruptions and suspensions; however, EDs may result from the events which are outside the control of contractors and clients, such as strikes, fire, differing site conditions and change in government law, etc. Particular construction contract documents need to be checked to identify EDs in a project. In the case of an ED, the contractor is entitled to EOT. Few amounts of delay analyses have been developed to figure out EDs and CDs and NDs to apportion the delays to the clients and contractors.

Methodology

To detect the major problems concerning delay analyses, unstructured interviews with 7 experts were conducted in addition to the in-depth literature review. Concerning the unstructured interview, the demographic information of participants was tabulated in Table 1 below.

Table 1. Demographic information of experts.

Expert #	Role of Participant	Experience (Year)	Project Budget	Project Type
Expert#1	MEP Planning Chief	7	US$1.17bn	Airport Project
Expert#2	Planning Manager	9	US$450m	Airport Project
Expert#3	Planning Manager	11	606m Euro	Hospital Project
Expert#4	Contracts Manager	18	US$300m	Oil & Gas Project
Expert#5	Contracts Manager	15	US$700m	Metro Project
Expert#6	Project Control Manager	14	US$5000bn	Finance Centre Project
Expert#7	Project Control Engineer	7	US$200m	Embassy Project

Note: Common themes of the participants' views were analyzed via content analysis and represented in the finding section.

Results

In the wake of the unstructured interview, comment theme of the experts' opinions were analyzed via content analysis and drawbacks of the existing delay analysis were detected under three headings which are "Not computing any further delay and improvement made by the contractor on the activities of fragnet", "An overwhelming number of Requirements of the delay analyses", "Lacking the Procedure of the delay analysis".

Computing Any Further Delay and Improvement Made by the Contractor on the Activities of Fragnet

For the determination of drawbacks concerning prospective and retrospective delay analyses, an opinion of Expert#1 that emerge as a result of unstructured interviews is as follows; "*most of the time, the contractor fails to compute the variance between the planned fragnet and actual dates of the fragnet since mostly one of the methods such as prospective or retrospective is adopted in a project. Consequently, for the projects adopting a retrospective delay analysis, it can be claimed by the owner that the actualized fragnet was completed in a very abundant time and delayed the project unnecessarily. Concerning projects adopting the prospective delay analysis, issues such as whether the planned fragnet which is on CP will be on the critical path in the schedule update or not, presence of concurrent delays of the contractor occurring with actualized fragnet, determination of mitigation or further delays made by the contractor during the schedule update can be questioned by the owner. These issues about Time Impact Analysis (TIA) and Windows Analysis (WA) can end up with a dispute between the owner and the contractor*". Giving an example from Expert#1's previous project, he continued his words as follows; "*The Contractor received 450 Site Instructions during the project. To compute the EOT, Windows Analysis Method was conducted. However, the owner didn't agree upon any of the delay analyses until the end of the project by claiming*

that the duration and sequence of fragnet delayed the project more than required and the contractor didn't take any mitigation measurement on the fragnet".

Expert #2 explained the problem arising from the prospective analysis applied in his project with the following words: "*there was an interface between the two main contractors. Time Impact Analysis was conducted to include the interface issues to the schedule and concluded with an impact of 220-days on the project. However, the owner and the Engineer were not convinced by the validity of fragnet and its impact. Settling this debate concerning fragnet took 4 months by conducting several meetings with a remarkable effort. If the type of delay analysis is not defined in the project contract, the owner quite often wants to see the possible effect of the fragnet on the project and the actual status of the fragnet. Therefore, the employer can take necessary precautions in advance thanks to the prospective analysis. Besides, the owner may also want to see the retrospective delay analysis since the fragnet which has a time impact in the prospective delay analysis may not be on the CP during the schedule update due to the contractor's concurrent delay*."

Expert#3 also highlighted a problem experienced in the prospective delay analysis by stating that "*According to the PPP contract of the Main Contractor, the project can be delayed a maximum of 6 months without reducing the operational period. During the project, the owner sent a change order concerning the increase in the closed area by 14%. The contractor requested 1 year EOT through conducting TIA and requested not to reduce the operation period since the delay in the project resulted from a change order. However, the owner didn't accept this request of the contactor by claiming that the contractor's actual delay or mitigation was not reflected in EOT*."

Expert #4 made the following remarks on the prospective delay analysis "*The owner tends to question the prospective analysis by claiming that it doesn't reflect the actual concurrency and actual mitigations. When the fragnet becomes actual, the contractor can conduct an additional analysis by comparing TIA with schedule updates including the fragnet. However, this additional analysis requires additional efforts of experts and new correspondings between the contractor and the owner.*"

TIA and WA are the most acceptable delay analysis methods adopted by practitioners and courts. TIA method may follow up on the project day-by-day from beginning to completion date (Arditi & Pattanakitchamroon, 2006). However, daily tracking of TIA requires plenty of time, cost and expertise. Consequently, in engineering practice, TIA is conducted mostly when a delaying event (Owner or acts of God-related delays) occurs to detect the possible effect of the delay on the completion date (Arditi & Pattanakitchamroon, 2006; Ekanayake & Perera, 2016; SCL, 2017). Therefore, TIA is often preferred for prospective delay analyses. In fact, SCL Protocol 2nd Edition revised its protocol to require the use of TIA for prospective analysis (SCL Protocol 1st Edition suggested to use TIA for both prospective and retrospective under section 3.2.11). "*The conclusions of a prospective delay analysis may not match the as-built programme because the Contractor's actual performance may well have been influenced by the effects of attempted acceleration, re-sequencing or redeployment of resources*" (SCL, 2017). Since TIA doesn't contain actual dates of a concerning delaying event (Calvey & Winter, 2006; SCL, 2017; Vasilyeva-lyulina et al., 2015), it doesn't include any mitigation, acceleration and/or further delays concerning fragnet. However, "*The Contractor has a general duty to mitigate the effect on its works of Employer Risk Events.*" (SCL, 2017); therefore, the potential variance between the planned fragnet included in TIA and the updated fragnet can be questioned by the owner to detect any further delay or

improvement made on activities of the fragnet. Comparing the dates of fragnet in TIA with actualized fragnet opens up an opportunity for overcoming this drawback. However, this method requires additional analysis and consequently much more time, cost and expertise. Like TIA, WA includes only the actualized delaying event since WA doesn't compute any further delays or improvements made by the contractor on the activities in the planned fragnet (Hegazy et al., 2005).

An Overwhelming Number of Requirements of the Delay Analyses

All the experts reached a joint decision that the requirements of time, cost and expertise of delay analyses depend upon the delay amount, delay type and type of delay analysis. Expert 5 stated the following about the subject; "*Although TIA and WA are very useful to some extent, their requirements such as expertise, cost, document control, close site monitoring, record keeping and time obstruct their usage in practice.*" Expert #6 underlined that if the numerical model and algorithm of the delay analysis are given, the analyst spends less time as well as spending less cost. Also, literature support this view as that applications of TIA and WA in practice are very demanding in terms of significant amount of requirements such as time, cost and expertise (Arditi & Pattanakitchamroon, 2006; Calvey & Winter, 2006; Hegazy et al., 2005; Perera et al., 2016; SCL, 2017).

Lacking the Procedure of the Delay Analysis

All the experts stated that the delay analysis applications may differ from project to project. Although the owner and contractor can agree upon the type of delay analysis at the outset of the project, it is quite encountered that the parties have different views concerning the implementation of the delay analysis method when the related procedure is not available. Expert#7 emphasized the importance of the procedure with the following words; "*Project Scheduling Specification which is part of the contract in our project obliges to use TIA for the delay analysis and provides its procedure. When a delaying event resulting from the employer or a delay resulting from force majeure occurs, we conduct TIA and notify the employer. Since we have a procedure, we did not have any technical problems in terms of time claims. However, I believe that lacking this procedure hinders the process.*

Conclusion

In this study, unstructured interviews were conducted with 7 experts experienced in the domain of delay analysis. Mainly 3 major drawbacks encountered during the practices of delay analyses in the construction industry were highlighted during the unstructured interview. These are computing any further delay and improvement made by the contractor on the activities of fragnet, an overwhelming number of requirements of the delay analyses, lacking the procedure of the delay analysis. A new delay analysis computing any further delay and improvement made by the contractor on the activities of fragnet and having a procedure with its algorithm is believed to speed the delay analysis process as well as the reducing the required man-hours.

Abstract

Changes such as change orders and site instructions resulting in resource diversion and work area congestion negatively affect the crew's productivity and thus a disruption occurs. Diminishing labor productivity ends up with an increase in the costs and time needed to accomplish the work and this jeopardizes the owner's return on investment, concluding with serious friction and even litigation among the contracting parties. Although disruption is a highly contentious event in construction projects, systematic disruption claim management (DCM) practices cannot be facilitated in construction projects successfully so that disruption events continue to be a major trigger of dispute among the contracting parties. Thus, in recognition of the problem described above, this study aims to identify barriers of DCM by conducting a comprehensive literature review. Furthermore, a questionnaire survey which was analyzed using the TOPSIS technique was conducted with the participation of 12 construction practitioners to set out the significance of DCM barriers. Besides rigorous theoretical contribution, this study is believed to provide construction practitioners with fundamental DCM knowledge that is necessary to create a DCM road map for their projects.

Keywords: *barriers, disruption claim management, MCDM, TOPSIS.*

Introduction

A construction project is generally recognized as successful when it is accomplished on the dot and within the budget; however, achieving this goal is often difficult due to numerous obstacles such as changes occurring in the construction projects. Any additions, omissions and revisions in the contract are referred to as changes in the construction project (Ibbs, 2013). Due to the dynamic and turbulent nature of the construction projects, changes are frequently encountered (Gibson, 2015; Ibbs, 2013). Such changes cause adjustments in the price and/or duration of projects as well as fluctuations in labour productivity (Ibbs, 2013).

Productivity is defined as the efficiency rate at which a contractor converts labour man-hours and materials to outputs (Park et al., 2005). The productivity loss occurs if the contractor is forced to alter its method statement upon the change order issued by the owner (McGeehin & Spangler, 2021). When the productivity is diminished, the contractor is required to spend more labour man-hours and/or equipment hours to produce the same output (Park et al., 2005). In turn, the contractor's time and cost estimates deviate from the plan substantially, inhibiting its profits and return on investment. The impact of changes becomes even more detrimental for the contractors if many changes occur on a project simultaneously due to the emergence of a special condition called cumulative impact (Ibbs, 1997, 2005). The cumulative impact is the unforeseeable productivity loss caused by synergistic and simultaneous effects of a series of changes (Ibbs, 2013). It can also be considered as an indirect or secondary effect of multiple changes. Hester et al. (1991) also highlighted the significance of cumulative impact by stating that the negative impact of each change compounds in the presence of multiple changes, which, in turn, leads to disruptions that are greater than the sum of all individual changes. In other words, multiple changes disrupt not only the changed work itself but also the whole project. Consequently, the contractor experiences 1 + 1 = 3 result (Ibbs, 2013).

Upon the abovementioned changes triggering disruption event/s, the contractor prepares a disruption claim (Society of Construction Law, 2017). A disruption claim is prepared to obtain the quantum of damages suffered by the contractor due to disruption events that make the construction works more difficult and/or more expensive to undertake (Williams et al., 2003). In the disruption claims, the contractor must present concrete evidence concerning productivity losses resulting from disruption events. Otherwise, the claims are likely to provoke a fierce rejection from the defendant who is usually a project owner (McGeehin & Spangler, 2021). Depending on the contract conditions, a typical disruption claim focuses on various aspects of disruption such as overhead, productivity loss, escalation of labour, escalation of plant, escalation material, loss of profits/profit-earning capacity, finance charges, off-site/on-site storage charges and claim preparation costs (Bramble & Callahan, 1992). The vast majority of these aspects are however sophisticated to be calculated accurately due to the high degree of ambiguity (Best & De Valence, 2002). Additionally, it is extremely complicated to dissociate the effects of various factors such as inclement weather, poor workmanship, poor supervision and the risks that the contractor has taken during the tender preparation stage (Best & De Valence, 2002). Although all these factors might lower the productivity and construction output, their effects are excluded from the disruption claims since these factors are not triggered by owners. In other words, the contractors must demonstrate a quantum of disruptions triggered by the events that are caused by the owner without considering other factors affecting productivity (Society of Construction Law, 2017). Thus, disagreements become inevitable about rates of compensation, the quantity of the individual and/or cumulative impacts of disruption events (Ibbs, 2013).

Cognitive conflict and conflict of interest are other major inhibitors that maximize the complexity of the disruption claims (Ibbs, 2013). Cognitive conflict in disruption claims escalates when the claimant and defendant interpret the disruption-related data differently. Inadequate information, information asymmetry, misinformation, and diverse views on what is convenient are among the major sources of cognitive conflict (Moore, 2003). Cognitive conflict prevails in the vast majority of disruption claims due to disruptions' retrospective nature and poor record-keeping (Gibson, 2015). On the other hand, conflict of interest occurs when the interests of the claimant and defendant extremely diverge from each other (Fenn et al., 1997). Conflict of interest is encountered frequently in disruption claims since the

contractors seek compensation for their losses and tend to favour their interests at an expense of the owners' interests (Ibbs, 2013). For instance, if a serious disruption occurs in a construction project due to an intervention of the owner and the contract administrator validates the disruption claim of the contractor, the contractor is entitled to recover compensation. Otherwise, in the case of the refutation of the contractor's claim by the contract administrator, additional costs spent to balance lower productivity are financed by the contractor. Therefore, disruption claim should be well-prepared by including convincing records related to the project facts to minimize effects of cognitive conflict and conflict of interest.

Information provided above reveals that DCM should be performed systematically to prevent the escalation of conflicts and disputes among the contracting parties. In this way, financial and non-financial losses stemming from prolonged dispute resolution processes could be prevented (Cakmak & Cakmak, 2014; Çevikbaş & Köksal, 2018; Marques, 2018). Despite the significance of DCM, the construction practitioners could not implement this concept due to various barriers that emerged as also stated by HKA (2020), Arcadis (2021). Thus, there is an apparent need to identify the barriers of DCM to provide significant knowledge to construction practitioners for the implementation of DCM practices more effectively. In this way, the practitioners could develop proactive strategies to avoid the impacts of these barriers on the efficiency and effectiveness of DCM. In the initial step, a comprehensive literature review was conducted to extract barriers of disruption claim management. This was then followed by a questionnaire survey. Next, collected data was analysed using TOPSIS to assess the significance of DCM barriers.

Related Works in the Disruption Claim Management Literature

Disruption is one of the major sources of diminishing labour productivity. Since cost and time are the functions of labour productivity, the subject of disruption has attracted various researchers' attention in the construction management literature. Thomas and Napolitan (1995) conducted one of the first researches related to disruption. The authors performed various quantitative analysis techniques to determine the effects of changes on labour productivity and efficiency. The study revealed that disruptions such as lack of materials and information, which lead to performing the work out of sequence, might reduce productivity in the range of 25 to 50%. Thus, the authors pinpointed that these severe effects of disruption should be claimed to prevent the contractor from losing money. Later, Ibbs (1997) investigated the quantitative impacts of changes in construction projects. The results suggested that the amount of change is negatively correlated with productivity. The study also made various recommendations to manage the changes efficiently. Another recommendation was proposed by Aibinu (2009). The study investigated the role of pre-contract negotiation to avoid and mitigate conflicts stemming from delay and disruption claims. The study conducted a questionnaire survey with the participation of the construction practitioners and revealed that pre-contract negotiation has great potential to avoid and/or mitigate disruption-related conflicts. On the other hand, Ibbs (2005) proposed that the timing of the change is also a significant issue due to having various magnitudes of impact on productivity. Thus, the impact of changes on the labour productivity for early, normal, and late timing situations was analysed within the scope of this study. The study showed that late change is more disruptive of project productivity than early change. Various studies also investigated the factors affecting the disruption claims. Norflee (2005) pinpointed that the level of learning and labour productivity tends to increase as the work progresses. Thus, the study highlighted the

significance of the learning curve and recommended that the effect of the learning curve needs to be considered in the disruption claims. Secondly, Ibbs (2013) suggested that the total negative effects of the disruptions are greater than the sum of the individual parts. The study, therefore, proposed that the cumulative impacts of multiple changes in terms of disruption should also be considered in disruption claims. To compute these impacts, multiple changes stemming from the owner and Acts of God should be well-documented and examined to present the project facts thoroughly. Furthermore, several authors such as Jayasena and Alwis (2011) and Kikwasi (2013) analysed the causes and effects of disruptions as per regions to improve the DCM process in the concerning regions.

As elaborated previously in this study, the productivity losses stemming from disruption events should be proved and analysed to prepare sound disruption claims. Thus, many efforts are also devoted to developing disruption analysis methods in the literature. The most common and well-known disruption analysis methods are Measured Mile Analysis, Global Claim, Control Chart Method (Gulezian & Samelian, 2003), Thomas's BP Method (Thomas & Zavrski, 1999), Improved Measured Mile Analysis (Ibbs & Liu, 2005), System Dynamics Modelling (Williams et al., 2003), Disruption Distribution (Finke, 1998), Demonstrated Labour Efficiency (McCally, 1999) and Data Envelopment Analysis (Lin & Huang, 2010). Furthermore, the effectiveness of the disruption method/s in projects was also analysed by several studies (Eden et al., 2000; Zink, 1986).

Various research was also conducted to develop a roadmap for the DCM domain roughly in the construction projects. William et al. (2003) developed an approach that aids decision-makers to prepare disruption claims logically and transparently. The approach is established on three pillars, namely demonstration of causality, responsibility, and quantum for the claim. Lastly, McGeehin and Spangler (2021) investigated the impact of the COVID-19 pandemic on the disruption of construction projects and developed various approaches to prepare disruption claims triggered by the COVID-19 pandemic. In addition to efforts conducted by researchers, organizations also developed/recommended best practices for preparing disruption claims such as AACE International (2011), Hill International (2011), and Society of Construction Law (2017).

Consequently, the in-depth literature review presented above shows that barriers of DCM have been so far, which formed the research question of this study

Methodology

The research methodology followed in this study is presented in Figure 1. As is depicted in Figure 1, the literature review was first conducted to extract barriers of DCM. This was then followed by a questionnaire survey designed to assess the significance of the barriers extracted from the literature. Lastly, the eligible experts were identified by using the systematic decision-making framework given in Figure 1. Following the expert selection process, the TOPSIS analysis was conducted to identify the priorities of the barriers. This step was crucial since developing a proactive solution to each barrier is a challenging task. By identifying the most significant barriers, the decision-makers are provided with barriers that need urgent and utmost attention.

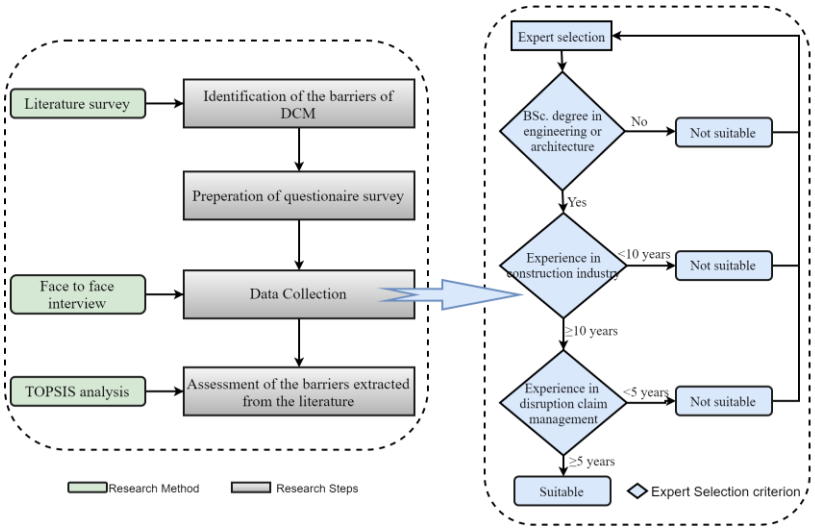

Figure 1. The methodology followed in the study.

Literature Review

As stated above, barriers that could diminish the efficiency and effectiveness of DCM in construction projects were identified by conducting an in-depth literature review. During the literature review, only peer-reviewed articles were initially examined to maximize the reliability of the study. The initial results of the literature review revealed that limited efforts have been devoted to the disruption claim management domain so that scope of the literature review was further widened in a way that includes guidelines published by various institutions. Consequently, 22 DCM barriers were extracted from the literature as shown in Table 1. Point worthy of note is that there is no specific study identifying the barriers of DCM so that barriers presented in Table 1 were identified by reviewing and synthesizing the knowledge related to DCM.

Table 1. The barriers of DCM extracted from the literature.

Data Collection and Data Analysis

Following the literature review stage, the questionnaire survey was designed to assess the significance of the DCM barriers. The questionnaire survey consisted of 3 sections. In the first section, the experts were asked to provide information about themselves. This information was crucial to ensure that experts are convenient for the study. The second section included the fundamental knowledge about DCM and the survey. In the last section, the experts were asked to rate the significance of each barrier with respect to each decision-making criterion. The decision-making criteria that are required by the TOPSIS analysis were determined as Impact on the reliability of disruption analysis, Impact on record-keeping and Impact on the assessment of disruption claims. In other words, each expert completed a decision matrix whose size is 22 by 2.

Next, the eligible experts were identified by following the systematic framework depicted in Figure 1. The demographics of the experts are provided in Table 2. As is seen in Table 2, the experts are capable of providing a substantial contribution to this study.

Table 2. Profile of the participants.

Expert ID	**Personal profession**	**Education**	**Years of experience**
E1	Planning Manager	Civil Engineer	CI: 15 years, DCM: 10 years.
E2	Planning Manager	Mechanical Engineer	CI: 12 years, DCM: 8 years.

E10	Owner	Civil Engineer	CI: 30 years. DCM: 20 years.
E11	Owner	Civil Engineer	CI: 25 years. DCM: 18 years.
E12	Owner	Civil Engineer	CI: 19 years. DCM: 12 years.

Note: CI: International Experience in Construction industry, DCM: Disruption Claim Management.

In the last step, the data collected through the questionnaire survey was analysed using TOPSIS analysis which is one of the most popular Multi-Criteria Decision-Making Methods (Salih et al., 2019). The main reasons behind its popularity are its stability, computational time, and simplicity (İç, 2012). In essence, the TOPSIS method determines the most ideal solution by considering the distances of each alternative from positive and negative ideal solutions (Rao, 2007). The term of positive ideal solution refers to the hypothetical solution which is composed of all the best values attainable from the decision-making criteria while the negative ideal solution is called the hypothetical solution which is composed of all the worst values attainable from the criteria (Rao, 2007; Wang, 2008). Consequently, the following methodology proposed by Rao (2007) was implemented to perform the TOPSIS analysis. The results of the TOPSIS analysis are provided in Table 3.

Results and Discussion of Findings

To interpret these results more precisely, the mechanism of the TOPSIS should be well-comprehended. TOPSIS analysis reveals the relative importance of the barriers of DCM practices. In other words, the barriers having a higher closeness coefficient could be deemed as more significant than those having a lower closeness coefficient. The statements such as barriers having lower weights are insignificant might be controversial to assert (Rao, 2007). Contrarily, in this study, all identified barriers were considered significant since they were extracted from the literature (Budayan, 2019). TOPSIS analysis, however, highlights the barriers that need more and urgent attention from the decision-makers.

Accordingly, the results revealed that "Insufficiency of the Contemporary Data" was rated as the most significant barrier by the experts who participated in this study. The rationale behind this result is that DCM practices are a data-intensive process so that productivity data collected before and after the disruption event is of paramount importance for the disruption claims (Gibson, 2015). Secondly, the barrier named "Uncertainty in what and how parts of the works were affected by disruption event" obtained the second highest result by the experts while "Insufficiency in describing events that lead to disruption" ranked in the fourth order. The loss stemming from disruption events that are triggered by the owner can only be claimable. The damages stemming from other disruption events should be subtracted from the disruption-related claims (Society of Construction Law, 2017)**.** Otherwise, fierce rejection by the defendant who is often the owner is inevitable. Thus, the disruption-related claims should be prepared in a way that includes detailed information about disruption events together with their impact on productivity. In case the owner fails to substantiate the disruption events and their impact, the disruption claim can hardly be negotiated by the owner.

The disruption analysis methods have various subjectivities arising from their inherent mechanisms and assumptions (Hill International, 2011). The subjectivities that exist in these methods could easily complicate the assessment process of the disruption claim since the subjectivities could cause the rejection of the owner. Thus, decision-makers should select the most appropriate disruption analysis methods that meet the needs of construction projects and their stakeholder. Thus, analysis results revealed that the subjectivities of the disruption analysis methods are another barrier in front of the DCM. "Insufficient human resources for record-keeping" was ranked in the fifth order. Record-keeping must be implemented continuously throughout the entire project so that it is not a one-time activity, unlike the other phases (Gibson, 2015). This is a very challenging task and requires significant human

resources. Thus, when the human resources are not sufficient for record-keeping, the entire DCM process could be affected.

Table 3. Result of the TOPSIS analysis.

Barriers	P	Rank
Insufficient communication of project stakeholders in the contract development phase	0.4431	17
Lack of knowledge in project scheduling	0.3791	20
Insufficient human resources for record-keeping	0.6210	5
Insufficient financial resources for record-keeping	0.5841	8
Lack of agreement on the type of records to be kept	0.5620	9
Ignorance of project team for tracking disruption events	0.5377	10
Improper frequency of programme update	0.4298	18
Unclear responsibility assignment of the project for record-keeping	0.3638	22
Uncertainty in what and how parts of the works were affected by disruption event	0.7742	2
Insufficient site observations to notice a disruption event	0.4189	19
Insufficiency in describing events that lead to disruption	0.7147	3
Lack contract clauses stating disruption analysis and its procedures	0.5305	11
Lack of expertise in analysis methods	0.6129	6
Lack of project scheduling software	0.3671	21
Lack of proper baseline schedule	0.4786	14
Improper storage and accessibility of the records	0.6108	7
Insufficiency of contemporary data	0.8042	1
Availability of disrupted works which are also impacted by events that are out of owner's control	0.5216	12
Over cognitive bias between contracting parties	0.4628	15
Over conflict of interest between contracting parties	0.4546	16
Subjectivities of analysis methods	0.6967	4
Unclear and lack of legal basis under the contract	0.5105	13

Conclusions

Disruption in construction projects has widely been seen as a significant problem hindering the productivity of the projects. Given the fact that diminished productivity puts the financial gains of the contractors in jeopardy, the disruption could even escalate the disputes among the contracting parties. Despite this significance, disruption claim management practices are barely implemented in construction projects due to various barriers that emerged during their implementation. Thus, this study aims to identify these barriers that present a roadblock to effective implementation of the disruption claim management practices. Accordingly, an in-depth literature review was conducted to extract barriers. This was then followed by a questionnaire survey designed to measure the impact of each barrier on the DCM. Lastly, the TOPSIS technique was performed to analyse the survey data.

Considering that generating proactive solutions to all barriers extracted from the literature requires significant resources, the decision-makers should focus more on the most significant barriers. In other words, the experts should develop solutions to barriers based on their ranks.

Accordingly, the results revealed that “Insufficiency of contemporary data”, “Uncertainty in what and how parts of the works were affected by disruption event”, “Insufficiency in describing events that lead to disruption”,” Subjectivities of analysis methods”, and “Insufficient human resources for record-keeping” were rated as the most significant barriers. Thus, decision-makers are advised to generate urgent solutions to these barriers. Otherwise, the benefits of DCM can hardly be materialized.

This study has some noteworthy limitations. Firstly, the framework developed within the scope of this study is generic and does not consider inherent differences of the regions and/or countries. Although this issue has a limited effect on its practical implication since it was developed and refined by internationally experienced experts, the decision-makers should be aware of that minimal modifications could be necessary throughout its actual implementation in different countries and regions. Secondly, the use of a small sample size might cause some degree of bias. However, the following systematic procedure during the expert selection is believed to minimize the effects of this issue.

Abstract

Legal processes in the construction industry are shaped in order to solve the problems and to prevent or compensate for all kinds of loss of rights in terms of stakeholders. Engineers and technical personnel, customers, contractors and subcontractors, employees, etc. sector members may encounter these losses of rights, during the construction process. However, legal rights and responsibilities are not limited to only the construction process in the construction industry. Development readjustment share, tender and bidding processes, zoning legislation, construction inspection law, occupational health and safety, compliance with laws, terms of contracts, the debt of loyalty, the fundamental issues such as the clearly reveal the importance of the concept of law in the construction industry. But, legal rights and responsibilities that should be considered in the planning, delivery, and use phase of construction are not taken into account by the stakeholders until a significant problem arises in any concrete case. In addition, many cases are encountered in the construction industry due to the weakness of the inspection mechanism and the fact that some issues do not find their place in the legislation and laws. These litigation processes wear out the parties. In this paper, legal approaches, some deficiencies and relevant laws in the construction industry are examined. It is desired to draw attention to the necessity of basic legal knowledge that concerns stakeholders of the construction industry, especially civil engineers.

Keywords: *building contract, building law, construction law, legal knowledge.*

Introduction

Legal rules are a set of rules that regulate social relations and living conditions, have material sanctions, and are supported by public power (Güriz, 1996; Kalabalık, 2012). Legal rules are about the actions of individuals and deal with human behavior in general. These rules mainly include the concepts of order, prohibition, permission and authorization. By force of these regulations, the rules of law have the sanction power. In addition, the law is dynamic because it can change due to human relations, which is a dynamic process, changing cultures and conditions required by the age. When required, it can be updated (Kalabalık, 2012).

A legal order is formed by classifying the rules of law according to the field they are related to. One of these fields is civil engineering. The civil engineering profession imposes some responsibilities on the relevant parties in terms of resolving disputes and preventing loss of rights during the implementation and execution of the work. Law within the scope of civil engineering is more frequently encountered in the literature with terms such as building law

and construction law. There are a large number of laws in Turkey that deal directly with construction or provisions that also include laws about construction (Daşdelen, 2006). Turkish Laws that contain important regulations *within the scope of civil engineering* are the Turkish Code of Obligations, the Zoning Law, the Occupational Health and Safety Law, the Labor Law, Construction Inspection Law, Public Procurement Law, and the Property Ownership Law. In addition, the Turkish Civil Code, which includes the provisions of the law of property that regulates the issues related to real estate, is one of the laws that can be needed. In addition to all these, there are many regulations prepared based on these laws for the construction sector. One of them is the Planned Areas Zoning Regulation, which regulates the procedures and principles regarding building and construction in accordance with the plan, science, health and sustainable environmental conditions. In addition, Unplanned Areas Zoning Regulation, Energy Performance Regulation in Buildings, Regulation about Site Chiefs, Building Earthquake Regulation, etc. are also sources for *which civil engineers are responsible* (TMMOB, 2011).

It is almost *impossible to have full knowledge* of all these laws and regulations and to know all the provisions, however, the responsibilities arising from these laws are *binding*. In other words, "not knowing" an existing law provision is *not accepted as an excuse* in terms of Turkish law. In this regard, the relevant provision within the scope of the "Law-binding" is as follows in the Turkish Penal Code.

- Not knowing the penal laws is not an excuse (Turkish Penal Code, 2004: 4/1)

However, the same law also included some regulations under the name of “Error” in the provisions regulated by 30/3 and 30/4 clauses. Relevant regulations;

- A person who makes an inevitable mistake regarding the fulfilment of the conditions related to the reasons that remove or reduce the criminal liability, takes advantage of this mistake. (Turkish Penal Code, 2004: 30/3).

- A person who inevitably commits an error that his act constitutes injustice is not punished (Turkish Penal Code, 2004: 30/4).

In accordance with the principle that ignorance of the law in this regard is not an excuse; It is clear that even if the person does not know that there is a criminal sanction for the action he has committed, he will not gain an advantage in terms of criminal law proceedings. However, *unavoidable injustice* is related to the actions that take place despite the fact that the person concerned does his due diligence and attention. It occurs when the person *inevitably believes* that he will not cause an unfair situation, regardless of the provisions of the Law, and therefore commits the criminal act. The *inevitable error* is not here as a fraud but is valid for actions performed in good faith, with the belief that the action that is not thought to constitute a crime will not lead to an unfair situation as well (Öztürk, 2021).

According to these circumstances, it is necessary for civil engineers to know the concerned laws within the scope of professional competence. For this purpose, the Turkish Laws that civil engineers should know directly or indirectly are explained in the following sections.

Turkish Code of Obligations Through the Eyes of Civil Engineers

One of the most common legal issues faced by civil engineers is the *contracts of work* and services. The contract of work is regulated in the Turkish Code of Obligations (TCO), articles 470-486. Conflicts encountered in terms of construction and engineering are more frequently caused by non-compliance with the provisions of this law or a lack of due diligence. A contract of work is a contract in which the contractor undertakes to create a work and the employer undertakes to pay a price for it (Turkish Code of Obligations, 2011: 470).

Without prejudice to the general provisions of the Code of Obligations and other related provisions, it is clearly beneficial for every civil engineer to know at least these provisions regulated by TCO 470-486. *Other related provisions;* (joint liability, the statute of limitations, written form requirement, tort, foreclosure, default in contract, etc.). These provisions, which are regulated by the TCO Part II, Seventh Chapter, start with the definition of the work contract and regulate the Contractor's Obligations and the Employer's Obligations, respectively. Subsequently, the provisions of TCO 482-486 include the cancellation of the contract.

The most common types of lawsuits in terms of the provisions of the TCO are liability due to defects regulated by Articles 474-478 and exceeding the approximate price regulated by Article 482. Another point that concerns civil engineers is construction contracts. Establishing a proxy relationship between civil engineers and the employer is a common situation in the profession. Under article 40 of the TCO, the employer's representative is authorized to act on behalf of the employer. FIDIC contracts and Joint Venture contracts are also a source for more detailed studies on this subject (Çetin, 2022; Tutkun, 2019).

The courts of competent jurisdiction regarding the disputes within the scope of the Code of Obligations may differ according to the content, type, and place of the case. In order to *avoid loss of rights* regarding these issues, it is of great benefit to know the relevant court correctly in terms of duties and competence. Also knowing the period of prescription, and knowing the court of the place where the case will be filed is needed. There are different decisions of the Court of Cassation on this issue (Ruhi & Ruhi, 2018).

Turkish Civil Code Through the Eyes of Civil Engineers

Some issues concerning civil engineering are also regulated by the Turkish Civil Code. Part one of this Code, which is about property law, starts with the right of property and continues with the ownership of *immovable property*. The term immovable is important for civil engineers. This section deals with unlawful construction, especially with articles 722-725, and explains the term "Unjust construction" and "Structural Encroachment" in the literature and law (Atlı, 2017; Erkan, 2014). In addition, the subject of “Building Mortgage” is regulated by articles 892-897 of the law (Turkish Civil Code, 2001).

Unjust Construction

Three different situations can be given as an example of the concept of unjust construction. The first and most common of these; is a type of building that is built on someone else's land with its own material. The second is the structures built on one's own land with someone

else's material. Finally, structures built on someone else's land with still someone else's material are referred to as *Unjust Construction*. There are many examples of lawsuits related to Unjust Construction, but the third type of these cases (someone else's land, and material) is an example that can be seen very rarely. The concept of Unjust Construction is misunderstood and misused generally. There are some factors that would be qualified a structure as an Unjust Construction (Savaşan, 2020). These;

- Privately owned land
- Land register
- Existence of a structure on this land
- The fact that this structure is a permanent structure
- Construction of the structure without relying on a real or personal right
- Material or land belonging to different people

The concept of Unjust Construction; should not be confused with concepts such as structural encroachment, superficies rights, servitude, construction contracts in return for land share, and usufruct rights. Civil engineers should also have sufficient and necessary legal knowledge on these issues.

Structural Encroachment

According to Turkish Civil Code article 725: The part of a building that is moved to someone else's land, becomes an integral part of the immovable belonging to him if the owner of the building has an easement right on the land. *"The part that is carried over to someone else's land"* from the *Structural Encroachment* definition is important. This is the main difference between unjust construction and structural encroachment (Turkish Civil Code, 2001; Öztürk, 2021).

Building Mortgage

One of the other issues regulated by the Civil Code is the subject of *building mortgages*. It is regulated between articles 892-897 of the Law. It is stated that the receivables of the craftsmen and contractors involved in the project, arising from the activities they carry out on a *certain immovable,* by expending labor or materials, can be secured with a building mortgage (Turkish Civil Code, 2001: 893). It is clear that there are problems in the collection of receivables for engineers or laborers due to construction costs and other factors in the construction sector.

According to the Civil Code (892-897) and legal doctrines, the persons who only carry out intellectual work, architects and engineers, and who have given only materials to the construction and oversee the construction do not have legal mortgage rights. However, it is important whether the contract between the owner and these persons is a *contract of mandate* or a *contract of work*. There are also opinions that a person who has a contract of work with the contractor on the subject of building mortgages is the right to mortgage the building in case. Examining the relevant provisions in detail may enable engineers to take precautionary measures against possible disputes in this regard (Akcan, 2018).

Zoning Law

The Zoning Law is a branch of law in which the suitability of construction works is regulated. Therefore, it is one of the *most important legal fields* for civil engineers and other stakeholders. This law was arranged in order to ensure its formation in accordance with the plan, science, health and environmental conditions of settlements and structures in these settlements (Zoning Law, 1985: 1). With the term *"plan"*, the necessity of a legal framework is understood in the planning process and its stages. The benefit of the public and society should not be ignored by the civil engineers who will take part and be responsible in the planning (Kalabalık, 2015).

The term "engineer" is used more frequently in the Zoning Law compared to other laws. The relevant articles, including the direct responsibilities of civil engineers, are regulated in Zoning Law and civil engineers should know the provisions of this law. As a matter of fact, many buildings can be incomplete due to the violation of the Zoning Law, and the concerned and rights holders can have problems. Because the purpose of this law is to ensure compliance with the plan, science, health, and environmental conditions of all public and private structures within the municipality and the adjacent. All article of this law, including the definitions section is important for civil engineers. The following are some of the concepts that are regulated in detail in the law and should be mentioned at least in name by this paper.

- easements,
- parceling and joining,
- partition and registration,
- expropriation,
- building permit,
- permit conditions,
- authorship, technical responsibility, site supervisor, building contracting and records,
- occupancy permit.

These concepts are that civil engineers should know in order not to incur any loss of rights, and lawlessness and not to be affected by natural damages. It should also be known that the laws only are not sufficient. The Planned Areas and Unplanned Areas Zoning Regulations prepared to depend on this law, should be examined together with Zoning Law.

Construction Inspection Law for Civil Engineers

The responsibilities of civil engineers are regulated by laws not only personally but also in relation to the organizations they are affiliated with. There are some legal responsibilities of Building Inspection Institutions which is one of the organizations that some civil engineers work affiliated. For this reason, also civil engineers which work at Building Inspection Institutions have legal responsibilities. Regarding provisions are regulated by Law No. 4708 on Construction Inspection Law. Purpose, scope, and definitions are specified in Article 1 of this law. The purpose of the law is to regulate the procedures and principles regarding "construction of quality buildings in accordance with the zoning plan, science, art and health rules and standards in order to ensure the safety of life and property" and to ensure its supervision (Construction Inspection Law, 2001: 1).

Article 1, also explains some definitions like the owner of the building, construction period, construction area, load-bearing system, *structural damage*, construction inspection institute, building contractor, project owner, the architect, and controller engineer terms. In the next

articles of law, the construction inspection organization and its duties, also responsibilities are explained.

Structural damage is a concept that should be taken into account from the above definitions. Because civil engineers can be held responsible in case of structural damage in accordance with the principle of faulty liability. In order for the fault liability of the building inspection organizations and the engineers or architects in this organization to arise, the damage to the building must prevent the use of the building or cause a loss of value in the building. Who the responsible persons are and in which cases the responsibility will be imposed are specified in the law (Construction Inspection Law, 2001: 3)

However, in order to be able to talk about liability, the *relation of causality* is a legal requirement. What is meant by the appropriate *relation of causality*; It is the cause-effect relationship between the damage that occurs and the event or behavior to which the liability is connected. So, two situations are necessary. The first is the structural damage, and the second is the relation of causality between the damage and the individual responsible (Okan, 2018). Indeed, as stated; also the technical responsibility for the inspection of buildings that are not subject to the provisions of this Law is assumed by the architects and engineers (Construction Inspection Law, 2001: 26-28). If the articles of the law are not taken into account, there are multiple provisions that impose an administrative fine as a sanction on those concerned. So these provisions should also be well known by civil engineers.

Occupational Health and Safety Law for Civil Engineers

Occupational safety specialists have more responsibilities within the scope of the Occupational Health and Safety Law and the obligations regulated by this law. However, the main occupation of these occupational safety specialists is civil engineering generally. Although there is a legal obligation, there is no occupational safety specialist at some construction sites or it is shown as if there was. In such cases, a possible occupational accident is the responsibility of the occupational safety specialist, the site supervisor, and other technical staff and engineers. In fact, the Regulation on Construction Site Managers imposes legal responsibility on contractors and site chiefs in terms of occupational health and safety. Regulation; It contains some explanations regarding the obligations of the construction site supervisor and occupational health and safety.

Civil engineers, whether they are occupational safety specialists or not, are required to have sufficient knowledge of the Occupational Health and Safety Law as part of their responsibility. However, matters related to the provisions of affiliate and the fault of third parties could be seen in occupational health cases. In particular, the care and attention of engineers, tasked with implementing a construction plan are taken into account by Turkish laws. For example, the fact that a construction plan has passed the approval of the administrative authorities *does not eliminate the possible fault of the civil engineer* (Erem & Toroslu, 1994). In occupational health and safety cases, the terms *"negligence", "intention"* and *"gross fault"* are important depending on the way the incident occurred.

Labor Code for Civil Engineers

Labor Code regulates the rights and responsibilities of workers employed on the basis of an employment contract with employers regarding the working conditions and working environment (Turkish Labor Code, 2003). However, whether civil engineers are within the

scope of the Labor Law *depends on the contract terms and working conditions*. Some civil engineers are considered within the scope of the Labor Law, and some are not within the scope of the Labor Law. For example, civil engineers working with a contract of mandate or a contract of work are evaluated according to the Code of Obligations.

In order for a civil engineer to be covered by the Labor Law, the engineer must work for an employer and the contract concluded between them must include the elements of the employment contract. These elements are *works and services debt*, *wage*, and *dependency*. With this contract, *both parties are under the burden of debt*. A continuing relationship is established and *not a contract of instantaneous performance*. It is a contract governed by private law (Sümer, 2019). There are certain conditions for a Civil Engineer included in this scope to benefit from employment security provisions in case of job loss or other negative events (Sümer, 2020). Even if engineers are entitled to benefit from these provisions, loss of rights may arise in cases when certain legal procedures are not followed. Mediator requirement, notice, complaint, objection, notification, etc. topics can be cited as examples of these legal procedures. In addition, it is seen that civil engineers have lost their rights due to reasons such as delays in some matters and ignoring the support of a lawyer. There are many lawsuits related to this issue. Within the scope of the subject, it may be insufficient for civil engineers even if to know the law, and it is useful to investigate sample cases and *Supreme Court decisions.*

Turkish Penal Code for Civil Engineers Working in the Public Sector

So far, important laws for civil engineers working in the private sector and what civil engineers should pay attention to have been emphasized. If in this section, it is aimed to raise awareness about articles 204-207, 235-236, 247-252, 257-262, and 279 of the Turkish Penal Code (TPC), which should be known to civil engineers working in the *public sector*. Within the scope of the Turkish Penal Code, every citizen, regardless of profession, is responsible for every article of the law. However, in law;

- Forgery or Falsification of official documents (TPC 204-207)
- Collusive tendering and the Offense of using fraud or trickery in the fulfilment of execution (TPC 235-236)
- Embezzlement, Bribery, Extortion, Neglect (TPC 247-252)
- Misfeasance in public office, Disclosure of secrets related to duty, Abandon or non-performance of public office… (TPC 257-262)
- Failure of a public official to report the crime (TPC 279)

these provisions, which are regulated under the headings, are the articles of law that civil engineers working in the public sector may encounter by using some privileges they will obtain due to their duties, in an *unlawful manner*. For example, one of these articles, item 257, is regulated under the name of *Misfeasance* in public office. With the offense of misconduct, the situations considered crimes are stated with expressions such as "by acting against the requirements of her duty", and "by neglecting or delaying in fulfilling the requirements of her duty". Misfeasance provisions do not apply to every unlawful act of civil engineers working in the public sector. The moral element of this crime is that it can be committed with *intent*. It should be known that the crime of misconduct cannot be committed with *negligence*, but it is committed with *intent* and the *perpetrator* must commit the crime *knowingly* and *intentionally*. This crime must have included "sufferer" and "unfair advantage" results (Tepe

et al., 2021). For this reason, civil engineers working in the public sector must act in accordance with the laws in the transactions to be made. It is possible to become a competent engineer if only on the condition of knowing and understanding the provisions of the law. Otherwise, if some of the actions are unlawful, difficult litigation processes may be encountered even if there is an *aggrievement situation* in accordance, with the provision "Not knowing the penal laws is not an excuse" (Turkish Penal Code, 2004: 4/1).

Other Laws and Ethical Principles Which Concerning Civil Engineers

It will not be enough for civil engineers to know only the laws explained in previous chapters. The provisions of the Public Procurement Law, the Law on Public Procurement Contracts, and the Property Ownership Law, especially the *Constitution*, should also be examined and known. Although not as much as a lawyer, *at least the professional provisions of laws* such as Civil Procedure, International Arbitration, and Turkish Commercial Code also should be known.

Figure 1: Supreme Court decisions in which civil engineers are directly a party to the case.

In fact, from a broader perspective, the law is not only a body of Codes with a social aspect but also a necessary tool for the uninterrupted and healthy execution of construction works. With this awareness, long and tiring litigation processes will be encountered less frequently. As a matter of fact, when the cases that directly concern civil engineers are examined, it is seen that these cases are much more than they should A search was made of the Supreme Court decisions, in which civil engineers were directly involved as *defendants or plaintiffs*. The cases examined are only those that have been submitted to the Court of Cassation. Civil engineers who examine cases as experts were not included in the filter. Despite these

limitations, it was seen that there were 21 Supreme Court decisions (Figure 1) in the last six months of 2021 (Supreme Court, 2022).

It should be noted that the Court of Cassation is the supreme court in charge of examining only appeals in the field of judicial jurisdiction. In this case, it should not be forgotten that there are also cases that have not devolved to the Court of Cassation, which resulted in first-instance court decisions or that were concluded in regional courts of appeal. In addition, there are many problems that are resolved through mediation or reconciliation or that are not applied to the legal authorities despite the loss of rights.

Considering all these *constraints*, it should be said that for Figure 1 there is only a small portion of cases that directly concern civil engineers. In these lawsuits, not only the victimization of civil engineers but also the victimization of other stakeholders caused by engineers can be prevented by legal knowledge and the application of this knowledge. As a matter of fact, the rights arising from the law are recognized not only for the protection of the person concerned but also for the protection of other persons. Acting in accordance with *good faith* in the use of these rights is a *requirement of professional ethics and law* (Demirboğa, 2018). This is not just an issue that lawyers focus on. The principles of rights, law, and ethics, which have absolute relevance to all kinds of problems, have been the subject of many studies. In engineering education, it is stated that *not only computational but also behavioral awareness* should be emphasized (Çoşkun, 2007). As a matter of fact, in another study on the subject, it was emphasized that in order for civil engineers to comply with ethical principles, professional ethics principles and codes and legal legislation should be created by taking into account the suggestions of all stakeholders. (Genç et al., 2016). Ethical principles do not have the power of *sanction* like laws. However, it should not be forgotten that all legal rules arise from human behavior and are subsequently accepted as written rules. So, due care should be given to both ethical principles and laws in professional life.

Discussion, Conclusion and Recommendations

Civil engineering is a profession focused on *people, the environment, and technology*. So, civil engineers, who are the practitioners of this profession, have rights and responsibilities in multiple fields. These rights and responsibilities naturally require civil engineers to interact with other stakeholders of the profession in the exercise of rights and fulfillment of responsibilities. The outcomes of these interactions can be positive or negative. Correct planning, implementation, awareness of rights and responsibilities, and healthy communication ensure that this interactions and works are positive and take place in the expected time. However, in other cases; If the laws and regulations are not followed, some problems are caused by the supervisory authorities or by civil engineers. These problems are often the subject of lawsuits and the progress of the works stops. The most common lawsuits are about the *negligence of duty, work accident, or unjust gain* in the construction industry. Financial disputes or the lack of work done as required cause disputes. This is back-breaking both *materially and morally.*

In this paper, some laws and legal provisions that should be known by other stakeholders of the sector, *especially civil engineers*, were mentioned in order to prevent or reduce the negativities in the sector. As it can be understood from the details of the provisions of the law and the number of cases, it has been seen that *it is not a choice but a necessity* for all civil engineers to have legal knowledge. In this context, some studies should be carried out in order

to acquire legal knowledge for civil engineers. These studies can be done with individual demands or courses, as well as by including *compulsory law courses* within the scope of the profession in the *civil engineering departments of universities*. In the civil engineering departments of universities, the Labor Law course is often given as an elective course in undergraduate or graduate education. However, it is recommended that this scope should be *expanded*, made *compulsory*, and not stay as just Labor Law.

Knowing and *applying* the laws directly related to the profession, only some of which are stated in this paper, will provide material and moral gains both in the fulfillment of the works and in the judicial processes. It is a *necessity and also a responsibility* for civil engineers to know their rights and to defend these rights in order to resolve disputes faster during or before judicial processes.

A Grouping Study of Domain Knowledge Representations in Building Regulations

M. Aydın
Ankara University, Graduate School of Natural and Applied Sciences, Ankara, Turkey
aydinmrt@ankara.edu.tr

Abstract

Building regulations are legal documents written in human language that are interpreted and enforced by people and are often controlled by local governments in the construction industry. Due to factors such as the uncertainty of the expressions in the building regulation clauses, the flexibility of application of the building regulation clauses, and the lack of definitions in the regulation clauses, these documents lack a definite and unambiguous language. In order to avoid this complexity, computerized building regulation representation studies are carried out by experts in the construction industry. With the efforts of professionals, building regulations are transformed into many different, official languages and integrated into existing systems. All kinds of information and data are selected and applied at various levels of accuracy by reasoning. Many works have been carried out for the domain knowledge representations of the building regulations for many years.

The languages and methods in the domain knowledge representations of the building regulations were investigated in this study. These were grouped under the headings: Human Language, Markup Languages, Formal Languages, Semantic Web Languages, Artificial Intelligence Methods, and Hybrid Methods. The languages and methods implemented in the studies were described in great detail.

Keywords: *domain knowledge representations, building regulations, languages and methods, grouping, construction industry.*

Introduction

Building regulations are legal documents written in human language that are interpreted and enforced by people in the construction industry, which is frequently controlled by local governments (Fenves et al., 1987; Sowa, 2006). These documents lack a precise and unambiguous language due to issues such as the ambiguity of the terms in the building regulation clauses, the flexibility of application of the building regulation clauses, and the lack of definitions in the regulation clauses (Lau & Law, 2004; Nawari, 2012b). Experts in the construction industry perform computerized building regulation representation studies to prevent this complexity (Dym et al., 1988; Kumar, 1989; Rasdorf & Wang, 1988; Rosenman & Gero, 1985). Building regulations are being transformed into a variety of official languages and integrated into existing systems thanks to the efforts of experts. All kinds of information and data are selected and applied at various levels of accuracy by reasoning. For many years,

several efforts have been completed for the domain knowledge representations of building regulations (Berners-Lee et al., 2008; Biagioli et al., 2004; Boer et al., 2008; Boley, 2006; Brickley et al., 2014; Brown et al., 1992; Cyganiak, 2005; Dym et al., 1988; Fenves, 1966; Fenves et al., 1969, 1987; Garrett Jr & Hakim, 1992; Gutierrez et al., 2005; Hakim & Garrett, 1993; Hjelseth & Nisbet, 2010a, 2011; Horrocks et al., 2004; Kiliccote et al., 1994; Kiliccote & Garrett Jr, 1998; Kumar, 1989; Lau & Law, 2004; Lee, 2011; Leibniz, 1923; Lupo et al., 2007; Mazairac & Beetz, 2013; Melzner et al., 2013b; Minsky & Papert, 1970; Nawari, 2012b, 2012a, 2012c; Nawari & Alsaffar, 2015; Nyman et al., 1973; Omari & Roy, 1993; Palmirani et al., 2011; Pauwels et al., 2011; Rasdorf & Wang, 1988; Rosenblatt, 1958; Rosenman & Gero, 1985; Rumelhart et al., 1986; Sartor et al., 2011; Sowa, 2006; Walton, 2007; Yabuki & Law, 1993; Yurchyshyna & Zarli, 2009; Zhang & El-Gohary, 2016; Zhang & Issa, 2011).

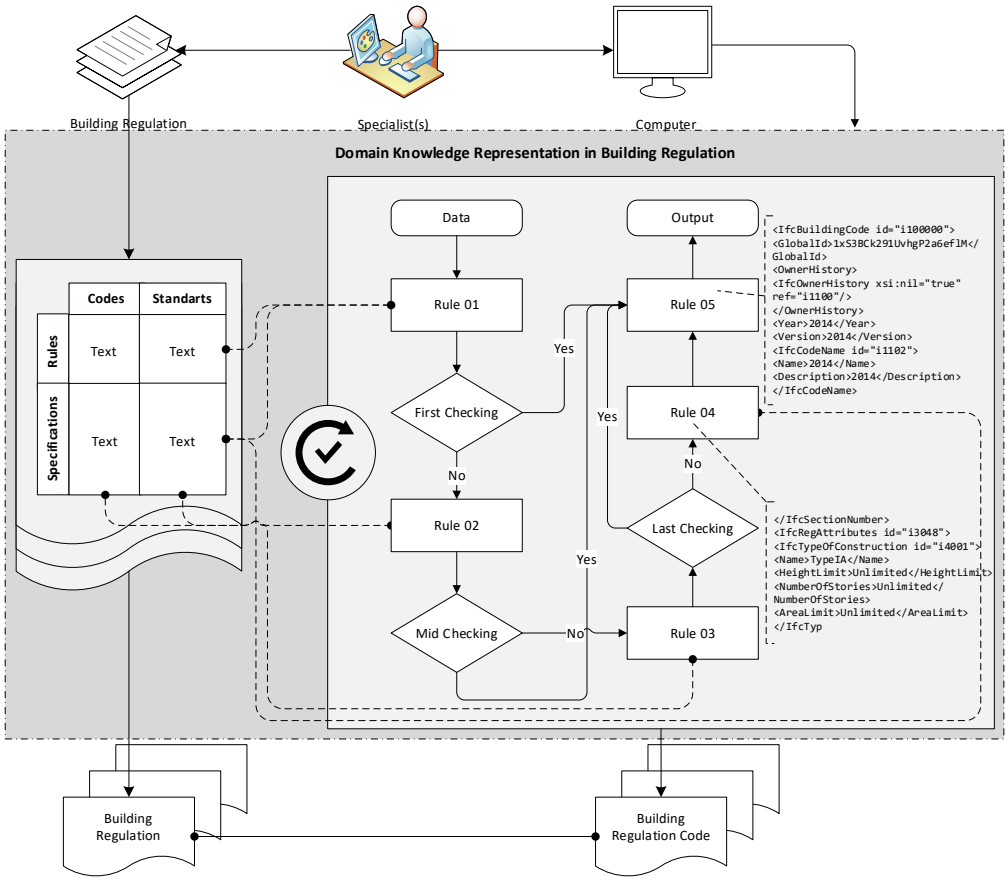

Figure 1: The concept diagram of the domain knowledge representations in building regulations.

The first stage in the automated code compliance checking (ACCC) process begins with the domain knowledge representations of building regulations. Building regulations need to be computably represented in the domain knowledge representations. First, an interpretation process is applied to transform the semantic structure of each building regulation into building regulation rules utilizing specific languages. Then, the ACCC application is begun with the BIM model data that provides data input between the building regulation rules and the software by integrating the building regulations with a particular software or programming language. Therefore, it is important in the ACCC process to represent building regulations in a computer readable format (Aydın & Yaman, 2020; Kiliccote & Garrett Jr, 1998; Minsky & Papert, 1970; Zhang & Issa, 2011).

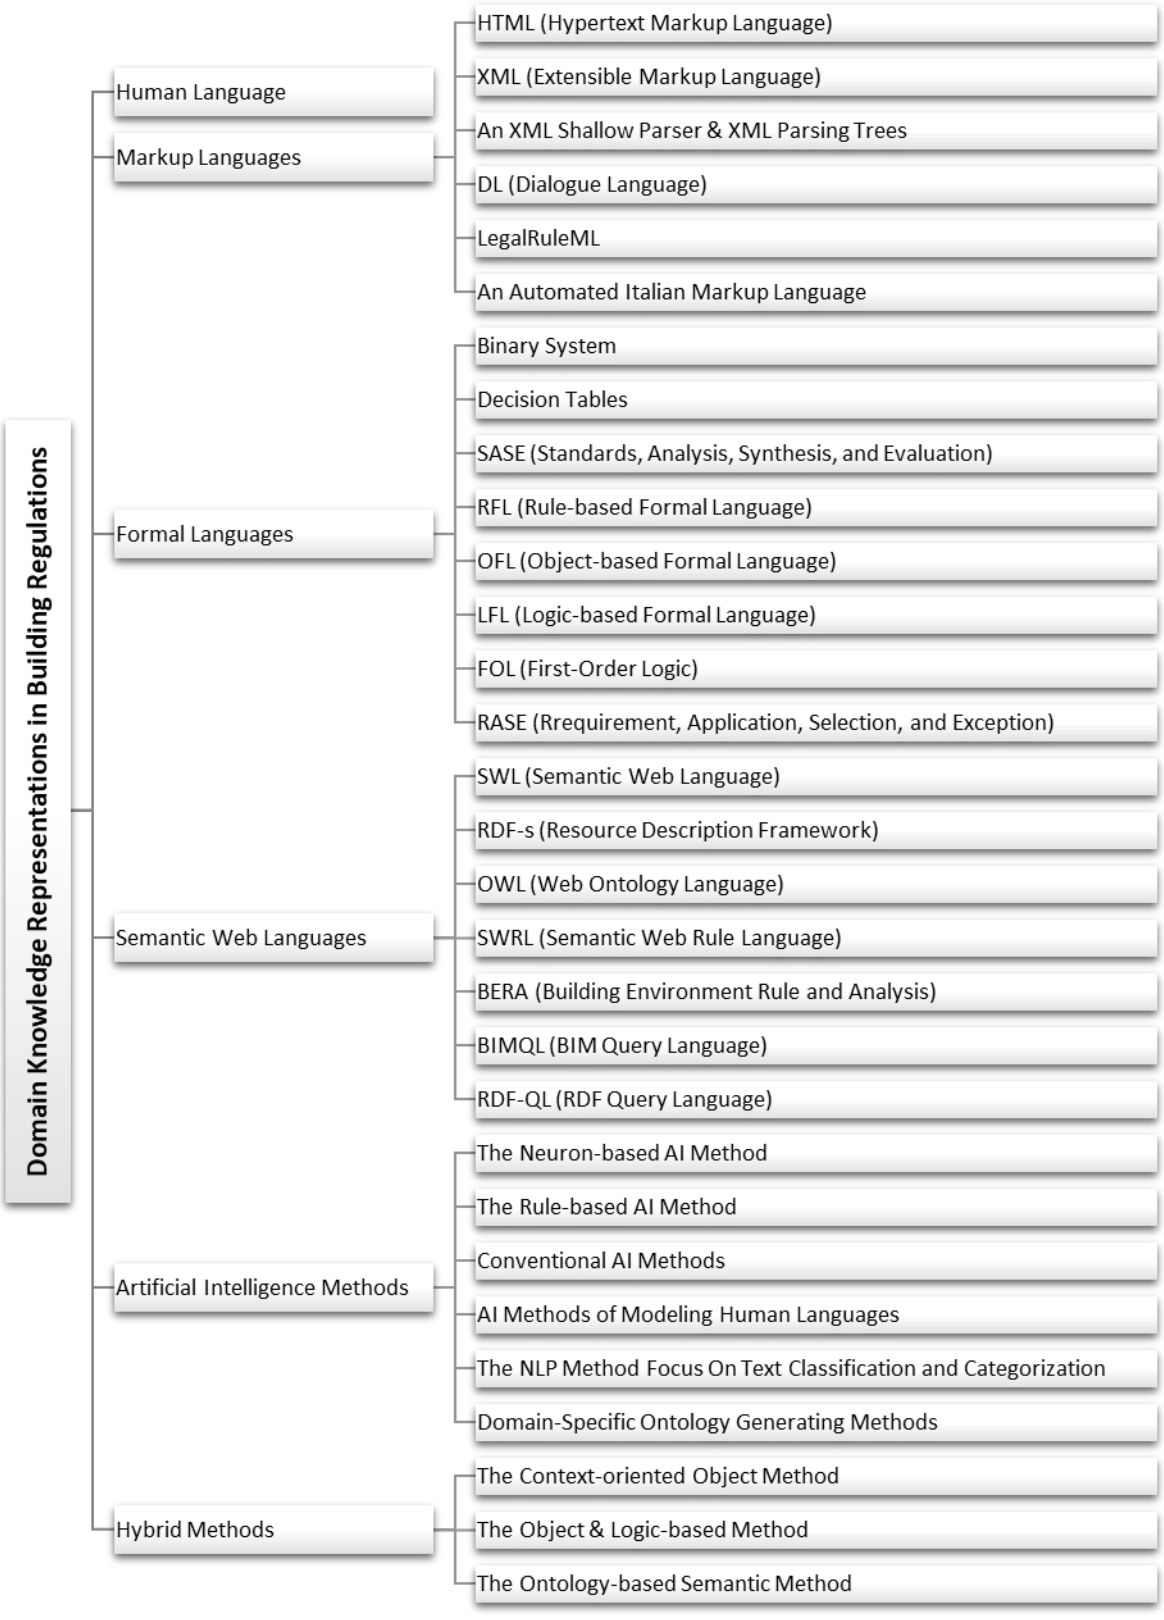

Figure 2: The list of domain knowledge representations in building regulations.

The concept diagram of the domain knowledge representations in building regulations is shown in Figure 1. A building regulation is required for the computable building regulation code representation. The content of the building regulations is parsed into its specifications

through domain knowledge representation languages. Each clause of the building regulation (or only the clauses containing control conditions) is classified within itself before the building regulation rules. The ACCC systems are used to control these rules, which are created in accordance with the relevant building regulations. If the conditions of each rule are met in the ACCC system, the following rule is checked. If not, the rule is re-checked (Berners-Lee et al., 2008; Brickley et al., 2014; Fenves, 1966; Fenves et al., 1969; Omari & Roy, 1993; Yabuki & Law, 1993; Yurchyshyna & Zarli, 2009).

Domain Knowledge Representations in Building Regulations

Figure 2 shows the list of domain knowledge representations in building regulations. The languages and the methods used in domain knowledge representations are grouped under common headings, and detailed information is given under the related headings. These are:

- Human Language,
- Markup Languages,
- Formal Languages,
- Semantic Web Languages,
- Artificial Intelligence Methods,
- Hybrid Methods.

Human Language

A Human Language refers to a language that a child can acquire cognitively in the process of self-expression. A seven-year-old boy is as proficient in human language as his parents in speaking and understanding. When an adult expresses his thoughts, he speaks human language according to the respiratory rate and the limitations of short-term memory. This demonstrates the numerous extensibilities of vocabulary and expressions. Many words in a human language are said to have open-ended meanings, and the ambiguity is unavoidable. The main features of the human language shown in Figure 3 are (Sowa, 2006):

- Phonology shows how words are related to sounds.
- Morphology shows how words are formed from more primitive morphemes.
- Syntax shows how words are ordered to form correct sentences.
- Semantics shows the meaning of words.
- Pragmatics shows how sentences are used in different situations.
- Discourse information shows how it determines the meaning of a sentence.
- Realm knowledge includes perceptions, feelings, beliefs, and local knowledge about the topics in a speech.

Languages have evolved and diversified over time. This situation has made the grammar of each language complex. Language can produce an infinite set of sentences to express any thought. Therefore, it is often difficult to talk about the single meaning of a sentence in human language. Likewise, it is often difficult for a person to understand every text or dialogue in their own language. Therefore, it is also unrealistic to expect a computer to easily understand human language. Difficulties in dealing with human languages come from the way the human brain works or the way languages express information. A significant part of the difficulty arises from the incompatibility of the different words used in the language. Throughout

history, many researchers have focused on this issue and realized that the difficulties experienced are an important component of human languages. They emphasized in their studies that the uncertainties brought about by the difficulties are not a flaw in natural language. They brought up the question of what kind of connection should be established between natural languages and formal languages created by humans.

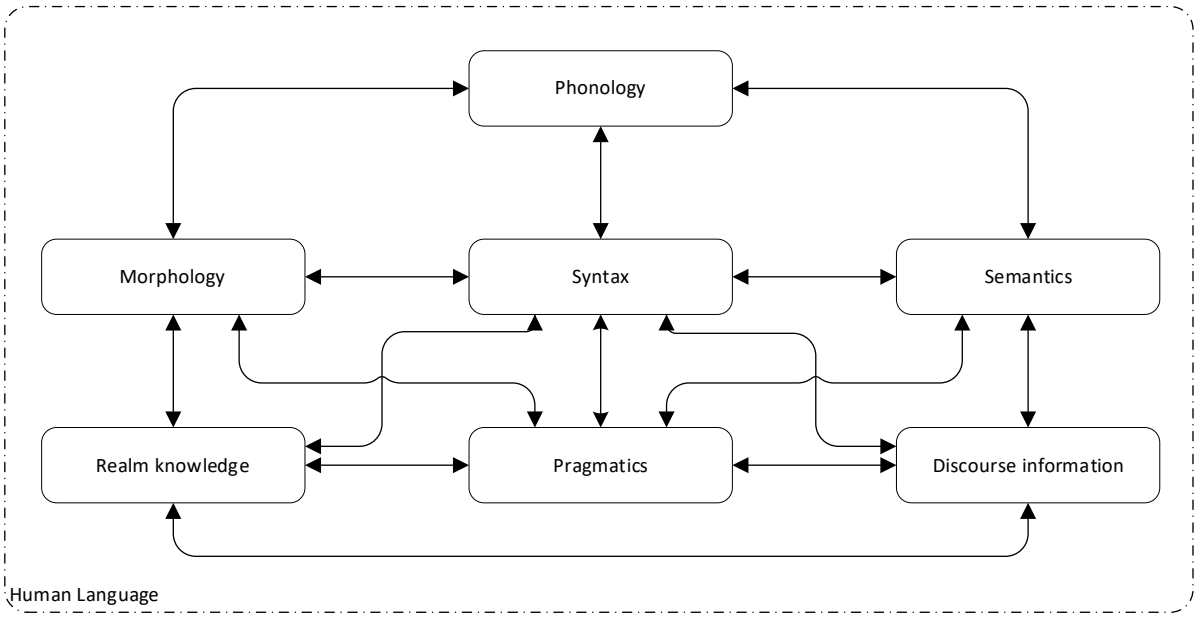

Figure 3: The main features of the human language (Sowa, 2006).

Markup Languages

The researchers used Markup Languages to illustrate and formalize building codes and regulations in their method. Standard markup languages (HTML, XML) are preferred in some studies, while new approaches that refer to standard markup languages have been proposed in others.

HTML (Hypertext Markup Language)

Today, most building regulations and standard documents are available in HTML (Hypertext Markup Language) format in addition to hard copy. HTML is the standard text markup language used to create web pages. HTML cannot be defined as a programming language. However, programs that can run through programs that can interpret this language can be coded.

XML (Extensible Markup Language)

XML (Extensible Markup Language) is a markup language for creating documents that can be easily read by both humans and computing systems. It is a standard defined by the W3C. Besides storing data, it also acts as an intermediate format for data exchange between different systems with this feature. An integrated format into XML was proposed by Lau and Law in 2004 to represent building regulations and codes (Lau & Law, 2004). The format shown in Figure 4 has two features: a markup language for building regulation resources, and a Web standard for digital processing capability.

An XML Shallow Parser & XML Parsing Trees

A combined XML format with XML's ability to handle semi-structured data was proposed by Lau and Law in 2004 to represent building codes (Lau & Law, 2004). An example of the XML representation of the building code is shown in Figure 4. In this study, an XML Shallow Parser was created as a first step in combining different building code rule formats into XML to partially automate the translation process. Semi-structured information from regulations is displayed in an XML schema; for other unstructured information, a feature extractor mechanism is used.

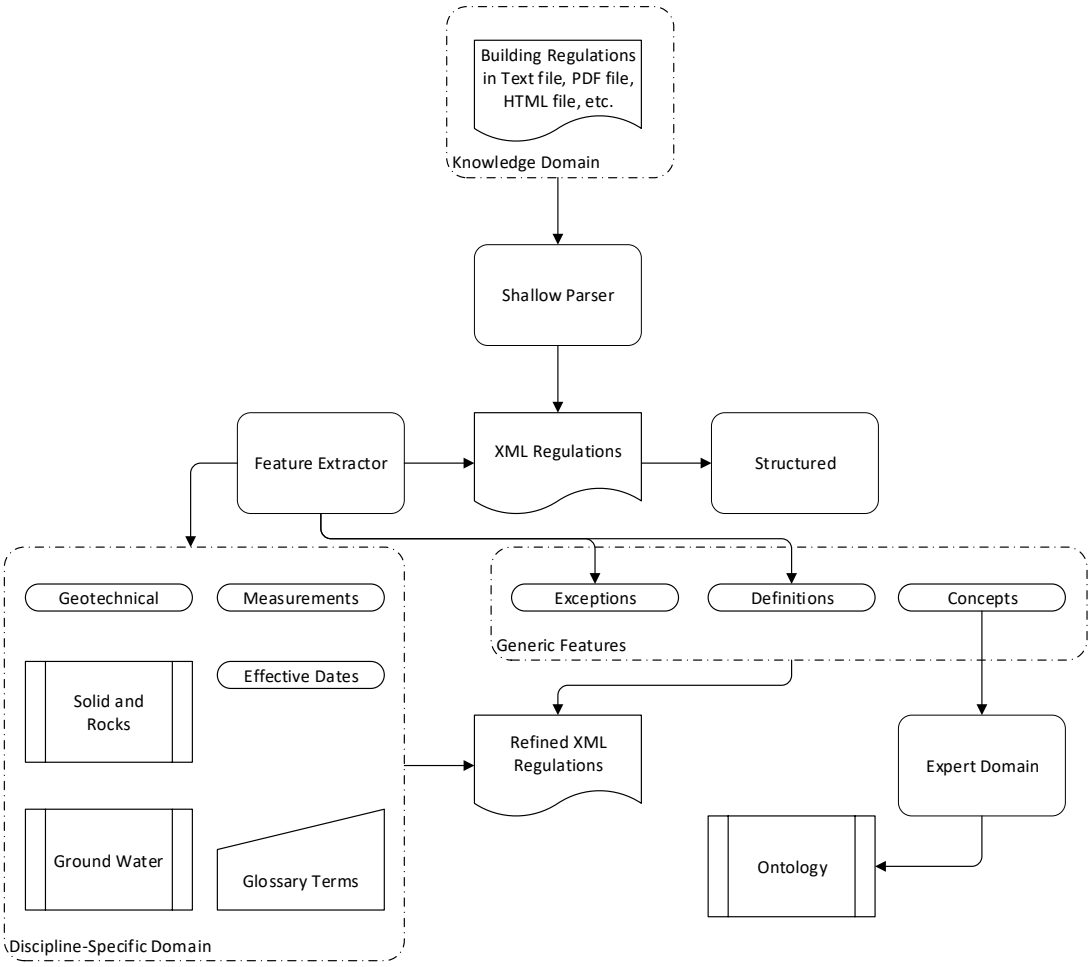

Figure 4: XML representation of a building code (Lau & Law, 2004).

In the study shown in Figure 4, XML Parsing Trees, which mark the contents of building codes with reference tagging, were developed by using the semantic technique, and an example is shown in Figure 5 (Lau & Law, 2004). The hierarchy of XML reference tags in the XML Parsing Trees structure first begins with the regulationID, which marks the building code. Then, elementID is used for the information from the section to the article of the relevant building regulation. Finally, the article is marked with the ID and the text reference tag. An example showing the hierarchy of XML reference tags is seen in Figure 5. In this example, XML Parsing Trees provide users with an easier understanding of building codes through the reference tag of properly extracted building code information.

```

                <regElementid="adaag.4.7" name="Curb Ramps"> ...
                        <regElementid="adaag.4.7.4" name="Surface">
                                <regText> Surfaces of curb ramps shall comply with 4.5. </regText>
                                <referenceid="adaag.4.5" num="1" />
                        </regElement> ...
                </regElement> ...
        </regElement> ...
</regulation>
```

Figure 5: An example of XML parsing trees (Lau & Law, 2004).

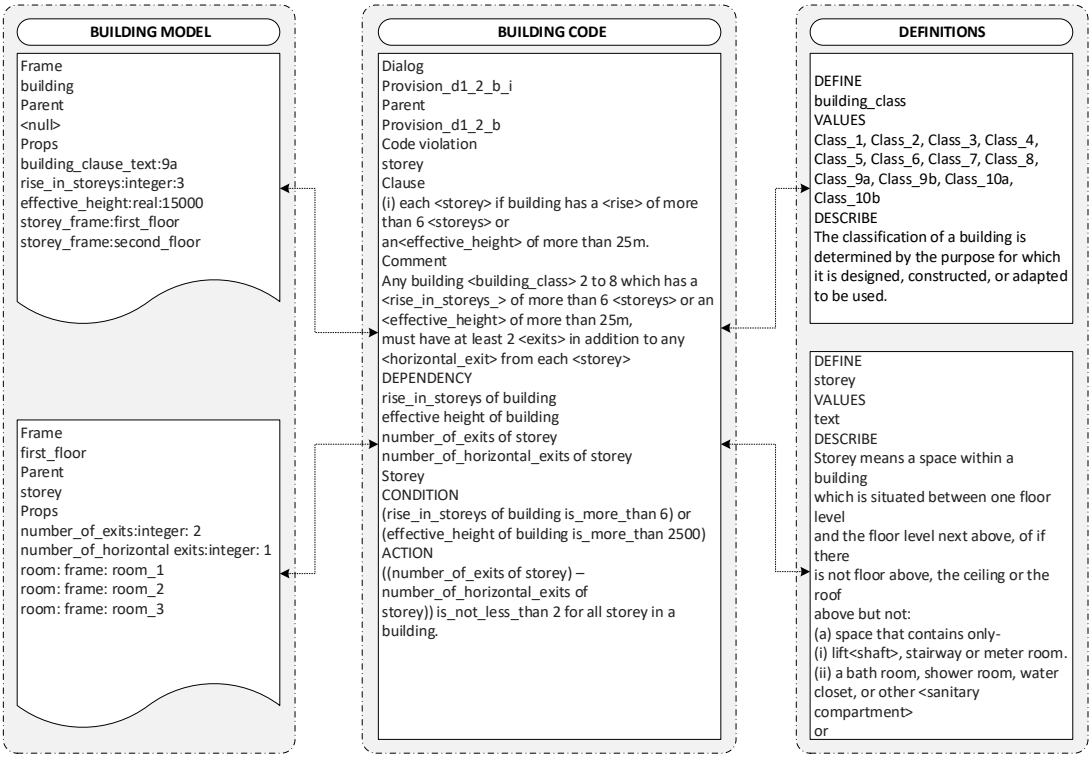

Figure 6: An example diagram of a building code created using DL (Omari & Roy, 1993).

DL (Dialogue Language)

DL (Dialogue Language), which was one of the first studies using markup language for domain knowledge representation of building regulations, was proposed by Omari and Roy in 1993 (Omari & Roy, 1993). DL was developed to interpret the Australian Life Safety Regulations in an expert system. It is used to represent the interactions between users and expert systems as well as the provisions of the regulation. DL provides a framework for the hierarchical organization of building codes, consisting of eight basic items. These items are Dialog ID, Parent ID, Clause, Condition, Code Violation, Action, Comment, and Dependency. DL provides a simple schema structure that allows designers to manage

hierarchical building codes and interactions with building models to create meaningful reports. An example diagram of a building code created using DL is shown in Figure 6.

LegalRuleML

In 2011, the XML-based LegalRuleML standard was proposed by Palmirani et al. for defining and displaying building codes and regulations with rules (Palmirani et al., 2011). The purpose of LegalRuleML is to represent the features of legal building codes and norms in a comprehensive, articulated, and meaningful markup language. For this reason, a customized XML markup language using Semantic Web technology is used within LegalRuleML, which meets the specifications of legal building codes and norms. The LegalRuleML representation of the text in Section 17, Clause 6, Sentence 602b of the US Code regarding copyright infringement is shown in Figure 7. (A) contains the textual expression of the text in the relevant clause, (B) includes the LegalRuleML expression of the relevant text. The LegalRuleML approach has been accepted by many researchers. Researchers have proposed using LegalRuleML modeling languages to express building codes with legal rules (Boer et al., 2008; Lupo et al., 2007; Palmirani et al., 2011; Sartor et al., 2011).

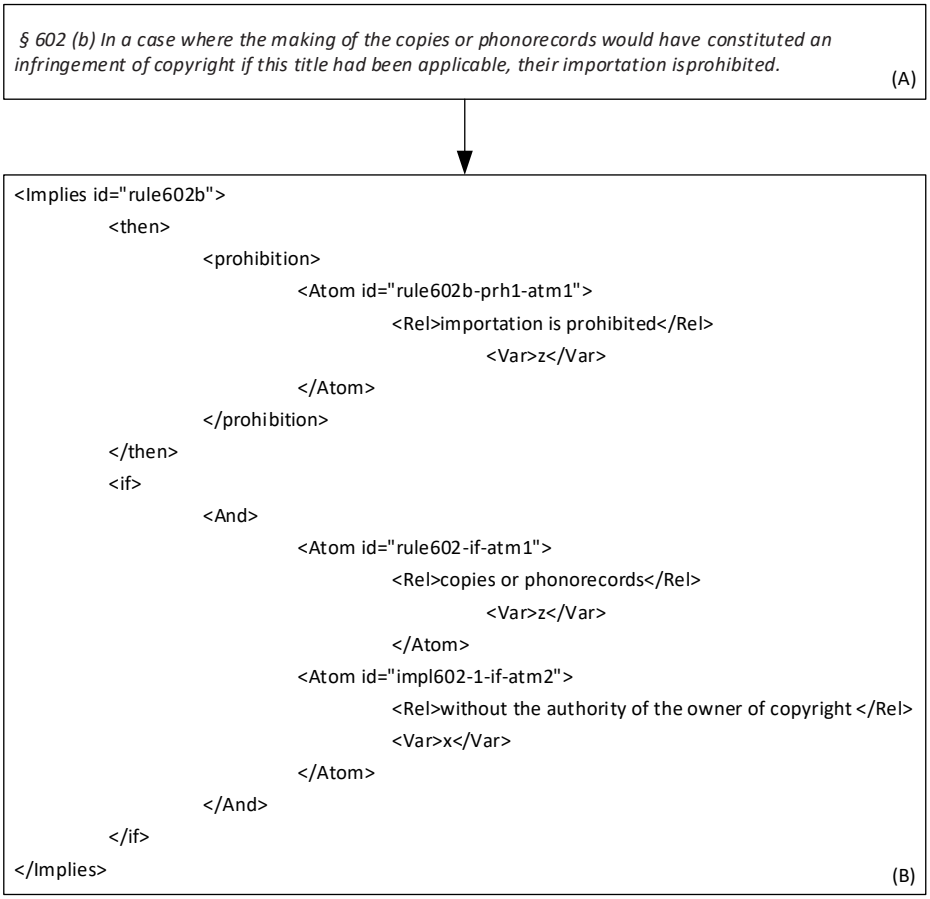

Figure 7: An example of LegalRuleML (Palmirani et al., 2011).

An Automated Italian Markup Language

In 2004, a study was conducted by Baigoli et al. on the automated marking of Italian building regulation texts in XML format (an automated Italian markup language) (Biagioli et al., 2004). In this study, in order to automatically convert the building codes to XML format, first

the content of the regulation is clustered, and then the text of the regulation is tagged. For clustering, the highlighted terms in the building regulation text are captured and transferred into a cluster. These terms are formalized as markup values in the XML representation of the regulation text.

Formal Languages

Many inconsistencies, errors, and abuses occur in the automated building code compliance checking process, which is done manually by humans. Many researchers use ACCC and BIM standardization to solve these problems. It supports the transition to machine-oriented automated processes for more consistent, accurate, and reliable building code compliance checking. The most effective solution to control of building codes is to implement Formal Languages shown in Figure 8, which are capable of creating computer-interpretable building codes.

Binary System

The first computable formal language was Leibniz's Binary System Habilitation Thesis, made by Leibniz in 1666 on automating Aristotle's assumptions (Leibniz, 1923). A sample study of the binary system used by Leibniz in the cover and content of his habilitation thesis is shown in Figure 9. This study was based on the most advanced logic and ontology systems. Reasoning rules based on four sentence order, which relate a subject in Aristotle's assumptions, were created (Nawari, 2012b). The computational probabilities of the four binary systems were analyzed to code these simulations. It is claimed that this system will eventually be utilized to compute logic rules for machine operations.

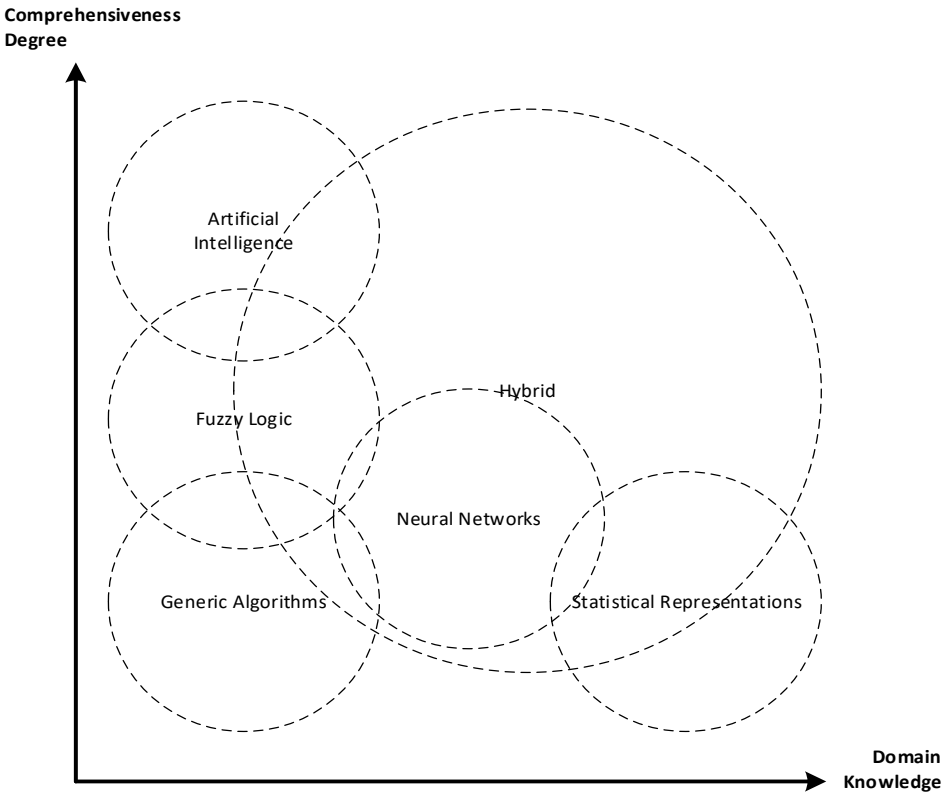

Figure 8: Application areas of formal languages (Nawari & Alsaffar, 2015).

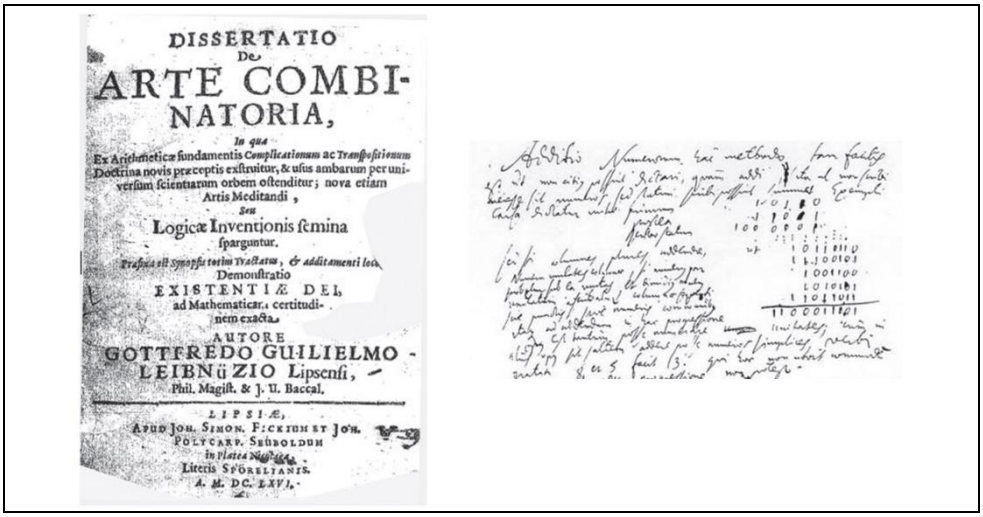

Figure 9: Leibniz's habilitation thesis (Leibniz, 1923).

	Rules Stub	Rules Entry		
Condition	Condition Stub			Condition Entry
	Related space of a door: Entrance	Y	N	N
	Related space of a door: Room	N	N	Y
	Related space of a door: Kitchen	Y	N	N
Action	Action Stub			Action Entry
	Minimum door width: 0.80 m		Y Y Y	Y
	Minimum door width: 0.90 m	Y Y Y	Y	N
	Minimum door width: 1.00 m	Y	N	N N N

Figure 10: An example of a decision table (Fenves, 1966).

Decision Tables

Decision Tables, proposed by Fenves in 1966, were one of the first attempts to represent building codes in a formal language (Fenves, 1966). In this study, building regulation clauses were presented in the form of a definite and clear decision table. Decision tables represent the clauses of the regulation as a set of conditions. The data contains a precise description of the building element information contained in the building regulation clause. The decision table, an example of which is shown in Figure 10, is divided into four parts. The condition stub in the upper left is a list of conditions that have an impact on the result. The condition entry at the top right lists the relevant combinations of conditions in the relevant columns. Each column specifies a clause rule. The lower left part of the decision table lists all the actions to be taken for the condition. The lower right part of the table shows the action entry to be

applied for the condition corresponding to the specified rule. The condition input can have only one of three possible values. Y indicates a true condition, N a false condition, and I an unimportant condition.

In 1969, Fenves, Gaylord, and Goel studied different combinations of decision tables (Fenves et al., 1969). In this study, different combinations of decision tables were created to which the building regulation rules and conditions could be applied. Fenves called this work a new if-then programming technique. He used the clauses of the AISC specification, which include the design criteria for building elements, to represent precisely and clearly with if-then. It has been a practical application in which interrelated decision tables are represented in the AISC specification sample.

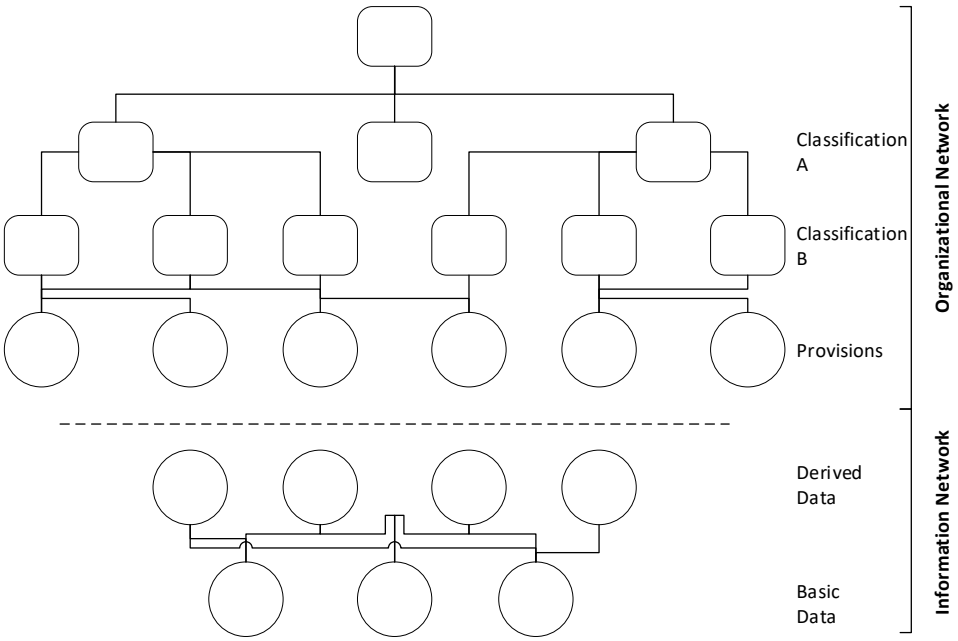

Figure 11: The concept of the SASE formal language (Fenves et al., 1987).

SASE (Standards, Analysis, Synthesis, and Evaluation)

Decision tables can precisely express possible combinations of conditions and actions of building regulation clauses in formal language. However, decision tables cannot respond to the general organization of the building code and the relations between the building regulation clauses. In 1987, the SASE (Standards, Analysis, Synthesis, and Evaluation) formal language was developed by Fenves et al. to represent building codes more broadly (Fenves et al., 1987). The concept of SASE was developed on the basis of the abstract model of the logical structure of building codes developed by Nyman et al. in 1973 (Nyman et al., 1973). Figure 11 shows the concept of the SASE formal language. SASE has four levels of layout to represent individual clauses, relationships between clauses, and building regulation layout. These are:

- The top level represents the outline and organization of building regulations.
- The intermediate level represents the compliance relationship between building regulation clauses.
- The detailed level represents building regulation clauses in the form of decision tables.
- The lowest level represents the basic data specified in building regulation clauses.

In SASE, data is divided into basic data and derived data. Each clause in the building regulations is represented by a decision table. The condition value of each decision table is limited to Y, N, and I. The information network is used to represent precedence relationships among building code data. The information network consists of networks, nodes, and branches. The SASE formal language enables the dynamic classification of building codes based on users' needs.

RFL (Rule-based Formal Language)

Many researchers have applied RFL (Rule-based Formal Language) in their studies to transform building regulations into rules (Dym et al., 1988; Kumar, 1989; Rasdorf & Wang, 1988; Rosenman & Gero, 1985). In the RFL, building regulation clauses are represented as a set of rules in the form of IF (condition) THEN (action) statements rather than decision tables. The IF statement defines the applicability conditions that the rule must meet. The THEN statement describes the actions to be taken. The RFL is considered to be more impressive than other building regulation representation approaches. The main advantage of this approach, which accepts the building regulations as a rule, is the ease of implementation in automated code compliance checking (ACCC) systems. However, as a result of rule-based modeling of building regulations, the problem of managing a large number of rules may arise. Some building regulation clauses may need to be represented by more than one rule. In addition, the user is expected to have expert programming or coding knowledge to create the IF and THEN relationships of the rules in the RFL. Although the rules representing the building regulation clauses are coded via computer, the relevant rules must also be revised due to the updates in the building code.

Figure 12 shows an example of an RFL rule created with the IF and THEN relationship for doors. In the example, three rules were created. Rule definitions are as follows (Hakim & Garrett, 1993):

- Rule 1: IF; If the door is an entrance door,
  THEN; The width of the door should be 1.00 meters.
- Rule 2: IF; If the door is a room or kitchen door,
  THEN; The width of the door should be 0.90 meters.
- Rule 3: IF; If the door is a cellar, wc or bathroom door,
  THEN; The width of the door should be 0.80 meters.

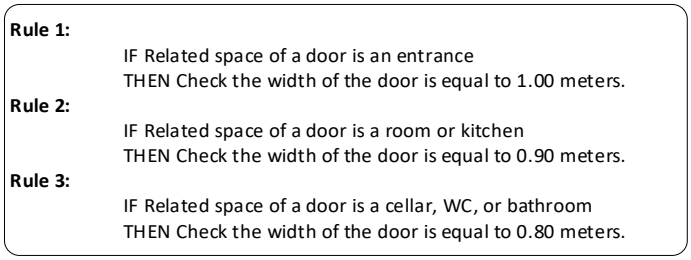

Figure 12: An example of the RFL rule created with IF and THEN relationship for doors (Hakim & Garrett, 1993).

OFL (Object-based Formal Language)

Building regulations contain many types of data in terms of scope. In particular, the building regulation clauses that include the definitions, properties, and conditions of different building elements lead to the definition of complex data types, which are numerous. To solve this problem, OFL (Object-based Formal Language) was proposed by Garrett and Hakim in 1992, which allows easy organization of building codes according to building elements. The OFL shown in Figure 13 consists of four basic object groups. These are (Garrett Jr & Hakim, 1992):

- The design object hierarchy represents subclass relationships between objects in the building code. Objects define design-specific properties and hierarchies such as shape, function, and material.
- The performance limitation hierarchy represents the boundaries of objects in the building code.
- The data item hierarchy represents the data types in all building codes.
- The data item instance network represents instances of the data types in a building code.

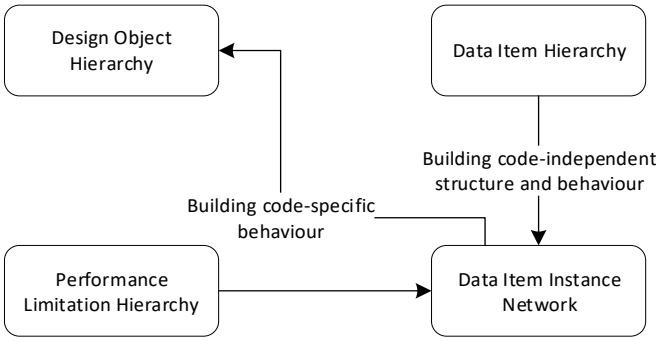

Figure 13: The four basic object groups of the OFL (Garrett Jr & Hakim, 1992).

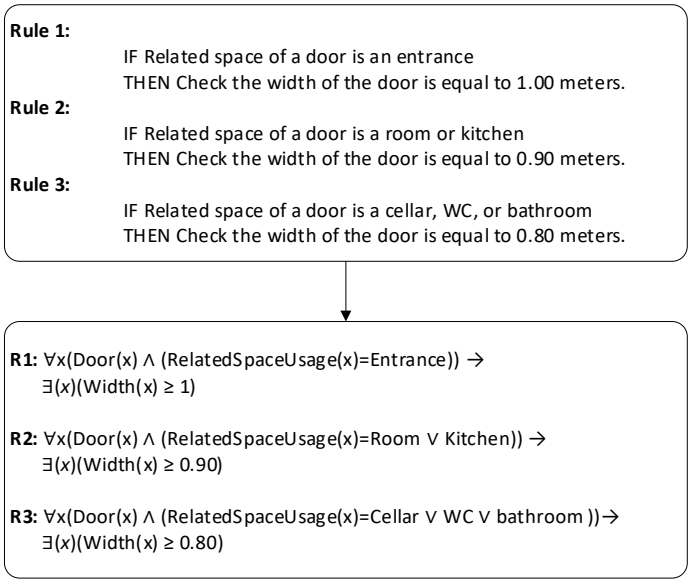

Figure 14: An example of the LFL rule created with predicate logic for doors (Hakim & Garrett, 1993).

LFL (Logic-based Formal Language)

LFL (Logic-based Formal Language), which is preferred in the CORENET e-PlanCheck system, is used to transform building regulations from human language to a more precise, clear, and understandable formal language (CORENET, 2018). During the logic-based interpretation procedure, there are assumptions and expectations that provide an understanding of what needs to be examined. In a study by Hakim and Garrett in 1993, it was emphasized that users should have knowledge of logic and logical predictions in order to understand the system of the LFL (Hakim & Garrett, 1993).

The LFL adopts predicate logic to represent building regulation clauses. Predicate logic provides a formal, well-known, and systematic knowledge representation language for the expressions in well-formed formulas. In Figure 12, the representation of the RFL rules created with the IF and THEN relationship for the doors in the predicate logic is shown in Figure 14. The applicability building element conditions of the rules denoted by the abbreviation R in this example are indicated to the left side of the arrow. The numerical conditions that the building element must meet are indicated on the right side of the arrow, and these are coded with this logic. The rule definitions are as follows (Hakim & Garrett, 1993):

- R1: $\forall x(\text{Door}(x) \wedge (\text{RelatedSpaceUsage}(x)=\text{Entrance}))\rightarrow\exists(x)(\text{Width}(x) \geq 1)$
- R2: $\forall x(\text{Door}(x) \wedge (\text{RelatedSpaceUsage}(x)=\text{Room} \vee \text{Kitchen}))\rightarrow\exists(x)(\text{Width}(x) \geq 0.90)$
- R3: $\forall x(\text{Door}(x) \wedge (\text{RelatedSpaceUsage}(x)=\text{Cellar} \vee \text{WC} \vee \text{bathroom}))\rightarrow \exists(x)(\text{Width}(x) \geq 0.80)$

FOL (First-Order Logic)

In 2012, FOL (First-Order Logic) was proposed by Nawari to code building regulation clauses via computer (Nawari, 2012a). The FOL transforms the written texts into a set of rules by extracting information from the building regulations. But this requires manual effort and technical knowledge. The FOL is built with terms, relations, and functions that describe the building objects. The FOL has two basic mechanisms: syntax and semantics (Nawari, 2012b). The syntax identifies terms with symbols. On the other hand, the semantics controls the meaning of these terms. The FLO is effectively used in building regulation clauses. The conditions are usually described in a sentence. This sentence is separated into its subject (S), predicate (P), and object (O). It is translated into the FLO, which is defined as S+P+O.

RASE (Rrequirement, Application, Selection, and Exception)

A RASE formal language has been proposed by Hjelseth and Nisbet, which directly translates building regulation requirements into building codes using four semantic markup operators (Hjelseth & Nisbet, 2010b, 2011). The RASE is considered a good starting point for generating updatable numerical representations of building codes. In this language, rule sentences are divided into sub-expressions. These sentences are defined in a common structure. In addition, the RASE provides an order that does not require programming knowledge for the creation and updating of building regulation representations (Macit & Günaydin, 2015). The RASE has the potential to be fully applied to building codes as a successful or unsuccessful output. However, it has limitations with cross-references in building regulation clauses and deep hierarchies between clause texts. In the RASE, the formal rules need to be defined manually by AEC experts. The RASE is designed on four operators. These are:

- R (Requirement),
- A (Application),
- S (Selection),
- E (Exception).

R, A, S, and E structures consist of topic, property, comparator and target value (Hjelseth & Nisbet, 2011). The topic and the property are derived from the objects described in the building regulation clause and the restricted properties of the objects. The comparator includes mathematical expressions such as greater, less, equal, not equal, and etc. The target value can consist of numerical or verbal values. Mathematical expressions are easy to apply if the target value contains a numeric value. If it contains a verbal value or object set, comparison expressions are used such as including, not including, excluding, and so on. The RASE formal rules are linked to the IFC sub-scheme. This sub-schema is initialized as an object that qualifies as a regulatory constraint. Figure 15 shows an example of a RASE formal rule of the ICC IECC 2006 moisture control regulation.

Code Clause Source	ICC IECC 2006 502.5 Moisture control
Rule Description	All {A/} framed {\A}{S/} walls, floors {\S}, and {S/} ceilings {\S} {E/} not ventilated {\E} to allow moisture to escape shall be provided with an {R/} approved vapor retarder {\R} having {R/} a permanence rating of 1 perm {\R} (5.7 × 10 –11 kg/Pa s m2) or less, when tested in accordance with the desiccant method using Procedure A of ASTM E 96. The vapor retarder shall be {R/} installed on the warm-in-winter side {\R} of the insulation. Exceptions: {E/} Buildings located in Climate Zones 1 through 3 {\E}. In constructions where {E/} moisture {\E} or its {E/} freezing {\E} will not damage the materials. Where there are other approved means to avoid {E/} condensation {\E} in unventilated framed wall, floor, roof, and ceiling cavities.

Figure 15: An example of a RASE formal rule of the ICC IECC 2006 moisture control regulation (Hjelseth & Nisbet, 2010b, 2011).

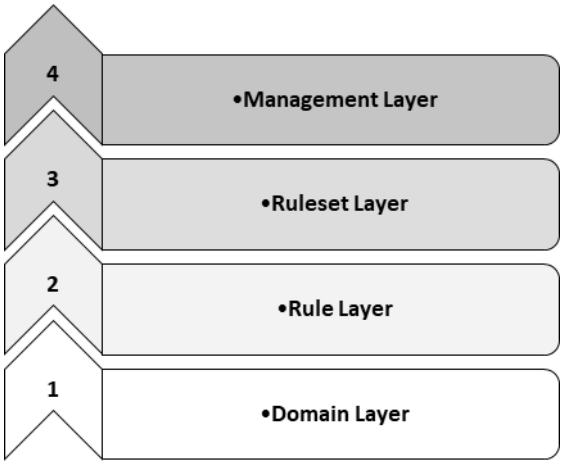

Figure 16: The four-layer structure of the RASE-based model (Macit İlal & Günaydın, 2017).

Another study focusing on the RASE was prepared by İlal and Günaydın in 2017. In this study, a new domain knowledge representation model was proposed in order to represent building regulations in a digital environment. A pilot study was conducted to evaluate the applicability of the RASE formal language in creating numerical representations of building

regulations. Within the scope of this pilot study, the rule statements of the Izmir Metropolitan Municipality Zoning Regulation regarding residential buildings were modeled as rule objects consisting of Requirement (R), Applicability (A), Selection (S), and Exception (E) operators. The RASE was taken as a reference in the new domain knowledge representation model. But it was rearranged with a four-layer modeling approach. A systematic structure consisting of four layers is shown for the new model in Figure 16. These are (Macit İlal & Günaydın, 2017):

- The domain layer defines the terms (concepts, objects, etc.) in the building regulation text.
- The rule layer represents the rule sentences in the building regulation text as rule objects.
- The ruleset layer creates rule sets by defining the relationships between rule objects modeled in the rule layer.
- The management layer represents the overall organization of the building regulation by classifying the rulesets.

Semantic Web Languages

Semantic Web means that web contents can be expressed not only in natural languages, but also in a way that can be understood, interpreted and used by related software. It is an evolving internet add-on that aims to enable this software to easily find, share, and consolidate information (Walton, 2007). Contextual information is added to existing unstructured information on the internet with the semantic web approach. This approach to web markup is a key concept underlying effective web coding, computing, universal usability, search engine visibility, and maximum screen visibility.

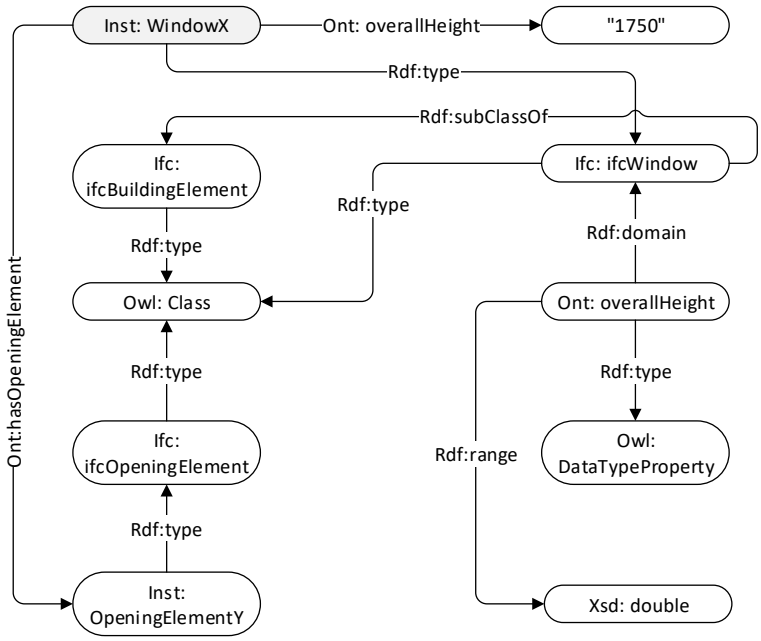

Figure 17: A semantic web language representation of the window building element (Pauwels et al., 2011).

SWL (Semantic Web Language)

One of the earliest studies applied to automated building code compliance checking of SWL (Semantic Web Language) was carried out by Pauwels et al. in 2011 (Pauwels et al., 2011). In this study, it was stated that IFC has limitations such as a limited range of explanation, difficulties in segmenting information, and the possibility of explaining the same information in different ways. This study aimed to provide compliance checking of BIM models according to the building acoustic regulation. The aim of the study was based on the SWL. The SWL defined concepts through a directed, labeled graphic.

In the graph shown in Figure 17, each node represents a concept (or an object), and each arrow represents the logical relationship between these two concepts. Two nodes and an arrow symbolize a sentence in this graph. A combination of logical sentences is created with two nodes and an arrow. Then, the logic of the combination is defined graphically. The SWL has the ability to define rules using logic-based rule language. However, a logic-based approach should be made possible for the implementation of the SWL in the rule-control environment (Pauwels et al., 2011).

RDF-s (Resource Description Framework)

The semantic web is based on XML's ability to define customized labeling schemes and RDF's (Resource Description Framework) flexible approach to representing data. The RDF is defined as a data model for objects and relationships between objects. It also has a graphical representation. An RDF chart is created using a set of logical operators containing objects and their relationships. These expressions, which contain a subject, a predicate, and an object, are called RDF triple. An example RDF triple is shown in Figure 18. Whether each concept described in an RDF chart is an object, subject, or predicate is identified via the URI.

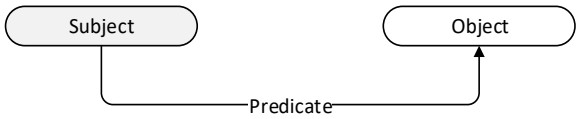

Figure 18: An example of an RDF triple.

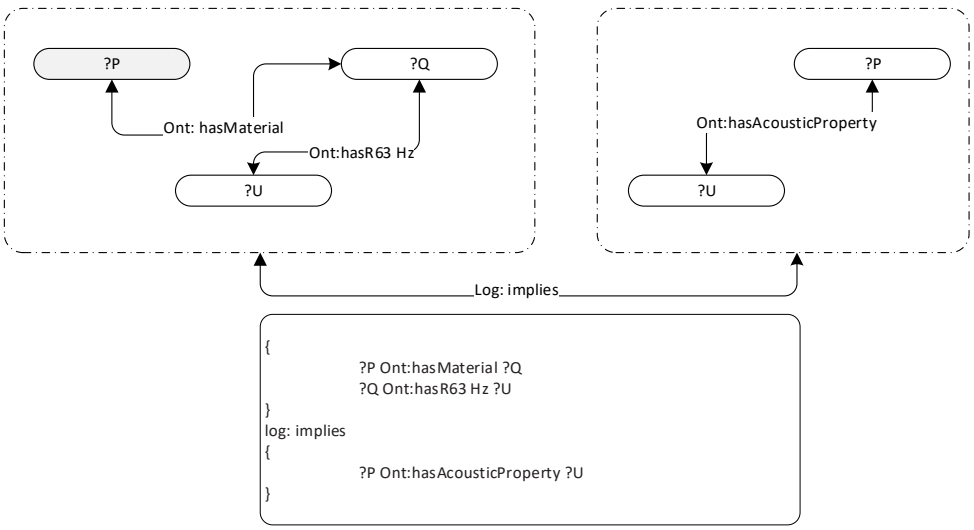

Figure 19: A representation of the N3- Logic rule (Pauwels et al., 2011).

A semantic structure developed using an ontology can be created in the SWL. The RDF-s (RDF words) are used to describe this ontology (Brickley et al., 2014). The RDF-s allows defining classes, subclasses, comments, and data types. For example, the ifc:IfcBuildingElement class, shown in the SWL in Figure 17, is a subclass of the ifc:IfcWindow class. In addition, Pauwels et al. used N3-Logic to define specific rules for the EN1235 Building Acoustic Performance Regulation (Pauwels et al., 2011). A rule in N3-Logic covers hypothetical formulas in general. The hypothetical formula uses brackets in the syntax to identify a subtitle; in other words, it represents a logical combination of expressions between brackets as shown in Figure 20 (Berners-Lee et al., 2008).

If the rule of an RDF triple expression indicates that one hypothetical formula (IF) is true, it means that the other hypothetical formula (THEN) is also true. Moreover, an N3-Logic rule is optimally abbreviated by using the URIs of the concepts. An example of the N3-Logic rule is shown in Figure 19 (Pauwels et al., 2011). This rule requires that a concept have the Ont:hasMaterial (IF) attribute. If it meets this condition, it is required to have the Ont:hasR63Hz (AND) attribute. After satisfying both conditions (THEN), it is understood that the Ont:hasAcousticProperty attribute of that concept has the same URI as the Ont:hasR63Hz attribute.

```
{
        ?BE     rdf:type EN12354:BoundaryElement.
        ?BE     EN12354:elementSurfaceArea ?a.
        ?BE     EN12354:partOfRoomBoundary ?RB.
        ?RB     rdf:type EN12354:RoomBoundary.
        ?RB     EN12354:facadeSurfaceArea ?atot.
        ?BE     EN12354:soundReductionIndex_4000Hz ?R_4000.
        ?a      math:notLess?Than 1.
        (?a ?atot) math:quotient ?value_i.
        (?R_4000 -10) math:quotient ?value_j.
        (10 ?value_j) math:exponentiation ?value_k.
        (?value_i ?value_k) math:product ?value_l
}
log:implies
{
        ?BE     EN12354:directSoundPowerRatio_4000Hz ?value_l
}
```

Figure 20: A rule representation of the EN12354-3:2000 ruleset (Berners-Lee et al., 2008).

inst:WindowX	rdf:type	ifc:IfcWindow.

ifc:IfcWindow r	dfs:subClassOf	ifc:IfcBuildingElement
ifc:IfcBuildingElement	rdf:type	owl:Class
ont:overallHeight	rdf:type	owl:DatatypeProperty
ont:overallHeight	rdfs:domain	ifc:IfcWindow.
ont:overallHeight	rdfs:range	xsd:double

Figure 21: An OWL ontology representation that specifies the IfcWindow class (Zhang & Issa, 2011).

OWL (Web Ontology Language)

Another important language associated with the semantic web approach is the OWL (Web Ontology Language), which enables applications to be used to process the content of information rather than simply presenting it to people (Zhang & Issa, 2011). The OWL facilitates further interpretability of web content by providing additional words along with the XML and the RDF. An ontology is represented as a set of concepts within a domain and a description of the relationships between concepts. It works like an encyclopedia for computers. It connects heterogeneous metadata information, explains all definitions, and lists all synonyms. Thus, it creates a global structure for the data on the web, allowing the data to be understood and shared by more than one application (Zhang & Issa, 2011).

The definitions, explanations, and abbreviations of the ifc properties of the window building element belonging to the ifc:IfcWindow class shown in the semantic web language in Figure 17 are shown in Figure 21. In the example of the OWL representation, the top class is defined with inst. A subclass of owl is created that depends on the top inst class. Ifc is associated with the ifcWindow property of the window, rdf is associated with the type of the window, and ont is associated with the properties of the window.

SWRL (Semantic Web Rule Language)

SWRL (Semantic Web Rule Language) has been defined as a language that combines the OWL and the RuleML (Rule Markup Language) recommended for the semantic web (Boley, 2006). The SWLR was proposed in 2004 by the Rule Markup Initiative, whose members are in industry and academia (Horrocks et al., 2004). The SWLR has a modular and a hierarchical layout for different rule types. The RuleML is an open and independent markup language developed for expressing web rules and performing rule transformations in XML. It cooperates with many software systems by enabling the exchange of rules on the web. The RuleM, shown in **Figure 22,** has a three-layer rule hierarchy. The first layer of the RuleML contains reaction rules. The second layer consists of integrity constraint rules and derivation rules. The third layer customizes the derivation rules according to the facts.

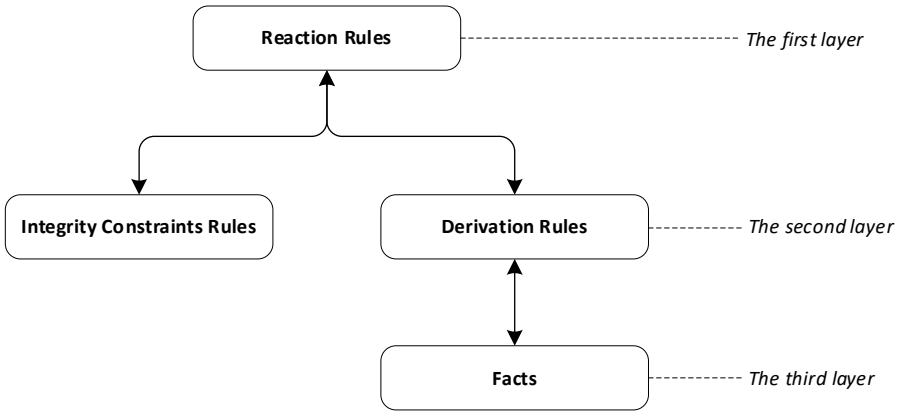

Figure 22: A three-layer rule hierarchy of the RuleML (Horrocks et al., 2004).

BERA (Building Environment Rule and Analysis)

With the expansion of the BIM domain, there has been a need for the development of domain-specific, customized semantic web languages to address the problems of building models in

the construction industry. In 2011, the domain-specific BERA (Building Environment Rule and Analysis) language was designed by J. K. Lee, and it was applied in building restoration works (Lee, 2011). The BERA handles BIM models to define and analyze rules at the design stage. The implementation of the BERA consists of three stages. These stages are defining rules, analyzing rules, and controlling rules.

The BERA allows ad-hoc connection of BIM models owned and operated by various stakeholders in a building project in the context of automated code compliance checking. It can be used as a starting point for the inclusion of software services that enable the conclusion of special operations such as performance calculations, quantity take-offs, spatial programming, energy analysis, and cost estimation. The target users of the BERA are BIM-based software developers, architects, designers, engineers, experts, managers, and students.

The BERA, the concept of which is shown in Figure 23, focuses on two main areas: building circulation and spatial programming. The BERA transforms BIM models into the BOM (BERA Object Model) with its own BERA tools to achieve both purposes. The BOM is a human-centered abstraction of computational building models. Users can easily access BIM data with the BOM. The BOM also has expandable potential. The objects presented in the BOM are not limited to building elements. The derived properties of building circulation, such as type, depth, metric distance, area, volume, walking distance, and number of spaces, are obtained with the BOM.

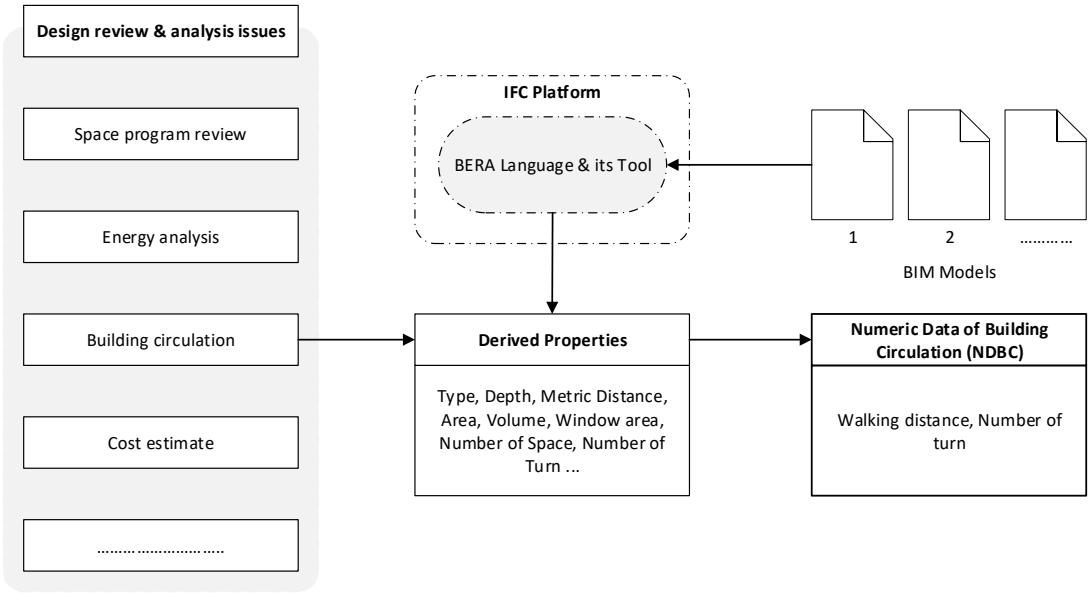

Figure 23: The concept of the BERA (Lee, 2011).

BIMQL (BIM Query Language)

BIMQL (BIM Query Language), a domain-specific, open BIM-based semantic query language for BIM models, was proposed by Mazairac and Beetz in 2013 (Mazairac & Beetz, 2013). The BIMQL is designed to select, update, and delete data stored in the IFC data models. Because the objects contained in the IFC data are often interconnected through a complex web of relationships, the BIMQL enables the IFC data models to simplify these interconnected accesses. The BIMQL is a prototype plugin for the open-source model server platform, bimserver.org.

The structure of the BIMQL consists of three parts. The first part provides an introduction to the problem of information extraction from complex models. It formulates requirements for a query language. In the second part, open problems are identified by reviewing studies at both general and domain-specific levels. In the third part, the query language is designed and applied to the examples. The Backus-Naur Form describing the syntax and grammar of the domain-specific query language BIMQL is shown in Figure 24. The language features of the implemented specification are currently limited to the "select" and "set" sections. For example, deleting a single window in the BIMQL can be accomplished by performing a simple query. The profiles and material properties of the window can also be obtained by query.

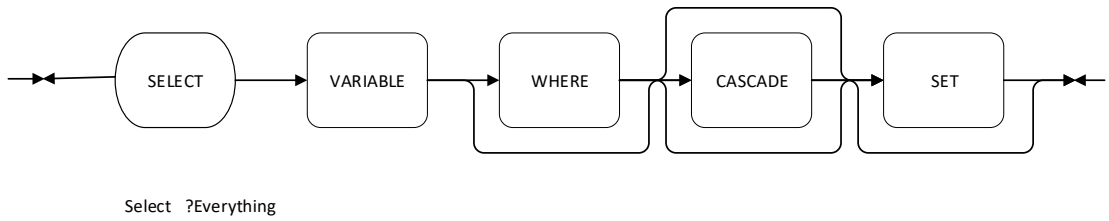

Figure 24: An example of the BIMQL (Mazairac & Beetz, 2013).

```
(?X, type, 21-century-student) ←
(?X, takes, ?C):[?T], (?C, type, Master) : [?T], 2000 ≤?T, ?T ≤ Now.
```

Figure 25: An example of the RDF-QL (Gutierrez et al., 2005).

RDF-QL (RDF Query Language)

RDF is the basic building block of the semantic web. It provides configuration of many queries. Thus, it effectively connects information from different sources (Cyganiak, 2005). The RDF-QL (RDF Query Language), an ad-hoc query language, was suggested for accessing the RDF graphics in a study by Gutierrez et al. published in 2005 (Gutierrez et al., 2005). In this study, temporal RDF graphics were presented by including temporal reasoning in the RDF. To access the RDF graphics, the user can access the desired graphic data using the RDF-QL. Figure 25 shows the RDF-QL format of a sample query: "Find the students who took master's courses between 2000 and the current year and copy these students to the 21st century group-student". In this example query, the group to which the students will be copied is selected before the arrow. After the arrow, the characteristics of the copied students are indicated. If desired by the user, the RDF graphics of temporary queries can be brought along.

Artificial Intelligence Methods

The purpose of Artificial Intelligence Methods is to simulate human intelligence, knowledge, and perception. This simulation is generally focused on two key areas:

- The first area is related to learning styles from a particular data set.
- The second area is focused on succinct explanation and reuse of people's acquired knowledge.

The Neuron-based AI Method

The first biologically inspired Neuron-based AI Method was proposed by Frank Rosenblatt in 1958 in his work simulating the behavior of brain cells (Rosenblatt, 1958). Another study was published as an article by Minsky and Papert in 1970 (Minsky & Papert, 1970). This work is based on the principle that a neuron produces an output with more than one input. This study, which draws the boundaries of the Neuron-based AI Method, remains up to date.

The Rule-based AI Method

The Rule-based AI Method has been a significant research area for many years. In 1986, Rumelhart et al. published a book examining neuronal networks that found the solution to the problem emerging in AI on their own (Rumelhart et al., 1986). In this study, it has been shown that neuron networks can self-learn a certain value, optional and infinity function, and produce solutions.

Conventional AI Methods

Most of the Conventional AI Methods are based on the Neuron-based AI Method work of Minsky and Papert (Minsky & Papert, 1970). In this study, knowledge is defined as a mixture of facts and rules. The facts consist of data items and value pairs. The rules allow new facts to be extracted from within the system. If a data item changes, everything in the system is potentially changed. The Rete algorithm is used for all changes. After the change, all rules and facts are renewed and added to the system. In the event of any change, the system repeats itself constantly.

AI Methods of Modeling Human Languages

Various NLP algorithms are used to extract meaning from natural language texts in the AI Methods of Modeling Human Languages. The NLP algorithms focus on human-computer interaction, allowing computers to extract meaning from building regulation texts and create logic rules. The probability distribution of the semantic expressions extracted in the study by Brown et al. was called an n-gram model in 1992 (Brown et al., 1992). The N-gram model specifies interconnected words as a single term. It estimates the probability of two words forming a term.

The NLP Method Focused on Text Classification and Categorization

An NLP Method Focused on Text Classification and Categorization focuses on the syntactic and semantic features of texts. In this method, text analysis, content source creation, automatic classification for ACCC, and text mining processes are applied. The entity concept is used for the output of the text analysis process. Each entity is classified as building elements such as floors, beams, columns, walls, windows, doors, etc. These classes are named, ordered, labeled, and categorized, and a sensitivity score is assigned to each class (Nawari & Alsaffar, 2015).

Domain-Specific Ontology Generating Methods

Domain-Specific Ontology Generating Methods focus on an ontology creation logic that captures the knowledge of domain-specific content with the NLP algorithms and ensures the

interpretability and intelligibility of the content. Domain-specific ontologies and semantics are used together to achieve the redundancy and complexity of building regulations. Certain rules have been extracted from building regulations using the NLP algorithms. An intermediate stage is used before the rule extraction. This stage results in a triple semantic element in the form of a subject, attribute, and value (Zhang & El-Gohary, 2017).

Preprocessing, feature generation, analysis of the extracted information, rule extraction, and coding implementation stages are performed to create a domain-specific ontology (Melzner et al., 2013). The created ontology is expected to be electronically accessible, computer-readable, represented in a standard format, interoperable, clear, and transparent (Nawari & Alsaffar, 2015). Therefore, domain-specific ontologies should be implemented with the help of consultants and professionals in building regulations.

Hybrid Methods

Hybrid methods are created by combining several building regulation representation approaches. The hybrid methods obtained from the studies are mentioned in the following headings.

The Context-oriented Object Method

In 1994, the Context-oriented Object Method was proposed by Kiliccote et al. (Kiliccote et al., 1994). This method organizes building regulations around contexts and reduces the complexity of the class hierarchies using the object-oriented approach. Context refers to all of the subclasses in the classification hierarchy to which the building regulation clauses are related. Although the contexts are used to describe the conditional parts of the applied clauses, they are insufficient to represent the applicability concepts of building regulation clauses.

```
define Concept {
        name = "Room";
};
define Concept {
        name = "Door";
};
```

```
define Classification {
        name = "Space";
};
define Concept {
        name = "Entrance";
is_a = Space;
}
define Concept {
        name = "Room";
is_a = Space;
}
define Concept {
        name = "Kitchen";
is_a = Space;
}
define Concept {
        name = "Bathroom";
is_a = Space;
}
```

```
define Relation {
        name = "related_space";
        domain = Door;
        range = Space;
}
```

```
define Instance {
        name = "kitchenDoor";
        instance_of = "Door";
        related_space = "Kitchen";
}
```

Figure 26: The four basic objects used in the SPF-CL (Kiliccote & Garrett Jr, 1998).

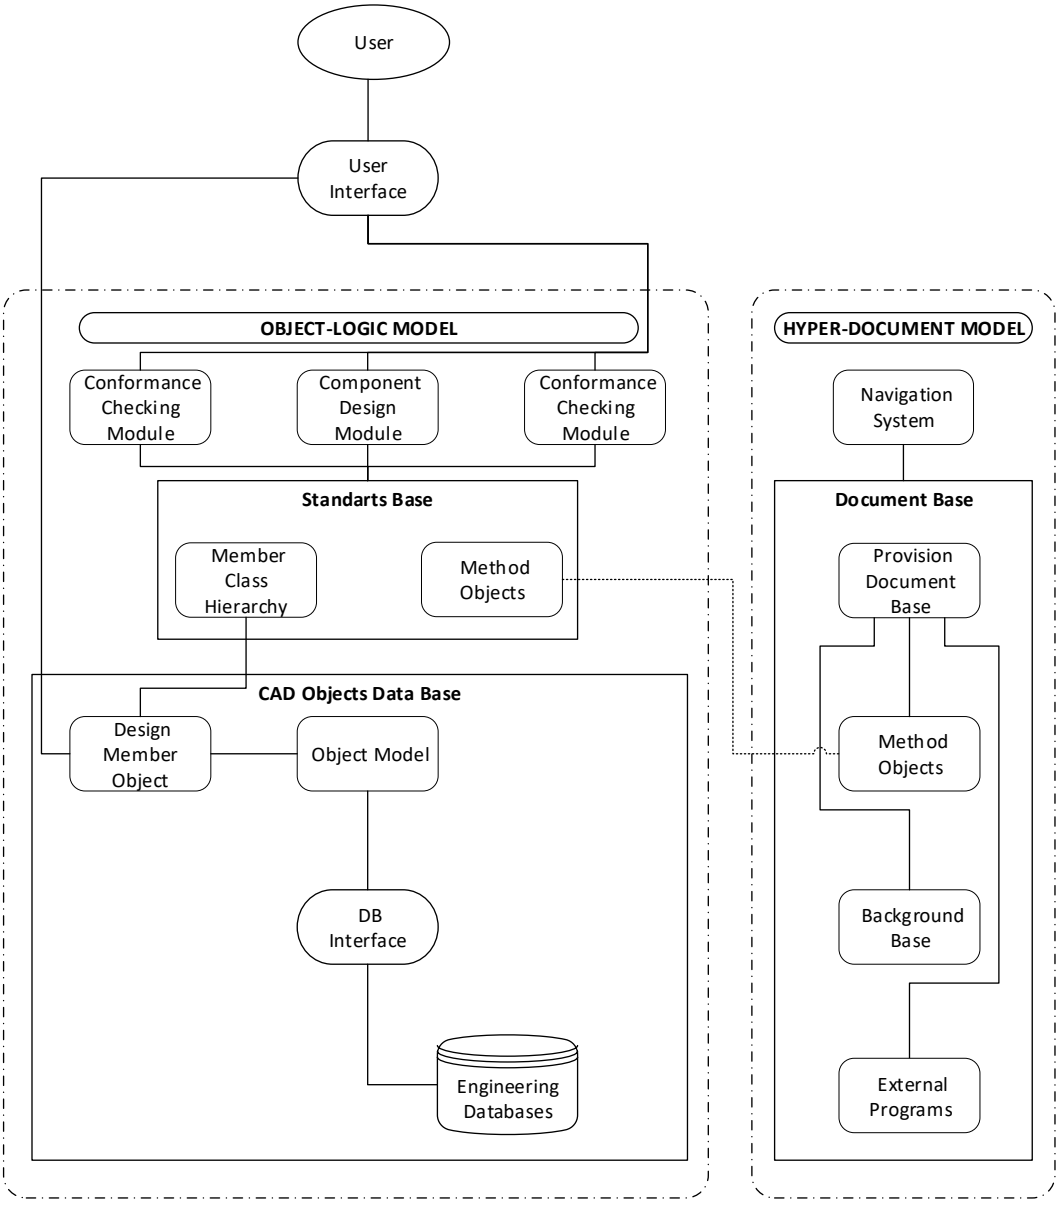

Figure 27: The structure of the object & logic-based method (Yabuki & Law, 1993).

Because of this lack, the SPF (Standards Processing Framework) was proposed by Kiliccote and Garrett in 1998 to represent building regulations, focusing on the Context-oriented Object Method (Kiliccote & Garrett Jr, 1998). SPF-Agents are independent entities that communicate through messages expressed in a common language. The SPF-CL (SPF Communication Language) was developed to allow interaction between various SPF-Agents. The SPF-CL consists of three languages. These are the ADL, the SML, and the SUL. As seen in Figure 26, the SPF-CL needs four basic objects to represent building regulations. These are:

- Concepts used to represent building elements such as a building, a room, a door, and so on.,
- Classifications that differ from each other,
- Relationships that define the relationship between a concept and another concept,
- Examples that represent assets that exist physically or conceptually.

The Object & Logic-Based Method

In 1993, the Object & Logic-based Method was proposed by Yabuki and Law, which combines object and logic-based approaches to represent building regulations (Yabuki & Law, 1993). The proposed method allows for formal procedures to be developed to check the integrity of the building regulations and to reduce conflicts between building regulation clauses. The Object Logic Method shown in Figure 27 consists of two sub-models. These are the object logic model and the hyper-document model. These two models integrate objects from building regulation clauses. The hyper-document model functions as a document store for generating building regulation clauses. It contains building code information, external programs, and objects. In the object logic model, building regulation clauses are stored in a standard database as object logic statements. The properties of this model are taken from the CAD object database.

The Ontology-Based Semantic Method

Some researchers have suggested using the Ontology-based Semantic Method, which combines the usage of ontology and semantic web formal language, to transfer building regulations to the computer environment. It was applied in the 2009 study by Yurchyshyna and Zarli to extract information from building regulation texts and match semantics with industry-specific ontologies (Yurchyshyna & Zarli, 2009).

Conclusion

Aristotle's assumptions historically show how intelligent categorization and verification systems developed 2000 years ago. In order to automate Aristotle's assumptions, Leibniz created the first computable binary system in 1666. Since 1950, a number of formal languages have been suggested for studying building regulations written in human language. These weren't enough to cover all of the building regulations, even if they were useful for processing and interpreting some areas of knowledge of the building regulations. Markup languages are required to address this issue by converting building regulations into logically applicable expressions that make them easier to understand in computer language. Markup languages serve as an intermediate format for data exchange between different systems that is simple for both people and computers to understand.

Today, in addition to human language, many building regulations are represented in computational markup language. Studies on domain knowledge representations of building regulations have emerged with the advancement of computer technology. Semantic languages that enable the contents of building regulations to be understandable, interpretable, and usable not only in human language but also by software have been proposed in light of the importance of the internet in computer language. These make it possible for software to easily find, share, and consolidate building regulation data. In addition to semantic languages, the concept of AI, which focuses on human intelligence, has begun to be used in the computable representation of building regulations. Many studies have focused on expert AI methods to easily translate and code building regulation clauses. Research is still being performed today on the automated or semi-automated extraction of information from building regulation clauses, its translation into a rule, and its implementation using AI methods. However, the manual update of building regulations in human language hinders the implementation of AI

methods. Therefore, the researchers propose hybrid methods, in which a variety of languages are combined and used as a combination.

As a result, efforts are underway to create a computable representation of the current building regulations and standards. In order to represent building regulations and standards in the AEC industry in a way that can be effectively calculated, researchers are looking for a more long-lasting answer. Various national and international ACCC systems are being created in the AEC industry as a result of BIM, allowing automated or semi-automated compliance checking with building regulations and standards.

Abstract

Construction project management literature is replete with numerous research studies on managing disruptive events during the life cycle of a project to avert failure. The conventional strategies to deal with disruption focus mainly on predicting all possible threats and managing them to reduce vulnerability. Nevertheless, construction projects' current high failure rate indicates the insufficiency of those proactive strategies in managing today's dynamic and complex projects. Therefore, considering the promising concept of resilience, a new approach is needed to improve the project performance and ensure bouncing back during or after a disruptive event by focusing on recovery besides reducing vulnerability in projects. This study intends to introduce a conceptual model to illustrate resilience in dealing with disruptive events in construction projects; therefore, to achieve this aim, a comprehensive literature review is conducted on disruption management strategies. The developed model may provide a bedrock for further studies on project resilience and disruption management.

Keywords: *resilience, disruptive event, disruption management, construction project.*

Introduction

Projects are temporary organisations that need multi-disciplinary people and different resources to create a unique product, service or result within time and cost constraints in an uncertain environment. Significant interferences or disruptions in projects can precipitate shock, raising project vulnerabilities and leading to a failure (Burr & Castro, 2016; Loosemore et al., 2005). Failure is described as one of the fundamental problems in construction projects. Disruptions that are integral parts of the projects are among the main causes of failure. Disruptive events can deviate projects from their primary objectives. The longer a project is exposed to disruptions, the lower the likelihood of success (Zhang, 2007) in achieving the project's objectives.

Construction project management literature is replete with abundant research studies on how to enhance the performance of projects to avert failure. Numerous research streams addressed this problem from different perspectives, which led to a wide range of approaches to enhance project

performance, such as risk management, opportunity management, change management and crisis management. Distinctive methods have been developed to decrease the impact and/or the exposure duration of disruptive events in projects and, therefore, increase the projects' success rate by concentrating on the source of those events. Finding sources of disruptions has been identified as one of the crucial tasks in disruption management to reduce the duration of the project's exposure to the disruption (Sears et al., 2015). The sources of disruption can be categorised into two different groups, namely known and unknown sources. Risk and opportunity management have been used to deal with known sources of disruption. In contrast, crisis and change management have been used to deal with unknown sources of disruption (Loosemore et al., 2005; Ward & Chapman, 2003). The former intends to predict and handle threats to avoid disruption, while the latter intends to decrease the project's vulnerability level prior to the disruption.

These proactive approaches provide brilliant guidance on managing disruption to avoid failure; however, the construction projects' current high failure rate indicates the insufficiency of those approaches in managing today's dynamic and complex projects (Dvir et al., 1998; Eden et al., 2000; Shenhar et al., 2001). It clearly shows that further research studies are still required to understand "why construction projects fail?" and "how projects can reach their objectives successfully even after experiencing severe disruption?".

Although the conventional approaches have differences in nature, they aim to protect projects from failure by predicting all possible threats for the whole life cycle of projects during project preparation and therefore reducing vulnerability (Qazi et al., 2016). In layman's terms, they intend to provide “fail-safe” projects. However, regardless of how hard project management teams work to identify all potential threats, reality shows that the likelihood of happening an unidentified (unexpected) threat is still high (Eden et al., 2000; Flyvbjerg, 2007; Shenhar et al., 2009; Williams, 2005) and there will always be significant unpredictability in construction projects (Cruz & Marques, 2013). It can be claimed that this common denominator (predicting all possible threats) makes these approaches insufficient for managing today's dynamic project. Thus, a paradigm shift is needed to resilience-based approaches, which intend to provide “safe-to-fail” projects by enabling recovery during or after a disruptive event (Naderpajouh et al., 2020; Park et al., 2011). To date, few research studies address project resilience, and there is a significant gap in knowledge pertaining to project resilience and how to guarantee project success.

This paper is an overview of four different conventional disruption management approaches (risk, opportunity, change and crisis management) and a preliminary attempt to introduce the potential of resilience concept in managing disruptions in projects. This paper is divided into four sections. The first section briefly explains risk and opportunity management and their used mechanisms to cope with disruption. Change and crisis management are discussed in the second section. The third section introduces the concept of resilience and presents the different definitions of project resilience available in the literature. The discussion section compares the pros and cons of these approaches for managing disruptions to draw a conceptual model, which may provide a bedrock for further studies in project resilience and disruption management.

Risk and Opportunity Management

Risk, known as a threat (Carr & Tah, 2001), an uncertainty that matters (Hillson, 2014) or a measurable uncertainty (Hillson, 2003), is a potential event that may or may not happen in the

future. If it happens, it may lead to a disruptive event which can positively or negatively affect the project's objectives (PMI, 2021; Tomanek & Juricek, 2015; Ward & Chapman, 2003). Reducing the negative severity of disruption is the main aim of risk management. It intends to achieve this aim by identifying those threats, predicting their occurrence and developing strategies to reduce their negative impact on the project's objectives (PMI, 2021; Qazi et al., 2016). The primary step in the risk management process is risk identification, which is predicting the possible future events that may alter the project's objectives and mostly rely on an individual's experiences, skills, interests and perception (Ward & Chapman, 2003; Zhang, 2007). The challenge is that individuals with different experiences and interests may have different perceptions of risks in a project and consequently identify and prioritise risks differently. The following steps in the risk management process, risk analysis, response strategies and monitoring during the project's life cycle (Qazi et al., 2016) entirely rely upon risk identification. Thus, any unknown threat could challenge the whole risk management and considerably affect the project. Risk management intends to create value in a project by mitigating disruptions or reducing their impact (Sanchez et al., 2009; Ward & Chapman, 2003). Some scholars, however, criticised its performance and effectiveness and described it as a check-the-box process rather than a process for creating value (Erol et al., 2020).

In contrast to risk management which targets the repercussions of a threat, opportunity management focuses on its positive consequences. In other words, opportunity can be described as a positive perception of risk (Olsson, 2007). Although the steps of opportunity management are similar to those of risk management (identification, analysis and responding) (Ward & Chapman, 2003), their responding methods are entirely different. As discussed earlier, there are four different responding strategies in risk management, including avoiding, transferring, mitigating, and accepting. In contrast, opportunity management responds by exploiting, sharing, enhancing and ignoring (Hillson, 2003). Contrary to avoiding strategy in risk management, which tries to reduce the probability of occurrence by eliminating uncertainty, exploiting strategy in opportunity management aims to raise the likelihood and make the opportunity happen (Hillson, 2001). Analogous to transferring strategy in risk management, sharing strategy seeks to allocate an opportunity to a party best able to manage it. Moreover, opposing mitigating strategy in risk management, enhancing strategy tries to increase the probability of occurrence and/or severity of impacts of an opportunity. Like accepting strategy in risk management, the ignoring strategy will be used when an opportunity cannot be exploited, shared, or enhanced (Hillson, 2001).

Both risk and opportunity management suffer from the inability to cope with disruptions fully and ensure project recovery after experiencing a shock. These approaches mainly concentrate on increasing the ability to identify the potential threat or opportunity to avoid shock; however, in the face of unidentified threats or opportunities, these approaches might be incapable of managing them and their consequences appropriately.

Crisis and Change Management

A crisis has been defined as "a breakdown of familiar symbolic frameworks legitimating the pre-existing sociopolitical order" (Hart, 1993). In simple words, it is an extraordinarily challenging situation (Boin & McConnell, 2007) that leads to a menace to the functioning of a system (Rosenthal et al., 2001) and disturb its balance. A threat, the element of surprise, and short response time have been described as three inseparable properties of a crisis (Seeger et al., 1998). Crisis management, in projects, fixates on handling issues that disturb the balance of

a project and tries to keep the project from being further disrupted. Crisis management approaches employ a pre-developed plan, command centre and training (Kerzner, 2013). After facing a crisis in a project, the pre-developed plan can be applied to buy some time for the command centre, which is responsible for assessing the situation and developing a strategy to reduce the initial impact of the disturbance. While training strategies try to predict the crisis's repercussions and response precisely (Boin & McConnell, 2007). Current crisis management approaches have been criticised for oversimplifying the crisis's severity, making projects more vulnerable to crisis (Kerzner, 2013). Moreover, most of these approaches ignore issues generally created during a crisis, such as behavioural instability, conflict and information problems (Love & Smith, 2016).

Change in construction projects generally refers to work status, processes, or methods altering the initial planned or specification (Park, 2002). Change management seeks to handle these alterations by constantly monitoring and modifying the direction and structure of a project (Chen et al., 2015; Motawa et al., 2007). Change management tries to ameliorate the consequences of an already happened change, but its first attempt is to predict potential changes that are likely to occur later and reduce their impact on the project (Hayes, 2018; Motawa et al., 2007). The current literature on change management primarily aims to discern the essential factors for the success of a change process and provide practice instructions for handling change (Cox et al., 1999; Ibbs et al., 2001; Motawa et al., 2007; Stocks & Singh, 1999). Moreover, there are research studies assessing change impact on particular project parameters. For example, the impact of a change order on labour productivity in a construction project (Hester et al., 1991), the effect of the change size and its impact time on a project (Ibbs et al., 2007) and the risk of safety regulations changes during projects (Williams, 2000). Another study developed an integrated change management system for the lifecycle of changes within the construction project. This generic change system aims to manage change scenarios and evaluate change effects on projects. It consists of four main stages: "start-up", "identify and evaluate", "approval and propagation", and "post change" (Motawa et al., 2007). In the first stage, proactive requirements are defined to manage change effectively, enabling the project team to respond readily to change. Then, in addition to identifying and evaluating change causes, types and effects, the relevant and/or involved project processes and departments in the change decision are defined in the second stage. Client approval will be taken in the third stage after reviewing potential changes against the project baseline using tangible and intangible criteria. Finally, when a dispute resolution is applicable, it needs to investigate change's direct and indirect causes (Motawa et al., 2007). Although the change management system can reduce the aftereffects of disturbance in a project by employing the provided requirements in the "start-up" stage, the requirements are not explicitly delineated. Change management may go wrong, especially when the sources of shock are beyond those perceived or permitted (Ward & Chapman, 2003).

All approaches discussed above intend to either avoid shock or reduce the project's susceptibility to shock-induced disruption. What is ignored here is the capability of the system to handle the shock and bounce back to an equilibrium state after a disruption, which is called recovery. Ponomarow & Holcomb (2009) claimed that vulnerability reduction approaches are insufficient to deal with project disruption and played readiness and response up to guarantee recovery. Some researchers support the idea that recovery may reduce exposure to future disruption. (Blay, 2017; Holling, 1973; Raco & Street, 2012). The concept of resilience has a solid history of ensuring recovery in many domains and can benefit construction projects.

Project Resilience

The concept of resilience was introduced by Norman Garmezy (Coutu, 2002; Geambasu, 2011) more than half a century ago. Since then, it has been extensively employed in a wide range of disciplines, including but not limited to ecology (Holling, 1973), organisational management (Al-Abrrow et al., 2019; Chen et al., 2021; Ortiz-de-Mandojana & Bansal, 2016; Sapeciay et al., 2017), supply chain (Sheffi & Rice, 2005; Tang, 2006), psychology (Coutu, 2002; Luthans et al., 2006), disaster management (Paton et al., 2000; Paton & Johnston, 2001), climate risk management (Hallegatte & Engle, 2019), urban planning (Wilkinson et al., 2010) and infrastructure (Giezen, 2013). Consequently, many definitions of the word resilience are presented by scholars in different contexts (Bhamra et al., 2011; Linnenluecke, 2017), showing the context-specific nature of resilience (Blay, 2017). Regardless of the significant differences among the definitions of resilience, those definitions include terminologies such as ability, capability, anticipate, monitor, resist, respond to, adapt to, learn, recover from and bounce back (Hollnagel, 2010, 2015). Those definitions are categorised into two fundamental perspectives: engineering and ecological resilience (Holling, 1973). From the engineering perspective, resilience is the system's ability to resist force, withstand disruption and improve its rigidity, while ecological resilience is defined as the system's capacity for renewal to maintain its performance under disruption or shock (Aven, 2011; Blay, 2017; Holling, 1973). The former lays emphasis on efficiency, stability, and predictability, while the latter focuses on persistence and flexibility (Blay, 2017). These perspectives differ so fundamentally that they serve as alternate paradigms for researchers (Geambasu, 2011).

There is a broad body of knowledge on organisational resilience (Bhamra et al., 2011; Hollnagel, 2010; Linnenluecke, 2017; Naderpajouh et al., 2020; Thomé et al., 2016); however, little is known about project resilience, and there is no consensus on project resilience theoretical definition. It might be claimed that the same concept of organisational resilience can be applied to projects since projects are a kind of organisation. This claim is partially valid because a project is defined as a temporary organisation (Sydow & Braun, 2018); however, resilience in an organisation is enabled by the long-term established relationship and challenged by the short-term transactional relationship. Whilst relationships in a project are generally transactional (Blay, 2017). Therefore, a clear conceptualisation and definition of resilience in a project is needed.

To the best of the authors' knowledge, few studies on project (as temporary organisation) resilience exist. The scarcity of research studies on project resilience strongly indicates the concept's novelty. Geambasu (2011) introduces project resilience as "the project's capacity to maintain positive adjustments when confronted with critical events inherent in its lifecycle". She claimed that project resilience should be seen from the ecological perspective rather than engineering resilience (Geambasu, 2011). Schroeder and Hatton (2012) interpret it as "the capacity of a project to evolve successfully in the face of unexpected threats or risks". Similarly, Hillson (2014) explains project resilience as "the capacity to maintain core purpose and integrity in the face of external or internal shock and change" and rephrases it as the "bounce-back-ability" of a project. In a like manner, Giezen et al. (2015) express it as "the ability of the decision-making process to deal with unexpected and the ability to entertain flexibility and preparedness to cope with uncertainty". Resilience in complex construction projects has been defined as "the ability of project systems to cope with uncertainty" (Zhu, 2016). Finally, Blay (2017) provides a comprehensive definition as "the capability of a project to prepare for, respond to, and reduce the impact of disruption caused by the drifting environment and project

complexity" and proposed recovery from a disruptive event as the consequence of project resilience.

After reviewing the studies mentioned earlier, it can be concluded that although what is known from project resilience is largely based on organisational resilience, those scholars make a distinction between these two concepts. Whilst organisational resilience, built upon the organization's permanent feature, follows the engineering resilience definition and focuses on reducing vulnerability, project resilience follows the ecological perspective and focuses on recovery (Blay, 2017). Moreover, they agree that project resilience is the ability/capability of the project to provide recovery. However, there is a disagreement about the type of event (shock, disruption, uncertainties, change, ...) that resilience is attempting to handle in a project. This disagreement and the novelty and vagueness of the project resilience concept indicate that researchers should debate this concept more. (Naderpajouh et al., 2020; Thomé et al., 2016; Zhu & Mostafavi, 2017).

Discussion

In this section, the authors intend to develop a conceptual model (Figure 1) within the construction project management context among the abovementioned approaches, risk, opportunity, change and crisis management, and project resilience by underlying the differences and similarities between these concepts.

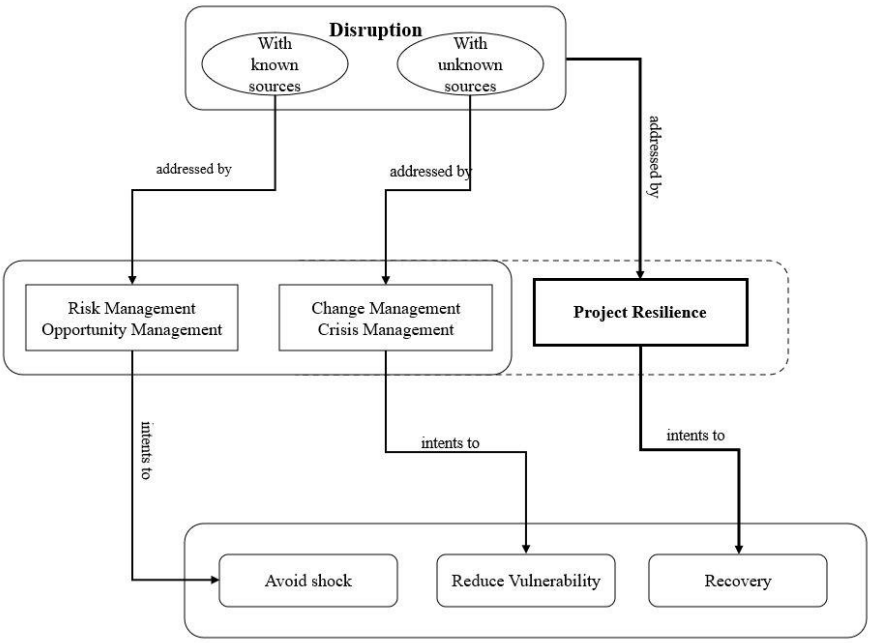

Figure 1: Delineation of proposed model among project resilience and conventional disruption management approaches.

Risk and opportunity management are successful approaches when there is a low level of uncertainty in a project and the sources of disruptive events are easily identifiable and analysable (Besner & Hobbs, 2012). It has been claimed that less risk or opportunity management is used when the uncertainty is high in a project (Besner & Hobbs, 2012). It could be because of their low productivity in a highly uncertain environment. A project's high degree

of uncertainty and ambiguity makes disruption source identification difficult or even impossible (Thamhain, 2013). These proactive approaches are commonly used to deal with disruptions with known (identified) sources. Simply, they intend to protect the project from failure by preventing disruptions from happening or reducing their impacts on the project. Both can be interpreted as a shock-avoiding mechanism in a project (Blay, 2017).

They pay more attention to the source of disruption rather than managing its consequences if it happens. It makes them incapable of handling disruptions with unknown (unidentified) sources. The reason is that predicting a disruption's consequences and impact on a project is extremely difficult because of the complexity and drifting environment of the project (Blay, 2017). However, On the other hand, identifying all threats, which are sources of disruptions, is almost impossible. Hence, more flexible approaches are required to deal with a disruption's consequences in a project after occurring, even if its source is unknown or unidentified at the beginning.

Change and crisis management approaches are also proactive approaches which take disruption from unknown sources into consideration. These approaches try to predict potential disruption, but they mainly focus on managing disruptions and reducing the susceptibility of the project to the consequences of disruptions. Therefore, they are praised for being more prosperous in coping with disruptive events with unknown sources (Blay, 2017), specifically where there is a medium to a high degree of uncertainty in a project. These approaches intend to protect the project from failure by reducing its vulnerability to disruptive events during its life cycle.

Given the high degree of complexity and uncertainty in construction projects which makes disruptive events unpredictable, the approaches mentioned earlier are not flexible and effective enough to provide an acceptable response and ensure success in the project (Schroeder & Hatton, 2012). Those proactive approaches intend to provide "fail-safe" projects; nevertheless, resilience, as a new-born concept in project management, targets recovery and tries to provide "safe-to-fail" projects. It may supply insight into responding better to disruptive events. Resilience allows for both proactive (adjustments before a disruptive event happens) and reactive (adjustments after a disruptive event happens) practices (Hollnagel, 2015; Klein et al., 2015). From the project management perspective, it adds a “thinking in action” mindset and increases the improvisation among project management team (Klein et al., 2015). Resilience intends to retain the project’s function by absorbing, adapting to or restoring from disruption. The absorptive function seeks to alleviate the impact of disruptive events before they arise. The adaptive function tries to adjust and transform the project to avoid failure and keep the project running during a disruption. Finally, after facing disruption, the restoring function returns the project to an equilibrium state (Zhu & Mostafavi, 2017).

Aven (2011, 2018) believes that the resilience concept has the potential to eliminate the need for other proactive approaches, such as risk management. However, we believe project resilience is still a very new and immature concept to reach that target and negate the importance or need of the conventional approaches. It can currently be considered an accompaniment to other approaches for increasing project success.

Conclusion

This study has provided a delineation of resilience concept within a project together with risk, opportunity, change and crisis management. As discussed earlier, risk and opportunity

management are proactive approaches that mainly focus on the source of disruptions and intend to protect the project by either preventing the disruptive event or reducing its negative consequences. These approaches have been criticized for their low efficiency and effectiveness in dealing with disruptive events with unknown or unpredictable sources. Therefore, more flexible approaches such as crisis and change management are introduced to cope with disruptions coming from unknown sources. These proactive approaches intend to predict potential disruptions and handle their consequences. Thus, they focus more on managing disruption within the project by reducing the project's susceptibility to disruption. Although all these approaches aim to avoid failure in a project, none of them can guarantee the project's success in the end. The high failure rate in construction projects is proof of this claim.

The successful results of applying resilience in other domains make this concept more attractive for the project. However, project resilience is still immature and a relatively new topic of study. Therefore, there is a need for further qualitative and quantitative research studies to complement and develop this theory in projects. What is understood from the current literature is that project resilience may provide projects with the ability to adapt themselves to any disruption. It keeps the project running during a disruption or returns it to an equilibrium state after experiencing a disruption. Recovery ensures success after experiencing disruption and strengthens the project to overcome future disruptive events easily.

This study has gone some way toward enhancing our understanding of project resilience in comparison with conventional approaches to deal with disruptive events in projects. Research into evaluating and enhancing resilience in public-private partnership projects is already underway. We are confident that this paper will serve as a base for future studies on project resilience. More broadly, further studies are needed to define the dimensions of resilience in a project more clearly, identify potential resilience activators, and propose indicators to measure a project's resilience level.

Abstract

Multidisciplinarity and complexity of construction projects generally keep them prone to encounter disputes between parties. In some cases, these disputes remain unsolved and parties verge their requests into more official forms in order to pursue compensation from the opposing party. This situation often necessitates a thorough, even forensic analysis of the course of events and all evidential documents in order to allocate disruptions and discrepancies with the liable party. As the expected remedy can be both monetary and time-wise; the main concern of Quantum Analysis is to correlate financial data with the events, consider contractual obligations and find the fair amount to be paid as indemnification to the affected party. Since the process involves the evaluation of financial data on a timeline with a series of events and their causal links; this endeavor necessitates the use of several renowned formulas. Based on the literature review this paper aims to investigate the use of Quantum Analysis formulas for EoT claims and prolongation cost estimations in construction projects. This paper is expected to be helpful for new researches on Quantum Analysis in the future.

Keywords: *construction claims, construction disputes, Eichleay formula, quantum analysis.*

Introduction

As one of the largest industries in the world with a significant share in economies of countries, construction industry maintains to be complex intrinsically due to participation of multiple stakeholders (Musarat & Ahad, 2016). Mills (2001) attributes the riskiness of construction projects to being ever changing and emphasizes on infamy of the industry for finishing projects over-budget due to poor risk management stemming from unforeseen changes. Sun and Howard (2004) put the complexity of the projects down to excessive amounts of project data. Furthermore, fragmentation of project teams due to the nature of construction projects make it difficult to communicate (Anumba et al., 2002). As a result, these factors cause turmoil, time and cost overruns, which often lead to disputes (Jallow et al., 2014).

Based on Blake Dawson Waldron (2006)'s report on Australian construction projects, the survey results show that changes in scope, misunderstanding of contract clauses and Extension of Time (EoT) claims are the top three reasons that gave rise to disputes. On the other hand, Mitropoulos and Howell (2001) presented the main three reasons as obscureness of construction projects, exploitive conduct of parties and contractual complications.

In order to avoid conflicts, a contract is prepared where general and technical conditions of the project, possible delay and dispute scenarios and several conditional measures are predetermined (Ahmed et al., 2003). Nevertheless, in despite of all precautions and conditional measure clauses in the contracts, it is quite common for a construction project to be delayed and finished in over budget (Koushki et al., 2005) due to many unforeseeable factors stemming from various sources (e.g., resource scarcity, weak performance, interrelations of parties) (Assaf & Al-Hejji, 2006). Eventually these issues build up and verge into conflicts and disputes that affect the project and relations of parties negatively (Sinha & Wayal, 2007). Moreover, Cheung et al. (2004) emphasize that unless being resolved quickly; these disputes often intensify and snowball into a claim or even litigation, which are both costly procedures.

Shah et al. (2014) state construction claims as an ex-parte or reciprocal atonement demand of parties to each other, which often stems from a failure to meet an engagement of work as specified in the contract and is expected to be compensated in means of time extension, additional payment or both. On the other hand, claims do not directly connote to an award; by conducting a forensic delay analysis on project records and diverse data with appropriate analysis method, all the events and responsibilities are displayed in order to settle an argument on the pillars of causality, liability and pricing calculations (Sanchez et al., 2019). After revealing the cause-and-effect relationship and presenting the delayed amount, quantum analysis is conducted to calculate the financial impact of delaying events (Mehany & Grigg, 2015).

Claims, delay analysis and quantum analysis are rarely embedded and questioned as topics of academia and university education, which compels these notions in shadows. In comparison with other subjects, there are just very few numbers of articles that examine the formulas of quantum analysis holistically. Therefore, this paper aims to present differences and similarities of formulas used in Quantum Analysis procedures based on the literature review.

Quantum Analysis – Definition and Types

After identification of delaying events and presentation of cause effect relationship between the parties and delaying events, various methods of delay analysis are used to find out the amount of time delayed and the cost of these delays are calculated accordingly (Khekale & Futane, 2015). This procedure is called a Quantum Analysis where after nature of events and their temporal repercussions are identified by a delay expert's work, a quantum expert processes number of financial records in various forms in order to calculate the impact of the affecting events and damages (Thompson, 2021). A quantum analyst's calculations should be based on contractual and project information and should be made with certain methods meticulously (DAC Consulting, n.d.)

In the academic literature a quantum analysis can be made in several claim situations;

- EoT Claims – after investigation of events and their impacts, if awarded by EoT, Contractor may claim the costs that would incur during this added time period (Hewitt, 2011)
- Prolongation Costs Claims - where a number of delayed days and responsible party are presented after running the forensic delay analysis and considering concurrent delays of parties in the calculation (SCL Protocol, 2017)
- Disruption or Loss of Productivity Claims – which cannot be easily but measured and proved in different forms to calculate the impact of wasted labour and productivity because of method or work sequence change (Cushman et al., 2000; Finke, 1998)
- Acceleration and Mitigation Claims – Costs that incur due to Contractor's preventive actions to avoid delays are calculated (Trauner et al., 2009)
- Variation Order Claims – Costs caused by variation or change of a deliverable (Cushman et al., 2000)
- Loss of Profit Claims – Claims based upon deprivation of parties' profit by failure of the other party's fulfilment of obligations (Cushman et al., 2000)

Contractual clauses have a significant importance on quantum analysis procedures as it puts the whole process through a "go/no-go" test. Cushman et al. (2000) claim that liquidated damages clause overrules the quantum analysis and deems all calculations as void. Djanett and Guitera (2019) state that unless there is a specific contractual clause on calculation methods and assumptions, Contractor can claim two outcomes from quantum analysis; direct monetary losses and expenses that happened due to the affecting incident and the amount that is supposed to be earned as a profit but lost due to the affecting incident.

There are a plethora of formulas and approaches under each claim type and in order to focus on a group of quantum calculations, this academic writing is limited to present the formulas, methodologies and approaches of EoT claims and prolongation costs.

EoT Claims and Prolongation Costs

Although EoT claims and prolongation costs seem similar, there is an apparent difference between these two concepts in the literature. Furst et al. (2021) draw attention to this misconception and declares that entitlement to EoT does not directly give entitlement to monetary compensation for the impacts of delay. In furtherance, SCL Protocol 2nd Edition (2017) under Clause 12.2 clearly states that EoT and prolongation events should be stated and investigated separately under the contract. Furthermore, "non-compensable Employer risk events" where costs are at Client's risk and delayed end date is Employer's risk; for instance, delays caused by unforeseen weather conditions are given as an example where Contractor is awarded by EoT but is not entitled to any monetary compensation. Nevertheless, in case Contractor is also entitled to compensation of costs incurred during the EoT, the quantum analysis considers a number of construction cost titles where main idea is to cover all reasonable and exigible expense (SCL Protocol, 2017).

In order to calculate the impact of delay, costs should be presented under several categories. Senogles and Raneda (2016) describe these costs categories as: direct costs (any cost that can be related to and substantiate the event that caused the claim); project overheads (site office costs) (any costs that is not directly related to any event but is necessary in order to run the project); staff costs (staff costs that would not incur if the claim event would not happen); head office overheads (HOOH) (a reasonable calculation of head office overheads that are related with this event); profit margins (a reasonable margin rate that would be earned if the

claim event would not happen). Additionally, Hewitt (2011) mentions two more categories to be considered while calculating EoT claims; contractual costs (e.g., letter of guarantee, insurances) and finance costs (e.g., loans and credit) which eventually builds up as the project proceeds. Similar to these aforementioned classifications, Trauner et al. (2009) elaborate the direct costs as labour, equipment and material costs. Similary, Zack and Badala (2016) make the same classification with an additional category as "subcontractor costs". Other than site office overhead, head office overhead, and machinery and equipment costs, rest of these costs categories are calculated with basic accounting methods. Therefore, only these three categories and formulas on these topics will be explained and rest will be excluded from this paper. Furthermore, methods such as total cost method or jury verdict will be excluded from this article.

Overhead Costs

There are several different definitions to the overhead costs. While Cilensek (1991) describes it as expenses that are not directly a part of the project but caused by the contractor to conduct the project and beared by all contractors. With a different point of view, Coombs and Palmer (1989) defined it as costs that are neither relatable to a construction project/project element nor can be appended to one. Nevertheless, different descriptions overlap at this cost category to be counted as an indirect cost (SCL Protocol, 2017; Trauner et al., 2009), since it is not related to project directly but incur during the construction procedure.

Site Office Overheads (SOOH)

CIOB New Code of Estimating Practice (2017) defines SOOHs as project expenses that are peculiar to the construction site, which cannot be associated with site activities or included in the cost of any services. SOOHs are expenses that incur on the site due to the management of the prolonged project (Trauner et al., 2009). Some of these costs can be classified as salaries, site office rent, heating, electricity, services taken by site office, office stock, etc. (Smith & Gray, 2001).

Zack and Badala (2016) state that there are two methods to calculate site office overheads; "Average Site Office Overhead for Project" and "Average Site Office Overhead for The Period of Delay"; where the first one considers all office costs and non-time related costs throughout the entire project with a retrospective approach while the latter considers these aforementioned costs in a time window with a prospective one. After calculating the average SOOH, in both cases, the number of delayed days is multiplied with this cost to calculate the total claimed SOOH (Zack & Badala, 2016). Another method for calculation of SOOH is proposed by Leśniak and Juszczyk (2018) where authors came up with an artificial neural network-based model that can predict SOOH by correlating specs of SOOH with SOOH index.

Home Office Overheads (HOOH)

HOOH are described as costs that incur in the headquarters of construction company to run the project which cannot be directly related solely to the project but is essential, such as salaries, office utility costs, rents, travel expenses, etc. (Schwartzkopf & MacNamara, 2000; Cilensek, 1991).

Similar to Zack and Badala (2016)'s statement on SOOH, Zack (2000) also states that there are no standard formulas or strict limitations on which formula to use other than several limitations on governmental projects by Federal Acquisition Regulations and other governmental bodies; therefore, many companies prepared different formulas since only reasonability and provability was expected. It has been stated that having more than one project simultaneously makes the HOOH calculations more complex as this would necessitate allocation and division of costs between projects (Trauner et al., 2009).

There are two types of HOOH that should also be considered in calculations, namely: Unabsorbed and Extended HOOH (Golnaraghi, 2011). While Extended HOOH defines the amount that will be claimed as HOOH for every owner-caused delay day, Unabsorbed HOOH purports to the amount that had to be beared by another project due to decrease in cash flow in the first project (Zack, 2000).

To calculate HOOH, there are plenty of different formulas in the literature such as Eichleay, Modified Eichleay – Variation 1 & 2, Hudson, Ernstrom, Burden Fluctuation, Manshul, Carteret, Canadian, Allegheny and Emden formulas (Singh & Taam, 2008; Zack, 2000). In this proceeding, only Eichleay, Modified Eichleay – Variation 1 & 2, Hudson, Emden and Canadian formulas will be examined.

Eichleay Formula and Modified Eichleay Formula – Variation 1 & 2: The original form of Eichleay formula is; in order to calculate the sum of all the overhead relatable to the project first the ratio of contract invoices to total invoices for actual contract period is calculated and multiplied with the entire overhead of company for that actual contract period (Zack, 2000). Then, total overhead relatable to the project is divided to actual days of contract performance, which gave the daily overhead relatable to the project and subsequently this number is multiplied by the number of days delayed by the faulty of owner (Zack, 2000). Limitations of Eichleay formula oblige that there must be a delay event that is entitled for a reimbursement, which cannot be mitigated and causes a loss in revenues (Cushman et al., 2000). Modified Eichleay Formula – Variation 1 is also quite similar to the original formula; instead of actual contract period and actual days of contract performance, original contract period and original days of contract performance are used which purports to the assumption of the calculated HOOH for the original contract is the same throughout the entire project regardless of prolongations and delays; which would add up to a higher HOOH amount in result (Singh & Taam, 2008). The second variation is similar to the first variation; the only difference is also expenses made over the prolonged time interval is also included in the calculation to remunerate these costs (Zack, 2000). The original formula has a retrospective approach as it considers all the "actual" data while the modified versions tend to consider everything at the contract preparation stage with a prospective method (Trauner et al., 2009).

Hudson Formula: Hudson Formula's HOOH calculation starts with a significant assumption that there is a predefined HOOH and profit rate that remains the same throughout the project; simply finding the daily contract cost and multiplying it with this rate and the number of days delayed by the faulty of owner gives the claimed HOOH amount (Zack, 2000). On the other hand, Donohoe (2000) states that the formula should be used carefully, and the extents of these formula should be considered as it would cause ingeminate payments; which is also remarked by the owner of Hudson Formula per se. Moreover, based on Davenport (1991)'s research on uses of Hudson formula, it is presented that there are two distinct versions; "Extra Cost Formula" which is used for entitlement to a compensation of HOOH for owner caused delay and "Lost Chance Formula" is used for calculating the owner caused delay's aftermath

– to calculate the HOOH that would be generated if the Contractor would not be delayed and produce more outcome and eventually more HOOH (Davenport, 1991).

Emden Formula: While Zack (2000) finds Emden formula's methodology similar to Eichleay formula, Davis and Watson (1999) infer the formula as an improvement of Hudson formula, where the formula neglects the project profitability and calculate predefined HOOH rate from the ratio of total overhead costs to total revenue.

Canadian Formula: Canadian formula is quite similar to the Hudson Formula; where Hudson formula includes a predefined rate that includes both HOOH and profit while Canadian formula only considers HOOH and no profit is included in that rate (Nagata, 2018).

Cost of Idle Machinery and Equipment

In the SCL Protocol 2nd Edition (2017) under clause 1.26 (a) equipment costs are presented as a direct cost. Cushman et al. (2000) state that these claims are often Contractor's demand for a compensation of expenses of idle machinery and equipment due to owner related delay events. Hewitt (2011) classifies the idle equipment costs that incur due to time extensions as either hire or amortization costs that includes fuel and maintenance costs as well and does not include full expense of obtainment of an equipment since it may be used in more than one project.

Stojadinovic (2018) considers with a rather different perspective where idle equipment costs are defined as expenses of depreciation, interest and insurance. Cushman et al. (2000) add taxes, warehousing charge and remoulding to these cost categories and suggest that because of difficulties in calculation and data collection, cost estimations can be based upon industry manuals prepared by trade groups and governments, which incorporates large sets of historical data.

Since interest rate and insurance calculations are performed with basic accounting methodologies, these two topics will be neglected and only depreciation formulas will be presented in this academic writing.

Depreciation is the decrease in the current price of a construction equipment over time due to wear and attrition and being outdated (Petronijević et al., 2012). There are four types of depreciation calculation; straight line, units of production, sum of years digits and declining balance method (CFI Team, 2022).

Straight Line Method: By using this simple method, the yearly depreciation rate is assumed as a constant and market value of the equipment is directly related to the number of years equipment or machinery is in use (Petronijević et al., 2012). There are also modifications to this formula where a fuzzy approach is taken to overcome the obscurity of attributed useful life and final salvage values (Khalili et al., 2014).

Units of Production Method: This method defines a number of units to be produced before the end of useful life span and calculates the depreciation over the units produced (CFI Team, 2022).

Sum of Years Digits (SYD) Method: Also as known as Accelerated Depreciation Method, SYD method calculates the maximum depreciation rate on the first year and then depreciation annually (Petronijević et al., 2012). First an assumption is made on total life span and salvage rate of machinery; in order to calculate the depreciation after a specific number of used years, remaining economic life is divided to the SYD of total life span and this value is multiplied by first value of equipment – salvage value (CFI Team, 2022).

Declining Balance Method: Also as known as "Constant Percent Formula" or "Matheson Formula", this method relies on a constant amortization value that is predefined and decreases annually (Giudice et al., 2016). Although it is a rather easy method to apply, different annual amortization constants and the fact that salvage value would always be more than zero are the downsides of this formula (Giudice et al., 2016).

Conclusion and Discussion

Notions of complexity and contingency in the essence of construction projects make disputes and claims inevitable. This proceeding aimed to show several quantum analysis formulas that are widely accepted and being used for proving the monetary impacts of delays. In order to maintain the focus on the subject, claims are classified and only the quantum analysis formulas regarding EoT and Prolongation Cost estimations in construction claims are investigated. Moreover, since many of the estimations were basic accounting calculations, only the cost categories that include complex and specific formulas are presented.

In the course of literature review and research, it has been noticed that the majority of books, papers and academic writing were belonging to at least 10 years or more. There were only a few recent articles and even less researches on the cost estimations of construction claims.

Several articles (e.g., Zack, 2000; Trauner et al., 2009) on SOOH and home office overhead calculations showed that although there are plenty of different formulas, the results of formulas on the same case are inconsistent; therefore, method selection phase is the key and the subject of which formula should be chosen in which situation is still vague. Furthermore, it has been noticed that there are quite a lot of depreciation cost calculations but none of these calculations consider legislations and account codex of different countries, which keeps these calculations susceptible to be void or conflicting with local law codes in international projects.

Quantum analysis in construction claims and disputes is a detailed subject with numerous clusters and subtopics. It has been suggested that further investigation on this subject will help to fill the gap in the literature in this field.

Examination of Organizational Perceptions on Risk Status of Events of Contractors' Claims and Key Control Measures on Construction Projects in Turkey

O. İlter and T. Çelik
Cyprus International University, Civil Engineering Department, Nicosia, Northern Cyprus
oilter@ciu.edu.tr, tcelik@ciu.edu.tr

Abstract

Construction projects are exposed to a lot of contractor's claims due to many factors. Project performances are significantly affected as a result of contractors' claims. Either contractor or owner involved in the project may have to cover the monetary value of the claim. The reasons for the claim may differ with respect to the project parties, the project region, and the project characteristics. This study aims to identify the top risk factors that lead to the contractors' claims and on the other hand, aims to identify the most effective measures with respect to controlling the claims in construction projects based on the views of contractors, consultants, and owners in Turkish Construction Industry. In this context, the causes of contractors' claims and mitigation measures have been examined based on a survey with construction professionals in different organizations in Turkey. Research findings have shown that in accordance with organizations characteristic features, organizations have exhibited different views with respect to the top risky events leading claims, together with the most effective measures that can control claims. According to the contractors, the top risky claims are "Design-Technical" flaws, while according to the consultants and project owners, the top risky claims are "Construction" flaws. On the other hand, according to the contractors, it was emphasized that the improvement of "technical document" components is the most effective measure, while the improvement of the "Construction implementation" based applications is stated as the most effective measures by the consultants and project owners. This study aims to raise awareness regarding contractors' claims in Turkey.

Keywords: *contractors' claims, changes in construction, mitigation measures.*

Introduction

Simon (1979) defined that, "claim is the right to the party who deserves a request for compensation of damages incurred by the other party". Adrian (1993) stated that claim is ''a request by a construction contractor for compensation over and above the agreed-upon contract amount for additional work or damages supposedly resulting from events that were not included in the initial contract''.

It becomes rare to complete the projects within the contract time (Katham, 1999), and contract cost (Harris et al., 2006), due to lots of variations and uncertainties in construction projects. Today, many construction projects combat cost and timeouts and quality deterioration (Sun &

Meng, 2009). Wu et al. (2005) referred that design changes occurring in many public projects lead to an increase in project duration and cost, as well as demoralization and legal disputes and moral disturbances among project stakeholders. Completing a project on a timeline has become a difficult task to complete in an uncertain, complex, multi-party, and dynamic environment of construction projects (Zaneldin, 2006).

Problem Statement and Aim of the Study

Jergeas and Hartman (1994) have referred that 72 percent of all contractors' claims are due to change orders in construction projects. Patil (2005) stated that when one of the parties denied the other party's claim in construction projects, a dispute arose between the parties. Crowley and Hancher (1995) have referred that the contractor's financial damage can be compensated by change orders to be made to claim extra financial resources throughout the construction process.

Zaneldin (2006) revealed that the most frequent claim causes in construction projects in Dubai and the Abu Dhabi Emirates are change orders. Diekman and Nelson (1985) analyzed 427 construction claims to identify types, frequencies and the average cost of claims. Authors were emphasized that 46% of contract claims were originated from design errors and design changes in construction projects. Hassanein and Nemr (2007) emphasized that the most common causes of construction claims are due to the "change orders" and "modification of the Project by owner party" in the projects. On the other hand, 54% of the causes of claims were due to change orders in the Egyptian construction sector. In 57 % of the project in Egypt, change orders are comprised due to poor documentation practices by the contractor's team (Hassanein & Nerm, 2007).

In another study, Semple et al. (1994) examined 24 construction claims in the Canadian construction industry to specify the causes and effect of claims on cost and time parameters. "Increase of scope of the work", "weather" and "Acceleration of project" are the most common factors that cause claims in Canada.

At the end of the comprehensive literature review, it has been realized that the most significant causes of claims vary depending on the organizational, regional and project characteristics, as the organizations and regions have their own characteristics, construction law, cultures, economies, and construction technologies. Within this context, based on a survey of construction organizations in Turkey, this paper aims to identify the top risky claim factors for a lump sum and design-bid-build contract building projects according to the construction organizations located in Turkey.

One of the important tasks to resolve the contractor's claims is to analyse the types and causes of claims (Ren et al., 2003). Diekman and Nelson (1985) stated that the construction industry should develop methodologies and techniques to reduce or prevent claims because project participants are becoming more aware of the high costs and risks associated with claims. Kululanga et al. (2001) developed a framework to handle claims to improve strategies for construction business processes in the Malawian construction sector. Besides, the performance of contractors was measured on the construction claim framework process. It has been noted that contractors have low awareness of the construction claim process framework in Malawi (Kulungana et al., 2001). It is revealed by past studies that, in order to achieve

success in the project, problematic events that lead to claims in projects should be recognized and controlled.

In past studies, it has been realized that various methods and measures were discussed to control the claims of the contractors according to the characteristics of projects, parties, and regions of the construction projects. For the success of the project, the most appropriate measure should be applied to eliminate the factors that cause the claims. In this context, to develop a strategy for the construction industry in Turkey the most effective measures were identified based on the views of organizations.

In thıs respect, in the second phase of the research, it is aimed to examine the measures of contractors' claims. In this context, the existing knowledge on claim management is comprehensively examined in the literature and presented as below.

Research and Analysis Method

In the first phase, factors influencing contractor's claims in construction projects were identified based on the validity of the literature. Hereby, a total of 21 different factors were defined (See Table 2).

In the next step, potential mitigation measures that can prevent the contractor's claims conditions in construction projects are determined by the literature review. In this regard, the identified mitigation measures are presented in Table 3 below.

In further step, factors of contractors' claims and mitigation measures were examined based on the survey of professionals in the construction industry in Turkey. Civil engineers and architects were interviewed on behalf of their organizations. A participant from each organization was included in the survey to make an organizational evaluation. Participants were asked to carry out the survey based on the organization's experience, as they participated in the name of the organization. The survey document was provided to the organizations as a hardcopy. A total of 103 organizations participated in the survey. The distribution of organizations and participants' profiles were presented in Table 1.

Table 1. Distribution of organization and respondents' professions.

	Architect	**Civil Engineer**	**Total**
Contractor	21	45	66
Consultant	8	16	24
Owner	5	8	13
Total	**34**	**69**	**103**

The research results were classified according to two types of organizational characteristics. Here the organization is meant the parties involved in the construction projects, namely contractors, consultants, and owners. The first type of organization was considered to be a contractor representing the party that undertakes the implementation of the construction projects and who claims and receives a financial benefit in return. Consultant and owner, both of them are the authority to produce technical and administrative decisions in throughout the

project. In this way, the negativity caused by a low number of owners participated in the survey was compensated. The data collection and the analysis methods are explained in the following. The research findings are classified and compared to emphasize the differences and consensus of the organizations' opinions regarding the contractor's claims.

In the survey, factors of contractors' claims were examined according to three parameters such as frequency of occurrence, impact on cost-time and frequency of disagreement between contractors and owners. On the other hand, claim mitigation measures were assessed in terms of effectiveness on preventing the occurrence of claims and, cost and time overruns.

Factors weighting method was chosen to measure how the participants think about the claim and measure factors. A five-point Likert scale was used to evaluate the factors in the evaluation parameters explained above. The factor's level of significance was determined by calculating factors relative Importance Index scores (R.I.I.) according to the Frequency Index (F.I.), Cost - Time Impact Index (C.T.I.) and dispute index (D.I.). On the other hand, Claim Prevention Index (C.P.I.), Cost Prevention Index (C.P.I) and Time Prevention index (T.P.I.) were calculated to determine the level of significance of the factors of mitigation measures. Factors Relative Importance Index scores were calculated using Equation (1):

$$R.I.I.(\%) = \frac{\sum W_i \times X_i}{A \times N} \quad (1)$$

Where,

R.I.I. (%): Relative Importance Index for Frequency of Occurrence (F.I.); Relative Importance Index for impact on project cost and time (C.T.I.); Relative Importance Index for the frequency of disputes (D.I.)

Wi: The weight assigned on Likert scale given to each factor by the respondents and ranges from 0 to 4, where; 0: Never, 1: Less, 2: Moderate, 3: High, 4: Very High

Xi: Number of choices of the (i) th weight in the Likert scale for the claim factor.

A: is the highest weight (i.e., 4 in this case) and;

N: is the total number of respondents

Risk Significance Index of Factors of Contractors' Claims

The risk levels of the claim factors were determined by calculating the Risk Importance Index (R.S.I.) of the claim factors. In this study, the risk score factors that contribute to contractors' claims were valued as the combination of the two components; the probability of the claim (frequency) and its impact after its occurrence (severity).

Factors Risk Significance Index (R.S.I.) scores were calculated by considering the frequency index as multiplier effect and by aggregating the cost- time impact index (C.T.I.) and dispute index (D.I.) (See Equation 2 and 3).

$$R.S.I.(\%) = \frac{F.I. \times AV.S.I.}{100} \quad (2)$$

Where;

F.I. = Frequency Index; AV.S.I. = Average Severity Index (Equation 3)

$$AV.S.I.(\%) = \frac{C.T.I. \times D.I.}{2} \quad (3)$$

Where;

C.T.I. = Severity Cost-Time Overrun Index; D.I. = Dispute Index

The highest risk significance index refers to the top risky factor, while the lowest refers to the minimum risky claim factors in construction projects.

The Benefit Index of Claim Mitigation Measures

The benefit levels of mitigation measures were determined by calculating the Benefit index (B.I.) of mitigation measures factors. The Benefit Index of measures (B.I.) was calculated by considering the claim prevention effectiveness index as the multiplier effect and aggregating cost- time overrun prevention indexes (See Equation 4 and 5).

$$B.I.(\%) = \frac{E.I. \times AV.C.T.P.I.}{100} \quad (4)$$

Where;

E.I. = Claim Prevention Effectiveness Index; AV. C.T.P.I. = Average Cost-Time Overrun Prevention Index (See Equation 6)

$$AV.C.T.P.I. = \frac{C.P.I. + T.P.I.}{2} \quad (5)$$

Where;

C.P.I. = Cost Overrun Prevention Index; T.P.I. = Time Overrun Prevention Index.

The highest score refers to the most beneficial factors, while the lowest refers to the least beneficial claim mitigation measure. The higher the benefit index score, the greater the effectiveness of preventing claims.

Project Success Rate

The likelihood of rate of the construction project was determined by establishing the link between the risk index of claim factor and benefits index of mitigation measures. In this regard, the success rate of the project was determined by the combination of the risk index of the claim and the benefit index of mitigation measures.

In order to have a high success rate, the claim factors should effectively be mitigated with the potential measures. The higher of this rate implies that the project is more likely to be completed successfully. In other words, greater of mitigation of claim factors means that the project still could be completed with a higher success rate. The project success rate has been determined for the types of claim factors. The project success rate is calculated with Equation 6 and given in Table 4.

$$P.S.S.(i) = \frac{1}{R.S.I.(i)} x \frac{\sum_{j=1}^{j} N.O.S.* B.I.}{n} \quad (6)$$

Where;

P.S.S. (i) = Project Success Rate for (i) th factor of claim,

R.S.I. (i) = Risk Significance Index of (i) th factor of claim,

N.O.S. (j) = Number of a choice of (j) th factor of mitigation measure for (i) th factor of claim,

B.I. (j) = Benefit index of (j) th factor of mitigation measure,

n= Number of Participants

Results

Top Risky Claim Causes

The Risk Significance Index of factors of claims is shown in Table 2. “Contractors” and “Consultant-Owner” were stated that “Errors/Insufficiencies in Design Documents” are the top risky factors of claims. The risk index score in the “Consultant-Owner” assessment has been relatively low compared to the contractors. Besides, the contractors highlighted that the “inconsistencies between different designs” and “lack of supervisor’s experience” as other major risks in construction projects. Consultants and owners stressed that subcontractors' mistakes and faulty organizations are the top risky demand factors in construction projects. Contractors referred that the factors that the consultants and owners have more responsibilities lead to more claims. However, according to the consultants and owners the factors related to the obligations of the contractors are referred to as the main reasons for the claims.

The highest risk score average was obtained by the contractors (See Table 2). According to the opinions of the contractors, it was emphasized that construction projects have become more prone to claims. In other words, according to the contractors, the necessity to claims more due to defects in construction projects in Turkey. Contractors have been observed to be more concerned concerning claims in construction projects.

Table 2. Risk significance index of factors of contractors claims according to the organizations.

Claim Factors	**Contractor**	**Consultants - Owners**	**All Participants**
Inadequacies in Contract Drawings	0.58	0.44	0.54
Low Constructability Design	0.37	0.27	0.33
Inadequacies in Specification	0.51	0.26	0.43
Inconsistencies between different designs	0.54	0.28	0.46
Changes in Scope	0.47	0.35	0.4
Inadequacies in Contract	0.46	0.36	0.43
Inadequate knowledge of client	0.51	0.29	0.43
Inadequate Experience of Consultants	0.53	0.31	0.46
Low contract price	0.36	0.37	0.36
Inadequate time in tendering	0.39	0.39	0.39
Inadequacies in Organizations	0.37	0.40	0.38
Lack of Communication between parties	0.37	0.21	0.33
Changes in Construction Method	0.34	0.28	0.32
Errors of subcontractors	0.36	0.41	0.38
Inclusion of Shop Drawings	0.49	0.38	0.45
Inadequate Experience of contractor	0.38	0.36	0.37
Inflation in Resources Cost	0.38	0.38	0.38
Natural Disasters	0.36	0.20	0.32
Subsurface Problems	0.44	0.30	0.41
Shortages of Materials	0.43	0.38	0.41
Changes in Law and Standards	0.33	0.20	0.3
Average Score	**0,43**	**0,32**	**0,39**

Top Effective Mitigation Measures

The benefit rate of mitigation measures according to the organization types is shown in Table 3. Contractors were emphasized that “detailed design and specifications”, “qualified architect/engineer” and “easy constructability design” are the most effective methods that could reduce claim risks in construction projects. On the other hand, “effective site management”, “qualified architect/engineer” and “awarding of the right contractor” in the tender process were determined as the most effective mitigation measures according to consultants and project owners. According to contractors, requests can be controlled by mitigation methods to be applied to problems related to the improvement of the design process and design documentation. However, according to consultants and owners, it has been stated that claims can be controlled strongly by improving the construction process works. The highest of the benefit index scores average was observed in the assessment of contractors

(See in Table 3). This result has revealed that there is a greater need for mitigation measures according to the contractors.

Table 3. The benefit index for claim mitigation measures according to the organizations.

No	Mitigation Measure Factors	Contractor	Consultant - Owner	All Participants
1	Standard form of Drawings	0,55	0,32	0,42
2	Detailed Drawing/Specification	0,63	0,50	0,59
3	Advanced Design Software (BIM)	0,42	0,37	0,41
4	Front-End Planning (Feasibility)	0,51	0,40	0,48
5	Qualified Architect-Engineer	0,59	0,55	0,58
6	Easy Constructability Design	0,59	0,45	0,53
7	Effective Communication	0,49	0,35	0,45
8	Sharing Historical Data	0,50	0,31	0,45
9	Qualified Project Manager	0,55	0,42	0,51
10	Detailed Contract	0,57	0,50	0,55
11	Staff training	0,50	0,47	0,49
12	Contractors well bidding organization	0,51	0,57	0,52
13	Risk sharing philosophy	0,56	0,33	0,49
14	Awarding Right Contractor	0,50	0,54	0,51
15	Effective Site Management	0,52	0,57	0,53
16	Pre investigation of site	0,49	0,53	0,50
17	Effective Quality Control	0,46	0,51	0,49
Average Score		**0,52**	**0,45**	**0,50**

Results of Project Success Rate

The project success rates according to the claim factors are shown in Table 4. According to the contractors, the project can be completed most successfully by the measures to be applied by the contractors to prevent the errors of subcontractors. In this respect, it was denoted that, construction projects can be managed most successfully by the measures to be taken in case of claims related to the construction process. In other words, it was stated that construction projects suffer less in the case of contractor originated claims in construction projects. However, according to consultants and owners, it is implied that construction projects can be completed most successfully through mitigation measures to overcome “Complex Design”, “inconsistencies between different designs” and “lack of supervisor experience”. In other words, these findings have revealed that construction projects suffer less in the case of consultant-owner originated claims in construction projects. In this context, the consultant-owner were indicated that the projects can be managed most successfully with the measures to overcome “technical related” problems.

In general, organizations implied that construction projects can be managed most successfully with the measures to be taken to address the problems under their responsibility. In other words, it was implied that the project could be completed unsuccessfully because of encountering claims events related to the other party's obligations.

Table 4. Project success rate relative to claim factors according to the organizations.

List of Claim Factors	Contractor	Consultants - Owners	All Participants
Inadequacies/Errors in Contract Drawings	1,18	1,17	1,12
Complex/ Low Constructability Design	1,66	2,71	2,00
Inadequacies/Errors in Specification	1,12	1,89	1,19
Inconsistencies between different design disciplines	1,03	1,90	1,18
Changes in Scope of Project	1,17	1,50	1,42
Inadequacies/Errors in Contract	1,27	1,30	1,10
Inadequate knowledge of client about construction projects	1,23	1,56	1,33
Inadequate Experience of Consultants/ Supervisors	1,24	1,74	1,21
Low contract price	1,57	1,55	1,36
Inadequate time in tendering process	1,71	1,37	1,55
Inadequacies / Errors in Organizations	1,60	1,00	1,40
Inadequate Communication between project parties	1,70	1,98	1,63
Changes in Construction Method	1,82	1,46	1,76
Low Quality/ Errors of subcontractors	1,96	1,19	1,67
Effects of Construction/ Shop Drawings	1,26	1,69	1,22
Inadequate Experience of Contractors	1,60	1,56	1,51
Inflation/ Rises in Resources Cost	1,57	1,27	1,44
Natural Disasters	1,68	1,26	1,63
Subsurface/ Ground Problems	1,36	1,50	1,34
Lack of Material in Market	1,61	1,59	1,44
Changes in Law /Regulations/ Standards	1,32	1,26	1,3
Average Score	**1,46**	**1,59**	**1,42**

Conclusion

Project performances are significantly affected due to contractor claims. Any organization involved in the project may be obliged to cover the cost of claims. It has been observed that organizations exhibit different approaches for claim factors and mitigation measures according to their organizational characteristics. This paper emphasizes that organizations exhibit a stance based on their interest concerning claim causes and mitigation measures. This paper reveals that more importance should be given to detailed project scope and comprehensive project preparation in the pre-execution process as well as to effective site management during the execution phase for construction projects in Turkey.

Construction projects in Turkey are extremely susceptible to the claims of the contractors. Many factors allow contractors to ask claims, thereby construction projects are exposed to a lot of contractor's claims. One of the most important factors affecting the claims is called "insufficient project documents" and "lack of party organizations during the pre-construction phase of the projects". Such activities are carried out in the design and tender processes in

common. In general, consultants and project owners play more active roles than contractors to build the technical and administrative structure of the project.

This study has revealed that construction projects may be subject to fewer claims if all organizations fulfil their responsibilities during the project stages. In this context, additional budget and time will not be required due to fewer claims in construction projects. The projects will be able to complete at the planned budget and time, thereby this result will be counted as a success for all parties involved in construction projects.

Abstract

The spread of the digital transformation, which started with Industry 3.0, along with the developing technology, has affected the construction and education sectors as well as different professions and industry groups. It is seen that the use of technologies such as building information modeling (BIM), cyber-physical systems (CPS), laser scanners, virtual reality, augmented reality and artificial intelligence has increased with Construction 4.0, especially in the design and construction management stages. It is inevitable that students, who are in these technological and digital transformations, need different methods in terms of perceiving information compared to other generations. While traditional methods are effective for the Y generation and the old, traditional methods lose their effect in the Z and future generations. This situation necessitated a change in education methods and revealed the concept of Education 4.0. In this study, new methods used in civil engineering education, especially in the last 10 years, were investigated. The results obtained from the use of the methods found as a result of the research in civil engineering education, and the advantages and disadvantages of these methods were examined.

Keywords: *civil engineering education, education 4.0, educational technology, industry 4.0.*

Introduction

Industry 4.0, which first came to exist in 2011, is a new industrial revolution based on robotics, the internet of things (IoT), real-world virtualization, big data storage, nanotechnology, energy storage and artificial intelligence (Mogoş et al., 2018; Esmer & Alan 2019). Technologies brought by the Industry 4.0 revolution have revealed many 4.0 concepts such as marketing, logistics, health, management, construction and education (Schircks et al., 2017). Each of these concepts refers to digital transformation and technological progress in its own field. With construction 4.0, it is seen that the use of technologies such as building information modeling (BIM), cyber-physical systems (CPS), laser scanners, virtual reality (VR), augmented reality (AR) and artificial intelligence (AI) has increased, especially in the project designing and monitoring stages. The size and complexity of the construction projects built with these technologies cause the need for technical personnel who can adapt to the

developing technology. This situation makes it inevitable to use the developing technology in engineering education. In order to train qualified personnel in the field of civil engineering, as in every field, there is a need for a project-based, life-long learning, developmental, innovative, technology and internet-using education system. Nowadays, the education system that aims to meet this need is called Education 4.0.

Education 4.0 has nine goals besides integrating high technology and digital data into education (Fisk, 2017):

- To ensure that education is not limited to classrooms and learning anywhere and asynchronously.
- To enable the student to choose the appropriate tools and programs for learning.
- To provide education with a personalized curriculum according to the student's abilities.
- To enable the student to learn by herself/himself, to gain independence in learning, and to ensure that the teacher takes a guiding role in the learning process.
- To ensure that practical training is included in the curriculum, to provide opportunities for students such as internships and industry cooperation projects.
- To provide project-based thinking, learning and working principle.
- To provide students with organizational, collaboration and time management skills.
- Determining student and sector needs in education.
- Using assessment methods such as data interpretation, questioning and answering instead of traditional exams.

It is also seen that the technological and methodological goals of Education 4.0 are compatible with the learning style of the Z generation living with technology. Young people (Generation Z), who grew up with technology, have difficulties in adapting to classical materials and techniques. Generation Z youth focus on first-hand access to information (Kuleto et al., 2021). Therefore, this generation of young people prefers web, computer, phone, tablet, etc. environments to access information, unlike the classical library environment. Educating civil engineering students with an appropriate pedagogical and technological approach will increase the capacity of universities to train engineers at a professional level. In addition, it is foreseen that students will gain a systematic perspective, lifelong learning, intergenerational experience exchange, interdisciplinary cooperation, and increase the entrepreneurship and innovation culture of students (Samaka & Ally, 2016). Due to the aforementioned reasons, it is thought that the blackboard and chalk system should be abandoned in universities, technological developments should be followed and Education 4.0 should be integrated into university education (Almeida & Simoes, 2019; Boz, 2019).

This study is aimed to investigate new methods and technologies used in civil engineering education that emerged with Industry and Education 4.0. For this purpose, new technologies used in civil engineering education have been obtained by researching studies in the literature in recent years. The results obtained from the use of the new methods found in civil engineering education, and the advantages and disadvantages of these methods were examined.

Methodology

Since the mention of Industry 4.0 in 2011, it is seen that studies related to educational technologies have increased in the literature. In this study, the keywords "Engineering Education" and "Education Technologies" were used to search for new technological approaches. The related studies conducted in the last 10 years were searched in the databases of “Scopus”, “Google Scholar” and “Thesis Center” with the determined keywords. In the investigations, seven technologies have been identified. These are “Audio-Visual Materials”, “3D Printers”, “BIM”, “Games and Animations”, “VR”, “AR” and “Mixed Reality (MR)”. Then, the usage of these technologies in "Civil Engineering Education" was searched in the same databases. In the following stages of the study, these technologies are examined in detail. The research methodology is given in Figure 1.

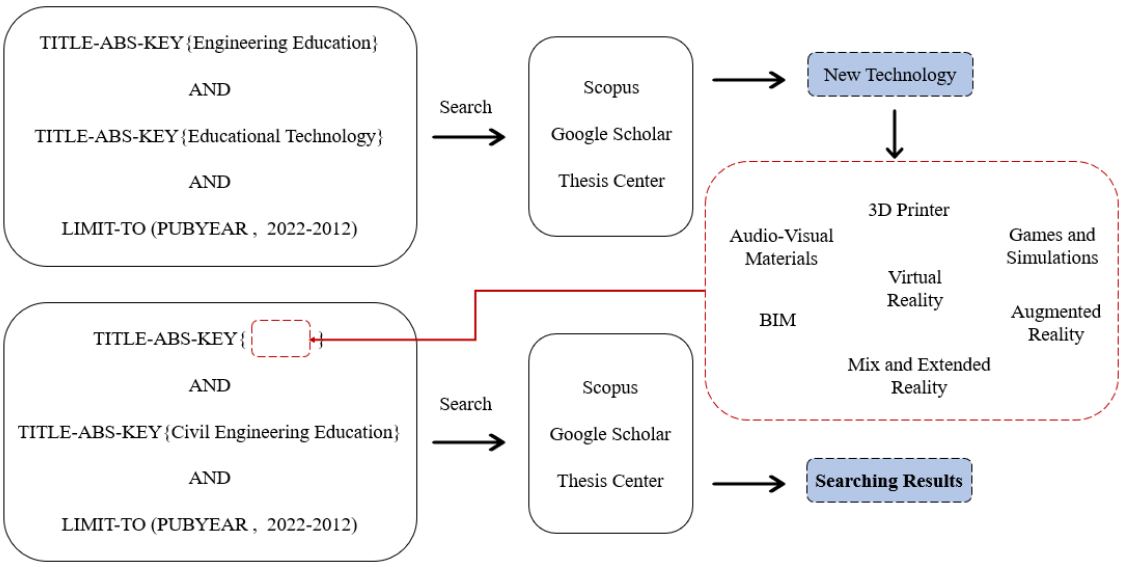

Figure 1: Research methodology.

In this study, a systematic literature review such as meta-analysis, bibliometric analysis, and statistical analysis of publications was not carried out. By using these keywords, new technologies were tried to be determined and these approaches' usage in civil engineering education was investigated.

Audio-Visual Materials

The invention and use of audio-visual materials, which were used before Industry 4.0, have changed considerably until today. The high quality of audio-visual materials used these days (videos, animations, simulations, animated presentations, audio slides, etc.) and their easy accessibility (mobile phone, television, computer, tablet, etc.) have greatly increased the use of these materials. The widespread usage and increasing speed of the Internet, the satisfactory video quality and the easy sharing of videos in the digital environment have made videos, one of the audio-visual materials, quite successful in education. The videos, which are used frequently during the Covid-19 pandemic period, have made a great contribution to the continuation of education regardless of place and time (Liu, 2021).

In the literature, it is seen that videos also contribute to the spreading of educational services, increase the quality of education, ensure memorability and attract the attention of students in education (Stefanova, 2014). In addition, the benefits of videos are stated as saving the time and cost of teaching the subjects, showing the details to the students by zooming the image in professional fields and providing practical education more easily (Boz & Toğan, 2021). It is also emphasized that audio-visual materials allow students to learn the subjects faster than written texts and to concentrate on the subject by stopping their education whenever they want (Kay, 2012). It has been demonstrated through surveys, observations and experiments that educational documentaries or practice videos about subjects that cannot be shown directly in the lessons are useful in education (Bétrancourt & Benetos, 2018) and that course materials supported by real-life pictures, simulations, animations and interactive narrations provide advanced benefits in education (Bikçe et al., 2011).

Bauer et al. (2021) stated that the necessity of using technology in civil engineering education is more understood in the Covid-19 period. In order to support distance education, the team of professors has prepared comprehensive training videos on environmental, geotechnical, transportation and structural engineering issues. They stated that the students who were educated with videos found it interesting and that the videos helped the students to understand the course content.

Boz (2019) argued in their study that practical training is necessary for civil engineering students to fulfill their professional responsibilities well after graduation, but internships, which cover a large part of applied education, cannot fully accomplish this task. For this reason, they explained the production of stone walls, which is in the professional practice of civil engineers, to civil engineering students using audio-visual materials. The videos include the designing phase of the stone wall, the technical terms in the projects and the real video on site under construction (Figure 2). As a result of the study, they determined that audio-visual materials can be used especially in practice training.

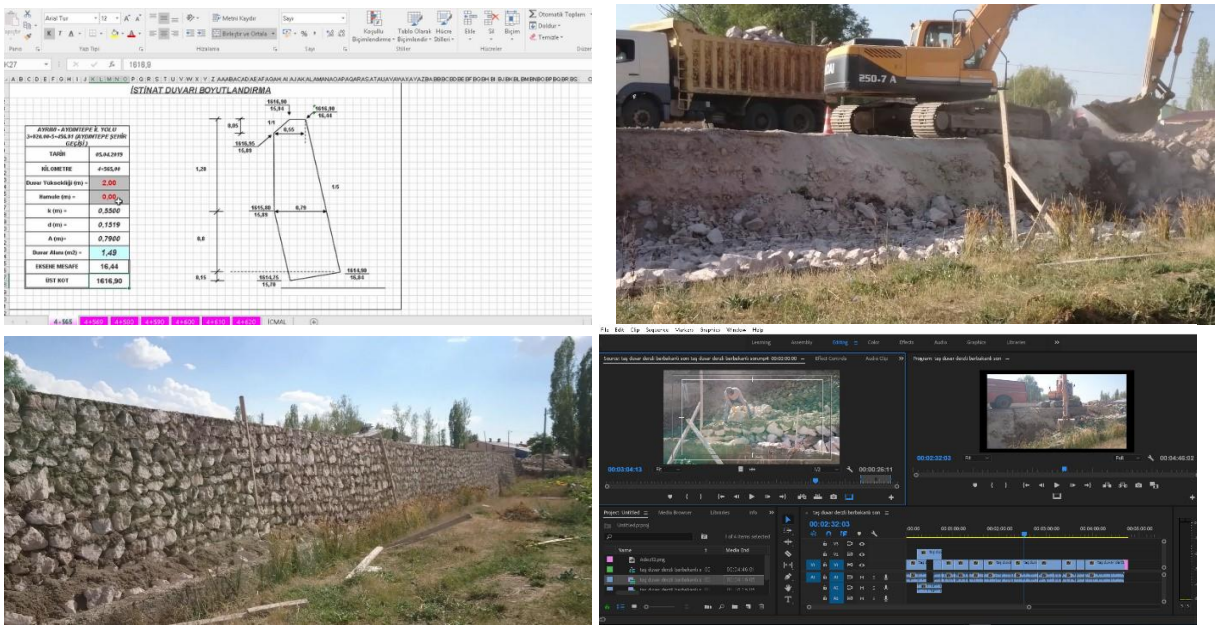

Figure 2: Stone wall video (Boz & Toğan, 2021).

Stefanova (2014) divided engineering students taking electronic measurement courses into two groups. They taught the lesson to one of the groups using audio-visual materials and the other group with traditional methods, and as a result of the study, it was determined that the students who were educated with audio-visual materials learned the lesson better.

3D Printers

3D printers, which became widespread with Industry 4.0, have managed to become a trend in the field of prefabricated manufacturing with their contributions to speed, design possibilities, economy and engineering. Today, it is used in many areas other than manufacturing and it has different usage areas day by day. It is thought that small-sized 3D printers, which can also produce 3D course materials, will create significant changes to engineering education (Kökhan & Özcan, 2018).

3D printers, which can be used in the education of fields such as architecture, art, biology, chemistry, geology and construction, are seen as an important tool for increasing creativity in mechanical and technical courses. With the effective use of this technology in the educational environment, students can quickly see their designs in 3D, improve their perspective vision skills (Lantada et al., 2010), find the opportunity to create physical objects (Syed, 2012) and learn by showing more interest in the lessons and having fun (Schelly et al., 2015).

While Tehrani et al. (2017) taught civil engineering students the working principles and necessary programs of 3D printers to make multidisciplinary designs, Katrenicova et al. (2020) used 3D printers in education to increase the geometric perceptions of civil engineering students. In addition, Kazemiroodsani and Kamat (2021) used 3D printers to better understand the land conditions and cut/fill works in the road project design in the civil engineering transportation department.

Building Information Modeling (BIM)

BIM is the process of producing digital models for the design, construction and operation of projects and using these models throughout the project lifecycle (McGraw Hill, 2009). This process includes stages such as static, architectural, machine and energy elements of the building can be modeled in three dimensions (3D), creating planning and scheduling documents and showing the construction phases. BIM is also becoming a new generation learning method in terms of pedagogy, thanks to the ability to see two-dimensional building components in 3D and the simulation features. From another perspective, BIM technology can provide an environment for students who have not seen the construction phase of a building to think and practice all building processes and behaviors close to digital and physical reality. Owing to these advantages of BIM, it is seen in the literature that BIM is used especially in architecture and civil engineering education (Bozoglu, 2016; Sampaio, 2018; Pomares Torres et al., 2017).

Meterelliyoz and Özener (2017) developed the operation of the Construction Technology course by using BIM technology. As a result of the case study, they have identified positive changes in the improvement of students' knowledge levels and also the design and development of building elements.

Lassen et al. (2018), in the Introduction to Civil Engineering course at Akershus University in Oslo, gave the students the task of designing a two-story wooden structure in the BIM-based Autodesk Revit program. As a result of the task, the students reported that they understood the design, implementation and construction details better. In addition, students have gained collaborative working experience. As a result of the study, it was determined that BIM supports students in understanding professional civil engineering. In Figure 3, there are images from the models created in the study.

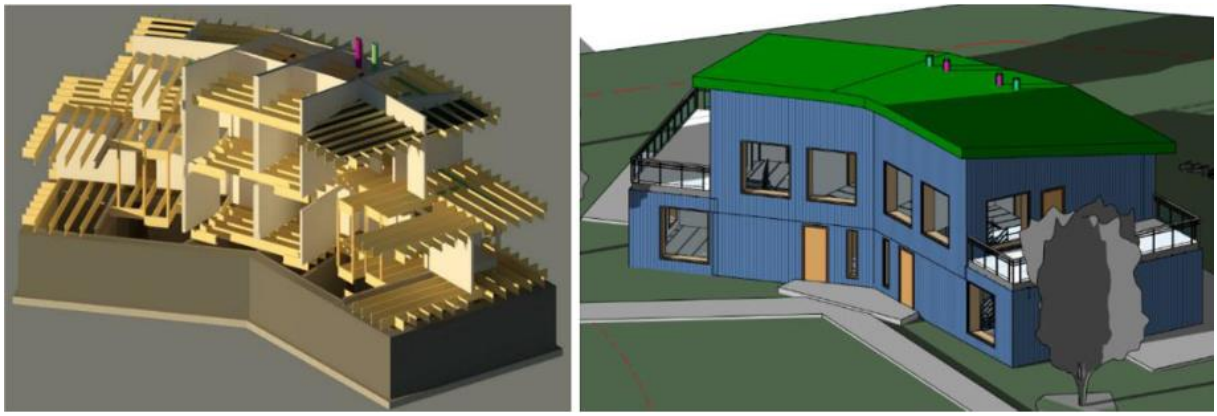

Figure 3: Images from the study (Lassen et al., 2018).

Games and Simulations

It is getting harder and harder to motivate Z generation students in the classroom with traditional methods for a long time. This generation, growing with technology, is looking for a more flexible and interactive educational environment (Proserpio & Gioia, 2007). It is thought that digital tools such as games and simulations will meet this need (Poole et al., 2014). Game-based learning, which is one of the new generations learning methods, creates high motivation and habits in individuals (Huang & Soman, 2013). In game-based learning, features such as virtual rewards, achievement badges and displaying students' success rankings according to various characteristics increase participation in education, create competition and improve learning (Alanne, 2016). It is also mentioned in the literature studies that the fun learning brought by games and simulations is better understood than the lessons presented as text or oral presentation (Chen & Wu, 2015). It is seen that the advantages of digital game-based education increase with the rise in the frequency of use of devices such as computers, tablets and phones (Sera & Wheeler, 2017). While this method provides the opportunity to present information without requiring a large investment, it also relieves students of the obligation to devote intensive time to classes (Kapp, 2012).

Fatahi and Khabbaz (2015) used a computer game to teach civil engineering undergraduate students about soil behavior. In the study, it was observed that game-based learning contributed to students' information gathering methods, creative thinking, problem-solving and lifelong learning skills. In addition, a fun competitive and collaborative learning environment was provided in the course, and students' motivation and critical thinking skills increased.

Sousa (2020) organized suitable games for two civil engineering courses and added them to the course curriculum. In the study, it was seen that game-based learning contributed to the

student's learning of transportation costs and construction terms. However, it was also stated that a lack of seriousness in the lesson may occur in game-based learning.

Zechner and Ebner (2011) applied the game-based learning method in the civil engineering structural analysis course. 159 students used the games and as a result, they found that the learning outcomes of the students who used the application increased. Although the learning outcomes of the students who played the game increased compared to those who did not, there was no difference between the students who played the game more and those who played less.

Virtual Reality

VR is a technology that allows a person to observe or do events in a virtual environment that may occur in the real world by isolating them from the real environment. This technology, which has a slow spread rate due to the expensive required equipment and the difficulty of preparing materials, has started to be used in fields such as health, engineering, military, automotive and tourism in recent years. It is thought that VR technology, which is preferred for personnel training in many areas that may pose a danger to humans and the environment, can make it possible to learn subjects and concepts that are difficult to understand at other levels of education in a more interesting, memorable and effective. Especially in civil engineering education, it is thought that the opportunity to gain experience without going to the construction site and the ability to visualize and interact with the 3D materials in the theoretical courses will both contribute to the practical training of the students and contribute to a better understanding of the theoretical knowledge and increase the academic success of the students.

VR applications are becoming more popular daily with developing technologies and various field-specific VR applications and simulators are being developed. The integration of VR into education has increased the potential of students to access education (Balak, 2019; Kılıç, 2020). Piovesan et al. (2012) stated that 3D virtual learning environments can improve spatial knowledge, facilitate impossible or impractical experiential learning, enable the transfer of knowledge and skills learned in virtual environments to real situations, and increase learning motivation and participation. Mikropoulos and Natsis (2011) stated that VR makes it easier to understand the basis of a subject, can transform intangible ideas into tangible representations, and offer users more situations than they can normally experience. Çoruh (2011) investigated the effect of using VR applications as a learning model in Art History courses in Fine Arts and Architecture Faculties on student achievement. At the end of the study, it was stated that the majority of the students were in favor of the use of VR applications and technologies both as a learning model and as a complementary element in Art History courses.

Sampaio et al. (2010) pointed out that VR technology can be used as a complement to 3D modeling in civil engineering vocational education and practice. They emphasized that the VR models developed for the construction process can provide a visual simulation of the physical progress of each type of work, can help to examine the necessary equipment and learn information about the operation in the field, and can evaluate the knowledge gained by the students in their professional practices.

Özel (2019) created a VR application to measure the ability of construction workers to recognize hazards at construction sites. The dangers that the workers may encounter in real

life were placed in the application and the workers were expected to walk around the virtual construction site and detect the dangers by wearing VR glasses. Thanks to this training, workers experienced dangerous behaviors and substances without going to the real construction site. An example of a virtual construction site is shown in Figure 4.

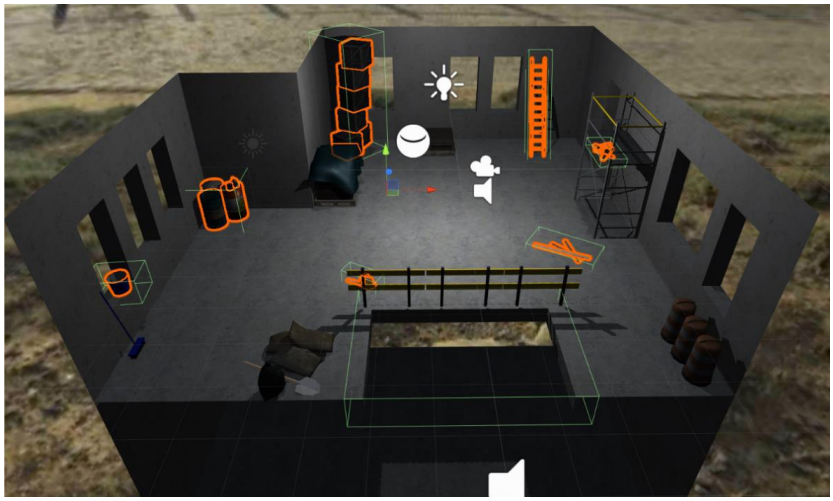

Figure 4: Virtual construction site environment with various dangers (Private, 2019).

İçten (2021) designed an educational virtual environment so that pedestrians and driver candidates can learn traffic rules in a virtual environment based on real traffic rules. It has been argued that VR can be a solution tool in eliminating the problems that pedestrians and driver candidates will encounter in traffic, with the training in this application in which natural hand movements are followed and vehicles move. Figure 5 demonstrates the images of the designed program and its use.

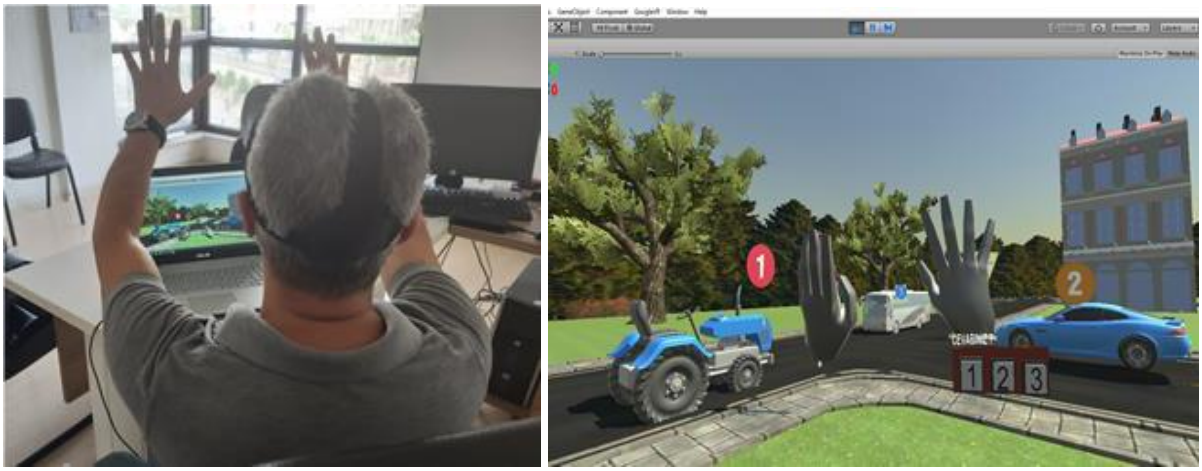

Figure 5: Interactive 3D virtual environment (İçten, 2021).

Kılıç (2020) mentioned that students have difficulty in understanding application issues such as finishing structure details, material, space and object scale in lessons. As a solution proposal to this problem, a VR application teaching model with an immersive effect and representing a virtual construction site, has been developed to be used in interior architecture education. In this study, the author revealed that VR application has an effect on accelerating

the interior architecture teaching process and increasing the quality of teaching. The designed VR application is shown in Figure 6.

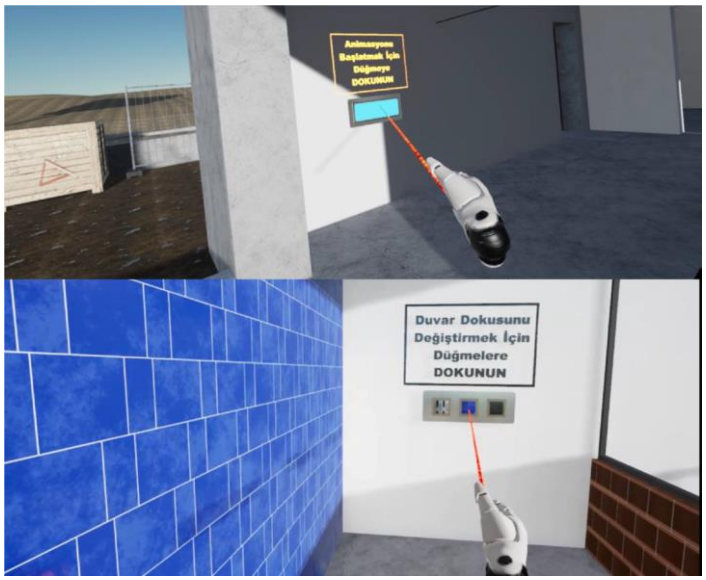

Figure 6: Interior architecture virtual training application (Kılıç, 2020).

In the above-mentioned studies, it has been determined that VR technology, adapted from real life, mainly helps students to understand and learn the information better because it opens new ways for learning and offers an interesting method.

Augmented Reality

The general purpose of AR and VR is to strengthen, support and enrich reality by providing information that people cannot see but can imagine under normal conditions. However, AR does not create a completely artificial environment, unlike VR. With the AR glasses, opportunities such as viewing the situations of objects in different environments, the details of machine parts and the process-result steps of the construction work guides are provided. These possibilities have made AR a new technology that can be used both in the sector and in education (Albahbah et al., 2021).

Nesterov et al. (2017) claim that AR is replacing expensive laboratory equipment and that students' interest level has increased due to the interaction of these technologies with students. Somyürek (2014) expresses some of the usage areas of AR for educational purposes as adding a 3D to 2D books, training on cognitive and psychomotor maintenance/repair tasks, and providing information/skills about tools and materials in engineering education. Balak and Kısa (2016) investigated the use of AR technology with smartphones in technical drawing education and emphasized that AR has critical importance for engineering students in the technical drawing course. Li et al. (2017), on the other hand, state that visualizing accurately and effectively using an AR platform for analysis and simulations involving engineering data types reduces false learning and interpretation.

Theodossiou et al. (2018) developed an AR application for hydrology education in civil engineering. Thanks to the application, the students gained the ability to better understand the effects of floods and structures on the flow regime, rainfall intensity and evaporation-

transpiration. Louis and Lather (2020) used an AR to teach excavation planning. As a result of this study, it has been suggested that AR virtual spaces can support planning and managing large-scale construction projects. It is also mentioned that the application can be used by excavation construction teams and professional engineers. Also, Waters et al. (2021) created an AR application for the Foundations, Soil Mechanics, Hydraulics and Hydrology courses in the civil engineering undergraduate curriculum of Villanova University. For the planning and implementation of these modules, faculty members from more than one discipline (geotechnical, water resources and structural engineering) worked in the department. It is aimed to support education with 3D materials for other courses at the university, as positive feedback is received on the 3D visualization and application skills of the students who use these modules.

Mix and Extended Reality

Nowadays, it is seen that the concept of MR is used as a term that covers both VR and AR applications (Sherman & Craig, 2018). The MR concept, which uses wearable technology instead of hand-held devices, provides the opportunity to interact with virtual objects in the real world (Künüçen & Samur, 2021). While the user is experiencing MR with these devices, they can interact with virtual menus or objects with their hands without the need for any additional device and can be more involved in the experience process than the classical AR concept (Langstone, 2021). Extended reality (XR) is a concept that brings all other realities together. With XR, which is less common in the literature, people will be able to feel as if they are anywhere in the world thanks to wearable technologies (Künüçen & Samur, 2021). These technologies require expensive equipment and are more complex technology than AR and VR, therefore, the possibility of using these technologies in civil engineering education reduces.

Discussion

Civil engineering education should not be limited to subjects such as the response of load-bearing elements under various loads and various environmental conditions, how the bearing elements are designed, and how the materials that make up the structural elements are produced. Civil engineering is a generally field-studied profession. When the theoretical knowledge taught in universities cannot be combined with field studies, the efficiency of the students' vocational education decreases. Civil engineers taking responsibility in many areas such as bridges, roads, tunnels, industrial structures, prefabricated structures, infrastructure works, dams and ports in their working life, cannot gain the necessary experience with traditional education methods. When it comes to the training of field applications, the use of current technologies is of great importance. It is much more practical and faster than traditional methods for students to learn, manage and develop the design processes and construction stages by using technology.

Within the scope of this study have been researched new technologies that can contribute to applications such as internships, technical trips and laboratories used in civil engineering practice education. Audio-visual materials, 3D printers, games, simulations, BIM, VR, AR and MR are some of these technologies. Audio-visual materials are very useful in providing asynchronous learning, transferring the experience acquisition that takes a long time to the student in a short time and in showing the construction stages. However, audio-visual

materials have some disadvantages such that they cannot be filmed under all conditions, some dangerous works cannot be recorded on video recordings, and the students feel a lack of perception of reality in animations. Although 3D printers increase imagination, design skills and perspective vision, the inadequacy of 3D design elements in crowded classrooms is one of its disadvantages. Although games are very advantageous in providing fun learning and keeping information in mind, the lack of seriousness while playing games in the classroom is one of the difficulties brought by this technology. Interdisciplinary BIM studies contribute to the collaborative learning of students, to have knowledge about design and development of building elements, and to examine the details of design and construction stages. The environment provided by VR technology to students and the opportunity to interact with objects can offer students unlimited experience, especially in practice training. The cost of the design of VR environments and the used materials slows the spread of this technology. AR technology, which can be easily accessed by tablets and phones used today, can be used in education with simple coding and 3D models. MR is a mixture of VR and AR technology. Similar to VR, it requires expensive equipment.

Conclusion

The expectation of Industry 4.0 and Education 4.0 is to train human power integrated with technology. In order to fulfill these expectations, new technologies should be integrated into education. For this purpose, educational technologies that can be used in civil engineering education, together with their advantages and disadvantages, are examined. It has been shown with examples from Turkey and the world that these technologies can be integrated into civil engineering education. It is thought that the technologies mentioned in the study, in addition to traditional methods, will contribute to the training of qualified and technology-skilled civil engineers with application knowledge. Nowadays, when the virtual classroom and Metaverse have become widespread, it is obvious that traditional methods are insufficient.

Future studies can investigate different new technologies that can be found by systematic literature review. Educational approaches other than engineering education can also be included in these studies. In addition, new pedagogical approaches used for the Z generation can also be explored for engineering education.

Abstract

Most post-war reconstruction initiatives consider revitalizing public places an appealing starting point; much effort is focused on guaranteeing a new phase and transitioning from conflict to peace, which has a different influence on maintaining peace. Barcelona was one of the cities affected by the conflict and the political transition from Franco dictatorship to democratic Spain; urban planning played an essential role. In the mid-1980s, the recovery of public spaces, the recreation of new parks, and the revitalization of the city centre were critical in translating a new culture and value into the city system. This study aims to learn from Barcelona about the process of revitalizing the city center and its influence on the city's transformation from war to peace. The study conducts a literature review of Barcelona, scanning the public space design process using the timeline, followed by an assessment of the function of public spaces in post-conflict rebuilding to determine the success and failure of the public space design process. The paper also aims to provide a point of reference that may serve as an example for nations experiencing or at risk of experiencing civil war.

Keywords: *Barcelona, civil war, post-conflict reconstruction, public space.*

Introduction

Public spaces were designed as a sign of democratic practice in Barcelona city; for this reason, almost two hundred parks were designed after the democratic election of the mayor in 1979 as a response to the citizens' demands to ensure their rights to political and civic participation. In addition to rebuilding a new culture and identity that emphasizes the local authority of the public spaces and provides the international community's recognition of the local claims and role.

The public spaces also played a significant role in building the connection between the segregated areas, as well as building the bridges between the different cultural groups through cultural activities and providing spaces for each of them to show their culture and identity. (Bollens, 2006; de Balanzó & Rodríguez-Planas, 2018). Understanding the Barcelona city

experience in developing the public spaces as a critical urban tool for democratic transformation and building a place-based identity that managed to gather groups from different ethnic groups. Assessment of the public spaces design process will provide a list of dynamics and references that can serve other cities experiencing conflict and recovery planning. Emphasizing that there is no recovery blueprint and understanding the internal and external context is essential for developing the recovery plan. The paper answers the following questions: How can public spaces play an essential role in recovering the cities experiencing conflict? And what are the requirements and conditions needed to ensure the effectiveness of the public space's recovery role?

The paper answered the designed question through the following methodology:

- A literature review by looking at the Barcelona case study, using the timeline tool to document the main event.
- Analyzing the public spaces' design process in Barcelona.
- Providing a point of reference for the role of the public spaces and the dynamics need to be considered as a part of the recovery work.
- The conclusion part of the paper will consist of several questions defined along the reviewing process of the current practices in Syria.

Background of Barcelona Public Spaces Design

Barcelona's city story with public spaces started as part of urban regeneration local policy and making the public spaces in the 1980s. Their policy had international recognition for its way of improving the city, where more than three hundred qualified inter-connected public spaces and facilities were created. The objective behind it is to respond to people's claims to develop their neighborhoods and to fulfil their need to play an active role in the civic and political realm (de Balanzó & Rodriguez-Planas, 2017). This policy was implementable because it resulted from the 1970s grassroots movements' proposals on urban rehabilitation, where the political parties found it acceptable within the political environment after a long-contested dictatorship that lasted for forty years. The reconstruction of Barcelona focused on the local urban interventions, including the public spaces, that participated in connecting the diverse areas to establish a network of democratic gathering spaces (di Masso, 2015).

The Olympiad in 1992 had a significant influence on the Barcelona public spaces journey; it is considered an important milestone where the city went through structural crises to fulfil the needs of hosting the Olympiad. For this purpose, a new public-private partnership established and guided the spatial dynamic and priorities of the design of the public spaces and negatively affected the role of the public spaces as a place of citizenship because the global dimension dominated the preparation needed for the Olympiad and became a tourist-centered designed process. This phase resulted in a higher level of exclusion and developed policies against migrants and minorities, in addition to the oppression and low freedom of expression (di Masso, 2015). in addition to another international event in 2004, the forum of universal culture participated in shifting the focus to global and going beyond the local political conflict. (Bollens, 2012). Such events put the urbanist in the dilemma of market-driven design versus citizenship and local community needs-driven design, where they manger with those global events to reinforce the relationship between national, regional and local policies (Bollens, 2012), which ensured the global sustainability of the city.

One of the events mentioned could explain the conflictivist relationship over the public spaces, in one of Barcelona's neighborhood, in late of 2000 there were a vacant placed as a result of demolition work planned to be a public space as part of the 1985 urban development plan for the people in one of the marginalized neighborhoods in the city, the people decided to take the action and shows their unacceptance for the long time passed and not designing the public space as well there were a plan for gentrifying the neighborhood by the council and the private sector, as a result of this circumstances, the people decided to reoccupy their public space and make as it was planned (garden) for the neighborhood, they plant a tree in the middle of the empty space which faced with a refusal from the municipality and several back and forth action took place ended with the municipality took over the planet trees and sieged the area, but the activist and the citizens took over the area and planted trees and flower as well established a playground and opened theater, the conflict lasted till 2007, and became a symbol of a public demands for a public spaces that's fulfil local communities needs and priorities, where the municipality designed the public spaces according the measures and responds to the public claim.

This event shows a un ended story where the conflict over spaces will never end, but at least having the community's culture and structure could ensure community-based urban interventions. The public spaces could be considered an indicator of the healthy implication of the urban interventions; as long as the public spaces reflect people's lives, diversity, cultures and needs, we are on the right track.

Another fact in Barcelona's case is the role of the architects and urbanists; they were in the street with the people and engaged in the political discussion because they believed that the city's role was to ensure the rights of the people to their streets and public spaces. The city's function and design reflect the more extended political situation, and that’s what the urbanist of Barcelona focus on as part of criticizing the franco city and applying the urban justifications as an indirect way to come for a democratic city (Bollens, 2012). Understating the historical and cultural relationship between the people and their city’s public spaces was essential in the development role of the architects and urban planners in transferring the city and standing against the policies developed during the Franco years, as shown in table 1, which affected the heritage and the authenticity of the city (Bollens, 2012). As well it's important to mention the dependency between urban peacebuilding and the political peace process. The death of Franco opened the space for the administrative entities to apply the changes of urban peacebuilding in public spaces. But still, the urban approach is essential for sustainable peacebuilding at the national and local levels (Bollens, 2006).

Table 1. Comparison between Franco’s planning and what the urbanist worked on.

Barcelona city during Franco's years (Wynn, 1979)	What the urbanist worked on
- It was an overbuilt landscape and shaped by private power - City of limited public spaces - Working class neighborhoods were under-serviced	- Helped neighborhood-based-movement associations to analyze their local problems and define possible solutions. - Provided a political-civic education on the needs for local democracy.

The establishment of the neighborhoods based-movement association was essential in requesting the design of more than 200 parks, where the demands at the urban level connected to the brooder movement for democracy. The public space at the neighborhood level developed

as part of the extensive work with the people; they defined their problems and solutions and were educated on what democracy means (Bollens, 2012).

In addition to the role of urban planners at a local level, the use of urban tools at the planning level managed to put together all opposition parties around one shared project, at a time when each party had their political agenda and vision of developing the community and transferring to democracy. Keeping in mind that the planning tools were guided by the community (neighborhoods associations), which ensured the focus of the urban interventions at the neighborhoods level played a crucial role in building trust and had a direct result of the community participation that's reflected in the provision of their urgent needs and the public spaces. In addition, implementing public spaces and parks in neighborhoods was an educational approach for the community.

In conclusion, the case of Barcelona is a case where they managed to transfer from in-group conflict and take stable steps in peacebuilding through urban governance and policy.

Public Spaces' Roles as Part of Peacebuilding

The public spaces' role in grounding the citizenship implication as part of promoting democratic practices through emphasizing the rights and responsibilities of the citizens on a practical and small-scale level, ultimately shaping the city's political frame (di Masso, 2015). How the dynamics taking place in the public spaces could participate in grounding the construction of citizenship at the community level. What are the criteria of those public spaces that can participate in the construction of the sense of citizenship, such as belonging, recognition, rights, and ownership, and where citizenship is experienced, performed, challenged, and demanded daily? That's called locational citizenship, which the paper explores in-depth as part of the Barcelona case study (di Masso, 2015).

Public streets and spaces are a living culture that shows the various identity in the city, for it should belong to the people, not to the state, where the people all people can raise their voices on the issues of their concerns through public spaces and streets (Bollens, 2012).

The urban spaces reflect the macro-political structure of the city, where each of the urban spaces has the ability, among others, to influence the city's order and political dynamic. Ultimately, the social and cultural life of the urban spaces is part of the broader state attitude, political structure and economic systems. And vice versa, they constitute a place's defining elements as a social context for political and other forms of social behavior (Parkinson, 2012.)

Based on the viewpoint of considering the public spaces as a conflictive space where the ongoing conflict is reflected on them, as well, it's a place where the various groups meet and are introduced to each other. They manage their differences to create a unique identity that belongs to the space and all of them simultaneously. Owning the public spaces and ensuring the inclusivity of all citizens and participating in the daily democratic life of the city, considering the public spaces as a place for citizenship from the social-psychological and political terms (di Masso, 2015). It is also regarded as a must right at the neighborhood level, regulated by the guidelines and policies of the neighborhood (Acebeillo & Gracia-Bragado, 2000).

Public spaces have a two-way effect; the value and the process of their development influence the community and the city act, and vice versa; the community's behavior and willingness for changes will influence the role of the public spaces.

Based on this two-way role, the public spaces present new values in the community, which educates the people about democratic and collective action in the city's daily life, which is a critical factor in democratic practice (Bollens, 2006). the urban design was an opportunity for joint planning across the different ethnicity, which brought them together and ensured equal participation. The public spaces were considered connecting areas between those groups from different ethnic backgrounds (Bollens, 2006), where post-war reconstruction aims to deal with the war causes and the issues raised during the war.

Guiding values for public spaces are summarized in the following (Bollens, 2012):

- Public access: is reflected in stakeholders who participated in the design that influenced the urban design and access.
- Equality: is reflected in working with most marginalized groups and improving across all neighborhoods.
- And democracy: is reflected in the process design, ensuring participation and the interventions' priorities.

Those values helped establish and reinforce urban-based identity, which included all ethnicity In other cases, the peace agreement might maintain segregation and ensure the power balance between the conflicted groups and communities and cannot transfer the city to act and progress as one body for a shared future. The urban intervention needs to develop spaces and policies that support democratic practices and ensure daily diverse group interaction. Ultimately, the city will be able to deal with the conflict that could lead it to creative development (Bollens, 2006).

The power of planning comes from its ability to translate democratic and civic objectives into concrete actions. Where in the Barcelona case, urban planning translated the economic and social program into action through 1) the process of developing and designing the urban spaces and 2) what the urban design focused on and had a priority based on the result of the participatory process. For this reason, this authority from urban design needs to be used in a way that supports the democratic transfer of the city and ensures equal opportunity and access for all groups (Bollens, 2006).

The urban has another role in educating the people on what the democracy terms mean in practice and how they can be applied daily and manage the relationship between the people and their city daily. Urban planning ensures a breath moment for the city to deal openly with challenges and problems of the city and paves the way for a shared future of the people in the city by connecting the spatial design with the social and civic objectives of the city (Bollens, 2006).

Working on the public spaces as part of the regeneration projects participates in the effectiveness of those projects, where the public spaces play a critical role in developing the low-income groups' situations which open space for their participation and defining their priorities. Otherwise, it is just a "renewal program" that works on the physical level (Arbaci & Tapada-Berteli, 2012).

Based on the above, we can conclude the success factors of public spaces' role in democracy and sustainable peace as following

1. Community participation and political education
2. Role of architects as activists and working with people
3. Implementing local thinking global
4. Planning's justification for claiming political issues
5. Ongoing process.

People in public spaces feel absorbed by what's happening around them. Those spaces take them to a unique dynamic where they gradually become part of it and have a memorable experience just by crossing through it. Public spaces create opportunities for all social groups to exchange and express themselves and protect people's rights to participate appropriately in urban spaces. As urban planners and designers, we must understand that democratic public spaces evolve through the processes and practices of times. We must focus on the functions and procedures that enhance democratic public spaces' roles (Sezer, 2020).

In conclusion, the public spaces are the symbolic presentation of the diverse" group, preserving the memory and identity and defining the political order of the city as well the economic system. Where those democratic streets can play an essential role in the democracy of the city, and the need to pay attention to what extent and how might streets' functions limit democratic action. Through understating the reciprocal role of the influence of physical on its social, cultural, and political structures (Parkinson, 2012). Dewey (1916) stated long ago, "a democracy is more than a form of government; it is primarily a mode of associated living".

Results

Urban design plays a significant role in building bridges between conflicted communities and a connection between them. It might also create barriers between those communities and divide the city by acting in a fragmented way, which will lose growth and development opportunities. That shows the critical role of urban intervention in defining the future shape of the city and how the people will act based on this shape.

For this reason, a set of criteria developed to assess the urban intervention that participates in playing the peacebuilding role of the urban interventions are (Bollens, 2006):

- Porosity and flexibility of the urban structure ensure a comprehensive option for the future development.
- Planning should participate in ensuring equity and dealing with the root causes of the conflict. Where all groups have equal access, opportunity, and spaces to be presented, and all are empowered to play an active role in the city's development.
- The sensitivity of urban land usage ensures respect for different ethnic groups, religions, and histories. As well as create spaces for interaction between all those groups. This raises the need for an urban-sensitive approach to conflict and ethnic differences.
- Promotion of the public shared spaces and sphere, which should include all ethnic, religious and people from different backgrounds, where people can deal with their differences and conflicts and find their way collectively to move forward as part of their right to the city. At the physical level, planners should carefully deal with the design of the public spaces to play this vital role, which ensures the city's resilience and disseminates the culture of citizenship and its transfer to democracy. At the institutional

level, those spaces should be run and managed by the people and aligned with the political will that ensures everyone's rights.

- Working in partnership with all actors from all sectors at all levels is essential for an urban role in peacebuilding, considering the bottom-up approach that ensures local grassroots participation and engagement in the urban planning process. And that need to be started in parallel with the negotiation meeting of the peace process, where practitioners, urban planners, politicians, conflicted groups, diplomates and peacebuilders all work together at the early stage of the peace-building process (Bollens, 2006).
- Leadership at the urban and architectural level played a significant role in the political and urban future of the city (Bollens, 2012), wherein sometimes we are looking for a political leader to do the democratic change, which could be found within urbanist professions.
- Building on the local assets (the neighborhood associations in the Barcelona case) played an essential role in building trust with the communities and ensuring their active role as active actors in claiming their rights in the public spaces (Astor, 2019).
- Urban is always in a dynamic position that raises the need not to wait for a peace agreement or settlement. Because it might be too late and used to ensure the policies of dictatorship; if we don't intervene, others will do; urban intervention is not waiting.
- Starting small at the neighborhood level is essential to practice the process with the community and showcase the benefit they got from their participation; urban equity intervention is a critical criterion for public spaces at the neighborhood level approach.
- The connection between public spaces to form a network as a step toward a general plan for the whole city is considered an essential factor for success. In addition, it ensured the connection between the various communities.

"Learning by Doing" Approach using Grid-shell Structures as Sustainable Construction Technology in Architecture Education

T. Seyman-Güray and B. Kısmet
Beykoz University, Department of Architecture, İstanbul, Turkey
tayibeseymanguray@beykoz.edu.tr, burcukismet@beykoz.edu.tr

Abstract

One of the main problems of architectural education is the difficulties experienced by students in establishing the relationship between form and structure and limitations to illustrate the relationship between form and structure in an integrated manner. However, today, instead of design approaches in which only form is considered, integrated design approaches with multi-purpose performance goals such as structure, facade, and performance are preferred. The innovative approaches in materials, construction and informatics are being guided by the Industry 4.0 and its reflections in the construction industry. In this context, the evaluation of grid-shell structures, which is one of the innovative approaches are aimed to be integrated in architectural education in terms of form finding and structural optimization. The methodology consists of literature review and a framework proposal based on grid-shell structures for a construction technology course in architecture. The main objective of this study is to provide flexibility in the form-finding process, explain the form-structure integrity, and provide the necessary environment for an ambiguous and creative design exploration in the early design stages.

Keywords: *computational design, construction technology, design exploration, form-finding, grid-shell.*

Introduction

Last century the mainstream architectural design approach was mainly based on form. Even though there were some limited trials such as Bauhaus, to reach holistic way of thinking, the common process of design was generally fragmented (Uluoğlu, 1990). This situation causes limitations to illustrate the relationship between form and structure in an integrated manner. This challenge reflects to the architectural education as one of the difficulties experienced by students in establishing the relationship between form and structure. One of the reasons of this gap, the disconnection between design studios and building construction technology courses. Moreover, the traditional approach of building construction technology courses involves theoretical lectures and repetition of 2D drawings (Seyman Guray & Kismet, 2021) which limits the student's perception and realization of form structure and their connection.

Today, architectural field is required to increase collaboration with various disciplines such as engineering, information technologies and materials science. This strong collaboration leads to design and construction of complex and high technology buildings & structures. Accordingly,

innovative construction technics and materials are being explored. These contemporary approaches in materials, construction and informatics are being guided by the Industry 4.0 and its reflections in the construction industry which is coined as Construction 4.0. (Sawhney, 2020) In this regard, to obtain current architectural requirements and performance objectives, integrated design approaches are providing certain advantages of multi-purpose performance goals such as structure, facade, aesthetics and sustainability.

This study focuses on grid-shell structures which potentially guide to sustainable building construction by allowing large spans with less material usage. On the other hand, these structures provide flexibility in form finding process which leads to exploratory and ambiguous environments in early design stages (D'Amico et al., 2015; Mesnil et al., 2018). In addition, form-structure integrity can be established effectively. In this context, the evaluation of grid-shell structures, which is one of the innovative approaches are aimed to be integrated in architectural education in terms of form finding and structural optimization. The main objective of this study is to be a response to the digital era of Construction 4.0, by integrating form and structure in early design stages in architectural education. Along with this aim, building technology course is developed to evaluate the potentials of grid-shell structures in terms of integrated design approach.

Theoretical Background

According to Schön (1985), what makes architectural education special is the learning system based on experience and doing. At the beginning of the 20th century, the Bauhaus School established the education model based on learning by doing. The education system was studio-based, in which design and production were carried out, and it liberated design education from the limited form-order bondage and opened it to practice and experimentation. Architectural education has transformed into a participatory workshop environment based on the sharing of the tutor and students (Özkar, 2009). Furthermore, starting from 1960s, informatics has begun integrating virtual and digital concepts to design studios (Cagdas, 2000). In the 1990s, information technologies became widespread all over the world rapidly (Cagdas & Tong, 2005). This has shifted learning away from traditional face-to-face, didactic lectures and tutorials to self-direction, collaborative peer learning, technology-enhanced teaching and learning through multiple technology delivery modes (Birt & Cowling, 2018). On the other hand, as a reflection of Construction 4.0, the development of skills in the AEC industry impacts the required approaches of educators, employers and sector leaders to enable a phase shift in terms of digitalization (Sawhney et al., 2020). In this regard, building construction courses need to be adapted and supported by the digital transformation to fulfill the industry demands. Also, there various studies about digital modelling, 3D representations, simulations increase student perception on construction techniques, materials and details (Arashpour & Aranda-Mena, 2017; Chan et al., 2019; Messner & Horman, 2003; Olawumi & Chan, 2018). Additionally, innovative construction technologies and materials are being adapted to curricula of building construction courses. In this regard, grid shell structures are one of them in which applied on courses for form finding and structural optimization objectives in different universities such as MIT, Princeton University, Aarhus University, University of Bath, Anhalt University, Edinburgh Napier University (Adriaenssens et al., 2015). Moreover, as the expectation of reaching sustainable construction techniques, grid shell has significant advantages on this topic by providing minimum material and structural optimization (Adriaenssens & Block, 2014).

Shell structures are one of the construction techniques used since ancient times. Since 1950s, it has been handled by pioneering researchers such as Isler, Frei Otto, Fuller, Candela who developed shell structures through hand-based drawings and physical models. However, especially since the second half of the 2000s, both the development and spread of computer-aided design (CAD), computer-aided manufacturing (CAM) and importance of optimization shifted architectural and engineering practices into computational and parametric design. Additionally, pioneering architects such as Zaha Hadid, Frank Gehry, Bjark Angels, Calatrava, Shirigu Ban are generating much more innovative architectural designs with these approaches. Computational design aims to achieve numerical and generative designs based on a certain rule, an algorithm (Singh & Gu, 2011; Menges & Ahlquist, 2011). In this regard, it is possible to extend the context of grid shell structures as a construction technology whose potential has been realized with the development of both computational design approaches and digital fabrication methods. Additionally, it is seen that researchers have shown increasing interest in grid shell systems in the last ten years (Adriaenssens & Block, 2014; Dimcic, 2014; Menges, 2016; Ochsendorf & Block, 2014). On the other hand, since sustainable construction techniques are extremely urgent and on the world's agenda, designing with optimum material, optimum energy and optimum form comes to the forefront in Europe, UK and the USA in the field of research as well as grid shell systems.

Methodology of the Proposed Framework

The proposed framework based on grid-shell structures is planning to be applied on a building construction technology course in architecture department. The course is re-designed to adapt Project Based Learning (PBL) since it targets students becoming active learners by the help of Dewey (1938)'s "learning by doing" approach. It provides advantages of internalized learning for the students. In the PBL, the active learning occurs through applying the knowledge of formal courses to a specific project by sharing informal learning experiences through groupwork (Adriaenssens et al., 2015). The targeted group of students taking the course are 3rd year undergraduates who had background courses of Building Science and Materials I, II, III, Digital Media in Architecture I, II. Thus, the students have knowledge and skills about building elements, construction techniques, building materials, building systems, structural systems together with digital knowledge and skills. The design and fabrication of grid shell structured pavilion will be conducted in 10 students per group.

The project component of the course formulated by the authors. It involves a semi-open, semi-closed pavilion design as grid shell structure. The design requirements of the grid shell pavilion given to the students as follows; 3m x 4m (12 m^2) layout area, with a maximum height of 3 meters. Initial shape to apply grid shell is selected as penci arch. Penci arch is a type of low pointed arch and had been used widely used in traditional Turkish architecture such as Mimar Sinan's mosques. It is formed by the intersection of circular archs drawn from two points of the middle section by dividing the stirrup line into five (Özyalvaç, 2017). The distance between two centers over the span equals to 1/5 (Figure 1).

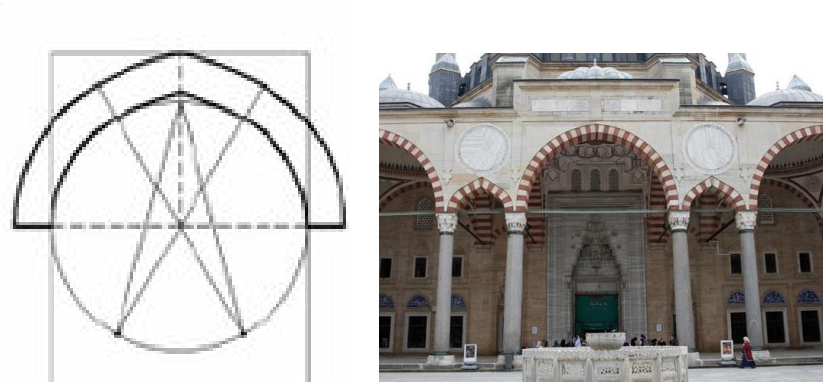

Figure1: Penci arches of Selimiye Mosque by Mimar Sinan.

Penci arch gives the opportunity to re-interpret the traditional architectural element with computational approach through digital skills. In this study it is found important to rethink the traditional arch & vaults and it is aimed to design their transformation into a contemporary non-linear shell structure. Besides their formal relation, vaults and pavilions have similarities in function such as being a passage and a shading element.

The proposed framework has two stages; first is digital workflow and second stage is physical prototyping (Figure 2). The proposed framework aims to extend the borders of form-finding to represent properly the complexities of scale, digital design systems and delivery workflow of grid shell structures. It investigates the cooperation of architecture, structure and manufacturing from file to fabrication process.

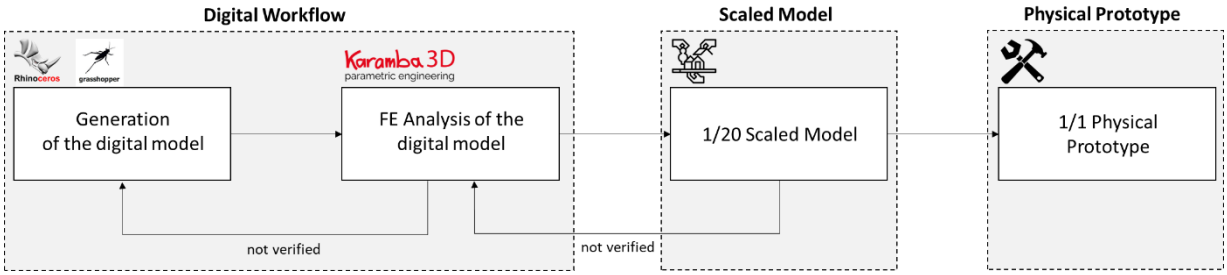

Figure 2: Process of proposed framework.

Digital Workflow

Digital workflow elaborates form finding process which relies on computational design approach. This process involves complexity, network, emergence, patterns, biomimetics, and non-Euclidian geometries (Akipek, 2010), which are highly challenging to be designed without computational tools. To model free forms, the Non-Uniform Rational Basis Spline (NURBS) function is selected as it is one of the most common ways. NURBS can be easily extended to allow more design freedom (Xia et al., 2019). The design alternative of grid shell pavilion is explored and modelled parametrically in the Rhinoceros 7 3D geometric modelling software and Grasshopper plugin. Firstly, the layout is modelled in 3x4 grids in Rhinoceros 7, then the penci arch is modelled accordingly. A series of surface operations - extrude, sweep, loft, boolean, trim- are used in the Rhinoceros 7 to generate forms. Finite Element Analysis (FEA) analysis is conducted to explore the structural behavior of the form alternatives through Karamba 3D which is a FEA add-on into Rhino-Grasshopper environment. According to the

result of FEA, optimal form is selected to be used in the second stage, prototyping. Digital workflow is shown in Figure 3.

Scaled Model

This is a stage between digital workflow and physical prototyping. 1/20 scaled model is made by students to verify the constructability of the 1/1 grid shell pavilion. Manual model making experience, provides better perception - a larger scale amplified the limitations of fabrication and material features, to understand the complexity of grid shell in the early design stage. 1/20 scaled model covers the dimensions of 60cm x 80cm layout area with the maximum height of 80cm; the material is 1mm corrugated cardboard, and students are guided to use pins for joints. Corrugated cardboards are planned to be laths for grid shell. Scale model making involves evaluation of mechanical behavior of the corrugated cardboard and evaluation of assembly details, including joints and connections (Figure 3).

Physical Prototype

1/1 physical prototype is produced according to the form alternative that is generated through digital workflow process and tested in scaled model production (Figure 3). Physical prototype as the material and tactile mode of prototypes help to evaluate the tectonic aspects as the structure, shell performance, material and system behavior in the physical world (Akipek, 2010). 1/1 physical prototype covers 3m x 4m layout area, with the maximum height of 3 meters. The material is selected as 5mm corrugated cardboard to form laths of structural grid elements. The corrugated cardboard is chosen as it is recycled material and cost-effective. Also, it can be renewable and reusable in further implications. It is lightweighted, easily carried and can be processed easily such as cutting, gluing, attaching. In addition, placement of corrugated boards according to the direction of internal structure increase the strength of the system. In this regard, boards can be attached to each other one-directional or bidirectional respectively.

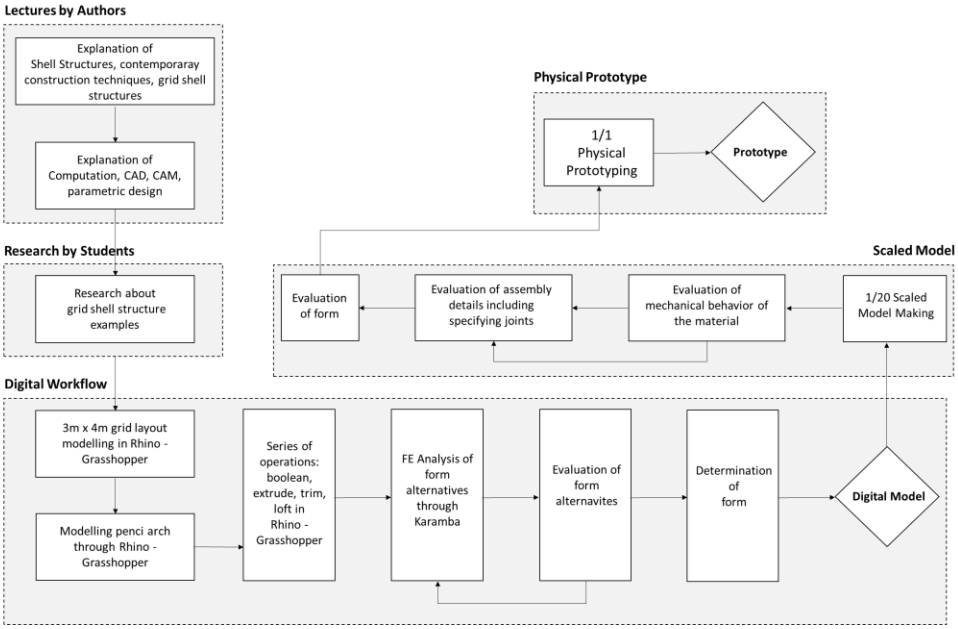

Figure 3: Process of proposed framework.

Conclusion

"Learning by doing" is a significant education approach in architecture as it transforms students to active learners and participants while designing, modelling and constructing. This approach increases learning outcomes of the courses as students experience the whole process. Additionally, PBL offers an environment to conduct concrete experiments. From this perspective, the proposed framework explores beyond the borders of theoretical construction courses by integrating project components. In this study, project component is designed to produce a grid-shell structured pavilion through form finding process. Combining grid shell structure and PBL in curricula provide opportunities for students to experience innovative techniques and technologies which is considered highly beneficial.

One of main contribution of this study is creating an integrated design environment for students in which form and structure are interrelated. It makes students to understand the behavior of form and structure. Also, this study can be considered as introducing the logic of computational thinking which is becoming much more important for the professionals of construction industry in today's digital era. Additionally, students are focused on the importance of planning, simulating and then fabricating which make them increase the management skills as well as provides a sophisticated experience. This process improves the perception of students on integrated design. On the other hand, re-interpreting the traditional Turkish penci arch provides valuable contribution on cultural heritage. Also, it is an example of interdisciplinary work between heritage and computation. Moreover, it offers social sustainability understanding for students. In addition, for the environmental sustainability, grid shells have less material consumption and are flexible to be designed in wide range of materials. The material that is chosen for this study is corrugated cardboard that is both recycled and reusable for future implementations.

For future studies, the proposed framework is planned to be applied. Students' experience will be taken into account to evaluate the effects of this framework to understand form-structure relation, mechanism of grid-shell structure and logic of prototyping.
