YTÜ

20 - 22 OCTOBER 2022

IPCMC2022

International Project and Construction Management Conference

7TH INTERNATIONAL PROJECT AND CONSTRUCTION MANAGEMENT CONFERENCE

PROCEEDINGS BOOK

EDITORS

Cenk BUDAYAN
Serkan KIVRAK
Serdar ULUBEYLİ

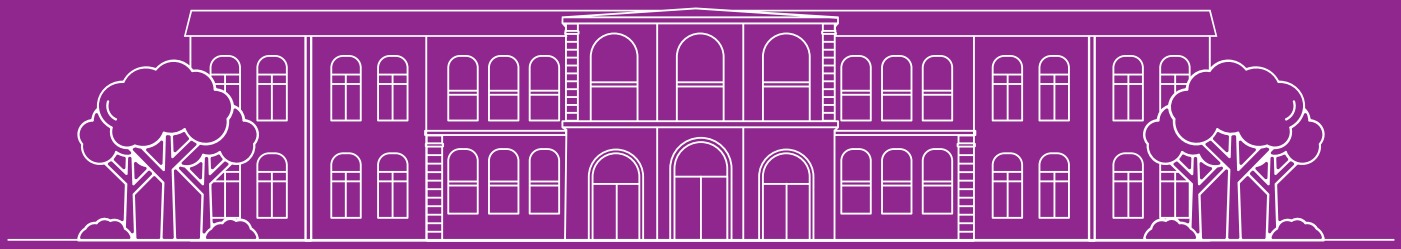

TABLE OF CONTENTS

Preface..... **I**

Conference Co-Chairs..... **II**

Organizing Committee..... **II**

Rewards Assessment Committee..... **II**

Secretariat..... **III**

Scientific Committee..... **III**

Project Management..... **1**

PAPER ID: 7 Comparison of The Benefits of CPM and PERT to Project Partners on Different Projects ***1 - 17***

Zafer Tarık Taner, Asena Soyluk and Zeynep Yeşim İlerisoy

PAPER ID: 11 Critical Construction Time Overruns Causes in Turkish Construction Industry ***18 - 31***

Merve Serter and Gülden Ayalp

PAPER ID: 12 Constructing the Added Value for AEC Industry: An Interdisciplinary Learning Method the Multidimensional Exploration Methodology ***32 - 41***

Zeynep Birgonul and Oriol Carrasco

PAPER ID: 15 Determination of Type of Construction Activities During the Construction Execution Phase ***42 - 53***

Ibrahim Karatas and Abdulkadir Budak

PAPER ID: 17 Identifying the Universal Rework Factors in Construction Projects ***54 - 65***

Eda Nur Erdem and Gülden Ayalp

PAPER ID: 20 Barriers to E-Tendering Adoption and Implementation in The Construction Sector: 2010 – 2022 Review ***66 - 79***

Aynur Kazaz, Yusif Inusah and Serdar Ulubeyli

PAPER ID: 23 Value Engineering in Construction Management Literature ***80 - 89***

Bengü Yogurtcu and Almula Köksal

PAPER ID: 36 A Systematic Literature Review on Lean Construction for Tendering ***90 - 99***

Abdullah Türkmen and Pınar Irlayıcı Çakmak

PAPER ID: 38 A Modified Oppositional Teaching-Learning-Based Optimization Model for Solving Construction Time-Cost-Quality Trade-Off Problems ***100 - 112***

Mohammad Azim Eirgash, Vedat Toğan, Manoj Kumar Trivedi and Kamal Sharma

PAPER ID: 61 The Importance of Value Engineering in the Construction Sector ***113 - 124***

Bahar Özbas and Esra Bostancıoğlu

PAPER ID: 62 An Integrated Multi-Criteria-Decision-Making Approach for Spare Parts Supplier Selection ***125 - 132***

Eren Esvap, Atilla Damcı, Serhat Yaşar, Fırat Doğu Akın and Ayan Pierre Abdi

PAPER ID: 70 Active Information Search as a Research Method in Construction Management Studies ***133 - 142***

Mina Aslan and Serdar Kale

PAPER ID: 75 Management of Building Restoration Projects: Key Areas of Concern and Challenges ***143 - 155***

Sezer Savaş, Emrah Acar and Damla Acar

PAPER ID: 84 Lean Construction and Simulation: A Case Study of Dry Batch Delivery and Concrete Placement Operations ***156 - 167***

Alime Şanlı, Buğra Özyurt, Muhammed Ali Çolak, Vedat Nalioğlu and Gürkan Emre Gürcanlı

PAPER ID: 87 Schedule Delay & Cost Overrun Analysis in Large Scale Construction Projects Using MS Project Software - A Case Study ***168 - 177***

Muhammed Lemar Zalmai, Cemil Akcay and Ekrem Manisalı

PAPER ID: 97 Lean Tools in the Construction Industry: A Bibliometric Analysis ***178 - 189***

Esra Aydın and Gizem Can

PAPER ID: 99 Estimation of Winning Bidding Price for Construction Sector ***190 - 203***

Akin Eren, Melih Sert and Altan Özkİl

PAPER ID: 100 Total Construction Duration Calculation of TOKI Housing Projects: A Case Study ***204 - 215***

Hakan Tirataci, and Hakan Yaman

PAPER ID: 101 A Proposed Model for Estimation of Ideal Construction Duration in Housing Projects ***216 - 231***

Hakan Tirataci, and Hakan Yaman

PAPER ID: 108 Construction Project Manager Selection for Superstructure Projects Using AHP and TOPSIS Multi-Criteria Decision Making Techniques ***232 - 252***

Rifat Akbiyikli, Anıl Demircan and Gökalp Karaçam

PAPER ID: 110 A Method for Determining the Probability of Achieving a Maximum Tender Price Score in Turkish Public Procurement Law Open Procedure ***253 - 265***

Emre Işıl, Salar Ahmadisheykhsarmast and Rifat Sonmez

PAPER ID: 151 Data scraping for corporate identity evaluation: a stakeholder engagement and management perspective ***266 - 275***

A.Tolga Ilter

PAPER ID: 154 Optimum Solution of Resource Leveling Problem ***276 - 287***

Tuğba Erzurum and Önder Halis Bettemir

PAPER ID: 177 Heritage Building Information System (HBIM) in Project Management of Cultural Heritage Building ***288 - 296***

Pelin Karaçar, Gülhan Benli and Aysun Ferrah Güner

PAPER ID: 180 Statistical Analysis of Cost Overrun Causes in Construction Projects: A Demonstration of Selection and Implementation Statistical Tests ***297 - 309***

Iman You, Tolga Çelik, B. Maina Joseph Jatau

PAPER ID: 185 Construction Productivity Improvement; A Case Study of Turkish Republic of Northern Cyprus ***310 - 316***

Ali Öztemir

PAPER ID: 189 The need for stakeholder management and engagement in projects ***317 - 327***

A. Zainab Aziz

PAPER ID: 191 Preliminary Estimation of Natural Gas Pipeline Construction Costs with Regression Analysis ***328 - 337***

Coşkun Çakmak and Mürsel Erdal

PAPER ID: 192 Evaluation of Update Rates of The Contracting Certificates and Work Experience Certificates ***338 - 349***

Aynur Kazaz and Alev Kaya

PAPER ID: 199 Subcontractor Management in Construction Projects: A Literature Review of Research Trends ***350 - 361***

Yunus Başaran, Ozan Okudan, Hande Aladağ and Zeynep Işık

Organization, Leadership and Strategy ***362***

PAPER ID: 55 Organizational and Team Resilience: Construction Industry Survival in the Pandemic Crisis ***362 - 373***

Emre Köseoğlu and Sema Ergönül

PAPER ID: 72 A model for Exploring the Overconfident Behavior In Construction Organizations ***374 - 384***

Bora Aldemir and Serdar Kale

PAPER ID: 102 The Changing Roles of Project Professionals in a Digitally Disrupted Environment ***385 - 398***

Christèle Mallet and Mohammed Dulaimi

PAPER ID: 114 Implementation of Geert Hofstede's Cultural Dimensions to Multinational Construction Management ***399 - 417***

Ender Şenkaya

PAPER ID: 141 Partnering in Total Quality Management Practices and Quality Culture ***418 - 424***

Aysun Ferrah Güner

Construction Methods and Technology ***425***

PAPER ID: 6 Reinforced Concrete Industrial Chimney Construction Management Site Application ***425 - 433***

Şahin Tolga Güvel

PAPER ID: 48 Roadmap for Integrated Usage of BIM and Lean Methods Throughout the Lifecycle of Modular Construction Projects ***434 - 443***

Sabah Khodabocus and Senem Seyis

PAPER ID: 168 Exploring the Critical Success Factors of Offsite Construction Method in Turkey ***444 - 451***

Büşra Yücel, Alper Zafer and Semra Çomu

PAPER ID: 169 A Review on Implementation of Lean Construction Principles into Off-Site Construction Methods ***452 - 460***

Cansu Coskun and Ali Murat Tanyer

Design Management…… ***461***

PAPER ID: 76 Design-Construction Interface Problems in Construction Projects ***461 - 469***

Emine Esra Buğan and Pınar Irlayıcı Çakmak

PAPER ID: 96 Comparative Evaluation of The Interior Design Processes of Rentable Stores in Shopping Malls in Turkey ***470 - 479***

Atacan Akgün and Gizem Can

PAPER ID: 147 Analysis of Parameters Affecting Decision Making to Retrofit of Existing School Buildings Using Ensemble Machine Learning Methods ***480 - 492***

Ümit Bahadır, Fatemeh Mostofi and Vedat Toğan

PAPER ID: 157 Design Strategies for Reducing Embodied Water of Buildings: Material Selection ***493 - 503***

Muge Goytan and Begum Sertyesilisik

Economics and Financial Management…… ***504***

PAPER ID: 16 Construction in Uncertain Economic Conditions ***504 - 513***

Yaprak Arıcı Üstüner and Burcu Balaban Ökten

PAPER ID: 64 The Effect of Economic Factors on the Bidding Decision of Contractor Construction Firms: The Case of Antalya Province ***514 - 524***

Aynur Kazaz and Ersan Erkovan

PAPER ID: 79 Causal Relationships between Construction Cost Index and Macroeconomics in Turkey ***525 - 533***

Serkan Aydınlı

PAPER ID: 81 Overview of Financed-Based Scheduling in Construction Management Research ***534 - 544***

Firat Dogu Akin, Atilla Damci, David Arditi and Sevilay Demirkesen

PAPER ID: 178 The Turkish Construction Sector from a Macroeconomic Perspective ***545 - 562***

Faruk Büyükyoran and Hakan Yaman

Real Estate Development and Management…… ***563***

PAPER ID: 22 Factors Determining Land and Real Estate Value: Comparison of Real World and Metaverse ***563 - 573***

Ilkim Güven and Tuğçe Ercan Şimşekalp

PAPER ID: 68 Research on the Importance of Feasibility Study in Real Estate Investment Projects: Example of Residential Land ***574 - 584***

Aynur Kazaz and Halil Esendal

PAPER ID: 82 Consumer Based Perceived Quality in Real Estate 4.0 ***585 - 599***

Çiğdem Karabağ and Gamze Özkaptan Alptekin

PAPER ID: 143 Examination of Projects of Privately-Owned Residential Buildings ***600 - 606***

Selman Aslan, Mert Sevil and Osman Hürol Türkakın

PAPER ID: 197 Investigation of Effectiveness of Real Estate Advertisements Based on Age of The Customers ***607 - 616***

Cenk Budayan and Sezin Nas

Digital Technologies…… ***617***

PAPER ID: 5 Investigation of Intended Use of Digital Transformation Applications Throughout Construction Projects' Lifecycle ***617 - 631***

Cansu Yalnız, İncinur Gökçe Erol and Hande Aladağ

PAPER ID: 10 Critical Challenges of BIM Implementation in AEC Industry in Turkey ***632 - 644***

Seda Tan, Gülden Gümüşburun Ayalp and Yusuf Berkay Metinal

PAPER ID: 24 Analysis of Industry 4.0 Technologies from A Lean Construction Perspective ***645 - 655***

Melike Cesur and Elcin Filiz Tas

PAPER ID: 32 Determination of Construction 4.0 Awareness in Project Management Processes: The Case of Kayseri ***656 - 668***

Selen Öztürk Ustaoğlu, Gamze Yalçın, Z. Özlem Parlak Biçer and Savaş Bayram

PAPER ID: 34 BIM Based Automated Code Compliance Checking System: TRegCheck Program ***669 - 679***

Bayram Ali Temel and Hasan Basri Başağa

PAPER ID: 37 Handling Imbalanced Data in Building Energy Benchmarking ***680 - 691***

Said Bolluk and Senem Seyis

PAPER ID: 39 Contributions of Augmented Reality Applications During Sustainable Building Life Cycle ***692 - 704***

Canan Bedur Doğruöz and İkbal Erbaş

PAPER ID: 44 Using Web Crawler for Construction Risk Assessment of International Construction Projects ***705 - 713***

Beste Ozyurt, Irem Dikmen and M. Talat Birgonul

PAPER ID: 47 Application of IoT Technology on Health and Safety in Construction ***714 - 725***

Volkan Arslan and Serdar Ulubeyli

PAPER ID: 51 Digital Transformation Era in Construction Management: Blockchain Technology – a Systematic Literature Review ***726 - 741***

Nazlı Döngez and Almula Köksal

PAPER ID: 53 Evolution of the Building Sector from Building Catalogs to BIM Catalogs ***742 - 753***

Damla Yildirim and Candan Çıtak

PAPER ID: 66 Using Blockchain Technology in the Construction Industry ***754 - 774***

Mehmet Parlak, Serkan Kivrak, Memduh Begenirbas and Gokhan Arslan

PAPER ID: 67 Use of Visualization Technologies for Increasing Efficiency of Construction Industry ***775 - 786***

Ilker Baki Alkan and Hasan Basri Başağa

PAPER ID: 71 Use of Industry 4.0 Technologies in Stakeholder Management ***787 - 798***

Jibid Bulgan and Elcin Filiz Tas

PAPER ID: 77 Big Data Applications in Construction Industry ***799 - 810***

Kübra Çimen and Elçin Filiz Taş

PAPER ID: 80 A Brief Summary on Facilities Management Technologies and BIM-FM Integration ***811 - 820***

Ecem Tezel and Heyecan Giritli

PAPER ID: 93 Digital Twin Practices for Enhanced Construction Management: A Literature Review ***821 - 833***

Berkay Aktürk and Pınar Irlayıcı Çakmak

PAPER ID: 113 Investigation of BIM Perception in Metro Projects ***834 - 845***

İlknur Akgüneş Ahmed and Esin Ergen Pehlevan

PAPER ID: 120 Challenges of BIM Implementation in Airport Projects ***846 - 857***

Ahmet Karacigan and Beliz Ozorhon

PAPER ID: 124 Potential Contributions of the Blockhain Technology to the Construction Industry and its Stakeholders ***858 - 866***

Uğur Yavuz and Begüm Sertyeşilışık

PAPER ID: 127 Impacts of Smart Megaprojects on Construction Project Management ***867 - 879***

Didem Ugurlu and Begüm Sertyesilisik

PAPER ID: 130 Potentials of VR and AR in Pre-Construction Phases ***880 - 889***

Tayibe Seyman Güray and Burcu Kısmet

PAPER ID: 135 A Simulation of Tunnel Operation Model Using Stroboscope ***890 - 899***

Ahmet Esat Keser, Oğuzhan Temur, Bartu Koloğlu, Kübra Bayrak, Benay Öngen and Gürkan Emre Gürcanlı

PAPER ID: 136 Using Blockchain Concept in Smart Home ***900 - 910***

Duygu Savur and Şeyda Emekçi

PAPER ID: 142 Major Research Areas in Smart Factory Research ***911 - 917***

Gozde Basak Ozturk and Busra Ozen

PAPER ID: 145 Distributed Ledger Technologies for Building Knowledge Management ***918 - 928***

Gozde Basak Ozturk, Eylul Adiguzel Rasmussen and Fatih Soygazi

PAPER ID: 146 Development of BIM-Based 3D Visualization and Quantity Take-off Calculation Software ***929 - 940***

Faruk Ergen and Önder Halis Bettemir

PAPER ID: 150 Development of a roadmap for the systematic implementation of artificial intelligence in construction companies ***941 - 954***

Jan-Iwo Jaekel, Fabian Faltin and Katharina Klemt-Albert

PAPER ID: 152 WEB Based Waste Management System ***955 - 965***

Önder Halis Bettemir and Ahmet Yıldız

PAPER ID: 153 Measurement and Analysis of Haul Routes ***966 - 975***

Önder Halis Bettemir and Alper Çırak

PAPER ID: 164 BIM Use in Retrofit Optimization for the Climate Change Mitigations and Adaptations Measures ***976 - 984***

Hatice Bıyık and Ali Murat Tanyer

PAPER ID: 195 Exploring the current implementation status of BIM, lean construction and sustainability concepts in construction industry ***985 - 1007***

A. Sada Hasan, Zeynep Işık

PAPER ID: 198 Investigation of Digitalization Tool for Circular Economy in Construction Industry ***1008 - 1018***

A. Taha Demirbağ, Hande Aladağ and Zeynep Işık

Disasters, Risk and Resilient..... ***1019***

PAPER ID: 18 Organizational Resilience and Agility: the Impact of COVID-19 Pandemic on the Construction Industry ***1019 - 1031***

Alime Şanlı and Elçin Filiz Taş

PAPER ID: 27 Risk Assessment in Construction Projects: A Case of Housing Project ***1032 - 1043***

Aynur Kazaz and Gökçen Arslan

PAPER ID: 29 A Decision Support Model on Risk Management in Construction Projects ***1044 - 1055***

Aynur Kazaz and Gökçen Arslan

PAPER ID: 40 Stress-Performance Relationship in Architectural Offices: The Effect of Covid-19 Pandemic ***1056 - 1066***

Miray Karabaş and Almula Köksal

PAPER ID: 69 A Bibliometric Analysis of Covid-19 Research in Built Environment Literature ***1067 - 1076***

Evren Ülkeryildiz

PAPER ID: 88 Preliminary Impacts of Covid-19 on the Construction Industry: A Regional Study ***1077 - 1085***

Manideep Tummalapudi, Jared Burgoon, Deniz Besiktepe and John Killingsworh

PAPER ID: 111 Integrated Risk Assessment Process (IRAP) for Mega Construction Projects: A Demonstrative Case Study ***1086 - 1098***

Huseyin Erol, Irem Dikmen, Guzide Atasoy and M. Talat Birgonul

PAPER ID: 158 Management of risks influenced by information asymmetry during construction: Framework for research ***1099 - 1110***

Anita Cerić and Ivona Ivić

PAPER ID: 167 Risk Assessment Between Prefabricated and Traditional Residential Construction in Tanzania ***1111 - 1120***

Büşra Yücel, Mustapha Kassim Salehe Mwamba and Semra Çomu

PAPER ID: 172 Asbestos Free Demolition- Case Study in İzmir ***1121 - 1130***

Ayşe Gizem Çamurcu, İbrahim Halil Özdemir, İrem Bayram Zümrüt, Yilmaz Ogunc Tetik, Özge Akboğa Kale, Alpaslan Ergör and Selim Baradan

PAPER ID: 181 A Glance at Financial Risks in Construction Companies in Volatile Market ***1131 - 1137***

Özlem Tüz and Şafak Ebesek

PAPER ID: 182 Currency Risk Analysis on Construction Cash flows ***1138 - 1144***

Özlem Tüz and Hakan Yaman

Clean Energy and Sustainability…… ***1145***

PAPER ID: 3 Carbon Footprint Reduction in Sustainable Earthen Buildings ***1145 - 1155***

Ayse Pekrioglu Balkis and Aya Ahmad

PAPER ID: 9 Material Wastes and Management Strategies in the Building Construction Sites (BCS) ***1156 - 1168***

Gizem Can and Elçin Filiz Taş

PAPER ID: 33 Evaluation of the Impacts of Mega Sports Events in Cities with the Sustainability Indicator: The Case of İzmir Olympic Village ***1169 - 1181***

Birsu Ece Kaya and İkbal Erbaş

PAPER ID: 49 Effect of Solar Shade Elements on Heating and Cooling Loads in Houses and Cost Relationship ***1182 - 1193***

Aynur Kazaz and Ender Yetim

PAPER ID: 50 Investigation of the Effect of Building Orientation on Building Energy Performance in the Mediterranean Climate Region ***1194 - 1205***

Aynur Kazaz and Ender Yetim

PAPER ID: 56 Assessment of Smart Sustainable Building-City Integration Level: An Analysis for Criteria in Building-City Intersection ***1206 - 1218***

Fatma Handan Sarıgül and Hüsnü Murat Günaydın

PAPER ID: 60 A Multi-Attribute Decision-Support System for Site Selection of Wave Energy Converters ***1219 - 1228***

Ayan Pierre Abdi, Atilla Damci, Veysel Sadan Ozgur Kirca, David Arditi and Sevilay Demirkesen

PAPER ID: 63 Evaluation of Construction and Demolition Wastes in the Context of the Waste Framework Directive of the European Union Member States ***1229 - 1245***

Nurşen Sönmez and Sibel Maçka Kalfa

PAPER ID: 122 How to Measure the Social Sustainability? Measurement Criteria for Architectural Design ***1246 - 1255***

Elif Ulu and Şeyda Emekci

PAPER ID: 123 An Investigation into the Sustainable and Green Building Certifications to Enhance Sustainability and Lean Performance of the Construction Supply Chain Management ***1256 - 1266***

Gamze Tatlici Küpeli and Begüm Sertyeşilışık

PAPER ID: 148 Bio-Based Construction Materials for Bio-Circular Transition: A Brief Bibliometric Analysis ***1267 - 1279***

Hafize Büşra Bostancı and Ali Murat Tanyer

PAPER ID: 149 Transitioning to a circular economy in the construction industry: enablers, barriers, and strategies ***1280 - 1291***

Zelal Koksal and Guzide Atasoy

PAPER ID: 155 Sustainability Analysis for the Construction of Rural Houses ***1292 - 1303***

Tuğba Erzurum and Önder Halis Bettemir

PAPER ID: 163 Current Concepts Regarding Sustainability Practices and Architectural Education ***1304 - 1316***

Merve Acar and Esra Bostancıoğlu

PAPER ID: 173 Analyzing the Effects of Occupants' Demographic Characteristics on Indoor Thermal Satisfaction in Office Buildings ***1317 - 1323***

Ezgi Kocaman and Gulben Calis

PAPER ID: 174 Simulation-Based Solar Energy Generation Potential Assessment of Houses ***1324 - 1329***

Farrukh Arif and Nida Azhar

PAPER ID: 179 Impact of partial replacement of in-situ reinforced concrete (ISRC) on materials and final embodied energy of the building: A case study ***1330 - 1339***

Duygu Erten, Mustafa S. Baykal, Ayşegül D. Erkan and Ömer Karayiğit

PAPER ID: 196 Application of Prisoner's Dilemma Game in Resolving Conflicts During Green Building Construction in Turkey ***1340 - 1350***

Lal Zeynep Nizam, Gökhan Demirdöğen and Zeynep Işık

Health and Safety…… ***1351***

PAPER ID: 21 Predicting Permanent Disability of Construction Workers Using Support Vector Machine ***1351 - 1359***

Kerim Koc, Handan Künkçü and Asli Pelin Gürgün

PAPER ID: 46 A Literature Review on Health and Safety Studies in Turkey ***1360 - 1367***

Volkan Arslan, Serdar Ulubeyli and Aynur Kazaz

PAPER ID: 54 Awareness of Occupational Health and Safety in Architectural Office Workers; Kayseri Example ***1368 - 1375***

Zübeyde Özlem Parlak Biçer and Gamze Lütfiye Gümüş

PAPER ID: 59 Construction Safety Hazard Recommendation using Graph Representation Learning ***1376 - 1386***

Fatemeh Mostofi and Vedat Toğan

PAPER ID: 65 A Framework for Management of Welfare Facilities in Construction Projects ***1387 - 1399***

Ibrahim Mert Uzun

PAPER ID: 74 A Review Study for Real-Time Monitoring in Construction Health and Safety ***1400 - 1409***

Tuğçe Altınkaynak Akıncı, Osman Hürol Türkakın and Ömer Giran

PAPER ID: 90 Assessment of Occuptional health and safety problems in the construction sector in the world and in Turkey ***1410 - 1420***

Şükran Demirkol Kürkçüoğlu and Esra Bostancıoğlu

PAPER ID: 105 Rethinking Occupational Health and Safety Standards: As a Key to the OHS 4.0 in the Construction Industry ***1421 - 1430***

Nur Efşan Erusta and Begum Sertyesilisik

PAPER ID: 128 Detection of Helmet Usage of Construction Workers with Image Segmentation ***1431 - 1440***

İpek Naz Semercioğlu, Hasan Basri Başağa and Kemal Hacıefendioğlu

PAPER ID: 144 Motivation Factors After a Work Accident in Construction Industry ***1441 - 1447***

Selman Aslan and Serkan Aydınlı

PAPER ID: 161 Work Conditions and Psychological Stressors among the Construction Workforce in South Africa ***1448 - 1459***

Mohlomi Raliile, Theo Haupt and Kahilu Kajimo-Shakantu

Legal Affairs and Dispute Resolution …… ***1460***

PAPER ID: 25 What Do Smart Contracts Solve in the AEC Industry: A Qualitative Study ***1460 - 1475***

Ilkim Güven and Hande Aladağ

PAPER ID: 30 Change Management in Construction: A Systematic Review ***1476 - 1489***

Aslıhan Ergin and Emrah Acar

PAPER ID: 31 Evaluating Readability Risks in Construction Contracts Using Fuzzy TOPSIS Method ***1490 - 1495***

Handan Kunkcu, Kerim Koc and Asli Pelin Gurgun

PAPER ID: 35 A Bibliometric Literature Review: Smart Contract in the Construction Sector ***1496 - 1503***

Ayşenur Tanrıaşıkı and Elçin Filiz Taş

PAPER ID: 58 Cardinal Changes: A Comparion of FIDIC 2017 and Turkish Public Procurement Law ***1504 - 1513***

Zeynep Sözen

PAPER ID: 89 Keyword-Based Risk Assessment for Construction Contracts ***1514 - 1525***

Hayri Burak Altuntaş and Hasan Basri Başağa

PAPER ID: 117 Detection of the Major Problems Concerning Delay Analysis with Unstructured Interviews ***1526 - 1532***

Ozan Okudan, Murat Çevikbaş and Zeynep Işık

PAPER ID: 118 Barriers of Disruption Management in Construction Projects ***1533 - 1543***

Murat Çevikbaş, Ozan Okudan and Zeynep Işık

PAPER ID: 119 Civil Engineering Subjects in the Turkish Legal System ***1544 - 1554***

Coskun Hilmi and Sancar Sezer

PAPER ID: 133 A Grouping Study of Domain Knowledge Representations in Building Regulations ***1555 - 1583***

Murat Aydin

PAPER ID: 159 Resilience Management in Construction Projects: A New Approach to Manage Disruption ***1584 - 1596***

Saeed Kamali, M. Talat Birgonul and Irem Dikmen

PAPER ID: 160 Quantum Analysis Approaches for Construction Claims and Disputes ***1597 - 1606***

Mehmet Kutalmis Okur and Begum Sertyesilisik

PAPER ID: 194 Examination of Organizational Perceptions on Risk Status of Events of Contractors' Claims and Key Control Measures on Construction Projects in Turkey ***1607 - 1617***

Osman İlter and Tahir Çelik

Professional Issues in Education and Practice...... ***1618***

PAPER ID: 98 New Approaches in Civil Engineering Education ***1618 - 1632***

Ediz Boz, Ümit Bahadır and Vedat Toğan

PAPER ID: 126 From War to Peace: How public space contributes: The case of Barcelona ***1633 - 1640***

Ghada Rifai and Şeyda Emekci

PAPER ID: 131 "Learning by Doing" Approach using Grid-shell Structures as Sustainable Construction Technology in Architecture Education ***1641 - 1648***

Tayibe Seyman Güray and Burcu Kısmet

Index..... **1649**

PREFACE

Welcome to Istanbul for the 7th International Project and Construction Management Conference (IPCMC), We expect this year's conference to be hosted by Yildiz Technical University with more participation than the previous conferences. The conference aims to facilitate interdisciplinary integration and international cooperation among academicians, industry professionals and researchers in the project and construction management field to share their latest research findings, experiences, and prospects. IPCMC 2022 is expected to serve as a forum especially for the early-stage researchers to discuss their research ideas, preliminary findings of their studies and develop new academic networks. Well-known keynote speakers from academia are invited to share their experiences and foresights. As a tradition of the IPCMC conferences, rewards will be delivered to the best papers. In this way, it is aimed to provide an interaction between academia and industry.

IPCMC 2022 attracted a great attention with a total of 143 full-text papers to be presented verbally. The regular increase in the number of papers in the IPCMC to date indicates the importance of project and construction management research at the international level. It can also be considered that the popularity of this year's host city, i.e., Istanbul, may have contributed to this attention. It is Istanbul's endless variety that fascinates its visitors. Istanbul is Türkiye's most developed and largest city, with the latest discoveries indicating that the history of human habitation here goes back some 400,000 years. The museums, churches, palaces, grand mosques, bazaars, and sites of natural beauty are countless.

Looking at the main topics of the conference, the most papers were written on (1) project management, (2) organization, leadership and strategy, (3) construction methods and technology, (4) design management, (5) economics and financial management, (6) real estate development and management, (7) digital technologies, (8) disasters, risk and resilience, (9) clean energy and sustainability, (10) health and safety, (11) legal affairs and dispute resolution, (12) professional issues in education and practice, respectively. These topics are of great importance as they highlight the current needs and trends of research society and the industry. These trends are expected to significantly guide young scholars and professionals who are at the very beginning of their research and/or working lives.

We would like to express our gratitude to Honorary Chair, Rector of YTU, Prof. Tamer Yılmaz, and co-chairs Prof. M. Talat Birgönül and Assoc. Prof. Zeynep Işık for their valuable contributions to the Conference, and all the researchers who took part in the Conference Organizing, Scientific, and Reward Assessment Committees. Finally, we would like to thank 12 companies that provided financial support to the realization of the Conference. We would like to thank all the participants for their contributions to the field of project and construction management by participating in the IPCMC 2022. We sincerely hope that the academic community and industrial practitioners will continue to support us in our attempts to provide even more meaningful conferences with numerous critical idea exchanges, diverse opportunities for fruitful networking and future collaborations between the delegates.

Yildiz Technical University, Istanbul, 20-22 October 2022

Conference Co-Chairs

Tamer Yılmaz (Honorary Chair – Rector of YTÜ)	Department of Naval Architecture and Marine Engineering, Yıldız Technical University, Turkey
M. Talat Birgönül	Department of Civil Engineering, Middle East Technical University, Turkey
Zeynep Işık	Department of Civil Engineering, Yıldız Technical University, Turkey

Organizing Committee

Hande Aladağ	Department of Civil Engineering, Yıldız Technical University, Turkey
Almula Köksal Işıkkaya	Department of Architecture, Yıldız Technical University, Turkey
Aslı Pelin Gürgün	Department of Civil Engineering, Yıldız Technical University, Turkey
Tuğçe Şimşekalp Ercan	Department of Architecture, Yıldız Technical University, Turkey
Şenay Atabay	Department of Civil Engineering, Yıldız Technical University, Turkey
Gökhan Demirdöğen	Department of Civil Engineering, Yıldız Technical University, Turkey

Rewards Assessment Committee

Serhat Başboğan	Department of Architecture, Yıldız Technical University, Turkey
Deniz Artan	Department of Civil Engineering, Istanbul Technical University, Turkey
Aslı Akçamete	Department of Civil Engineering, Middle East Technical University, Turkey
Semra Çomu Yapıcı	Department of Civil Engineering, Bogazici University, Turkey
Vedat Toğan	Department of Civil Engineering, Karadeniz Technical University, Turkey

İkbal Erbaş	Department of Architecture, Akdeniz University, Turkey

Secretariat

Kerim Koç	Department of Civil Engineering, Yıldız Technical University, Turkey
Ozan Okudan	Department of Civil Engineering, Yıldız Technical University, Turkey

Abstract

The increase in the need for industrialization due to urbanization with the rise in the world population increases the demand for planning. Increasingly complex projects in the construction industry and the fact that each project is unique increases the importance of planning. Optimization of time, cost, and quality parameters is a vital mission of modern project management. The effect of time delays in projects on planning and budgeting is an essential problem for project partners and especially project manager. However, the work program, which is mandatory at the contract stage in the Turkish public construction sector, has not reached the desired level in the private sector. At the same time, scientific studies dealing with business programming methods such as CPM and PERT are limited. In this study, The work programming of the productions selected from the projects of the housing and school building in Kayseri was done using CPM and PERT. Thus, the benefits that different projects and methods can provide to the project manager have been compared over time and cost. Based on the data obtained, it was determined that the main difference between the CPM and PERT diagrams was in the time estimates. It was concluded that the project partners should manage the planning process by observing the time and cost together.

Keywords: *construction work planning, project management, CPM, PERT.*

Introduction

The biggest share in the growth of the country's economies; It belongs to sectors such as agriculture, industry, trade and construction. Among these sectors, the construction sector has the largest share. It is seen that the share of the construction sector in the Gross Domestic Product (GDP) is around 30% (KPMG, 2020). Completion of the projects produced in the construction sector, which has an important share in the country's economy, within the desired time, quality and cost is possible with a coordinated work. This coordinated work is provided by the concept of project management.

Project management is the art and science of coordinating people, equipment, materials, money and programs to complete a given project on time and at the desired cost (Oberlender,

2000). Project management covers all phases of the project and ensures that the investor's organization is organized and followed up with the project management team (Sorguç, 2005). The American Construction Management Association (CMMA) has defined project management as controlling time, cost, profit, and quality by applying professional management methods at all stages of a project (Gökuç, 2006). Kezner et al. (2001) defined project management as the whole system of planning, executing and controlling the resources required for a job to achieve the desired goal. Oberlender (2000) defined project management as the balance management between scope, budget and planning and stated that quality is an indispensable element in this balance (Figure 1). In project management, scope means the amount and quality of work, budget means measurable cost, and schedule means the logical sequence and timing of the work (Oberlender, 2000).

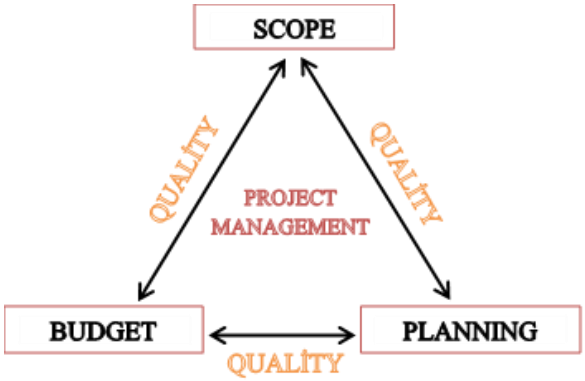

Figure 1: Balance in project management (Oberlender, 2000).

Today, the importance of project management has become an element of competition between companies, due to the coexistence of different disciplines in projects, the originality of projects and the growth of project volumes. In today's economic conditions, it has gained importance to evaluate projects in terms of time and cost, and it has become the most important goal to present the best quality work at the most appropriate time and cost. The concept that constitutes the appropriate method and strategy system to achieve this goal is project planning. Project planning is the creation of a method and strategy system in accordance with the project objectives (Taner, 2019). It continues from the beginning of the project until its closure.

Planning and Planning Techniques in Project Management

In the construction sector, which covers a significant part of the economies of developed and developing countries in the world, project planning has gained importance with the increase in technology and the volume of projects carried out in recent years. Project planning is the process of determining the actions necessary to achieve the project management objective (Gültekin, 2007). İnceoğlu (1980) defined planning as bringing together tools and directing actions to achieve goals. Oberlender (2000) stated that planning is the creation of an action plan to guide the completion of a project (Oberlender, 2000). It is a dynamic process that includes the questions of why, how, when and for whom the work in project planning will be done (Figure 2). In this dynamic process, the actions of the works are checked, and revisions are made according to possible deviations.

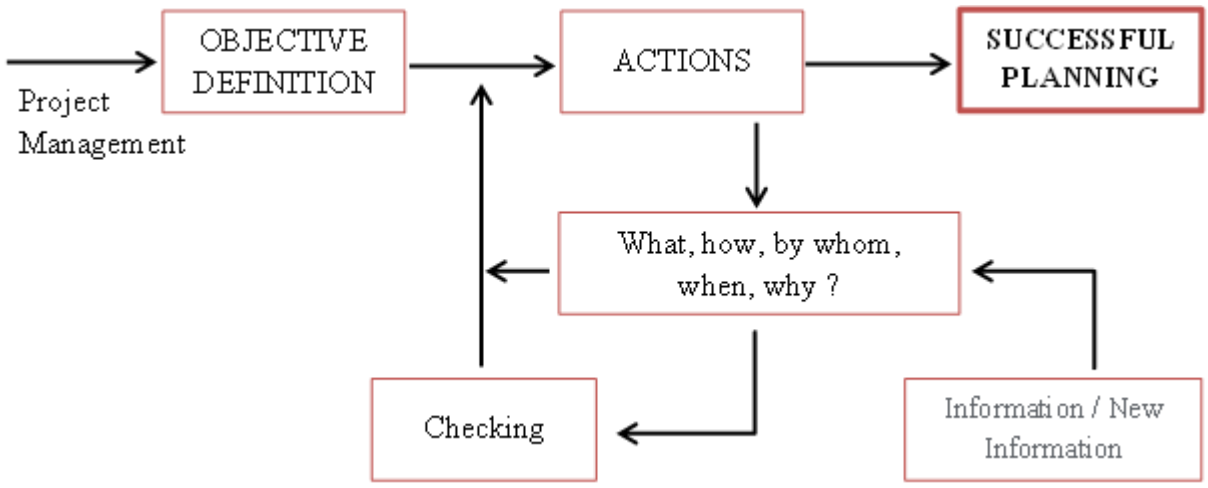

Figure 2: Project planning process cycle (Gültekin, 2007).

In order for the planning to be successful, it is very important that all parties involved in the project participate in the planning process and that constraints and critical activities are identified (Oberlender, 2000). Project planning enables taking the right decisions and carrying out and following the activities accordingly, allowing the necessary measures to be taken for the opportunities and dangers in the project process (Barutçugil, 1988). While some of these activities are independent of each other, the realization of some activities is dependent on the successful completion of another activity (Durucasu et al., 2015). Determining the relationships and durations of these activities, arranging them in line with the priority relationship, and controlling them during and after the implementation are provided by project planning techniques.

Planning Techniques

Towards the end of the 1950s, studies on the development of project planning and programming techniques began to be carried out and have reached the present day by developing. Project planning techniques include Gantt diagrams, Critical Path Method (CPM), Program Evaluation and Review Technique (PERT), Balance Bar Method and Saddle Method (Günaydın, 2001). PERT and CPM diagrams are widely used to observe critical information such as the sequence of activities in the project, the impact and priority of activities on each other, and the effects of problems affecting the operation between activities (Seker, 2007). Based on this, in this study, PERT and CPM methods were examined and used in the field study.

CPM Technique

The Critical Path Method (CPM) was developed in 1956 by the DuPont Company as Rernington Rand consultants as a deterministic approach to planning (Oberlender, 2000). Critical Path Method: It emerged as a result of a parametric programming model developed to solve the project planning problem (Zareei, 2018). It aims to provide the relationship between the activities involved in the project and the timing of costs and resources (Oberlender, 2000). It is used to estimate the minimum project duration, respectively, of the activities with the critical path or the longest duration in the project (Hiller, 1990). Five parameters are

considered for each activity to determine the critical path, including earliest start (EEBa), earliest finish time (EEBi), latest start (EGBa), latest finish time (EGBi), and scheduling flexibility. In order to obtain the data for these five parameters, three separate calculations are performed: forward calculation, backward calculation and total delay time (Yalkı, 2019). These; 1. Forward Calculation: It is done to find the earliest start and earliest finish time of each activity in the project. This calculation is made for all activities throughout the process (Yalkı, 2019). The calculation consists of three steps. These are (Yalkı, 2019);

- Step 1: EEBa (0) =1
- Step 2: EEBi = EEBa + Activity Time (Sj) (j=1,2,3 for n (n is the last activity.))
- Step 3: EEBa = EEBi + 1 for Next Event

Backward Calculation

It is done to find the latest start time and latest finish time of each activity in the project. It consists of two steps. These are (Yalkı, 2019);

- Step 1: EGBa = EGBi - Duration of Activity (Sj)
- Step 2: Latest Start for Next Event = EGBi + 1

Total Delay (Delay) Time

Calculates the total amount of delay time (TGS) allowed for each activity in the project. If this time is equal to zero, it means that the activity must be done on time and the activity is critical activity (Zareei, 2018; Yalkı, 2019) to calculate the total delay time;

- EGBa – EEBa = EGBi - EEBi = TGS

In line with the data obtained, the CPM diagram is created according to the duration of each activity and the interdependence of the activities. In the diagram, the earliest start and end time of each project, the latest start and end time, the activity name and the activity duration are expressed as data (Figure 3) (Zareei, 2018).

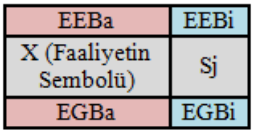

Figure 3: Activity show at CPM (Yalkı, 2019).

PERT Technique

The Program Evaluation and Review Technique (PERT) was developed by the US Navy in 1957 as a probabilistic approach to timing (Oberlender, 2000). The program evaluation and review technique is a management science for project planning and control (Siswanto et al., 2011). The purpose of PERT is not to create a program but to analyze the project network (Nicholas & Herman, 2012). The biggest difference between the PERT method and the CPM is the estimation of activity times (Oberlender, 2000). PERT addresses uncertainty in time using three-time estimates: optimistic, average, and pessimistic. Optimistic time (a) is the

shortest time the activity can be completed, assuming everything is going well. average (m); It is the time that will occur with the repetition of the activity. pessimistic time (b); assuming everything is going badly, is the longest the activity can require. PERT uses three different formulas to find the expected duration (te), variance (o2) and standard deviation (o) of each activity. These are;

- Expected Duration of Each Activity: te = (a + 4m + b) / 6
- Variance and Standard Deviation: o2 =[(b-a) / 6]2 o = (b-a) / 6

In line with the data obtained, the PERT diagram is created according to the duration of each activity and the interdependence of the activities. The diagram shows the optimistic time (a), the most likely time (m), the pessimistic time (b), the name of the activity (x), and the expected duration (te) of the activity for each activity (Figure 4).

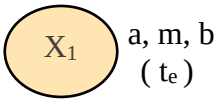

Figure 4: Activity Show at PERT (Yalkı, 2019).

In line with these data, it has been determined that temporal data of the projects are obtained with CPM and PERT methods in project management planning. Since it is aimed to obtain the best quality product with the most appropriate time and cost in project management, there is a relationship between time planning and cost. Therefore, it is necessary to make the necessary cost analysis for each activity (Gültekin, 2007; Siswanto et al., 2011). With cost analysis, if there are activities within the project that can be accelerated in the project, the effects of these activities on the whole project are examined by calculating which activities, their duration, and costs (Siswanto et al., 2011). The relationship between time and cost is calculated by accelerating cost (Siswanto et al., 2011). This calculation is;

$$\text{Acceleration cost (slope)} = \frac{\text{Accelerated Cost} - \text{Normal Cost}}{\text{Normal Time - Accelerated Time}}$$

In line with these data, within the scope of the study, time-cost analyzes were carried out in projects with different functions and volumes using CPM and PERT methods. In line with the data obtained, the effects of the time and cost problems that may arise with the changes in the programming on the project stakeholders were examined and suggestions were made to the stakeholders.

Study Area and Method

Today, in direct proportion to the growth of cities, people's needs for housing, education, public, health and sports structures have increased. Since the population density and human needs are directly proportional, the buildings selected in the study area were selected from the central districts with the highest population density. Within the scope of the study, residence and school projects located in the central districts of Kayseri were examine. Located in Talas district, the school (A) with 15 classrooms consists of three floors, a basement floor, a ground floor and a normal floor. The school, which was built by the public, has a construction area of 1,820,00 m² (Figure 5). The residence (B), which is located in Melikgazi district and consists of 44 flats and 3 shops, consists of 16 floors, including a basement, a ground floor, 13 normal

floors and an attic. Built by a private construction company, the residence has a construction area of 9,448.00 m² (Figure 6). The data of the projects are given in Table 1.

Figure 5: School project (MEB, 2020).

Figure 6: Residence project (İkonProje, 2020).

Table 1. Information on the projects.

Projeler	**School (S)**	**Residence (R)**
Location (District)	Talas	Melikgazi
Construction Area (m²)	1.820,00 m²	9.448,00 m²
Number of Floors	3	16
Number of Classrooms / Flats	15	44
Number of Shops	-	3

All activities related to each floor in the projects are carried out by separate worker groups. "Mould Activities (A), Iron Activities (B), Concrete Activities (C), Brick Wall Activities (D)" were selected among the activities to be carried out in the project. The priority relationship between these activities is expressed in Table 2 over the basement and ground floor. Activities A1, B1, C2 etc. Expressing it as the form was made to show the activities related to the floors. Durations are calculated in days.

Table 2. Priority relationship between activities.

Activities	**Priority Relationships**
A1 (Basement Floor Formwork Activities)	-
B1 (Basement Floor Iron Activities)	A1 (Basement Floor Formwork Activities)
C1 (Basement Floor Concrete Activities)	B1 (Basement Floor Iron Activities)
A2 (Ground Floor Formwork Activities)	C1 (Basement Floor Concrete Activities)
D1 (Basement Brick Wall Activities)	C1 (Basement Floor Concrete Activities)
B2 (Ground Floor Iron Activities)	A2 (Ground Floor Formwork Activities)
C2 (Ground Floor Concrete Activities)	B2 (Ground Floor Iron Activities)
D2 (Ground Floor Brick Wall Activities)	C2 (Ground Floor Concrete Activities)

Quantities of these activities were made, and the duration of the activities were analyzed according to the unit price list prepared by the Ministry of Environment and Urbanization for 2020 (Table 3). CPM and PERT diagrams were created in line with these data.

Method

Today, project planning, which will lead to success in project management, has gained importance due to the fact that project management is a competitive element. Projects with different functions and volumes were selected to examine the effects of CPM and PERT techniques, which are among the techniques that provide project planning, on project stakeholders. After the network diagram of the projects was created, the critical ways that could cause the delay of the projects were examined. Possible problems that may be encountered in terms of time were defined and alternative solutions were searched.

Since the concepts of time and cost are in a relationship in project management, cost analysis has been carried out. Since the PERT method was carried out in an environment of uncertainty, the cost analysis was examined over the PERT data. With the study, the benefits that both different projects and the methods used can provide to the project manager are compared. In line with the data obtained, the effects of the changes in programming and the cost and time problems that may arise on the project stakeholders were examined and suggestions were made to the stakeholders.

Table 3. Quantity takeoff abstract.

Quantity Takeoff Abstract							
Project	Field of Activity	Activity No	Poz Number	Activity	Quantity	Unit	Time to Perform with the Team (Days)
SCHOOL	Basement	C_1	Y.16.050/16	Concrete	278,01	m^3	6
		A_1	Y.21.001/03	Formwork	1.884,69	m²	177

		B_3	Y.23.014	Iron	236,60	Tonne	181
		D_3	Y.18.001 /C16	Wall	2.480,21	m²	256
	Total Days						1093

Findings and Discussion

In order to plan each project with the CPM method in line with the data obtained; Five parameters were calculated for each activity: earliest start (EEBa), earliest finish time (EEBi), latest start (EGBa), latest finish time (EGBi) and total latency time (TGS) (Table 4). Afterwards, CPM diagrams were created according to the duration of each activity and the interdependence of the activities. First, the CPM diagram of the activities selected from the school project was created and it was determined that they could be completed in 83 days (Figure 7). Afterwards, a CPM diagram was created for the housing project, and it was seen that it could be completed in 418 days (Figure 8). The critical path of the projects has been determined as "A1, B1, C1, D1, A2, B2". It has been seen that any delay in these activities will cause disruption of the entire project.

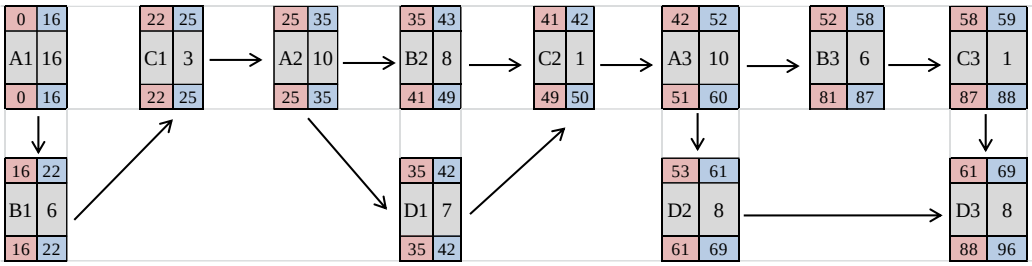

Figure 7: School project CPM diagram.

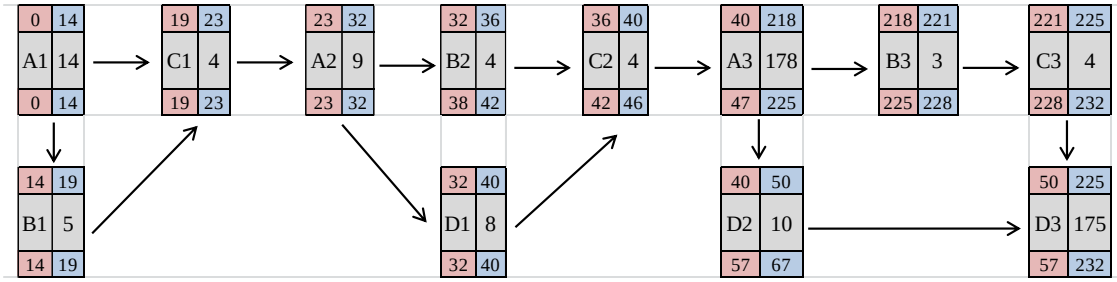

Figure 8: Residence project CPM diagram.

Table 4. CPM data of activities.

CPM VERİLERİ								
Project	Activity Area	Activity Number	EEBa	EEBi	EGBa	EGBi	TGS	Activity Duration

Afterwards, triple time estimates for each activity determined within the projects, expected durations, variances and standard deviations of these activities were calculated (Table 5). Then, according to the PERT technique, the network diagram of the project was created with the data of optimistic time (a), average (m), pessimistic time (b), expected time (te). First, the PERT diagram of the activities selected from the school project was created, and it was determined that they could be completed in a period of 97-131 days (Figure 9). Afterwards, a PERT diagram was created for the housing project, and it was seen that it could be completed in 265-412 days (Figure 10). The critical path of the projects has been determined as "A1, B1, C1, D1, A2, B2". The standard deviation of the school project is 9 days, which is obtained by adding the standard deviations of the critical activities. The standard deviation of the housing project is 16 days.

Table 5. PERT data of activities.

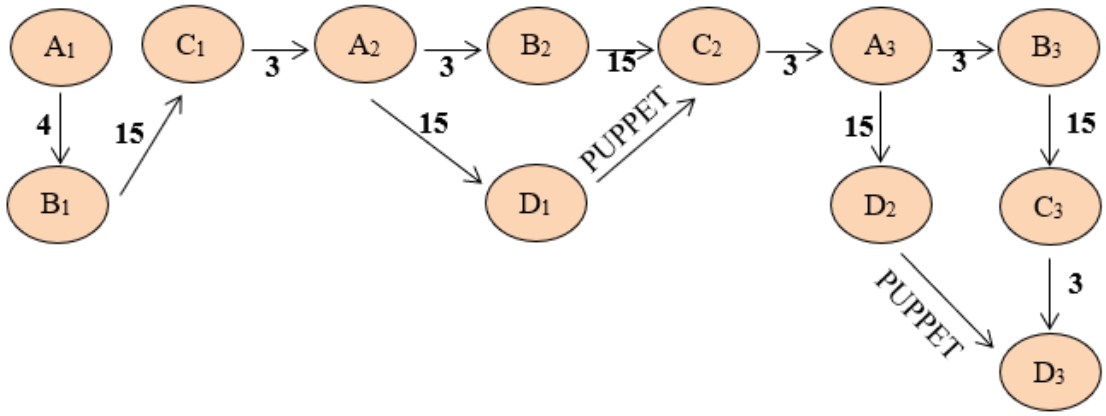

Figure 9: School project PERT diagram.

The activities with the most delay time in the school project are B1, D1, B2, D2, B3, D3 activities with 2.5 days. These activities are followed by activity A1, which has a lag time of 0.66 days. Since these activities have more delay time than other activities, it is possible to transfer resources from these activities to critical activities in the form of time and labor [22]. In this direction, it has been determined that the activities of B1, D1, B2, D2, B3, D3 can be accelerated by allocating additional worker groups to critical activities A1, C1 and A2.

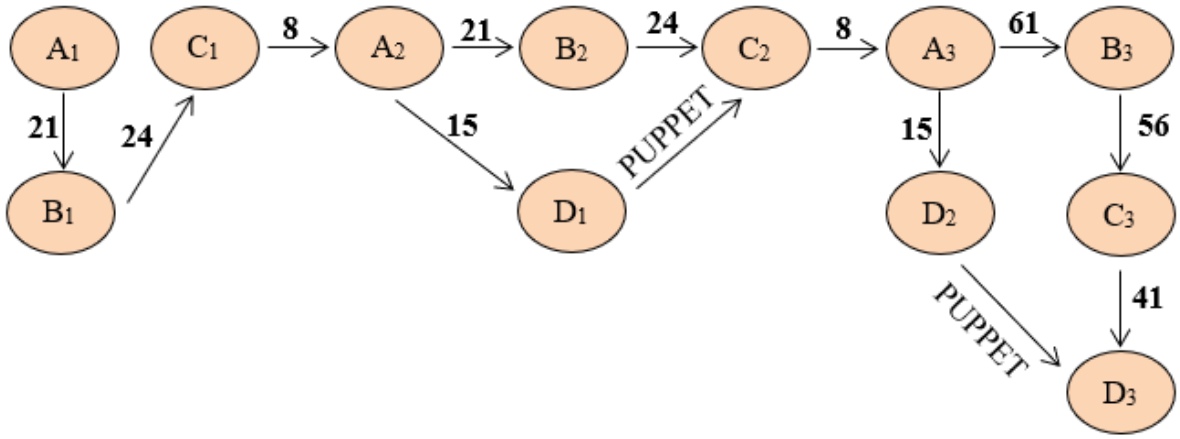

Figure 10: Residence project PERT diagram

The activity with the highest delay time in the housing project is the A3 activity with 16 days. This activity is followed by activity B3 with a latency of 14 days and activity C3 with a latency of 10.33 days. Additional worker groups can be allocated from the A3, B3, C3 activities in the project to the critical activities A1, B1, C1, D1, A2 and B2.

The completion times of the activities were determined by creating CPM and PERT diagrams of the selected activities within the projects examined in this study (Table 6). Due to the different functions and volumes of the projects, it allows the project managers to choose the optimum or near-optimal alternatives by comparing the different time combinations of the projects. It has been determined that planning the projects separately with CPM and PERT techniques provides convenience to the project managers in establishing different perspectives and problem structure. Thus, the project manager can easily decide which activities should not be interrupted and which should be emphasized.

Table 6. Architectural and planning information of the projects reviewed.

PROJECTS		SCHOOL	RESİDENCE
Architectural Information	Location (District)	Talas	Melikgazi
	Construction Area (m²)	1.820,00 m²	3.800,00 m²
	Number of Floors	3	16
	Number of Classrooms / Flats	15	44
	Number of Shops	-	3
Planning Information	CPM (Day)	83	418
	PERT (Day)	97-131	265-412

In line with these data, it has been determined that temporal data of the projects are obtained with CPM and PERT methods in project management planning. Considering that the project, which was planned with the PERT method, was carried out in an environment of uncertainty, and could be affected by some changes arising from various factors, the cost analysis was carried out over PERT. First of all, the costs of the selected activities within the housing and school project were calculated according to the unit price list prepared by the Ministry of Environment and Urbanization for 2020. Assuming that the activities are accelerated by 2 times, the accelerated durations of the activities have been determined (Table 6).

								Total Cost	**10.037.755,16 ₺**

In line with these data, acceleration costs, accelerating times and acceleration cost (slope) of the activities in the project were calculated (Table 8).

It has been determined that the costs selected within the school project can be completed to 2,506,977.21 ₺ by accelerating the activities by 2 times, and the costs selected within the housing project can be completed to 30,113,265,48 ₺. Acceleration processes can be performed with this data obtained. In this direction, while accelerating, three activities with the smallest slope were selected on the road to be accelerated.

The activity with the lowest slope in the school project is the D1 activity with 20,150,40 ₺. This activity is followed by D2 activity with 28.255.40 ₺ and D3 activity with 29.257.43 ₺. Accordingly, D1, D2 and D3 activities were selected. The activity with the lowest slope in the housing project is the D1 activity with 13,167.09 ₺. This activity is D2 activity with 21,316,15 ₺ and A1 activities with 45,561,60 ₺. Accordingly, D1, D2 and A1 activities were selected. Acceleration processes were applied to the selected activities, and as a result of this process, the completion times and costs of the activities were determined (Table 9).

	Ground floor	D_2	Y.18.001 /C16	Wall	324,20	m²	7,5	63.948,45 ₺
							Total Cost	**240.134,52 ₺**

D1, D2 and D3 activities in the school project were accelerated and the completion time of the activities selected from the project was reduced from 114 days to 92.5 days. With the acceleration of the activities, its cost increased from 835,659.07 ₺ to 987,979.44 ₺. Accordingly, the acceleration cost (slope) of the school project was calculated and found to be 7,084.66 ₺ (Figure 11).

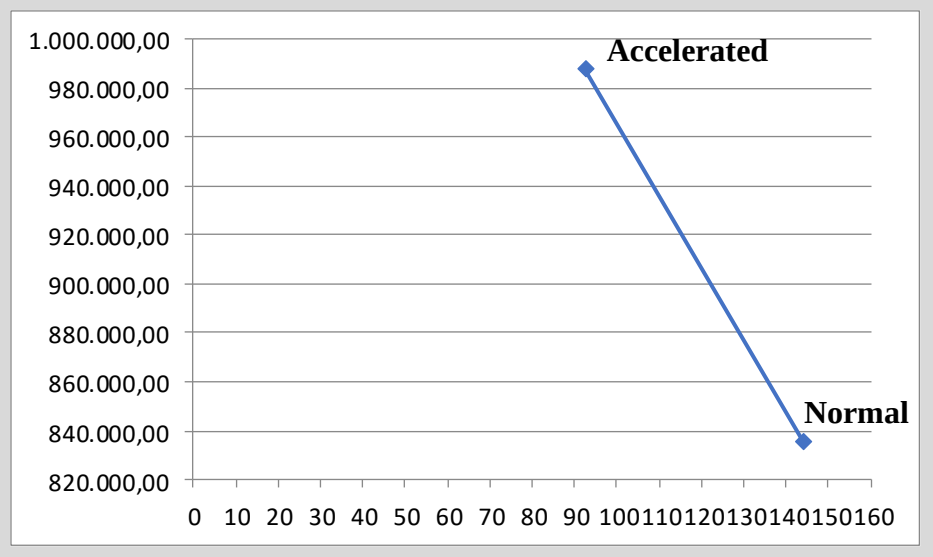

Figure 11: School project duration-cost analysis

D1, D2 and A1 activities in the housing project were accelerated and the completion time of the activities selected from the project was reduced from 344 days to 318.5 days. With the acceleration of the activities, its cost increased from 10,037,755.16 ₺ to 10,197,844.84 ₺. In this direction, the acceleration cost (slope) of the housing project was calculated and determined to be 6,278.02 ₺ (Figure 12)

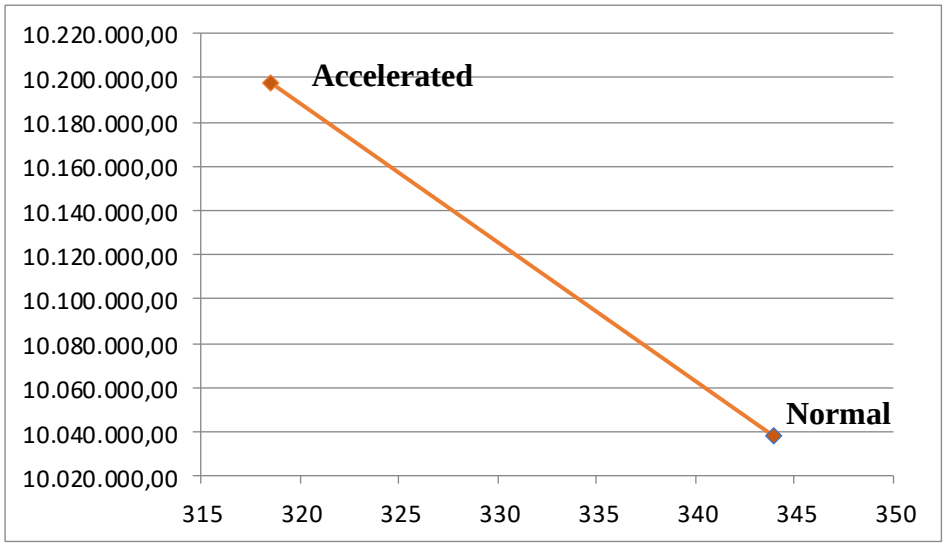

Figure 12: Residence project duration-cost analysis.

Conclusion and Recommendations

Within the scope of the study, CPM and PERT diagrams were created by selecting projects with different functions and volumes to examine the effects of CPM and PERT techniques on project stakeholders. In line with the data obtained, it has been determined that the main difference between CPM and PERT diagrams is in the time estimates (Figure 13). While the completion time of the activities in the school project was 83 days in the CPM technique, it was determined as 114 days in the PERT technique. In the housing project, while the completion time of the activities was 418 days in the CPM technique, it was determined as 339 days in the PERT technique.

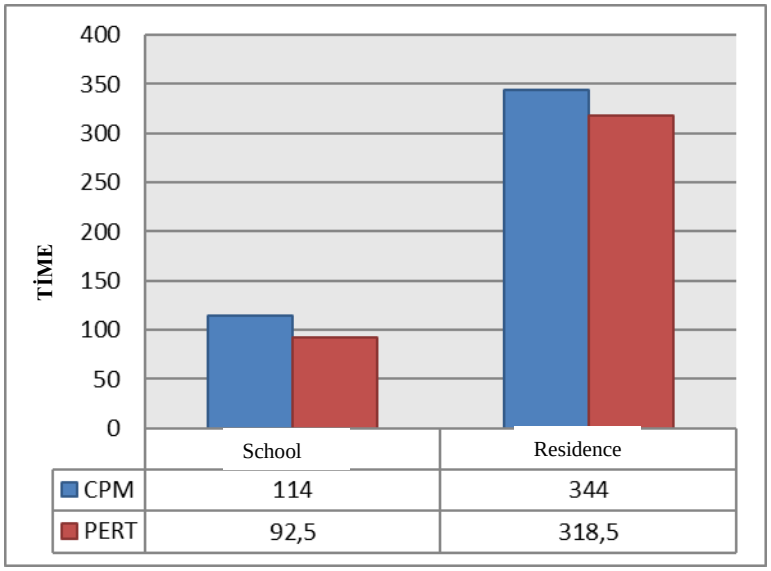

Figure 13: Comparison of projects CPM and PERT times.

Afterwards, the acceleration costs of the projects were determined by making cost analyzes with the temporal data of the projects (Figure 14). While the acceleration cost of the activities accelerated for 21.5 days in the school project was 7,084.66 ₺, the acceleration cost of the activities accelerated for 25.5 days in the housing project was determined as 6,278.02 TL.

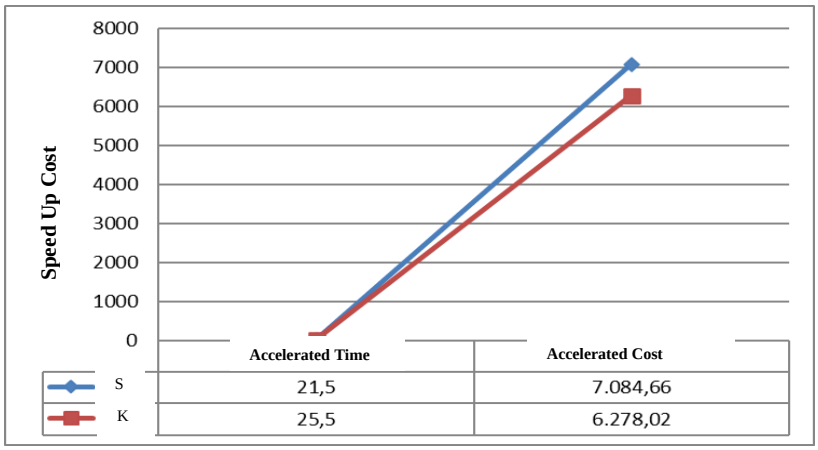

Figure 14: Comparison of acceleration costs of projects.

With the use of CPM and PERT methods in project planning by the project stakeholders, critical activities and ways that affect the realization time of the activities were determined, and it was seen that from which non-critical activities labor can be transferred to critical activities and the duration of the activities can be determined. In line with the data obtained, it has been seen that the project manager must make a time-cost analysis in order for the project management to be successful. Thus, it was emphasized that the project manager should manage the project planning process by observing the activities that can be accelerated in the projects, their duration and costs. With this type of analysis, the accuracy of which is trusted, the project management will be successful and quality products will be achieved by making time-cost analyzes of the project stakeholders in the planning process of the projects in public and private sector investments. It is aimed that this study will contribute to future academic studies and stakeholders in the building sector.

Critical Construction Time Overruns Causes in Turkish Construction Industry

M. Serter and G. Ayalp
Hasan Kalyoncu University, Department of Architecture, Gaziantep, Turkey
merve.serter1@std.hku.edu.tr, gulden.ayalp@hku.edu.tr

Abstract

Time overrun is one of the most serious issues in construction industry throughout the world, which may result in many negative impacts on the construction project like budget overrun, low productivity, contract expiration, work acceleration resulting in bad quality, and disputes among construction stakeholders, and construction industry overall. Construction industry has a large share in the country's economy and in the employment of the workers in Turkey. Considering the importance of the sector for the countries, it is essential to determine the critical causes of the time overrun in order to prevent or minimize this problem. Therefore, this research aims to determine the critical time overrun causes in Turkish construction industry. To reach this aim first, time overrun causes for construction projects were determined with systematic literature review, and critical causes of time overrun were identified thereafter. Using Web of Science database, 181 articles indexed in SCI-E, SSCI, AHCI, and published last 10 years were reviewed through a systematic literature review (SLR). As a result of SLR, 60-time overrun causes were identified under eight categories. The questionnaire was designed by the obtained 60 causes with 5-point Likert scale as measuring instrument and conducted to 600 architects and engineers occupied at construction industry. A total of 127 valid questionnaire were returned, representing a 21.16 % response rate. Obtained data analyzed using reliability analysis, and mean score ranking. The findings of this research revealed that "decision change of the employer during the design and implementation phase"," shortage of supplies, delays in delivery", "poor communication and coordination among stakeholders", "price fluctuations", "delayed permits from the municipality", lack of skilled workers", "design changes", and "unpredictable weather conditions" are the most critical construction time overrun causes. Considering these critical causes, the suggestions have been developed to improve the current situation.

Keywords: *time overrun, construction management, construction industry.*

Introduction

The construction industry in Turkey considered one of the key drivers of the economy. The construction industry contributed $33 billion USD to the national GDP, with a share of 5.4% (Tekçe, 2020). Further, the industry employs as much as 10% (excluding agriculture) of the Turkish workforce (Turkish Contractors Association, 2016). A construction project is considered as successful when it is completed on time, within budget, and in accordance specified quality standards (Yılmaz, 2020), with the specifications (Olawale & Sun, 2013).

Time overrun is one of the most significant problems in construction industry which directly affect the project success, adversely.

Time overrun is often defined as delay the beyond a project completion date (Ansah & Sorooshian, 2018) that the parties agreed upon for the delivery of a project (Parchami Jalal & Shoar, 2017). Construction projects might overlay time overrun in different stages, from project start through project completion (Zaman et al., 2022). However, most time overruns occur at the construction phase (Ansah & Sorooshian, 2018). Time overruns in construction projects, affect negatively the planning and delivery dimension of operations, regardless of the socio-economic status of the country involved (Yap et al., 2021). This problem is a major phenomenon in construction industry, particularly in emerging countries (Amoatey et al., 2015). The cause and effect of the length of time spent on building in Tanzania are presented by Kikwasi (2013). According to another study conducted in Qatar, between 2000 and 2013 72 percent of public construction projects were not completed on schedule (Senouci, 2016). Similar to this, Maceda (2016) notes that time overruns occur in 70% of projects in Dubai. These studies present that construction projects are often delayed, which are demanding for both developed and developing countries. Notably, the construction holdup will result in an increase in project expenditure overall (Faridi, 2006).

Hitherto many effects of time overrun have been identified at previous studies (Amarkhil et al., 2021; Ansah & Sorooshian, 2018; Jahangoshai Rezaee et al., 2019) and the subject is still a critical topic of research among construction management researchers globally (Zaman et al. 2022). Amarkhil et al. (2021) identified frequently studied topics on the project delay to understand type and impact of delays to manage project. Kazaz et al. (2012) particularized causes of delays in construction projects in Turkey. Zidane and Andersen (2018), studied about universal delay factors in construction projects in Norway. As seen from a brief review, several obstacles were identified, all of which are important; however, it is unclear which of them are the critical and significant at the construction phase. Understanding the causes of time overrun that can affect the project at construction phase is important to recognize the mitigation measures to diminish the effect on the project performance. Hence, the objective of this study is to identify the critical causes of time overrun in the Turkish construction industry.

Research Method

This research aims to determine the critical time overruns causes in Turkish construction industry. The research methodology is divided into four phases; identification of time overrun causes with systematic literature review, organizing the questionnaire, data collection and data analyses to reach the aim of the study.

In the first stage, time overrun causes for construction projects were determined with systematic literature review (SLR). Conducting SLR, that involves “planning the review,” “conducting the review,” and “documenting the review” stages, extensive literature was examined and presented in Figure 1.

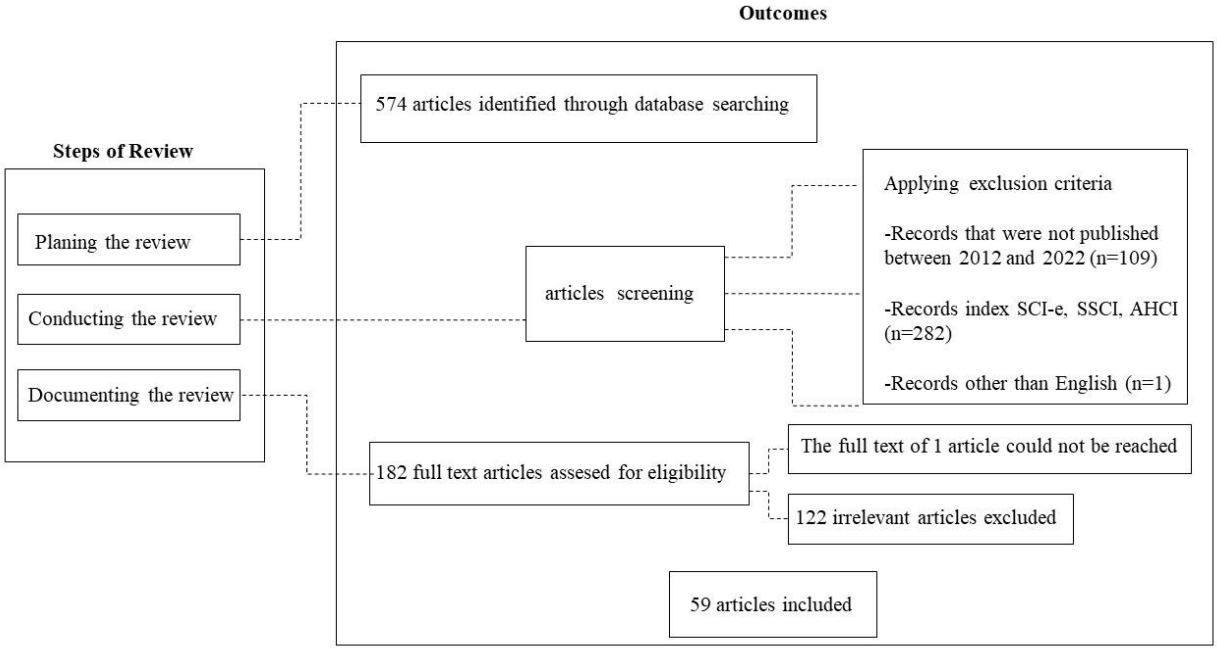

Figure 1: Stages of systematic literature review.

Web of Science (WoS) search engine was used to find scientific papers regarding time overruns at construction industry. WoS was considered for its accuracy, comprehensiveness, and skilled coverage of several study fields (Hong & Chan, 2014).

Keywords were used to set search parameters in the WoS database. The search parameters were remarked as keywords "time overrun" AND "construction" NOT "road" NOT "highway" NOT "infrastructure". In total, 574 journal articles were identified during the initial search. Based on the study topic, researchers should define inclusion and exclusion criteria (Kitchenham & Charters, 2007). The search was limited to English-language articles, and review papers published in academic journals between 2012-2022, and indexed in SCI-E, SSCI, AHCI. Among the 574 records, 392 of them extracted applying the exclusion criteria. The full text of 1 article could not be reached, therefore 181 full-text studies having full access. Due to irrelevancy, 122 studies were excluded. Finally, 59 studies were considered relevant and included selected for thorough examination to identify critical time overrun causes. Finally, 60-time overrun causes (TOCs) that were directly related to these eight categories were determined and are listed in Table 1.

At the second phase of the methodology, a questionnaire was designed for architects, and civil engineers and contractors working at construction firms in Turkey based on SLR results. Considering the time overrun causes, the questionnaire is consisted of eight sections, and total of 60 TOCs with 5-point Likert scale. The questionnaire conducted to 600 architects and engineers occupied at construction industry. A total of 127 valid questionnaire were returned, representing a 21.16 % response rate.

Table 1. Construction time overruns causes.

Cause category	Codes of causes	Time overrun causes (TOCs)	Sources
Contractor and Employer (CE)	CE1	Contractor's financial problems	[1-5], [7], [9], [11], [12], [16], [17], [24], [37]
	CE2	Contractor's experience and skills training	[1-7], [9], [11], [12], [15], [16], [22-24], [27], [59]
	CE3	Slow decision making by the employer	[1], [2], [6], [7], [9], [12], [13], [23]
	CE4	Employer's shortage of funds	[1], [9], [15], [16]
	CE5	Contractor origin/quality	[1], [4], [9], [11], [30]
	CE6	Decision change of the employer during the design and implementation phase	[1], [4-7], [9], [12], [13], [15], [18]
Equipment and Material (EM)	EM1	Frequent equipment malfunctions	[12], [15], [16]
	EM2	Insufficient modern equipment	[3], [4], [6], [7], [12], [15], [18], [24]
	EM3	Low equipment efficiency	[2], [12], [15], [16]
	EM4	Lack of equipment	[5-7], [15], [16], [23]
	EM5	Inappropriate equipment	[1-3], [5], [15]
	EM6	Shortage of materials	[4-9], [12], [13], [15], [16]
	EM7	Late supply of material	[1], [2], [5-8], [12], [15], [16], [37]
	EM8	Shortage of supplies, delays in delivery	[1], [2], [4], [5], [7], [12], [15], [16], [23], [24], [37]
	EM9	Low quality building materials	[1], [11], [15], [16]
Control, Communication, and Management (CCM)	CCM1	Poor communication and coordination among stakeholders	[1], [2], [3], [4], [7], [9], [13], [15], [16], [20], [21], [23], [24], [31-34]
	CCM2	Lack of information flow between the parties	[1], [2], [4], [13], [15], [16]
	CCM3	Ineffective site management and supervision	[1], [2], [4-7], [11], [12], [16], [30]
	CCM4	Delay and lack of supervision in the quality control process	[2-5], [7-9], [11-13], [15-17], [23], [24], [36]
	CCM5	Resource shortage and management issues	[4-8], [12], [15-17], [19]
	CCM6	Project management issues	[2], [3], [5-7], [11-13], [15], [16], [31], [34], [43], [46], [47], [49], [55]
Bureaucratic and Economic (BE)	BE1	Bureaucratic effects	[2-4], [6], [7], [9], [12], [16], [28], [31], [55]
	BE2	State, Law and Order Status	[2], [3], [5], [9], [10], [12], [15], [16]
	BE3	Making extremely low bids	[1], [3], [4], [7], [15]
	BE4	Price fluctuations	[1], [2], [4], [6], [7], [15], [24], [35]
	BE5	Payment delays	[2], [4], [5], [6], [9], [12], [15], [16], [23], [24], [31], [37], [45], [48]
	BE6	Economic problems and poor financial market conditions caused by inflation and sanctions	[3], [4], [9-11], [13], [15], [23], [34], [50], [51], [55]
Scheduling (S)	S1	Delays in responses to information requests	[4], [5], [7], [20], [43]
	S2	Control and approval delays in design documents	[1-4], [7], [12], [13], [28], [37]
	S3	Delayed permits from the municipality	[1], [2], [5], [13]
	S4	Delay in performing final inspection and certification	[2], [7], [12], [20]
	S5	Delay in delivery of the construction site to the contractor	[2], [3], [5], [7], [9], [24]
	S6	Suspension of work	[5], [9], [12]
	S7	Ineffective project planning and work schedule	[1-7], [9], [11], [12], [15-17], [19], [21], [23], [33], [36], [41], [56]
	S8	Unrealistic deadlines and work schedules	[1-7], [9], [13], [16], [17], [21], [23], [35]

Table 1. Construction time overruns causes (continue).

Cause category	Codes of causes	Time overrun causes (TOCs)	Sources
Labor Conflict (LC)	LC1	Shortage of qualified white-collar (architects, engineers, project managers)	[4-6], [7], [12]
	LC2	Insufficient labor productivity	[1], [2], [4], [5], [7], [11], [12], [14-16], [21], [24], [42], [44], [54]
	LC3	Lack of skilled workers	[1-7], [11-13], [15], [27], [55]
	LC4	Low productivity of skilled workers	[1], [4], [7], [9], [11-13], [15], [21], [27], [39], [42]
	LC5	Personal conflicts between workers	[5], [9], [11], [13], [14], [16], [21], [23], [43]
	LC6	Frequent change of subcontractors	[2], [4], [9], [12], [13], [15]
	LC7	Delays in subcontracting work	[4], [7], [9], [12], [15]
	LC8	Problems between contractor and subcontractors	[2-5], [9], [13], [14], [16], [21], [23], [42]
Reworks (R)	R1	Design changes	[4], [5], [7], [9], [12], [13], [15-18], [20], [21], [24], [29], [35], [40], [45], [52], [58]
	R2	Material changes	[4], [5], [7], [9], [12], [13], [16], [20], [24], [40]
	R3	Drawings are not clear	[4], [5], [7], [12]
	R4	Technical specifications are not clear/not prepared at all	[2], [3], [7], [9], [12], [13]
	R5	Change in business volume	[2], [6], [12], [13], [16-18], [20], [40], [51]
	R6	Rebuilds due to errors	[2], [4], [5], [7], [12], [13], [15], [21], [25], [38], [53]
	R7	Design errors and shortcomings	[5-7], [12], [13], [15], [16], [20], [21], [23], [24], [25], [33], [39]
	R8	Errors and delays in the production of design documents	[2], [7], [9], [12], [13], [15], [16], [18], [23]
	R9	Inappropriate/old/wrong construction methods	[1], [2], [7]
	R10	Incompatibility between projects	[3], [9], [12], [13]
Construction Site and External Sources (ES)	ES1	Limited access to construction site	[2], [5], [7], [12], [15], [16], [28]
	ES2	Delay/start delay in site mobilization	[2], [5], [7], [9], [28]
	ES3	Accidents and injuries during construction	[2], [12], [24], [31], [36]
	ES4	Unexpected surface and subsurface conditions (soil, water table, etc.)	[1], [2], [5], [7], [13], [16], [24], [26], [39]
	ES5	Unpredictable weather conditions	[1], [2], [5-7], [12], [13], [15], [16], [24], [34], [39]
	ES6	Environmental restrictions	[5], [11], [15], [16], [26], [49]
	ES7	War, earthquake, pandemic etc. as force majeure.	[4], [9], [12], [24], [57]

To identify the internal consistency among questions using a Likert scale in a questionnaire, reliability should be measured (Nunnally & Bernstein, 2007). Cronbach's alpha (α) was utilized to determine the statistical reliability and validity of the participants' replies. The α

coefficient ranged from "0" to "1"; the minimum acceptable reliability threshold was determined as 0.7 (Cronbach, 1951; Tavakol & Dennick, 2011).

To determine the critical time overrun causes (CTOCs) among identified TOCs, normalized mean values (NMVs) analysis was conducted for each of the 60 TOCs. The calculation of NMVs for each TOCs follows Equation 1.

$$Normalized\ mean\ value = \frac{(mean\ of\ TOC - lowest\ mean)}{(highest\ mean - lowest\ mean)} \quad (1)$$

Any TOCs with an NMV higher than 0.5 is considered to meet the CTOCs.

Findings

To determine the internal consistency of the questionnaire reliability analyses was conducted using Cronbach α coefficient. The α coefficient of the data set for the 60 TOCs were determined to be 0.950, which is above the minimum threshold of 0.7 (Tavakol & Dennick, 2011).

Regarding the critical time overrun causes the means, normalized mean values (NMV) and standard deviations (SD) were computed and presented at Table 2.

Sd = Standard deviation, NVa = normalized value = (mean - minimum mean)/ (maximum mean - minimum mean)

Normalization value ≥ 0.50 Critical time overrun cause:*

The results revealed 18 CTOCs out of 60 TOCs have normalized values greater than 0.50, which can be listed in descending order as follows: BE4, BE6, BE5, LC3, S3, LC7, CE6, LC4, BE3, EM8, LC8, R1, LC2, LC1, EM7, S4, R10, S2.

When the distribution of the determined 18 CTOCs analyzed according to groups, 1 of contractor and employer; 2 of Equipment and Material; 4 of Bureaucratic and Economic; 3 of Scheduling; 6 of Labor Conflict; 2 of Reworks found to be critical. It is significant that none cause related to communication, control, and management and construction site and External Source were found to be critical.
Top ten CTOCs were determined as follow:

1. Price fluctuations (BE4)
2. Economic problems and poor financial market conditions caused by inflation and sanctions (BE6)
3. Payment delays (BE5)
4. Lack of skilled workers (LC3)
5. Delayed permits from the municipality (S3)
6. Delays in subcontracting work (LC7)
7. Decision change of the employer during the design and implementation phase (CE6)
8. Low productivity of skilled workers (LC4)
9. Making extremely low bids (BE3)
10. Shortage of supplies, delays in delivery (EM8)

It is significant that top three CTOCs are related to bureaucratic and economic issues. In addition, three CTOCs are related to labor conflict. Therefore, economic and labor related problems play significant role for time overrun during construction.

Conclusion

In Turkey, the construction industry contributes significantly to the national economy. Time overrun is a problem that this industry encounters frequently. In order to prevent or minimize this issue, it is crucial to identify the critical causes of the time overrun given the significance of the industry. The results of this research have a considerable impact on the construction sector in this regard.

A systematic literature review methodology is used to investigate time overruns causes. A total of 181 full-text studies are examined, and 59 of these studies are included. From the initial systematic literature review, 60 causes were obtained for time overrun categorized under contractor and employer (CE), equipment and material (EM), communication, control, and management (CCM), bureaucratic and economic (BE), scheduling (S), labour conflict (LC), reworks (R), and construction site and external sources (ES), only 18 out of 60 TOCs were determined as critical tine overrun causes. While this does not imply that the other 42 causes do not have any importance in term of time overrun, their impacts may not be adequate to be deemed as “critical” for this study.

When the context of the top ten CTOCs were analysed, it is significant that most of them are related to bureaucratic and economic and labour conflict issues. Whereas communication, control, and management and construction site related issues are not critical for time overruns during construction.

This study provides some implications to government regarding to CTOCs as the results revealed that Price fluctuations (BE4), Economic problems and poor financial market conditions caused by inflation and sanctions (BE6), Payment delays (BE5), which are mainly attributed to government policies, are among the causes that can give rise to time overrun during construction. Governments should border the limit cost for the project.

This study contributes construction project managers with an understanding of the main sources of delay. They can provide corrective solutions for their projects by using the identified critical reasons. With the awareness of the most important delay factors identified, they can reduce the impact of these factors on their projects so that they can make the most improvement in the system. These elements need to be considered and effectively integrated into the construction processes for developing countries. Overall, the study significantly raises awareness and can be applied to work evaluating the performance of projects as well as delay control in project environments.

oriol.carrasco@iaac.net

Abstract

The Multidimensional Exploration Methodology (MDEM) is a holistic learning approach based on spiral progress loops of design-thinking and experimentation. The main objective of the methodology is to augment creativity, productivity, and learning efficiency thanks to cognitive learning styles and self-challenges that trigger design-driven innovation. This method helps the learner to align with the recent developments in the industry and adapt to the contemporary world as active thinkers and future change-makers. Previously, under the title, 'The Adoption of Multidimensional Exploration Methodology to the Design-Driven Innovation and Production Practices in AEC Industry', the methods of adaptation from the academy through industry were discussed. In this paper, the basis of this learning method is explained briefly. Also, the method is discussed as a learning style, by its' interconnected relationship with the methodological references and their global impacts in the future.

Keywords: *challenge-based learning, design-driven innovation, digital design-thinking, fabrication and construction tools, interdisciplinary approach, prototyping and production practices.*

Introduction

The Multidimensional Exploration Methodology (MDEM) is a holistic learning approach based on spiral progress loops of design-thinking and experimentation (Birgonul & Carrasco, 2021). Our proposal for the learning method for architectural design studio education is based on various learning methods such as Cognitive Learning Theory (Greenwald, 1968; Bloom & Krathwohl, 1984), Kolb's' Experiential Learning Methodology, (Kolb, 1984; Kolb et al., 1999) and Design Science Research Methodology (Van Aken, 2005; Henver et al., 2004; Peffers et al., 2006). Our learning methodology is developed based on aforementioned learning techniques and adapted to the Challenge-Based Learning theory (CBL) (Apple Inc., 2010). The CBL is a collaborative learning experience in which teachers and students work together to learn about compelling issues, propose solutions to real problems, and take an action (Birgonul & Carrasco, 2022).

MDEM is a current approach for design education that blends those learning methods for creating a more actualized learning style for architectural design. MDEM aims to cover solution oriented projects for global concerns by encouraging the learning to work within interdisicplinary approaches.

Previously, under the title, 'The Adoption of Multidimensional Exploration Methodology to the Design-Driven Innovation and Production Practices in AEC Industry' *(*Birgonul & Carrasco, 2020), the methods of adaptation from the academy through industry were discussed. In this paper, from a bottom-up perspective, the basis of this learning theory is discussed and explained with the interconnected relationship between the methodological references and their' future global impact.

The main objective of this paper is the introduction of the learning style: Multidimensional Exploration Methodology (MDEM). Accordingly, this study questions 'why interdisciplinarity is the current trend in both learning and practice?', and discusses 'how the MDEM can lead a sustainable practice for the Architecture, Engineering and Construction (AEC) Industry?'.

Basis of the Proposed Learning Method

Interdisciplinary has become a standard practice that should be applied to all business segments including the AEC industry. However, the gap between the educational models and application in industry field is still unbalanced and incompatible. There is an increasing need for interdisciplinary professionals who are capable of managing various tasks for organization and execution. Academy is the first step that the practitioner meets with the specific discipline. The skills that lead the production and application practices are developed in the university. Therefore, MDEM aims to create a sustainable solution for the question that asks; how the learning methodologies can shape the impact of AEC and global issues, by challenges and interdisciplinarity.

During the very first phases of this method, the cognitive knowledge is aimed to align with the essentials of the current architectural design understanding. To do so, adding the new values to the design-thinking and blending it with the active experimentation during the design education; students' cognition is re-shaped by the necessities of this alignment, which involves a responsible manner of new generation essentials for shaping the future. Training the future's practitioners require this new methodology that applies to interdisciplinary problem solving by a collective way of learning. To conclude, MDEM provides a holistic design thinking (Birgonul, 2020) that has an innovative learning technique, depending on the real-world challenges.

'Architecture is a representation saturated problem domain' (Akin, 2001) and consequently, design is not linear (Oxman, 2006) so the learning methodology neither should be. Thinking is also an organic process, and it is inseparable from its means of representation and expression (Herbert, 1992) in an intellectual way. Architecture and design students use diverse knowledge, versatile representation mediums and digital tools for augmenting the creative design thinking with multi-disciplinary ways.

In this section, we briefly discuss the existing learning theory 'challenge-based learning', define the references that we took for our proposed learning method, and moreover explain how this approach is applied to the MDEM.

Challenge-Based Learning (CBL)

'Challenge-Based Learning (CBL) is a collaborative learning experience in which teachers and students work together to learn about compelling issues, propose solutions to real problems, and take an action. The approach asks students to reflect on their learning and the impact of their actions and publish their solutions to a worldwide audience' (Apple Inc., 2010) and (Nichols et al, 2016), (See Figure 1).

Similarly, Problem Based Learning (PBL) is a method evolved from innovative health sciences and triggered by the existing problem, in which students learn about a subject through the experience of solving an open-ended problem found in trigger material. The PBL process does not focus on problem solving with a defined solution, but it allows for the development of other desirable skills and attributes (Schmidt, 1983; Boud & Feletti, 1998; Wood, 2003; Savin-Baden & Howell Major, 2004; Savery, 2006). Yet there is only a limited literature available on the relevancy and effectiveness of CBL and PBL implementation in architectural education (Maitland, 1998; Bridges, 2006). Although CBL and PBL resemble each other, in PBL, students are aspired to explore a set problem which has been provided by the tutor (Roberts, 2007), on the contrary in CBL, the challenge is created by the learner.

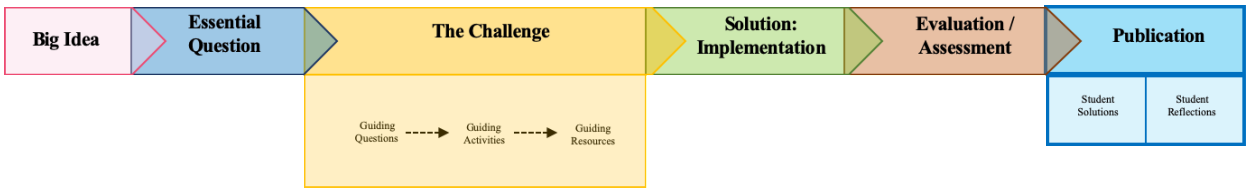

Figure 1: Challenge-Based Learning Framework, context from (Apple Inc., 2010), visualized by the authors.

Both CBL and PBL are methods that are based on an interdisciplinary way of thinking. The versatile approach that the learner creates is a key point on those methods, that triggers an authentic idea, which would suggest a good solution for an existing problem.

Multidimensional Exploration Methodology (MDEM)

MDEM takes reference from the challenge-based learning, and reflects this method to AEC industry with an interdisciplinary standpoint. Interdisciplinarity is essential of this learning method due to create a sustainable practice environment for the learner. This fact is directly connected to the cognitive learning approach that is included in the MDEM. This method aims to reshape the cognitive skills of the learner by aligning with the actual concerns that applies to the design problems. Additionally, developing strong cognitive bonds between the researcher and the topic of research generates a more consolidated knowledge, thanks to the experiential approach.

The main objective of this method is to create collective consciousness of design students as they will be the futures' change-makers. The methodology steps are constructed by taking the reference from CBL. The constituents of CBL are adapted to architectural design context. The methodology application steps are as following (see Figure 2): Big Idea: Introspection**,** Essential Question: Identification of the problem**,** The Challenge: Learning by designing**,** Solution / Implementation: Design Development**,** Evaluation / Assessment: Discussion**,** Publication: Communication; Repeating (Spiral Development).

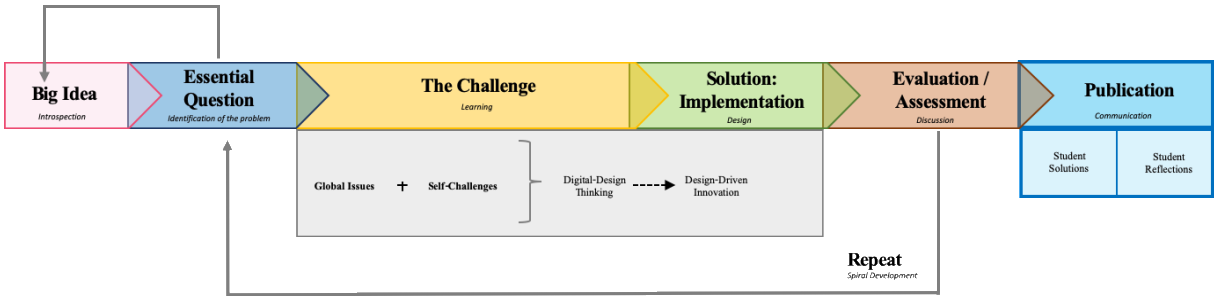

Figure 2: Multidimensional Exploration Methodology Flowchart.

The first step of the proposed methodology is Introspection where the big idea emerges. It is the initial step which is 'an ongoing process of tracking, experiencing, and reflecting on one's own thoughts, mental images, feelings, sensations, and behaviors' (Gould, 1995) and "introspection, as a humanistic, interpretative, and naturalistic approach to understanding subjective experiences has a unique value for experience-driven design" (Xue & Desmet, 2019). Starting the design thinking by introspection; creates the big idea of CBL by the student's cognition. The aim is to oblige the student to dream and define the problem-solving by a personal approach. While design thinking, it enables them to be creative without limits. Introspection; out of the case study experiences and its results that will be explained in further chapters, is most probably the most critical step through the projects' development because it is where the unique ideas are being conceived creating thus, a new standard. The significance of the identification of the problem and its' connection with creativity have been studied and discussed by various authors previously (Newell & Simon, 1972; Holyoak, 1990; Rosenman & Gero, 1993). On the second step, the essential questions are asked and the main problem of the project is defined by the student. The importance introspection leads the student to find the essential questions, which derives from the uniqueness of the personality of the designer (student).

The teaching process and learning action interact intensely with each other as a collective operation. This operation is creating hybrid moments where knowledge is exchanged in the classroom by digesting the necessities of the brief via experiencing the ample resources of the projects in its different representational aspects. The acquisition of the student is usually more significant in terms of knowledge acquired (Gould, 1995) and produces a new learning style in the first position, and secondly, a new way of dealing with problems and taking design decisions. As a consequence, thanks to challenge-based learning applied to MDEM, knowledge is not thought; it is generated by the collective actions of the learner and the mentor.

The questions and concerns lead to the third step where the challenges emerge. This step involves the main learning and development stages of the research project. This step is subjected to the personal learning styles and each student has their own way of doing and

learning. This is the fundamental formation of this method where the self-exploration and the creation happens. “Study behaviors stem from cognitive preferences which are broadly manifested as personality. Specific learning preferences are called learning styles, and they serve as stable indicators of how learners perceive and interact with learning environments” (Schmeck, 1985).

Learning styles are personal and unique. By blending cognitive learning theory with CBL, it is possible to observe the value of specific preferences for processing information. Learning through cognition, ensures each student to think and create uniquely, within the same context and the results would be surprisingly diverse. It is strongly believed that, the inclusion of personality in design education and design-thinking processes would augment the creativity, productivity and the uniqueness of the designed artifact. This fact could be the key for proposing this new methodology for extending the creativity limits, by liberating the design student by their cognitive actions.

During the solution/ implementation step covers the design development and digital-design thinking. On this step students’ progress by self-challenging to discover the possibilities of each concern. This step is followed by the evaluation step where the public presentations are made and discussions occur. Lastly, the students should communicate their outcomes and reflections by their own way of preference.

These steps and functions generate the spiral diagram of the methodology by being repeated until the required results are fulfilled. Each step is self-challenge based, meaning that the learning progress is the variable for each subject. Therefore, the multidimensional learning evolves, not only in one direction but also through various axes, by time, self-knowledge generation and knowledge flows. Early phases of design decisions and problem-solving generally start with analog methods, followed by digitalized representations. The methodology also creates an extra complication as classical design studios follow a top-down design approach, whilst in this method, most of the processes are bottom-up and design decisions are solely taken upon theories and profound interdisciplinary research and data-analysis. Additionally, this method highly encourages the learner to align with digital-design thinking. Regarding the design thinking and design phases, the digital tool using abilities are getting developed within the scope of this methodology.

To sum up the application phases of MDEM, it is crucial to apply a versatile and interdisciplinary manner both for learning stages, and for productive and genuine professional practice.

Discussion: Challenges and Interdisciplinarity

Interdisciplinarity is one of the most important values in innovative projects in both learning and practice. Currently, research and development projects are pursued by various disciplines due to add radical and disruptive outcomes.

Even though AEC industry is considered as a technical discipline, the core of it is based on its’ user. Human-centered approaches that facilitate good solutions for the user are achieved by a multidimensional standpoint that involves interdisciplinary way of thinking. As it was mentioned previously, in challenge-based learning and multidimensional exploration methods, the challenges that address global concerns also involves the ‘human-centered’

proposals for sustainable solutions. Therefore, it is crucial to approach the design problem with a multidimensional and interdisciplinary way.

On the other hand, by MDEM the understanding of many terms and context has got under reformation. One of the significant ones is the way of creation of knowledge. Eventually, the teacher is not a classical authority symbol with full decision power nor with an absolute truth. Yet, the teacher position became expanded to become a moderator for students' exploration journey. Teachers are now a project leader, where they may have the last word, but the learning methodology is built based on the self-challenges, cognitive styles and creativity of the students. It is important to note that, neither the students or the teachers have the answers on the questions proposed by the course syllabus, but the challenges direct the research through ‘big ideas.’ This blurriness of the outcome allows design evolution to be the predominant tool for refine, evolve projects and find a design solution to complex topics. Moreover, excluding the authority also enables more margin to include various disciplines and standpoints to a defined problem.

The architectural design studio education by MDEM does not search for absolute truths, but; it encourages the student to search for possible creative ways to approach a current problem. By this method, we value the process as much as the end result.

Upon constant discussion in class and self-evaluation of the learner, the project evolves more profoundly within the cognitive development processes. It is essential to discern which design solution should be developed further. These findings from the previous iteration are then documented and used as inputs for the next one, where more complexity will be added, creating thus, and a richer artifact. Above all, a challenge-based, hands-on learning process shapes the latest findings in each week, and consequently the knowledge gains of the semester.

MDEM can lead a sustainable practice for AEC Industry through its unique learning style. By collectively creating an actual cognitive position for the student, would induce fruitful products when the student starts working in real practice after graduation. Therefore, learning with challenges trains the student with a more conscious way. Also challenging the student by this method helps them to develop skills in multi-disciplinary ways, in contrary with the classical learning styles.

Teaching design with MDEM aims to transform the design students to the change-makers; thanks to the CBL and also to the availability of information and technologies**.** The application of this methodology inevitably changes both the perception of architecture and the ways of designing it. Architecture of the current era has become something much more complex than just a decade ago. It has social implications that expand further into the digital world, environmental considerations and added values and new ways of interaction between user and spaces. The resulting architecture is a hybrid that deals with a wider variety of inputs and offers a more abundant array of the solution to classical problems. Designers of the new age should have a responsible manner on global issues and receive education with an interdisciplinary approach; which could be achieved MDEM.

Conclusion

This study investigated the CBL application to architectural design and AEC education the proposed methodology. The process is defined as MDEM, which aims to train the students with a self-challenging approach, as well as augmenting creativity and creation of collective consciousness upon global issues by challenges. Results of our experience for the past years applying this method in our classes showed that the students using the MDEM on their research project, propose interdisciplinary solutions that aligns with the global concerns. Furthermore, the students create their own challenges during the semester to put the project proposal and project's design thinking further. Those challenges include, the questioning the project context itself, conducting interdisciplinary research, having the digital-design thinking, mastering necessary software, and developing the big idea with respect to global issues. Moreover, the highest correlation was between the proposed challenge and overall creativity of the project. At last, but not the least, in both case studios, the positive effect of discussion of their introspection with the classmates was highly oblivious as the students' challenge each other, while learning from each other too.

The spiral applications of the phases are repeated until the required results are achieved. Moreover, the spiral development expands through three dimensions, as the student develops skills and reforms cognitive activates, knowledge flows by between participants, and by emergent information and experience, knowledge flows are enhanced within time. Learning by exploration method and re-framing cognition by experience is a new approach to link all generated knowledge together. The method is very much related to thinking, testing, re-thinking, and consequently uniting previous knowledge and skills to new contexts while learning and producing. This method enables the student to reach edges of creativity since it focuses on personal interests, skills, and cognitive styles. The results of the case studies show that the main contribution of the method is successful. The method provides a sustainable learning technique for design studio education, aligning with the current architectural design understanding and with the requirements of the information age.

The most significant difference between the classic methods and the MDEM is due to the type and style of the education received and partly to the topic to study, which goes much more than the classic distribution in the plan. This emergent context of the contemporary architectural design understanding is much more complex than what any design student could know by a classic education method. Moreover, adding interdisciplinary approaches to simple problems crates extraordinary outcomes. The only way to acquire that knowledge and make the shift from classic to advanced design is to use new learning techniques, blending actual technologies, current problems, new working methods, innovative problem-solving skills, digital-design thinking approach, and new representation mediums all together in a melting pot.

Determination of Type of Construction Activities During the Construction Execution Phase

I. Karatas and A. Budak
Osmaniye Korkut Ata University, Department of Civil Engineering, Osmaniye, Turkey
ibrahimkaratas@osmaniye.edu.tr, abudak@osmaniye.edu.tr

Abstract

Today, the more complex design of construction projects becomes even more important in terms of construction management, especially in the control and supervision of workers during the construction execution phase. Therefore, this study, it is aimed to create machine learning models to predict workers activities in construction work. For this purpose, data were collected with the sensors attached to the arms of workers working in tiling, formwork, rendering, and waiting activities. This raw data is trained and modeled by machine learning algorithms such as Extra Tree (ET), Support Vector Classifier (SVC), Decision Tree (DT), Random Forest (RF), K Nearest Neighbors (KNN), and Logistic Regression (LR), after preprocessing and statistical feature extraction. According to the analysis results, the best prediction was obtained with the SVC algorithm with an accuracy of 96.66%. In the ET, RF, and KNN algorithms, approximately 95% prediction accuracy was obtained. In consideration of the results obtained, it was seen that the type of construction activities determined were highly predicted. In this way, together with the developing technology and artificial intelligence, the activities of the workers can be detected automatically with a certain accuracy.

Keywords: *construction technology, construction worker activities, machine learning, estimation, artificial intelligence.*

Introduction

The construction site is one of the most complex work environments due to its dynamic nature, combination of different stakeholders and knowledge domains (Behzadan et al., 2008). Therefore, it is essential to use construction technologies to manage the construction more effectively and more productivity. Recently focused on advanced technologies and cyber-physical systems, significant technological developments with Industry 4.0 emerged in the 21st century (Boyes et al., 2018). The construction industry has also endeavored to adapt to these technological developments and the term Construction 4.0 emerged in 2016 (Berger, 2016). Technologies researched for use in the construction industry include Building Information Modeling (BIM), Cloud-based Project Management, Augmented Reality, Virtual Reality, Laser Scanning, Big data and Analytics, Blockchain, Artificial Intelligence, Internet of Things (IoT), and Sensing Technologies (Forcael et al., 2020). With the concept of Construction 4.0, it is thought that project performance and worker productivity will increase in the construction industry (Bock, 2015).

It is clear that technologies will increase worker productivity. However, this requires measuring worker productivity. In addition, to measure worker productivity, it is necessary to know which technologies to use and how to use them. In traditional construction projects, data on worker productivity is often collected manually. This makes the data error prone. In addition, data collection in this way requires significant time and cost (Roberts & Golparvar-Fard, 2019). Therefore, the development of an automated site data collection method for construction worker monitoring and automated recognized worker activity is important for worker productivity (Ryu et al., 2016). Recently, researchers investigated construction worker activity monitoring and recognizing with by means of sensing technology tools such as global positioning system (GPS), radio-frequency identification (RFID), ultra-wide-band (UWB), QR code, smartphones and Inertial Measurement Unit (IMU) sensors (Akhavian & Behzadan, 2016; Jiang et al., 2015; Valero et al., 2017; Zhou & Ding, 2017).

The use of body worn IMU sensors and smartphones to measure workers' motions and to recognize their activities has received more attention. In addition, IMU sensors are flexible and robust in harsh conditions and have a small size, good accuracy, and reasonable power consumption. Therefore, these sensors may be more appropriate to use instead of smartphones (Joshua & Varghese, 2011). In addition, the activities to be used in this study will generally focus on the manual work of the skilled workers and data will be collected with IMU sensors embedded in wristbands in order to obtain more accurate results. The aim of this study is to estimate what work the workers working at the construction site do with the help of this data collected by machine learning algorithms. In this way, the use of IoT, one of the digital technologies, on the workers at the construction site can be evaluated and the workers can work more efficiently. It is inevitable to increase the efficiency of the entire project by increasing the productivity of the workers.

Literature Review

Since approximately 50% of the total project cost in the construction industry is worker cost, the construction industry is considered a labor-intensive industry (Kazaz & Ulubeyli, 2004). Therefore, it is important to monitor workforce activities and effectively manage these activities in order to increase the performance and productivity of construction projects (Kim & Cho, 2020). In addition, the need for a real-time or non-real-time performance monitoring system is increasing day by day in order to increase the productivity of the workers at the construction sites (Luo et al., 2018; Sherafat et al., 2020). Recently, the use of wearable IMU-based sensors for recognition of workers' activities has gained popularity (Antwi-Afari et al., 2019).

Joshua and Varghese (2011), in their study, collected data in a laboratory environment with a cabled accelerometer sensor attached to both the right and left sides of a mason's waist. The data made ready for the model were trained with Naive Bayes (NB), Decision Tree (DT) and Multi-Layer Perception (MLP) algorithms. With these trained models, the activities of bringing mortar and spreading, bringing, and laying bricks and filling joints were tried to be estimated. As a result of the analysis, the estimation accuracy of the activities ranged from 76% to 79% (Joshua & Varghese, 2011).

Akhavian and Behzadan (2016) aimed to design an activity recognition system that can predict various types of worker activities at construction sites. In line with this purpose, accelerometer and gyroscope data collected from smartphones worn on the arms of the workers were collected. The collected data was processed and made ready for the model. The estimation model was

created Multi-Layer Perception (MLP), Decision Tree (DT), K-Nearest Neighbors (KNN), Logistic Regression (LR) and Support Vector Machine (SVM) algorithms. With this estimation model, activities were estimated in 3 different categories. In category 1, only two activities are considered, Sawing and waiting (wasting time). In the second category, hammering, turning a wrench, and waiting activities were classified. Finally, in the third category, loading of the wheelbarrow, pushing the loaded wheelbarrow, unloading the wheelbarrow, returning with the empty wheelbarrow, and waiting activities were estimated. According to the results obtained, the estimation accuracy obtained in the 1st category varies between 95-97%. In other categories, as the activities to be estimated increased, it was seen that it decreased compared to the 1st activity and changed between 78-88%. It was determined that the algorithm with the highest estimation accuracy was SVM in the 1st category, MLP in the 2nd and 3rd categories. It was stated that the potential of using the estimation of worker activities in the construction sector is high. However, it was stated that the experiments were not carried out at the real construction site and the workers were not real workers, which would affect the results. In addition, the limited battery power of smartphones, limited storage space, inability to work properly in sudden movements and the large size affecting the work of the worker can be said as another factor affecting the results (Akhavian & Behzadan, 2016).

When the studies carried out in recent years are examined, Zhang et al. (2018) collected accelerometer and gyroscope data from nine workers with smartphones. With the obtained data, he tried to predict standing, walking, squatting, clean up the template, fetch and place rebar, locate the rebar, band rebar and place concrete pad activities in the rebar work. The classification estimation accuracy obtained in the model analyzed using the DT algorithm was calculated to be 89.85% (Zhang et al., 2018). Ryu et al. (2019) tried to estimate the activities of spreading mortar, laying blocks, adjusting blocks, and removing mortar in masonry work with the help of data collected with an accelerometer sensor worn on the wrist of a masonry worker in a laboratory environment. For this, 10 workers were used. Afterwards, the model was analyzed using KNN, MLP, DT and SVM algorithms, and the SVM algorithm gave the best result with 88.10% prediction accuracy (Ryu et al., 2019).

When the literature studies are examined, construction worker activity recognition studies were generally carried out in the laboratory environment. In addition, in most studies, either only accelerometer data or accelerometer and gyroscope data are used together as sensor data. In this study, workers were selected from the workers at the real construction site and data were collected with sensors attached to their arms. In addition, it is aimed to make the workers activity recognition the more accurate by using the magnetometer sensor in addition to the accelerometer and gyroscope sensors.

Research Methodology

In this study, it is aimed to estimate the data collected from the formwork, rendering, and tiling workers in the construction site and the activities of these workers by using machine learning algorithms. For this purpose, a flowchart was created as shown in Figure 1. According to this flowchart, data were collected and made ready for the model. Afterwards, the model was analyzed with machine learning algorithms. Finally, the results were evaluated by using evaluation metrics to evaluate the results obtained.

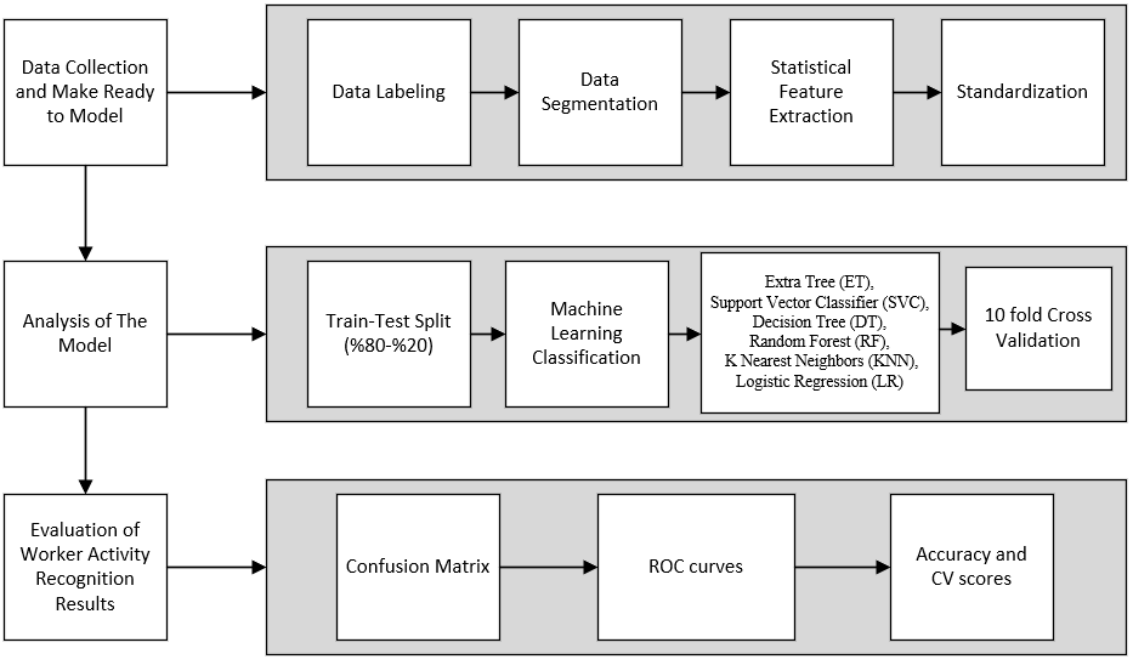

Figure 1: Flowchart for worker activity recognition.

In the first stage of the study, as shown in the Figure 2, the data of the accelerometer, gyroscope and magnetometer were collected with the sensors attached to the arms of the workers working in the formwork, rendering, and tiling work at the construction sites. In addition, the collection of these data continues at 50 Hz and for approximately 40 minutes.

a. Formwork activity b. Rendering activity c. Tiling activity

Figure 2: Data collection with sensor attached to the workers' arm.

Collected accelerometer, gyroscope and magnetometer data in x, y, z axis was labeled in 4 different activities as formwork, rendering, tiling and waiting according to the work done by the workers. The accelerometer, gyroscope and magnetometer data in the x, y, z axis of the tiling activity is shown in the Figure 3.

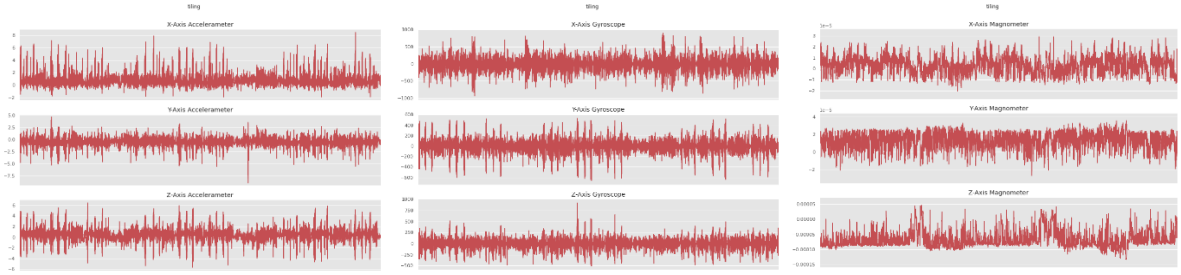

Figure 3: The accelerometer, gyroscope and magnetometer data in the x, y, z axis of the tiling activity.

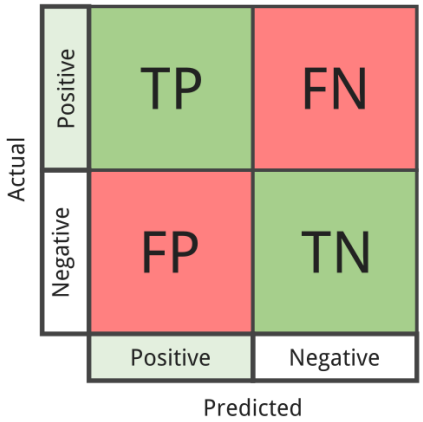
Data segmentation process was applied in order to make the labelled data ready for the model. With this process, the data is separated into fixed width sliding windows consisting of 100 data, starting from the beginning. These windows are created by running on top of each other with 50% overlap. In these windows, statistical properties of each accelerometer, gyroscope and magnetometer data were extracted. The statistical properties made are given in the Table 1. After this process, the data were standardized so that the mean value was 0 and the standard deviation was 1 in order to increase the accuracy of the model.

Table 1. Features and description created with statistical feature extraction.

Statistical Features Names	*Description*
Sum values	Calculates the sum over the seperated windows values
Median	Calculates the median the seperated windows values
Mean	Calculates the mean the seperated windows values
Length	Calculates the length the seperated windows values
Standard deviation	Calculates the standard deviation the seperated windows values
Variance	Calculates the variance the seperated windows values
Root mean score	Calculates the quadratic mean the seperated windows values
Maximum	Calculates the maximum value the seperated windows values
Minimum	Calculates the minimum value the seperated windows values

In the second stage of the study, the data prepared for the model was divided into 80-20% train and test data for analysis. Because the model analyzed with the train data will be compared with the test data and the estimation accuracy will be calculated. In this study, train data analyzed using machine learning algorithms such as Extra Tree (ET), Support Factor Classifier (SVC), Decision Tree (DT), Random Forest (RF), K-Nearest Neighbors (KNN), and Logistic regression (LR) were used to estimate worker activities. After creating and analyzing these models, k-fold cross validation was used to verify whether these models were random and to eliminate bias of the data (Farooq et al., 2021). In this study, the proposed 10-fold cross-validation (CV) (Kohavi, 1995) was performed to obtain the optimum variance. With 10-fold cross validation, the data is divided into 10 layers and analyzed as 1 different layer validation data and the other 9 layers train data in each round. CV accuracy values were calculated by averaging the accuracy values found for each layer.

At the last stage of the study, the results of the analysis were evaluated. Confusion matrixes of all models were created to evaluate these results. In addition, TP (True Positives) and TN (True Negatives) values obtained with confusion matrices as in the Figure 4 show the correct estimated values of the model. FN (False Negatives) and FP (False Positives) values are expressions that show incorrectly estimated values of the model. While evaluating the results in this study, accuracy score values, which is one of the evaluation metrics, were calculated as shown in Equation 1. In addition to these evaluation metrics, the ROC (Receiver Operating Characteristic) curve, which is determined by the ratio of TP values to FP values, was also used.



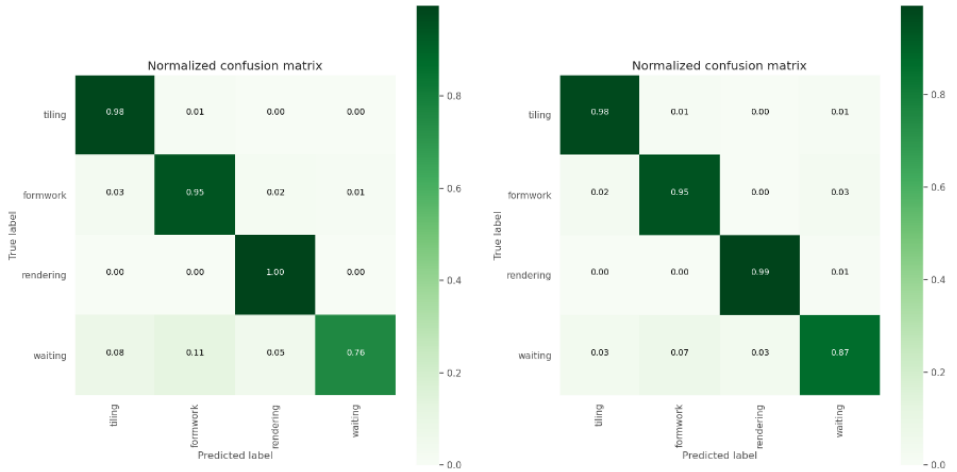


Figure 4: Confusion matrix example.

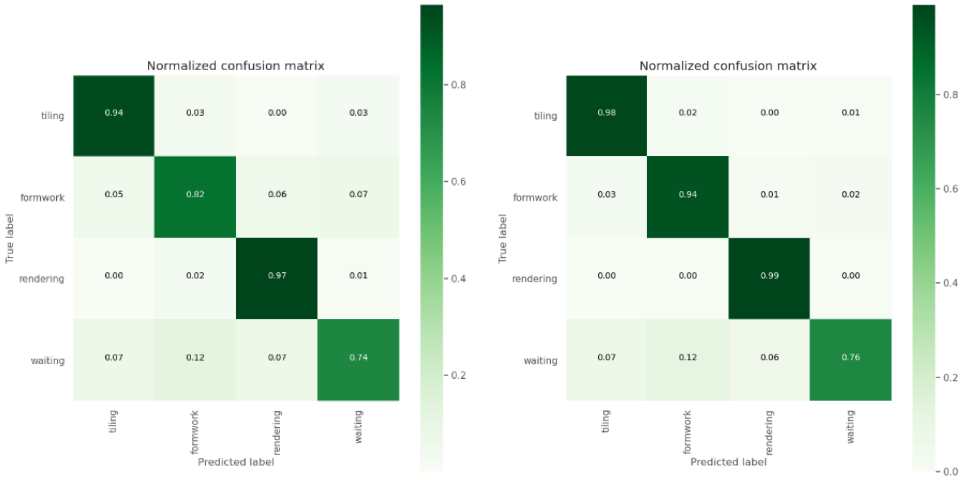
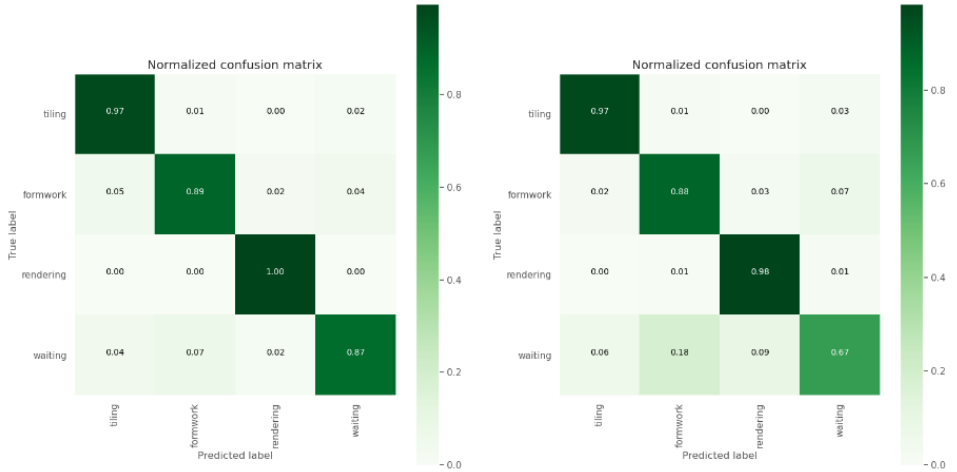
$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$



Results and Discussions

6 machine learning models such as ET, SVC, DT, RF, KNN, and LR, which were created to estimate the activities and waiting activities of the formwork, rendering and tiling workers working at the construction site, were created and analyzed. According to the analysis results, firstly confusion matrixes of the models were created. Confusion matrixes created as a result of the analysis of ET and SVC models are shown in Figure 5. Accordingly, although the predictions of tiling, formwork and rendering activities in the ET model have high accuracy rates, the estimation accuracy of waiting activity was calculated as 76%. On the other hand, in the SVC model, tiling activity was 98%, formwork activity 95%, rendering activity 99% and waiting activity 87% accurate. Confusion matrixes created as a result of the analysis of DT and RF models are shown in Figure 6. In the DT model, tiling and rendering activities were obtained with estimation accuracy of 94% and 97%, respectively. On the other hand, 82% of formwork activity and 74% of waiting activity were predicted correctly. In the RF model, similar to the ET model, the estimations of tiling, formwork and rendering activities have high accuracy rates. Waiting activity was estimated correctly at the rate of 76%. On the other hand, confusion matrixes created as a result of the analysis of KNN and LR models are as calculated in Figure 7. In these models, the activities with the highest prediction accuracy are rendering, tiling, formwork and waiting activities, respectively. The waiting activity in the LR model, on the other hand, has the lowest prediction accuracy among all models, with a prediction accuracy of 67%.



a. ET model b. SVC model

Figure 5: Confusion Matrix of the ET and SVC models.

a. DT model b. RF model

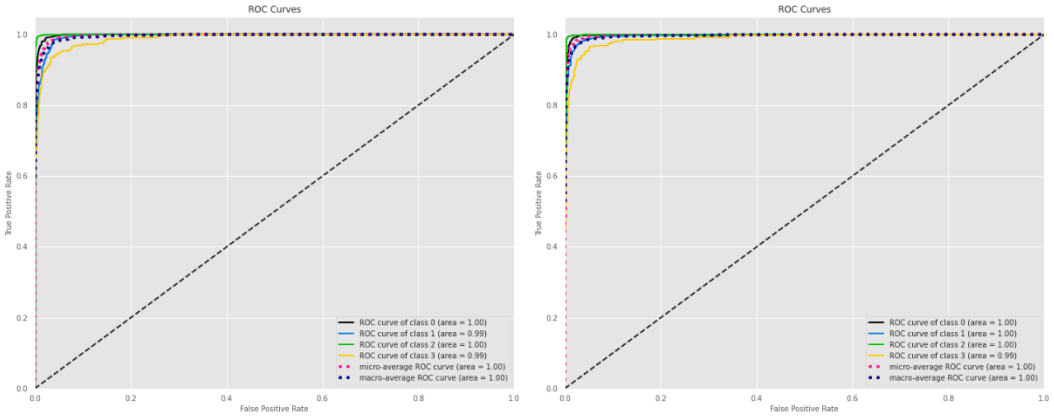


Figure 6: Confusion Matrix of the DT and RF models.

a. KNN model b. LR model

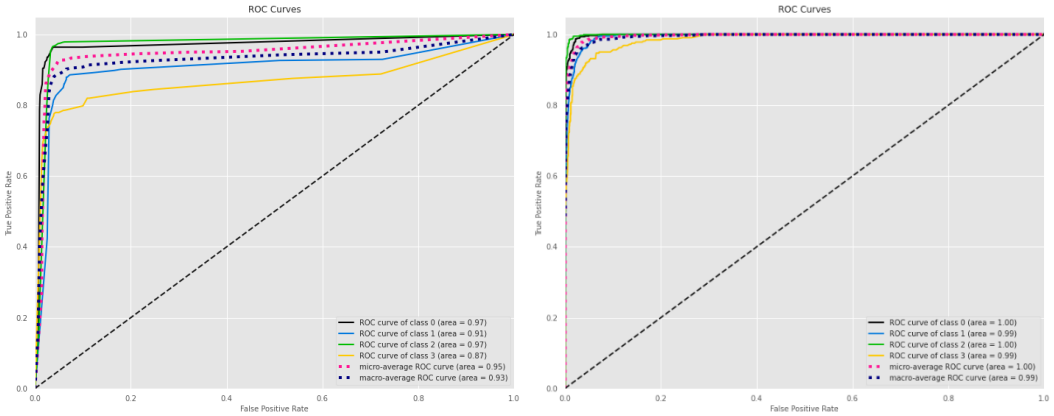

Figure 7: Confusion Matrix of the KNN and LR models.

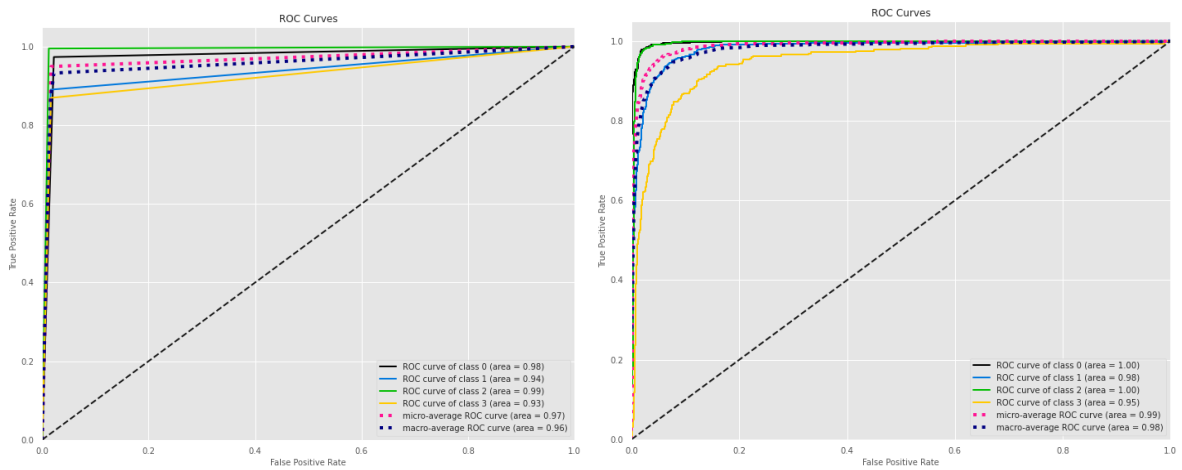
In addition to confusion matrixes, another evaluation metric used in this study to see the estimation accuracy of machine learning models and also to see which activity these models estimate more accurately is ROC curves. As the area under the ROC curves increases, the prediction accuracy will increase. Figure 8 shows the ROC curves obtained as a result of the ET and SVC models. It is seen that the estimation accuracy of both models is quite high. Here, class 0 denotes tiling activity, class 1 denotes formwork activity, class 2 denotes rendering activity, and class 3 denotes waiting activity. Figure 9 shows the ROC curves created as a result of the DT and RF models. The RF model has high predictive accuracy for all activities, similar to the ET and SVC model. However, although the tiling and rendering activities achieved high estimation success in the DT model, the formwork activity and waiting activity achieved a estimation success of 91% and 87%. Figure 10 shows the ROC curve obtained from the KNN and LR models. In the LR model, it is seen that the waiting activity is estimated correctly at a rate of 95%. Other activities showed higher estimation success than this activity. In the KNN model, the estimation success of tiling, formwork, rendering and waiting activities is 98%, 94%, 99% and 93%, respectively.



a. ET model b. SVC model

Figure 8: ROC curve of the ET and SVC models.

a. DT model b. RF model

Figure 9: ROC curve of the DT and RF models.

a. KNN model b. LR model

Figure 10: ROC curve of the KNN and LR models.

Confusion matrices and ROC curves are used to find the estimate success of any activity in any model. Considering the general estimate success, which model has the higher estimate success will be determined according to the accuracy scores of the models as in Table 2. The accuracy scores of the models were explained in two ways in this study. Each model was evaluated first with training accuracy scores, then with accuracy values generated using 10-fold CV, a more accurate and robust technique for modeling evaluation. It is seen that the accuracy score values obtained by using 10-fold CV in all models are higher than the training accuracy scores. When the models are compared, it is seen that the SVC model has the highest estimation accuracy with a value of 0.9666. After this model, the models with the highest estimation success are ET, RF and KNN models, respectively, with 95% estimation success. LR and DT models show a lower estimation success than other models.

Table 2. Accuracy score for machine learning models.

	ET	*SVC*	*DT*	*RF*	*KNN*	*LR*
Training	0.9523	0.9633	0.8982	0.9474	0.9493	0.9164
10-fold CV	0.9581	0.9666	0.9041	0.9533	0.9513	0.9195

The results obtained in this study, which was carried out within the framework of construction worker activity recognition, are given above. According to these results, it is seen that the formwork, rendering, tiling and waiting activities determined within the scope of the study are highly estimated by the analysis of the collected sensor data. Joshua and Varghese (2011) achieved approximately 79% estimation accuracy with the MLP model using only the accelerometer sensor. On the other hand, Zhang et al. (2018), when she analyzed the accelerometer and gyroscope data with the DT model, achieved 89.85% estimation accuracy. Ryu et al. (2019) obtained 88.10% estimation accuracy with the SVC model in the laboratory environment and using only accelerometer data.

In this study, the estimation success of all 6 machine learning models was found to be over 90%. The reason for the high estimation accuracy in all models is that the activities are thought to be more distinctive by collecting the accelerometer, gyroscope and magnetometer data together while collecting the data. In addition, when the models are compared, it has been found that the SVC model has higher estimation accuracy than other models. Considering the

estimation accuracy of the activities, the reason why waiting activity is underestimated compared to other activities is explained as the fact that workers can make different kinds of motions during the waiting phase.

Conclusion

Today, the rapid development of technology also affects the construction industry. However, since the construction industry is a labor-intensive industry, it is thought to be very difficult to adapt to technology. In addition, recently, studies have been carried out on the adaptation of the construction sector to technology. Accordingly, in this study, it is aimed to estimate the activities of the workers with machine learning models in line with the data obtained from the construction workers. As a result of this study, it is thought that it will provide automatic estimation of worker activities, automating the controls performed by the technical staff at the construction sites and facilitating the construction activity.

This study is especially important in terms of collecting data from the worker who does the work in the construction site environment. In addition, accelerometer, gyroscope and magnetometer data from the workers were collected together and analyzed. These data collected to estimate 4 different activities such as formwork, rendering, tiling and waiting, were analyzed with 6 different machine learning models such as Extra Tree (ET), Support Factor Classifier (SVC), Decision Tree (DT), Random Forest (RF), K-Nearest Neighbors (KNN), and Logistic regression (LR). According to the results of the analysis, the activities showed an estimation success of over 90% in all models. In addition, the SVC model has the highest estimation success with 96%. KNN, RF and ET models showed 95% estimation success. On the other hand, LR showed 91% and DT 90% estimation success. Considering at the estimation success of the activities, the highest estimated activity was rendering, and the lowest estimated activity was waiting activity.

It is considered that the results obtained from the analyzes are sufficient for the recognition of the activities of the workers. In addition, adding different activities to the models or using advanced alternative models may result in better estimate performance. The contribution of this study is thought to be the enhance of productivity measurement processes, as well as continuous monitoring of construction activities and automatic activity recognition and increasing labor productivity at construction sites. In addition, new models can be created by developing the artificial intelligence models used in this study. As a result of the sensors attached to the worker, the tracking of the worker and the tasks he performs can be automatically arranged and an efficient working strategy can be followed. In addition, the use of technology in construction management is expected to assist the three construction milestones of time, cost and quality.

Abstract

Rework is described as an activity that carried out more than once or activities that involve the removal of previously completed work which arises due to changes, errors, and omissions that occurs in the design and construction phases of the project. Rework is a common and global phenomenon that caused by many factors. While it remains problematic issue in construction industry, there is limited study to date has examined rework even though it significantly affects project performance negatively such as cost and time overruns. In order to minimize negative rework impacts and improve project performance, the causes of reworks at construction industry should be known. Therefore, this paper aims to identify, classify and rank the root causes of universal rework factors in construction projects. To reach this aim, a systematic literature review was conducted on the causes of rework and studies from 13 different countries were examined. Based on this investigation in the study area, a total of 41 different rework factors were identified and classified in six groups which are client, design team, project manager, labors, site related and general/external factors. The study concluded that the top five universal factors causing rework as: (1) ineffective management of project manager, (2) errors and omissions in design, (3) poor planning and coordination, (4) lack of labour skills, and (5) poor communication. The results of this study establish that effective rework management is necessary. The detection of rework factors assumed to lead identification the indicators, contribute to the construction management and reduce the occurrence of rework factors.

Keywords: *rework, rework factors, construction management, project management, systematic literature review.*

Introduction

Construction projects performance depends on particular success criteria such as completion on time, reaching the desired quality, fulfilling the requirements and not exceeding the estimated budget. Since construction projects consist of multiple stakeholders and various

phases of practices, the majority of them experience time overruns, cost overruns and quality defects. Although, one of the main causes of poor project performance is rework, there are few studies on its occurrence and consequences.

According to Construction Industry Institute (CII) (2001) rework is defined as "activities that have to be done more than once, or activities that remove previously work that installed as part of the project." Many construction professionals recognize rework as one of the most significant elements in project failure (Love and Edwards, 2004); since it is thought to be as a factor that responsible for delays, cost overruns and quality failures. Calculations of rework cost have been done in numerous studies, and the results range from 16.5% (Forcada et al., 2014) to 52.1% (Love, 2002) of the total cost overrun of the project. While projects can expect a certain amount of rework that can be estimated during the architectural practice, the real impact of late change orders and rework is often greater than expected (Kermanshachi et al., 2018).

It is difficult to identify a single cause for rework in construction projects, because there are complex and interdependent variables or conditions that interact with one another to produce rework events (Love et al., 2016). Since rework causes and potential consequences are largely unclear, it remains an unsolved problem. (Enshassi et al., 2017). However, by identifying and managing common root causes, it can be reduced and manageable (Al-Janabi et al., 2020). Therefore, this study aimed to investigate and rank the most significant rework factors in construction projects. To achieve these objectives an extensive systematic literature review was conducted to identify the main causes of rework.

Literature Review

The occurrence of rework in construction projects is a global problem. As a result, many countries are still being investigated the reasons of rework to be able to manage this issue. Researchers made classifications of rework factors under different groups. Love (2014) and OLove (2017) categorized rework factors as "People", "Organization" and "Project". Another study suggests five categories that cause rework as process, human resources, materials and equipment, technical and general/external (Asadi et al., 2021). Errors, changes and omissions at the design or construction stages are other examples of classification for causes of rework that have been used in the literature (Love & Li, 1999). In brief in the literature different methods have been proposed to classify causes of rework.

Ye et al. (2015) investigated the reasons for rework in construction projects in China through semi-structured interviews and a questionnaire survey with professionals. The results concluded that 11 main groups are responsible for rework; communication management, design management, field management, project process management, project scope management, active reworks, project plan changes, subcontractor management, contract management, owner capability, and the external environment (Ye et al., 2015).

Enshassi et al. (2017) categorized 57 rework factors under seven groups to be able to analyze and investigate their impact on project performance. According to this study, contractors' related rework and rework relating to human resource capability are the two groups that have the most influence on projects performance. In addition, the top five rework factors were identified as attempts to fraud, competitive pressure, ineffective management, schedule pressure and the absence of job security (Enshassi et al., 2017).

In addition, Forcada et al. (2017) analyzed 788 construction incidents that occurred in Spain and revealed that characteristics of construction have an impact on factors of rework costs such as complexity of a project, project type and type of contract. This study identified that errors and defects assumed by contractors, and extensions to project scope requested by clients were the most critical factors (Forcada et al., 2017).

Trach et al. (2019) carried out a study on factors for the emergence of rework in 42 Ukrainian construction projects and results revealed that design modification and lack of coordination were the factors with the highest effects. In addition, researchers stated the following key finding as all rework causes resulted one from the other (Trach et al., 2019).

Mahamid (2016) carried out a study related to rework in residential building projects in Palestine and identified most severe causes of rework as poor communication between construction participants, use of poor-quality materials and poor site management (Mahamid, 2016). He conducted another study in the Kingdom of Saudi Arabia on rework causes and revealed that errors and omissions, lack of labour skills, non-conformance with specifications, insufficient supervision, and changes of scope were the top causes (Mahamid, 2020).

As seen from brief review, of related research, several causes were identified particularly focusing on one country, all of which are important, however, it is unclear which of them are universal rework factors in construction projects. Therefore, in the first stage, it is impossible to take precautions to minimize the amount of construction reworks. From this perspective, knowing the universal rework factors is crucial.

Research Methodology

Rework data are usually challenging to collect, and the majority of studies have been carried out in developed countries (Trach et al., 2021). This research aims to gather these studies under a single roof and determine whether or not rework causes differ from one country to another. To achieve the main objective of identifying the universal rework factors, systematic literature review (SLR) was conducted.

Using SLR, extensive literature was examined. SLR is identified as a method-driven, transparent, and reproducible method (Booth et al., 2012) for analysing and understanding all research related to a certain issue, subject, or phenomenon (Wolfswinkel et al., 2013). Data collected from Web of Science (WoS) and Scopus databases that involves articles, conference papers, and book chapters. At the initial screening, 1071 documents were obtained with using search terms; “rework” AND “construction” on topic. 393 of them were remained after filtering, the rest 678 documents were out of research scope. After reviewing these documents, the following parameters were used to specify the research scope; search term “rework in construction” on title, subject areas “Engineering Civil” and “Construction Building Technology”. According to these inclusion criteria, total of 91 articles from 2002 to 2022 were chosen for the search, 4 of article could not be accessed. Then obtained 87 articles were examined and 41 items that cause rework in construction projects were determined and classified under six categories (client related factors, design team related factors, project manager related factors, labour related factors, site related factors and general - external related factors).

At the second phase, obtained data was classified based on the country that the studies conducted. Based on these analyses, the top 5 rankings of rework causes are determined and discussed.

Findings

Based on the findings of the systematic literature review, 41 rework factors were identified and divided into six groups; “client related factors”, “design team related factors”, “project manager related factors”, “labours related factors”, “site related factors” and “general - external related factors”. The major rework factors are summarized in Table 1.

Table 1. Selected rework factors with categories.

Factor categories	**Factor Code**	**Rework Factors**	**Sources**
Client related factors	C1	Client directed changes	[1], [2], [7], [10], [15], [16], [17], [20], [29]
	C2	Poor communication	[2], [5], [16], [18], [21], [25], [29], [32]
	C3	Lack of client involvement	[1], [2], [15], [16], [18], [21], [25], [29]
	C4	Changes of plan or scope	[2], [9], [17], [21]
	C5	Inadequate or weak feasibility study	[1], [2], [5], [18]
Design team related factors	D1	Incomplete design	[1], [2], [5], [9], [10], [15], [16], [17], [18], [21], [25], [29]
	D2	Design changes	[2], [6], [9], [15], [16], [17], [21], [22], [23], [25], [29]
	D3	Errors and omissions in design	[2], [5], [6], [7], [8], [9], [10], [17], [20], [21], [25], [28], [29]
	D4	Poor contract execution	[2], [6], [9], [25], [32]
	D5	Lack of understanding of user	[2]
	D6	Insufficient experience	[1], [2], [5], [15], [20], [21], [29]
	D7	Design management failure	[9], [10], [15], [16], [18], [20], [25], [29]
	D8	Fixed time for a task	[2], [7], [18], [20], [21], [25], [32]
	D9	Lack of using modern technology and software	[2], [18], [20], [29]
Project manager related factors	P1	Ineffective management	[1], [2], [5], [6], [8], [16], [19], [20], [21], [22], [23], [25], [31], [32], [33]
	P2	Lack of experience	[2], [5], [15], [18], [22], [23
	P3	Poor planning and coordination	[1-2], [5], [8], [10], [16], [18], [21-22], [23], [25], [29], [31-32]
	P4	Poor workload planning	[1], [15-16], [21], [31]
Labours related factors	L1	Lack of labour skills	[2], [5], [6], [8-9], [16], [18], [20-23], [25], [29], [31]
	L2	Time pressure	[1], [2], [8], [19], [21]
	L3	Poor workmanship	[1], [2], [6], [9-10], [17], [20], [25], [28], [29]
	L4	Non-compliance with specifications	[22-23], [29]
	L5	Shortage of skilled labours required to complete work tasks	[1], [2], [9], [15-16], [18], [21-22], [25], [29]
	L6	Lack of motivation	[5-6], [8], [22-23]

Site related factors	S1	Poor site condition	[1], [2], [6], [17], [21-23], [25], [31-32]
	S2	Complexity of design	[7-8], [21]
	S3	Inaccurate or lack of site investigation	[1-2], [8], [15-16], [20-21], [29]
	S4	Lack of safety considerations in the site	[1-2], [5], [21], [25], [32]
General - External related factors	G1	Changes in project scope	[8-9], [16], [21-23], [29], [32]
	G2	Wrong initial budget	[6], [32]
	G3	Poor information flow	[28], [31]
	G4	Poor communication	[2], [5], [6], [8], [9], [21-22], [28], [31-33]
	G5	Use of poor-quality materials	[1-2], [16-18], [20-22], [25], [28], [32-33]
	G6	Lack of technological equipment // Ineffective use of technology	[1-2], [5], [16], [20-22], [25], [31-32]
	G7	Economic situation of the country (inflation, currency exchange)	[2], [5], [9]
	G8	Change of laws	[2], [5], [32]
	G9	Natural Disasters (such as rain, wind, earthquake) // Force major	[2], [5], [6], [9], [17], [21-22], [32]
	G10	Shortage of construction materials in market	[32]
	G11	Time constraints // Schedule pressures	[5], [6], [8], [15-16], [19], [21], [23], [31]
	G12	Inadequacies in contract documentation	[1], [2], [16], [21], [28-29], [32]
	G13	Changes in construction method to improve constructability // Errors due to inappropriate construction method	[1-2], [9], [15-17], [21-23], [25], [31-32]

To reveal the country-based studies obtained articles reviewed, and 59 out of 91 articles were excluded due to not having specific country information in the studies. Then, 10 of remained 31 articles were excluded from the study due to limits of research scope and one of them was not accessible. Finally, 21 articles were analyzed, and findings presented in Table 2. From the existing studies that cover 13 countries worldwide; all factors could be listed and ranked according to number of mentions. Table 2 shows all selected studies based on countries and authors.

Table 2. Rework factors according to countries.

| Rework Factor Code | Countries | | |

L5	*	*	*					*					*			*		*		*	
L6				*	*										*	*					*
S1	*	*	*		*	*		*	*			*				*					*
S2			*											*	*

S4	*	*	*	*		*		*													
G1			*		*	*							*		*	*		*		*	
G2						*															*
G3									*								*				
G4	*	*	*	*		*	*		*						*	*	*			*	*
G5	*	*	*			*	*	*			*	*	*			*	*					
G6	*	*	*	*		*		*	*		*		*			*						
G7	*			*																	*	
G8	*			*		*																
G9	*		*	*		*						*				*					*	*
G10						*																
G11			*	*	*				*	*			*		*							*
G12	*	*	*			*							*				*	*				
G13	*	*	*		*	*		*	*			*	*			*					*	

According to the findings of SLR of country-based articles, rank order of the 41 items was determined by the number of studies they were uploaded. The top five most cited factors were mentioned in more than 10 articles, whereas others were not.

Table 3. The top five universal rework factors and related groups.

Rank	Factor Code	Related Group	Rework Factor	Number of Related Country-based Articles
1	P1	Project manager related factors	Ineffective management of project manager	15
2	D3	Design team related factors	Errors and omissions in design	13
3	P3	Project manager related factors	Poor planning and coordination	13
4	L1	Labours related factors	Lack of labour skills	13
5	G4	General - External related factors	Poor communication	11

Even though the results vary, studies have shown that specific conditions of countries have little impact on rework factors; there is a certain level of similarity among them. The findings of the systematic literature review show that the top five most cited rework factors are ineffective management of project manager, errors and omissions in design, poor planning

and coordination, lack of labour skills, poor communication. These factors are discussed in more detail in the following paragraphs:

1) Ineffective management of project manager: Ineffective management leads to misunderstanding and poor communication between construction parties, which prevent labours to perform the job as designed or scheduled, as a result led to conflicts between them that may lead to rework. Poor management has significant influence on construction project productivity (Enshassi et al., 2017).

2) Errors and omissions in design: Poor communication flow between design team members and client may result in errors and omissions in design documents (Love and Edwards, 2004). In addition to that, unskilled designer, fixed time for a task, inefficient use of technology for architectural drawings may lead to errors and omissions. This is a critical issue; especially after construction started, later design failures directly influence performance, cost and productivity (Love et al., 2014). To achieve correct and complete design documents and minimize changes some quality management practices should be adopted like, producing drawings according to the specifications, coordinating team and checking the documents regularly (Love & Li, 2010).

3) Poor planning and coordination: Poor planning and coordination may result from failure in job distribution, poor skills of the project manager, insufficient work separation. All of these quality failures are responsible for large part of rework cost (Hammarlund & Josephson, 1991). In order to prevent that and to avoid conflicts; specifications should be clear, and distribution of work should be balanced and realistic.

4) Lack of labour skills: Skilled and well-trained labours perform mistake free works that prevent rework and enhance the productivity on the contrary to unskilled labours (Mahamid, 2020). There is no construction project that is free of labor-related faults (Al-Janabi et al., 2020). However, to be able to reduce the probability of occurrence, Mahamid suggested that a method should be improved for selecting subcontractors (Mahamid, 2020). Since Subcontractors prefer to work with unskilled labours in order to pay less which affect project performance negatively (Al-Janabi et al., 2020).

5) Poor Communication failure: According to a questionnaire survey done in Palestine; three of the five most influential factors were poor communication between construction parties which affects workflow negatively (Mahamid, 2016). Another study done in Malasia (Yap et al., 2020) that is in line with previous studies, ranked insufficient communication highest. BIM suggested as one way to strengthens communication and opens communication channels, because that it makes visible connections (Hwang et al., 2019).

Conclusion

Rework has significant influence on project performance such as cost overrun, schedule overrun, and quality failures. It is an ongoing issue in construction industry. There have been no reports of a project achieving zero rework; almost every construction experiences some degree of rework. The study's goal is to highlight significant rework factors through a systematic literature review.

This study identified rework factors through systematic literature review which are classified under six groups: client related (5 items), design team related (9 items), project manager related (4 items), labors related (6 items), site related (4 items) and general/external related (13 items). As a second contribution, all country-based studies were gathered that investigate reasons of rework in construction projects and aimed to draw attention to the most significant ones. The results of this investigation show that the top five most cited universal rework factors are ineffective management of project manager, errors and omissions in design, poor planning and coordination, lack of labour skills, and poor communication. Based on the findings, the major rework factors do not differ significantly among countries; there is some degree of similarity. The findings of this research will raise the awareness of construction stakeholders on the critical sources of rework in construction projects, which can contribute to decrease its occurrence.

Abstract

Recent technological advancements are making the traditional paper-based tendering methods quickly becoming obsolete. E-tendering is widely regarded as a valuable tool for enhancing efficiency and empowering construction industry experts to better oversee the tendering process in order to reduce project delays and increase profits. Despite the benefits of e-tendering over the years, it is new to some construction industry stakeholders, and its acceptance and implementation have encountered many problems, according to global reports. This research aims to identify the critical barriers to e-tendering implementation in the construction industry. A systematic literature review technique was used to determine the barriers. A thorough literature analysis was undertaken using the relevant scientific databases. The findings were distributed based on six geographical regions. The eight (8) critical barriers that were consistent in all the 6 geographical regions include; inadequate data security, the high investment cost of implementation, resistance to change, lack of support, technical challenges, lack of uniform standard or policy and legal framework, inadequate ICT infrastructure, and inadequate technical/skilled personnel. This study contributes to the in-depth understanding of global e-tendering barriers in the construction industry based on geographical regions. The findings could help researchers, practitioners, and governments make strategic investment decisions and overcome e-tendering challenges.

Keywords: *barriers, challenges, construction industry, e-procurement, e-tendering.*

Introduction

Tendering has long been regarded as the most equitable method of awarding government contracts and the method most likely to result in a favorable outcome for a government's spending of public funds (Betts et al., 2006). The fundamental principles of the traditional tendering process have been applied to many business areas, including purchasing goods, seeking service providers, business consulting and selecting general contractors for construction work for several years (Du et al., 2005) and is prone to many limitations. According to Arslan et al. (2006), the traditional bidding process are time-consuming and labor-intensive. Abdullahi et al. (2020) added that, the manual paper-based tendering processes are

known to be inefficient, less transparent, and prone to corruption, particularly in public sector procurement. As a result, nowadays, researchers, marketing managers, and business leaders are searching for innovative ways to exploit e-business technologies for business purposes (Naeem, 2021). Ilhan and Rahim (2017) buttressed that, in recent years, many business organizations worldwide have streamlined and automated their manual procurement process using software solutions that are known as e-procurement systems.

Alsaç (2017) observed that the term "e-procurement" has probably been the trendiest word in the public procurement profession in recent years. As a result, e-tendering has been defined in several ways according to the literature. Notable among the definitions are; "*E-tendering is the use of electronic communication systems and tools to disseminate information about tender opportunities, as well as to submit, receive, store, and make decisions on bids/tenders or proposals for construction works, goods, and services. In simple terms, e-tendering is an online process that manages the tendering cycle from notice advertisement to awarding" (Ibem & Laryea, 2017).* "*E-tendering is a platform for the exchange of construction project information between geographically dispersed individuals via the internet" (Solanke & Fapohunda, 2015).*

The primary goal of implementing e-tendering technology is to reduce transaction costs, increase order placement effectiveness, develop good relationships with suppliers, reduce the level of paperwork and time to order inventory, and reduce the purchasing cycle and overhead costs associated with the purchasing process, (Naeem, 2021). Despite the widespread e-tendering adoption and its benefits, (Yevu et al., 2021) argued that, within the construction industry, the anticipated increase of e-procurement adoption for construction procurement processes has suffered many setbacks in its implementation.

Additionally, there are many barriers to the adoption of e-tendering. In the Organisation for Economic Co-operation and Development (OECD) countries, the following e-tendering barriers have been identified to jeopardize the adoption of e-tendering: quality and understanding of the information provided, size of contracts being too large, an administrative burden too high, difficulties relating to the proportionality of qualification levels and financial requirements, lack of visibility on available contracts of smaller value, lack of dialogue and feedback with public contracting authorities, late payments or lengthy terms of payment, access to relevant information, emphasis on price only rather than value for money, too short a time to draw up tenders, and lack of integrity in the procurement process (OECD, 2020).

In the previous years, a lot of publications have been conducted on e-tendering in a bid to raise awareness and facilitate the adoption of e-tendering. Notable among them include: Critical success factors for e-tendering implementation in construction collaborative environments (Lou & Alshawi, 2009), E-Tendering: Benefits, Challenges, and Recommendations for Practice (Kajewski & Weippert, 2004), E-tendering readiness in construction (Al-Yahya et al., 2018), A cross-discipline comparison of rankings for e-procurement drivers and barriers within UK construction organizations (Eadie et al., 2010). Similarly, a systematic review of the drivers for electronic procurement adoption for construction project procurement, and barriers to electronic procurement adoption in the construction industry has been explored by (Yevu & Yu, 2019; Yevu et al., 2021). Even though a study on the barriers to e-tendering has been conducted by Yevu et al. (2021), a full understanding of the trends and barriers has not been presented in the literature, especially according to geographical regions leaving a research gap.

In an effort to fill this gap, this study is aimed at conducting a systematic literature review to identify the critical barriers to e-tendering based on geographical regions because of

homogeneous physical and cultural attributes. In this study e-tendering or e-procurement is defined as a digital framework that automates the management process of tenders which allows for smoother and more controlled procurement that lets the procurer manage and evaluate bids with ease electronically.

Background of E-Tendering in the Construction Industry

Since the late 1960s, electronic commerce has existed in various forms, such as Electronic Data Interchange (EDI), Electronic Tendering (e- tending), Electronic Mails (e-mails), and e-procurement (Anumba & Ruikar, 2002). Grilo and Jardim-Goncalves (2011) added that early e-procurement was associated with the proliferation of inter-organizational systems, communities, electronic platforms, meeting places, virtual locations, and infrastructures, which were often referred to as electronic marketplaces. After the introduction of the World Wide Web (WWW) and internet browsers in the early 1990s, internet electronic commerce has grown exponentially (Anumba & Ruikar, 2002). As a result, in the early 2000s, studies on the implementation of e-procurement in the AEC industry surfaced Isikdag et al. (2011). Researchers such as Neef (2001) studied E-Procurement from a strategy to implementation perspective and McIntosh and Sloan (2001) discussed the importance of electronic procurement and global sourcing procedures in the UK construction industry in 2001. The authors recommended that the construction sector should abandon traditional sourcing practices in favour of using the global marketplace to improve efficiency, competitiveness, and profits.

Moreover, e-tendering is gaining worldwide recognition in recent years (Goswami et al., 2020; Ibem & Laryea, 2013; Ibem & Laryea, 2017), primarily as a stand-alone and one of the tools for assisting in changing the culture and improving the processes of the construction industry. Even though Isikdag (2019) argued that the adoption of e-procurement for conducting project procurements to improve traditional paper-based procurement has had limited uptake in the project procurement process. Despite the widespread organizational adoption of e-procurement systems, the construction industry continues to witness disappointing performance outcomes from their implementation (Oyediran & Akintola, 2011; Kajewski & Weippert, 2004). Al-Yahya et al. (2018) opined that e-tendering guidelines requirements for organizations' successful implementation lack clear guidelines which cause confusion, particularly among stakeholders who want to use e-tendering. As a result, the systems and processes have raised a number of concerns among construction industry stakeholders which are impediments to the use of e-tendering (Ibem & Laryea, 2017; Oyediran & Akintola, 2011; Arslan et al., 2006). Therefore, understanding the barriers is crucial in the implementation of e-tendering. The section below presents a broader picture of the barriers that hinder the implementation of e-tendering in the construction industry.

The Barriers of E-Tendering

Despite all of the advantages of electronic tendering, there are certain fundamental challenges that must be addressed in order to boost public confidence in the use of electronic tendering apps. According to Anumba and Ruikar (2002), electronic tendering barriers can be divided into two categories: barriers common to all industry sectors, including the construction sector, and barriers specific to construction electronic tendering applications. The common barriers to electronic tendering mainly fall into three categories, that is issues related to infrastructure, trust and reliability, and regulatory issues. On the other hand, construction-specific barriers to

electronic tendering include the high initial investment required to build the necessary infrastructure and train personnel, quantifying the return on investment (ROI), data security in online transactions, integration with legacy systems, and interoperability of distributed software applications over the internet.

In addition, Goswami et al. (2020) opined, e-tendering focuses on ensuring transparency throughout the tendering process, however, it has flaws such as a centralized database that is vulnerable to attacks. Betts et al. (2006) buttressed that, the uncertainty caused by a lack of understanding of the legal rules and principles that are applied to electronic tendering systems makes security compliance for an e-tendering system paramount. Ibem and Laryea (2015) outlined the three main barriers to e-tendering use in the South African construction industry as slow internet connectivity, resistance to change, and expensive internet services. Oyediran and Akintola (2011)'s study revealed that there is a general lack of basic facilities required for the process, as well as a low level of proficiency in its application and the critical barriers are irregular power supply, the financial implications of putting up e-tendering infrastructure, poor telecommunications infrastructure, and lack of legal support for electronic transactions.

Furthermore, Tran et al. (2021) identified the most significant impediments to e-tendering adoption as people-related, such as a lack of awareness, a shortage of competent workers, poor cross-disciplinary communication, a fragmented supply chain, and inadequate industry standards for information transfer. Wimalasena and Gunatilake, (2018) carried out research to unveil the readiness of construction contractors and consultants to use e-tendering in Sri Lanka. They concluded that the main barrier to e-tendering implementation was a lack of e-tendering-specific legal rules, lack of awareness of the employees and senior management, and lack of legal rules and regulations.

The results from the literature suggest that despite the adoption and the benefits of e-tendering, its application has faced numerous challenges. To assist in mitigating e-tendering barriers in the construction industry, the barriers to e-tendering must be first identified. The major barriers to e-tendering have been identified through a systematic literature review below.

Research Methodology

The purpose of this study was to explore the barriers to e-tendering application in the construction industry through a systematic literature review. According to Chan and Owusu (2022), in order to perform a comprehensive systematic literature review, an appropriate approach or strategies to aid the review process must be chosen. This study employed the systematic review methodology as used by previous researchers (Chan & Owusu, 2022; Yevu & Yu, 2019) to guide the selection of relevant papers from the database and journals. The systematic review was selected because it compares and integrates the findings of the relevant studies (Yevu & Yu, 2019). The study used a comprehensive and in-depth three-phase process to extract relevant journals initially targeted and subsequently conducted a desktop search followed by another specified search as described below.

Phase 1: Search Target Journals

As in the work of Lu et al. (2015), in phase 1 of this study, relevant papers were chosen from the top 12 construction management journals in Wing (1997)'s ranking because they are generally recognized in the construction management community. The rationale behind this

was to increase the scope of the search (Yevu & Yu, 2019). The journals targeted were Construction and Architectural Management, Proceedings of the Institution of Civil Engineers – Civil Engineering, International, Construction Management and Economics, Journal of Construction Management and Engineering (JCEM), Engineering, Journal of Management in Engineering, International Journal of Construction Information Technology, Transactions of American Association of Cost Engineers, Automation in Construction, Journal of Construction Procurement, Journal of Project Management, Building Research and Information and Cost Engineering. The virtual libraries of these selected journals were used to find relevant English papers using the keywords listed below: "Barriers" OR "Challenges" AND "E-procurement", OR "E-Tendering" AND "Construction Industry" within the relevant databases and search engines, respectively. The systematic procedure for the literature review is depicted in Figure 1.

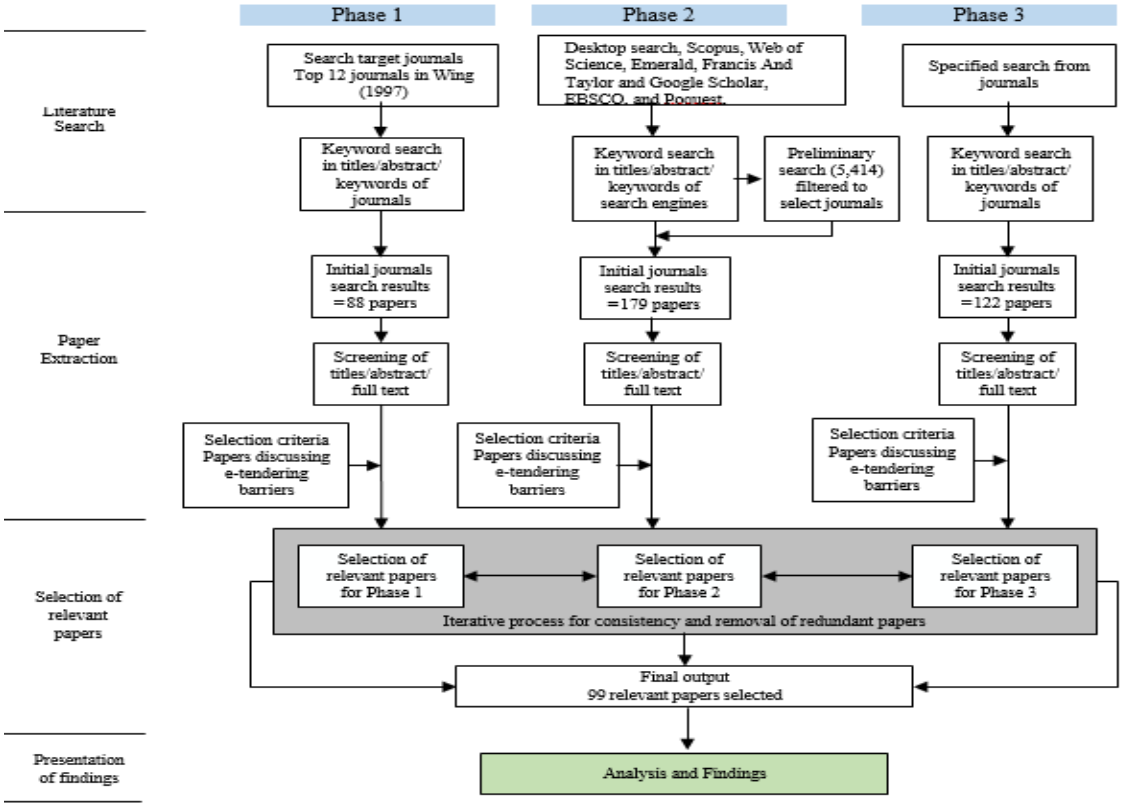

Figure 1: Systematic process for literature review adopted from (Yevu & Yu, 2019).

Phase 2: Desktop Search

To identify other construction journals relevant to the study, the largest database recognized in academia Web of Science, Scopus, EBSCO, Francis and Taylor, ProQuest, and Google Scholar using the same keywords. According to the search results, papers relevant to the study were selected for further analysis.

Phase 3: Specified Search from Journals

Finally, the obtained papers were analysed for duplication using Mendeley and excel. A total of 99 papers were considered relevant for the study after examining the papers. All the journals were searched in May 2022.

Results

The analysis and summary of findings from the selected papers are presented using descriptive analysis of papers and examination of the barriers identified. The first dimension adopts descriptive analysis to show the characteristics of selected papers for the yearly distribution of papers by journals and the geographical region of publication. This was done by recording the year of publication of the study and the number of authors in the geographical region.

Publication Trend

Figure 2 shows the annual publication trend of the reviewed papers. The papers identified showed a slow rise from 2010 and reached the peak in 2014 and 2015 recording 14 papers each, the highest number of publications. This could be the acceptance of e-tendering in the construction industry, especially the developing countries. On the other hand, Gunasekaran and Ngai (2008) attributed the rise to the emerging internet and the concept of applying e-procurement for project procurement. Subsequent years had declined publications until 2021 with five papers. In addition, 2022 recorded only one which was not surprising because the data was retrieved up to May 2022 which could have more than one number by the close of the year. Apart from the year 2022 recording just one, 2012 recorded the least number of publications with four number. The publication trend has been generally constant, with an average of 7.6 papers per year cumulatively.

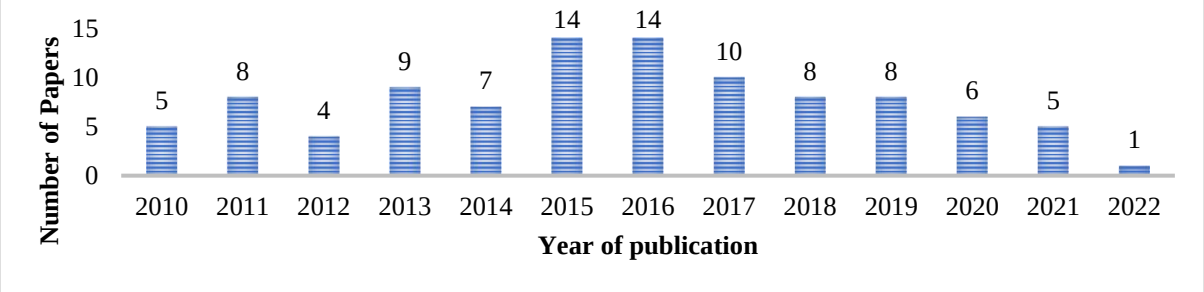

Figure 2: Number of papers published from 2010 to 2022.

Publication by Geographical Regions

Figure 3 shows the number of papers published according to geographical regions on the barriers to e-tendering adoption and application in the construction industry. From the figure, Africa is the leading geographical region with the highest number of publications (37). This can be attributed to African countries embracing new technologies to catch up with the developed countries in the quest to improve construction productivity. It was followed by Europe (24). After the year 2010, research about e-tendering in reduced according to the findings, and this may be that researchers in Europe turned their focus on other initiatives such as Building Information Modelling and other emerging software. Asia (20), Middle East and North Africa (10), Pacific (5), and North America (3) respectively. The number of papers by geographical region on the current study suggests the impact of the topic on industrial developments. In this case, the number of papers suggests the impact of the e-tendering on industrial developments.

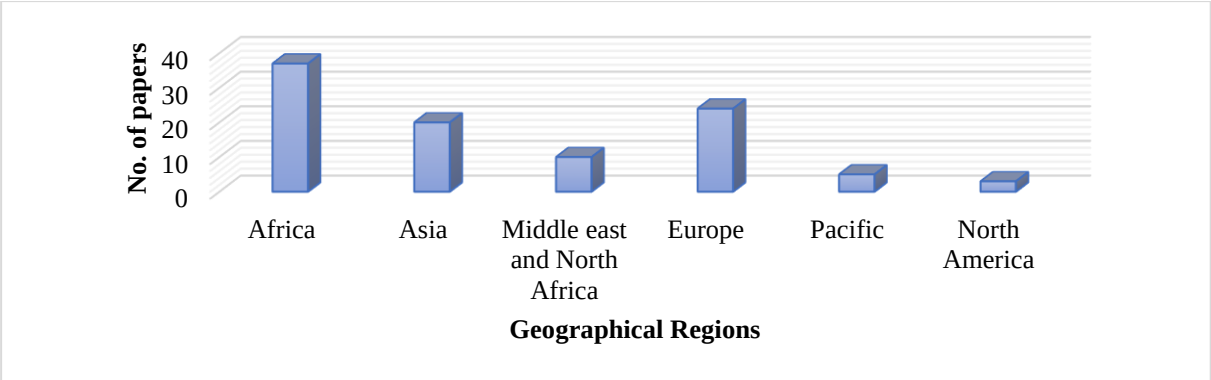

Figure 3: Number of papers by geographical regions.

Identification of Barriers to E-Tendering Implementation

After a thorough examination of the 99 relevant publications, 16 main barriers to e-tendering adoption and application were identified. Table 1 contains information about these barriers. The study identified 8 factors that appeared in all the regions in the literature as (1) inadequate data security (2) high investment cost of implementation (3) resistance to change (4) lack of support (5) technical challenges (6) lack of uniform standard or policy /Inadequate legal framework (7) inadequate ICT and internet infrastructure (8) inadequate technical/skilled personnel.

Table 1. The main barriers to e-tendering based on geographical regions.

E-tendering Barriers	Africa	Asia	Middle East & North Africa	Europe	Pacific	North America
Inadequate data security	X	X	X	X	X	X
High investment cost of implementation	X	X	X	X	X	X
Reluctance/ resistance to change	X	X	X	X	X	X
Lack of support	X	X	X	X	X	X
Technical challenges	X	X	X	X	X	X
Lack of uniform standard or policy /Inadequate legal framework	X	X	X	X	X	X
Inadequate ICT and internet infrastructure	X	X	X	X	X	X
Inadequate technical / skilled personnel	X	X	X	X	X	X
Lack of trust and awareness of benefits e-procurement systems/skepticism	X	X	X	X	X	-----
Software non-compatibility / interoperability challenges	X	X	X	X	----	----
Lack of widely accepted e-Procurement software solutions in construction	----	----	----	X	X	X
Lack of integration with business partners	-----	X	----	----	-----	X
Unreliable electric power supply	X	----	----	----	----	----
Ineffective communication/ very poor cross-disciplinary communication, Complex user interface	---	X	----	----	----	----
Lack of forum, pioneering firms, studies and pilot projects of e-tendering	-----	----	----	X	-----	-----
Other competing initiatives, Excessive number of e-platforms	----	----	----	X	----	----

Apart from North America, lack of trust and awareness of the benefits of e-procurement systems/scepticism is a key barrier that appears to be consistent in all geographical regions. This suggests the low level of e-tendering awareness and benefits in the construction industry. Software non-compatibility / interoperability challenges are also a major barrier in Africa, Asia, the Middle East & North Africa, and Europe. The lack of widely accepted e-tendering software solutions in construction was recorded as a key barrier in Europe, the Pacific, and North America. This can be attributed to technological advancement and as result too much unprofessional software available.

Lack of integration with business partners and ineffective communication/very poor cross-disciplinary communication complex user interface were recorded in Asia. This is a great challenge if business partners find it difficult in integrating e-tendering systems beyond company borders in supply chains if partners lack capacity. Furthermore, the unreliable electric power supply is also a major barrier that hinders the implementation of e-tendering in Africa. Most African countries are still struggling to meet the demand for electricity supply. This does not allow the full implementation of new technologies. Moreover, lack of forums, pioneering firms, studies and pilot projects of e-tendering, and other competing initiatives which are more advanced than e-tendering like Building Information Modelling and excessive number of e-platforms were recorded only in Europe.

Discussions

Based on the research findings in this study, certain critical barriers have been identified for further discussion in this section.

Lack of uniform standard or policy/Inadequate legal framework: Describes lack of legal rules and regulations to cover the e-tendering process, lack of laws or guidelines to resolve the disputes when processing e-tendering or in breach of legal transaction, lack of a reliable and uniform standard system, and lack of enforcement of electronic contracts. In addition, inadequate legal framework/ lack of a national IT policy relating to e-procurement issues, bureaucratic dysfunctionalities in practice, lack of pertinent case law, and e-signature issues. Anumba and Ruikar (2002) revealed that companies see unclear regulatory issues (such as tax issues, legal issues, ethical issues, etc.) as major deterrents to adopting e-tendering. A key determinant of e-tendering effectiveness is how well regulatory systems achieve their policy objectives. This implies that a standard policy is required for easy implementation of e-tendering, thereby minimizing disputes.

Inadequate data security: Under the umbrella of inadequate data security, the possibility of hacking, virus attacks, and data loss, confidential information getting into the wrong hands, lack of trust in electronic documents, document tampering / online crime, and authentication issues. This implies that a well-secured alternative must be chosen when applying e-tendering. Anumba and Ruikar (2002) opined that, according to electronic commerce researchers and analysts, the most crucial barrier stopping organizations from implementing electronic commerce measures is security. As a result, governments and organizations are launching a number of steps to counteract these widespread fears.

Technical malfunctioning of the portal and technical issues: In the case of e-tendering, it includes compatibility and support, system instability, frequent system errors, unknown errors of the system, technological updates, high maintenance cost, and the system crashing on the

very day the bid is due. Khalil and Waly (2015) revealed that Egyptians' lack of trust in any government-provided service has caused a great fear that the portal may malfunction (broken links, service unavailability, poor page load, etc.), particularly during the tender submission process. Furthermore, if the portal's technological fault makes it impossible for tenderers to submit their bids, many will be suspicious and will make charges of corruption against the company running the portal. Hence, the IT system must be user-friendly, and site managers must receive prompt support. Moreover, there is the need to train technical people to handle the technical issues.

Inadequate ICT and internet infrastructure of organization to support e-tendering: Inadequate ICT and internet infrastructure include unreliable internet, slow internet network connectivity, high cost of accessing the internet, etc. Mind Commence (2022) defines ICT infrastructure as the hardware and software required to construct and operate systems and networks for communications services, as well as to support applications, digital content, and e-commerce. Switching, transmission/transport, signaling, network access (such as radio base stations), and numerous platforms, databases, and ICT data are all components of ICT infrastructure. Most countries still lack this ICT infrastructure and as a result, hinder the full operationalization of e-tendering in the construction sector. This is confirmed by Wimalasena and Gunatilake (2018) in Sri Lanka, Hassan (2021) in Finland, and Sánchez-Rodríguez et al. (2019) in Canada. Therefore, governments and top managers must invest in ICT infrastructure to accelerate the implementation of e-tendering in the construction industry.

Reluctance/ resistance to change: From the findings, resistance to change could be an internal cultural issue. The culture of a company determines how employees should conduct their business within the company; lack of organizational readiness due to inadequate resources. According to Schnitzler and Österlund (2015), employees that are resistant to change do not want to learn a new system or working approach, especially if the system is still in the early stages of installation and some features may still need adjustment. Pop (2011) attributed resistance to change to a lack of information system skills and fear. Users are afraid and resisting to change because they don't have the required e-procurement skills. Khalil and Waly (2015), added high investment costs to adopt and maintain e-tendering with no substantial benefits realized. Bowmaster et al. (2016), suggested that cultural elements, organization, and strategy, and changing IT technical needs of an organization are some of the contributing factors to resistance to change. Khalil and Waly (2015), emphasized that it is generally assumed that if existing ways of doing things are good, there is no need to go the extra mile and do something contrary to the norms (e.g., transitioning to paperless procedures). Consequently, organizations need to be convinced of the benefits of the new working method and will not be forced to adopt it. It is therefore recommended that; top management should know and educate their organization about the benefits of e-tendering to pave way for smooth adoption of e-tendering technology.

Lack of support: For the successful implementation of e-tendering, maximum support is needed. According to the findings, lack of support can be attributed to; lack of top management support, lack of government support, limited resource, SMEs access difficulties, and lack of capacity issues to implement e-tendering. Ibem et al. (2017) ranked the fear that e-procurement will help curb corruption in the Nigerian construction industry. This implies that in an institution whereby the top management is corrupt, they will do their possible best to hinder the successful implementation of e-tendering. The efficacious implementation of e-tendering requires massive support hence the construction industry stakeholders and governments must

support the adoption and implementation of e-tendering to help improve the numerous limitations of the traditional tendering systems.

Inadequate technical / skilled personnel: Lack of e-tendering skilled personnel includes, for example, older generations who are less acquainted with IT-Systems and rely heavily on traditional working techniques. Amuda-Yusuf et al. (2019) stated that ICT skill/competency capability specifies the extent to which IT workers have the abilities and knowledge to undertake jobs outside of their initial area of instruction or domain. As a result, a high level of skill in the use of ICT technologies is required for industry stakeholders to use the e-tendering facility. Therefore, knowledge/skill of technological innovation is recommended in this study as another organizational component that can influence firms' adoption of e-tendering.

High investment cost of implementation: E-tendering implementation costs include IT systems cost, system licenses cost, cost of training staff affects many organizations, especially small and medium scales companies. Since most firms cannot afford for the paradigm shift from paper-based to a paperless system, it deters them from adopting e-tendering as has been reported in Hassan (2021)'s study for Finland.

Lack of trust and awareness of benefits e-procurement systems/skepticism: Since the traditional paper-based has been used for several years, the organizations are used it and are reluctant in finding new solutions and therefore not aware of the e-tendering. Others too do not trust the system and are skeptical about the benefits of e-tendering. This is confirmed by Mehdipoor et al. (2022) for Malaysia, Hassan (2021) for Finland, and Khalil and Waly (2015) for Egypt.

Software non-compatibility / interoperability challenges: In the construction industry, compatibility of tools and resources among projects is essential because numerous organizations work significantly on unique projects in temporary groupings. The interchange of data in e-tendering is critical inside the construction process. The project partners should use an e-tendering solution offered by the same or compatible manufacturers to ensure a flourishing exchange of data and prevent information loss. By developing a specification for an open data format, the industry can make a reasonably early start to facilitate data exchange (Hassan, 2021). In support of this, previous researchers such as (Wimalasena & Gunatilake, 2018; Oyediran & Akintola, 2011) have confirmed this.

Conclusions and Recommendations

This study investigates the critical barriers to e-tendering adoption and implementation in the construction industry through a systematic review from January 2010 to May 2022. The aim of the study was to identify the main barriers to e-tendering in the construction industry. This was achieved through a systematic review based on geographical regions. The following conclusions can be drawn from the findings. The barriers identified were grouped based on six geographical regions as Africa, Asia, Middle East & North Africa, Europe, Pacific, and North America. 16 critical barriers were identified. Out of the overall barriers identified, (1) inadequate data security (2) high investment cost of implementation (3) resistance to change (4) lack of support (5) technical challenges (6) lack of uniform standard or policy /Inadequate legal framework (7) inadequate ICT and internet infrastructure (8) inadequate technical/skilled personnel are the 8 critical factors that consistently appeared in all the geographical regions. The unreliable electric power supply was also one of the major barriers to e-tendering in Africa

and some parts of Asia. Lack of widely accepted e-tendering software solutions in construction dominates Europe, the Pacific, and North America while lack of integration with business partners and ineffective communication/very poor cross-disciplinary communication complex user interface was common in Asia. This research is a foundation for the development of solutions by construction stakeholders to identify and address the barriers in the construction towards the adoption and implementation of e-tendering, hence improving the uptake of e-tendering specifically for the construction public works globally.

This study contributes knowledge to existing theory and can be used for further reference. In addition, managers from organizations operating in the construction industry may apply the results for decision-making when they consider implementing e-tendering or when they aim to assess the barriers of e-tendering.

Value Engineering in Construction Management Literature

F. B. Yoğurtçu and A. Köksal
Yıldız Technical University, Department of Architecture, İstanbul, Turkey
bengu.yogurtcu@yildiz.edu.tr, almula@ yildiz.edu.tr

Abstract

Value engineering (VE) is an effective management approach in construction industry to maximize value and reduce cost of a project composed of multidisciplinary teams. It provides an understanding the needs of the budget, ensure objective perspective on project durations, costs, and other functions for the project investors. Additionally, value engineering enables a base for decision-making while decreasing the risks of design variations. However, the studies conducted in the construction management literature are limited. The aim of this research is to convey a comprehensive literature review of value engineering in the construction management body of knowledge. Scientific articles which were published between 2000-2022 years were reviewed and analysed according to research themes, related sub-themes, applied methodology types and country's attention.

Keywords were defined as "value management, value engineering, earned value management, construction management" for descriptive analysis. By using Web of Science, Scopus, and Google Scholar databases 291 articles were retrieved. These studies were categorized through thematic coding method and then frequencies were determined. The literature review indicated that the majority of the researched areas focused on the adoption of Value Engineering (VE)/Value Management (VM)/Earned Value Management (EVM) to construction industry (14,43%), following the use of knowledge management in VE/VM/EVM (10,31%), decision making strategies (9,97%), and finally the integration VE/VM/EVM into sustainability (9,28%). On the other hand, contract management, facility management, creating a guideline, innovation management and legal regulation themes were the least researched areas (each 0,34%) within the construction management literature. Additionally, the most common methodology types in VE/VM/EVM implementation are case studies (26,80%), model proposal (18,90%), only exploratory survey research (16,40%) and literature review (15,80%) respectively. Researches from Egypt, Malaysia, Hong Kong, USA, China and India were the countries where VE/VM/EVM in construction industry studied the most.

Keywords: *construction management, earned value management, value engineering, value management.*

Introduction

Researchers attributed "Value" different meanings, such as need, desire, interest, standard/criteria, beliefs, attitudes, and preference (Katzell, 1964; Rescher, 1969; Rokeah,

1973). Value Engineering (VE), on the other hand, is an organised effort based on systematic workshops managed by multidisciplinary teams through investigating the functions and costs of a system, supply, equipment, service, project or facility (Shen, 1993). VE aims to achieve optimal balance between client's goal values, time, cost, quality, performance and functions of a project all at once (Shen, 1993). From this point of view, VE approach can be also defined as a success factor of a project. It also enables a base for dynamic decision-making process and an organizational behaviour system within the context of decision rationality, psychological value and goal setting theory, (Lewin et al., 1944; Kluckhohn, 1959; Locke & Latham, 1990) while decreasing the risks of design variations. Beside all, VE accepted as an important cost management tool in construction management literature.

Value analysis (VA) technique was first mentioned in the 1940s by Lawrence Miles in the manufacturing industry during Second World War (Bowen et al., 2010). Afterwards, it was used to control the cost in the construction industry in 1963 within the construction projects (Cheah et al., 2005). The concept of VE was evolved by the time of progress, and it has primarily accepted in US and then in many countries such as UK, Australia, China, Malaysia etc, (Oke et al., 2018). Nowadays, Value Management (VM) referred to as VE in the construction management literature (Lin et al., 2007).

Male et al. (1998) defined VE/VM/EVM as a proactive, innovative, problem-solving method to increase the functional value of a construction project during decision making process. Moreover, this methodology aimed to accomplish the total budget of a construction project at the lowest cost and at the highest performance within context of life cycle cost. This tool effectively enables decision- making strategy and optimize project output in the context of cost and function. Olawumi et al. (2016) emphasized that an efficient VE/VM/EVM approach can be achieved at least 5– 15% total cost saving for a project.

The construction industry is one of the important drivers that significantly lead the economic growth (Musarat et al., 2021). Construction projects generally have high budgets and long-term building period. Although VE/VM/EVM is an effective technique for cost management, project planning, cost control, conflict management, and dispute resolution of a construction project, the implementation and adoption of VE/VM/EVM is still at the lowest level especially in developing countries. (Alsehri, 2020; Abd-Karim et al., 2017).

Though VE/VM/EVM can be applied to any type of a construction project and has capability to save cost and increase the function of a construction project, studies are limited in construction management literature. The main aim of this research is to understand the current status and future trends of VE/VM/EVM in literature through conveying a comprehensive literature review of VE/VM/EVM in the construction management body of knowledge. Literature review is accepted as an efficient technique to achieve comprehensive information on the present practice (Li et al., 2019). It provides to researchers in capturing the trends for future studies (Nabawy, 2020). This review also attempts to point out that VE/VM/EVM can be widely applied. It provides information for scholars to gather a map of past, current, and even future research on the topic and also promotes the development of VE/VM/EVM studies in the construction industry.

Research Methodology

A semi-systematic literature review approach is an efficient strategy for themes approaches. It offers an overview of current knowledge, allowing to identify relevant theories, methods, existing gaps and future trends within the literature (Snyder, 2005). Therefore, a comprehensive literature review of VE/VM/EVM was conveyed in the construction management body of knowledge related with research objectives.

Firstly, the related keywords were produced such as "value engineering", "value management", "earned vale management" and "construction management". Then, these keywords have been grouped to attain the studies for descriptive analysis. The keyword group was "Value engineering and construction management", "Value management and construction management ", "earned value management and construction management ". Next, Google Scholar, Scopus and Web of Science databases were selected as research tools to reach for articles from journals published between 2000 and 2022 years. These databases contain high number of publications, including scientific journals, books and conference proceedings. The articles achieved from literature have been eliminated regarding to title reading, abstract reading and full paper reading related with research question. All accessible articles have been listed with their access web links. After eliminating articles which were repetitive, off-topic and had different context level, 291 article were gathered for analysis. Workflow of the semi-systematic literature review was illustrated in Figure 1.

Basically, two quantitative evaluation techniques termed as thematic coding and frequency analysis were used for descriptive analysis. First of all, to explore the occurrence of these studies in the context of research themes, subthemes, country, applied methodology types they were categorized by using thematic coding method through reading title, abstract, keywords and full paper. Following, each context was analysed by means of frequency technique. The findings were visualized by VOSviewer (version 1.6.18) software programme which is a common science mapping tool used for creating maps based on network data and visualizing maps (Van Eck & Waltman, 2019).

Findings

According to research themes, the findings of frequency analysis are discussed in this section. While the majority of the research areas were focused on the adoption of VE/VM/EVM to construction industry (14,43%), the use of knowledge management in VE/VM/EVM (10,31%), decision making strategies (9,97%), and finally the integration of VE/VM/EVM into sustainability (9,28%) follows that respectively. The analysis indicate that the least studied themes are contract management, facility management, creating a guideline, innovation management and legal regulation (0,34%) within the construction management literature. The occurrence of research themes map was retrieved by using VOSviewer software illustrated in Figure 2.

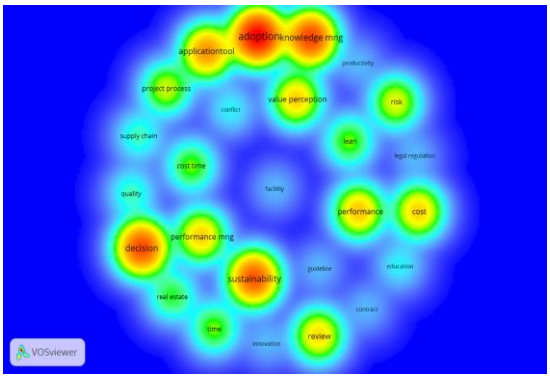

Figure 2: The occurrence map of research themes.

The findings of frequency analysis within the framework of applied methodology types in VE/VM/EVM in construction management literature are case studies (26,80%), model proposal (18,90%), only exploratory survey research (16,40%), and literature review (15,80%) respectively. The prevalence of methodology types is demonstrated in Figure 3.

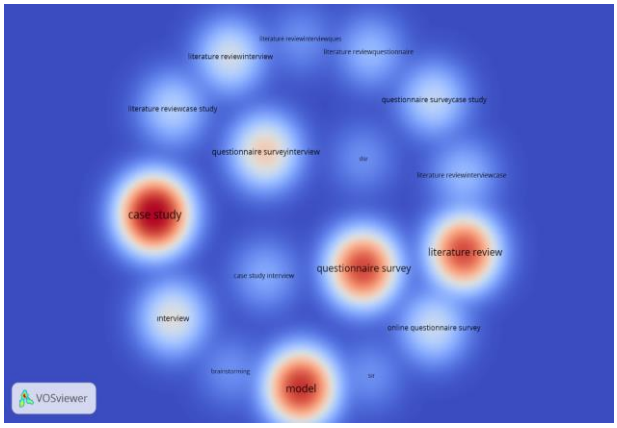

Figure 3: The prevalence of applied methodology types.

The findings of latest frequency analysis in the context of country's concentration on VE/VM/EVM methodology are visualised through a map shown in Figure 4. According to this map it is specified that Egypt, Malaysia, Hong Kong, USA, China, and India are the most concentrated countries on VE/VM /EVM approach in construction management literature.

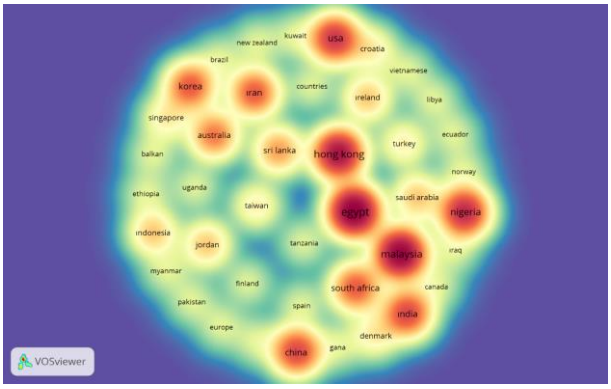

Figure 4: The deployment of country's concentration.

Conclusion

In this study a comprehensive literature review conveyed on VE/VM/EVM approach in construction management body of knowledge between the years 2000 and 2022. After gathering and eliminating the articles from journals 291 relevant studies are reviewed, and the content of themes are classified as per articles in recent research main themes, subthemes, country's concentration and applied methodology types in order to detect the current status and future trends for these methodologies. Following the in-depth review of themes, methodology types, country's attention and the categorization, the studies analysed via frequency method as a quantitative study. As a consequence, it is derived from the analysis that the majority of the researched areas focused on the adoption of VE/VM/EVM to construction industry (14,43%). Thus, the implementation and acceptance of these approaches is still open to research which is also identified by Alsehri (2020) and Abd-Karim et al. (2017). Additionally, the VE/VM/EVM studies for the construction sector in Turkey are very limited. The researcher was able to access only two articles with subthemes "design management" and" quality management" within the context of VE/VM literature. Therefore, this area is open for further research.

Concerning cost management problems in construction project, it is highly beneficial for construction projects to adopt VE/VM/EVM path to be able to take significant precautions against negative results on total cost before building constructed. In conclusion, if these methodologies would be used regularly in construction sector, the unnecessary cost would be eliminated, and final budget of construction would be reduced.

A Systematic Literature Review on Lean Construction for Tendering

A. Türkmen and P. Irlayıcı Çakmak
İstanbul Technical University, Department of Architecture, İstanbul, Turkey
turkmen20@itu.edu.tr, irlayici@itu.edu.tr

Abstract

Research concentrated on lean construction demonstrates that the adoption of lean principles has a great impact on the construction industry. However, it is believed that the industry does not benefit from the implementation of lean principles during the tendering process. In this regard, it is important for the stakeholders to be aware of how to integrate lean construction principles into the tendering process, and what gains will be achieved. The lean construction awareness of the stakeholders in the tender processes, as well as the results of the implementation of the lean principles during the tender process, are the motivation of this study. Therefore, this study comprehensively reviews and analyzes lean concepts, principles, and implementations in the tendering process by applying a systematic review approach. The study will raise the level of awareness and show the potential of the integration of the principles of lean construction to present solutions for the encountered problems during the tendering process.

Keywords: *lean construction, lean principles, literature review, tendering.*

Introduction

Construction projects are completed by the organization of many different expert stakeholders and sectors that feed each other. This ensures that construction projects need qualified organizations. Regardless of its function, a well-organized construction project can be completed within the targeted time, within the specified budget, and with the desired quality (Nanda et al., 2016). Considering the opposite situation, it will not be possible to talk about the success of construction projects that were not completed in the planned time, could not reach the targeted quality, and exceeded the determined budget. Such a failed construction project negatively affects its stakeholders and other sectors in the organizational chain (Dargham et al., 2019).

To consider projects to be successful in the construction sector, they must be planned, implemented, and made ready for delivery in a systematic way. All this process planning will be possible by achieving the targets in the triangle of time, budget, and quality. However, it is observed that the sector is more wasteful in achieving these targets compared to other sectors. Of course, the approach of the stakeholders and their competencies in their fields of expertise make this situation worse (Zimina & Pasquire, 2010).

Lean thinking or lean principe approach aims to provide a product or service with better quality, in a shorter time, with less effort and cost. With this philosophy, ways to achieve higher quality in a short time and with less budget are sought, a continuous improvement and development approach is shown by not being satisfied with the quality obtained. It is seen in the ongoing projects and process planning that the construction sector adopts innovations and developments in a long time compared to other sectors, as well as for lean principles (Vilasini et al., 2011). Due to the wide and complex structure of the construction sector, it is normal for the stakeholders of the sector to show resistance to changing a conventional step with a new method and technique. For this reason, it may take many years to adapt to change and development. Despite this, it is an inevitable end that lean principles will gain a place in the construction sector as well as in many other sectors in recent years. It is thought that the necessity of using limited resources together with the technological developments and the lean principles will penetrate every stage of the projects in the construction sector. As a matter of fact, the steps taken, and the developments experienced by the stakeholders of the sector show that the adoption of lean principles has a great impact on the construction sector. Even if the adaptation process will take a long time, there is no doubt that the gains to be achieved by applying lean principles will whet the industry's appetite. Thus, it is up to the construction sector to close the gap with other sectors (Kim et al., 2016).

Despite the lateness in the construction sector in the research carried out in this field, it is seen that the lean principle practices adopted day by day do not take enough place in the tender processes and this area of the sector does not benefit (Heidemann & Gehbauer, 2010). Raising awareness for the sector to adopt lean principle practices in the tender process and gaining more works in research may be the first steps to be taken. It is thought that with the research concentrated in the field, the stakeholders' knowledge on how to integrate lean principle practices into the tender process and what gains they will gain will enable adaptation in a short time (Forgues & Koskela, 2009). The results of the implementation of lean principles in the tender process and their awareness of lean structure constitute the motivation of this study.

This study aims to comprehensively review and analyze lean concepts, lean principles, and lean practices in the tendering process by applying a systematic approach. With the aid of the study, the awareness level of the stakeholders will increase, and it will reveal the potential of lean principles to find a response in the tender processes and to offer solutions to the problems experienced. The study will be a guiding step for future research, and a reflex for stakeholders to gain competence in lean policy implementations in the tender process.

Research Method

In the study, a comprehensive and two-way scanning method of the literature has been adopted to examine and analyze the integration of the lean principle concept into the tender process in the construction sector and to present the results of the gap in the study area for future research. First, a systematic literature review was conducted to observe the relational association of the concepts of 'lean', 'construction', 'tender' in current studies. Thus, findings on the density and coexistence of the concepts in the literature were reached. Then, the research findings were evaluated with the meta-analysis method. The meta-analysis method helped to reveal much more concentrated and unfocused research areas by associating the obtained findings with each other in terms of the investigated concepts.

Systematic Literature Review

In the first stage of the study, a search was made on the Scopus database that covers. publications from academic publications such as the American Society of Civil Engineers (ASCE), Elsevier, Emerald and Taylor & Francis,.. and others. Keywords for the search were determined as “lean”, “construction”, “tender”, “procurement” and “bidding” and these keywords were scanned as title/abstract/keyword. As a result of the search, a total of 214 papers containing the specified keywords between the years 2005-2021 were reached. A total of 214 articles were reviewed, and 74 related papers that were suitable for the purpose of the study, were selected for more detailed examination. Flowchart outlining the protocol adopted in this systematic review is represented in Figure 1.

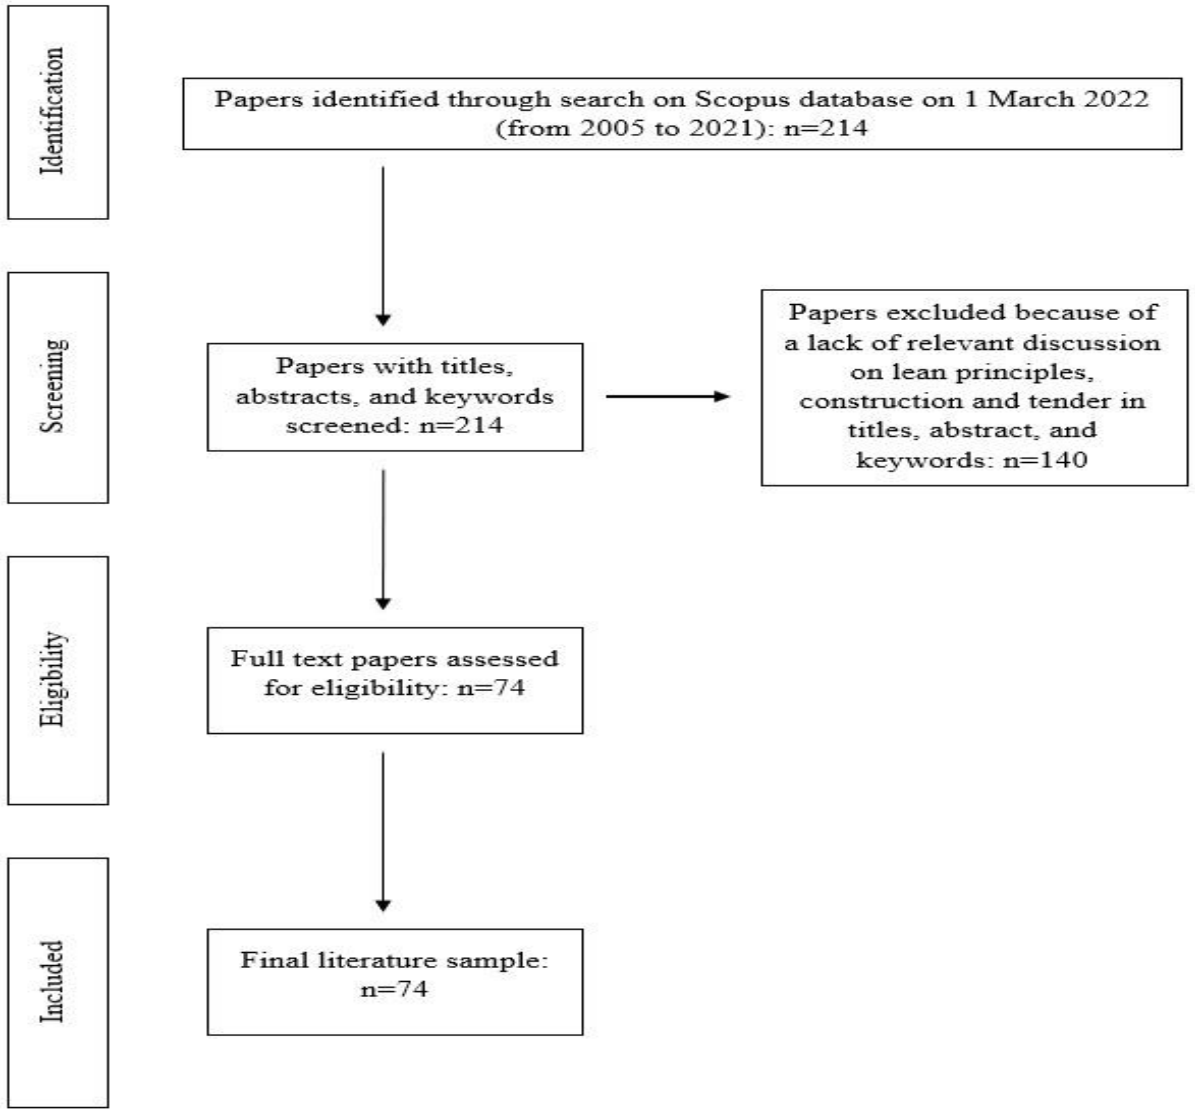

Figure 1: Flowchart for systematic review.

Meta-Analysis Method

In the second stage of the study, selected papers were classified e using the meta-analysis method, and in the framework of 7 main categories such as publication year of the papers, scientific database, journal or conference name, keywords, research focus, information source,

and future directions. 15 subcategories connected to 7 main categories, analyzed as shown in Table 1. For each of the 74 papers, different and more analysis results can be seen according to the evaluations in the main and sub-categories.

Data Analysis and Results

The literature review covering certain years for the adoption of lean principles in the construction industry and their integration into tender processes was analyzed according to the meta-analysis classification method given in Figure 2. In Figure 2, it is examined that the first steps were taken, but not enough yet, depending on the increasing trend of the idea of integrating lean principles into processes in the construction industry between 2005 and 2021, as well as the awareness of using them for tender processes. As a matter of fact, the majority of the studies have been published at the Annual Conferences of the International Group for Lean Construction, and currently, the conference is organized with the aim of applying lean principles to all areas of the construction industry. For this reason, it will not be possible to talk about the fact that the research field has still reached sufficient saturation today.

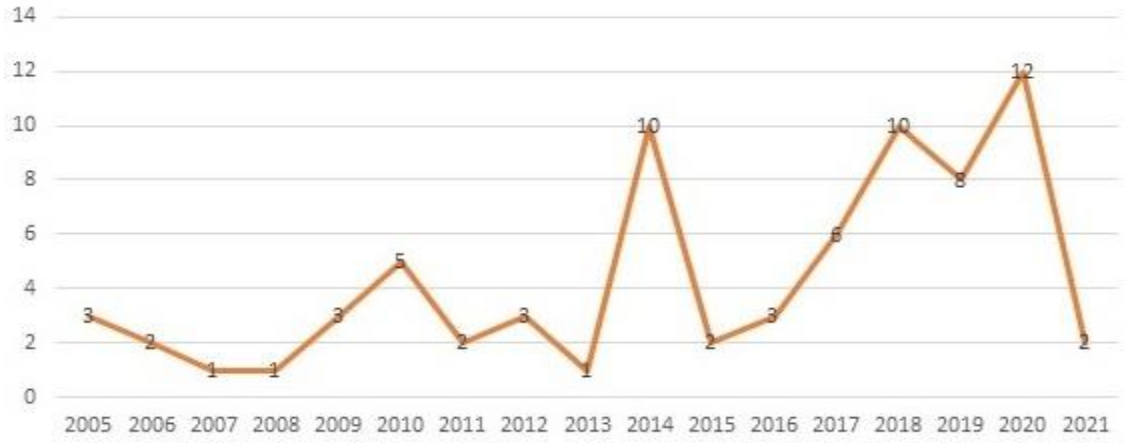

Figure 2: Distribution of the selected papers within the time span.

In Figure 3, the distribution of use of the keywords in the publications over the years is examined. The use of keywords together or separately shows us that the concepts of construction, lean, tender and procurement together take more place in research, researchers have examined the subject, but the latest situation is not sufficient for the construction sector in the current situation. Again, in Figure 3, it is predicted that the concept of 'lean construction' is accepted in the literature as lean principles begin to gain ground in the construction sector, so that the researches will move in depth and penetrate the tender processes of the sector, opening a research area for future research. Considering that more than half of the publications belonging to the research study covering a total of 17 years between 2005 and 2021 were published in the last 5 years, it is thought that lean principles for tender processes in the construction sector will be intensively examined in the coming days.

Figure 3: Analysis of selected papers according to the research focus for keywords.

As a result of the analyzes made in the papers in the research, the most frequently used keywords are examined in Figure 4. Accordingly, ‘Lean Construction’ is the most observed keyword (24.30%). This shows that, as stated before, the concept of lean construction is accepted in the sector and awareness of lean principles will increase day by day. The number of papers with the keywords ‘Lean Construction’ and ‘Procurement’ together is the second highest total number of studies (14.80%). In the third place comes the studies in which the ‘Construction’ and ‘Procurement’ keywords are used together (12.10%). These are followed by studies covering the use of Lean and Construction, Lean, Construction, Lean and Procurement (6.70%), Construction and Tender, Lean-Construction-Procurement, Lean Construction and Tender (4%), Procurement, Lean-Construction-Tender (2.70%), Lean and Tender, Lean-Procurement-Tender and Construction-Procurement-Tender (1.35%) keywords together.

Figure 4: Analysis of selected papers according to the keywords.

The analysis of the publication distribution of the papers in different journals and proceedings by years is presented in Table 2. As a result of the examination of the table, it is seen that the publications were published in 21 different journals, 22 different serial conferences, and 2 different congresses. In this context, it is concluded that lean principles have been determined, researched, and scrutinized for tender processes in the construction sector as an agenda in a wide range of academic media. This proves the statement of this study that the field should be approached with more appetite and focused.

As can be seen in Table 3, the area where lean principles remain weak in the examined studies is the tender process. Despite the increase in the subject title in recent years, the tender process could not get what it wanted from these developments. These studies focused on areas such as selection of qualified contractors, decision-making techniques for the right offer, and supplier processes. The benefits to be gained by the construction industry by integrating lean principles into the tender process still remain an exciting area for researchers today.

Conclusion

These findings further support the idea that researchers should focus more on this area to integrate lean principles into construction tendering processes. For this reason, some papers show that lean principles have not yet achieved the desired integration in tender processes and that the lean concept will have much greater potential for gains in the construction industry. In addition, these results coincide with the idea that the contributions of lean principles to procurement, production, material selection, bidding, contractor selection and similar topics can contribute to tender processes in the construction industry, as mentioned in previous studies. The study aimed to address and analyze the previously uncontacted research field gap in past research.

The lean principle approach is applicable to all production based industries. As a priority, it is necessary to realize the lean principles and take steps with this awareness. Since the implementation of lean principles requires a full disciplinary process, there is no phase that can be ignored or any step that can be considered later. However, it always supports steps that can be improved and developed. Considering the wide range of work areas covered by the construction industry, it seems difficult to adapt the lean principle applications with full capacity at the same time. However, the lean principle approach offers a constructive picture to the stakeholders of the construction industry, with improvement and continuous development at every step.

More qualified execution of the tender process, which affects the construction projects from the design to the implementation and post-delivery process, and then to the system maintenance and repair processes in the facility management process of the building, will be

possible with the application of lean principles. In addition, although the integration of the construction industry with lean principle practices has improved in recent years, it has been observed in the researches that the tender processes are weak in this integration. It is concluded that in order to find the desired level of the lean policy response in the tender processes in different titles where the researches are examined with the meta-analysis method, the research intensity should increase in this field, the awareness of the sector stakeholders should be drawn, and the tender experts should be trained on the lean principle implementation principles.

The aim of the study is to reveal that lean principles are not adequately met in the construction tender processes. With the research, it has been examined that the lean principles are still in their early stages for the construction industry in general, and that there are studies on proposal preparation, project duration calculation and similar titles in the tender processes, but that sufficient research saturation has not been reached.

As the results show, it is predicted that lean principles will experience the infancy and development process of the building information modeling process in the construction sector, and their integration into the tender processes will again take place with the legal legislation and stakeholders' awareness of the lean principle.

As a result, the study was conducted to observe the reflections of lean principles on the tender process in the construction industry. The literature examines that not enough research has focused on lean principles for the tendering process. Future research should take a holistic approach to the procurement process and focus on the integration of lean principle practices. It is expected that this systematic review will be a guide for future research and gaps in the literature and contribute to the tender process for the construction industry. The fact that the concept of lean has been adopted and gained ground in the construction industry in recent years shows that the number of papers in the specified years is not sufficient and the field is open to further research.

Abstract

This paper intends to develop a modified oppositional teaching-learning-based optimization (MOTLBO) model for solving construction Time-Cost-Quality Trade-Off problems (TCQT). The model is based on a negative correlation scheme of opposition-based learning concept for population initialization and generation jumping of the current population. Furthermore, to handle objectives effectively, the MOTLBO is incorporated with non-dominated sorting (NDS) approach and crowding distance computation mechanism. Well-known 7- and 13 activity construction benchmark problems are solved to illustrate the applicability of the model proposed in the current study. The obtained results are compared with genetic algorithm (GA), ant colony optimization (ACO), and differential evolution algorithms. The simulation results exhibit that the utilized MOTLBO is able to ensure a superior set of Pareto-front solutions maintaining good convergence speed as well as diversity.

Keywords: *opposition-based learning, time-cost-quality trade-off problem, generation jumpin, construction projects.*

Introduction

In a construction project, efficiency can be maintained with good project management, and based on project requirements, the application of knowledge, skills, and techniques to use time and cost resources appropriately is the key point to be considered. To achieve it, optimizing the project duration, and total cost has to be performed effectively. Moreover,

Time–cost trade-off analysis is a part and parcel of any construction work and both the researchers as well as contractors are enthusiastic about paying attention to this glamorous subject, due to the academic/real field nature of the issue. Another crucial development is to increase the number of objectives i.e. quality of each alternative as an objective in the optimization algorithm.

Reviewing the literature, solving the TCTPs were not straightforward for ages. In spite of existing the vast majority of techniques developed in optimization research and other fields to handle this problem. The complex nature of it calls for alternative approaches such as weighted sum method and non-dominating sorting approach. Particularly, weighted sum method is one of the firstly used methods on solving the time-cost trade-off problems. It is the approach which involves the straightforward formulation and easy to be fulfilled. It is able to obtain optimum or near optimum solutions despite having a basic formulation.

Deb (2001) has indicated for the first time that the weighted sum method (WSM) combines a series of objectives into a single objective by pre-multiplying each objective with a pre-known weight. Despite the simplicity of the concept, the issue is specifying which weight value to be utilized. It is determined by the importance of each objective in the context of the problem, as well as a scaling factor.

Ascertaining the most suitable combinations of weight factors for the wieght approach to enhance the multi-objective solution process seems to be extremely complicated. However, Adaptive Weight Approach (AWA) (Gen & Cheng, 2000) and Modifie Adaptive Weight Approach (MAWA) (Eirgash & Dede, 2018; Toğan & Eirgash, 2019a; Afshar et al., 2006; Feng et al., 1997) still have been utilized in the literature. Time and cost parameters are highly correlated with the quality which is a critical parameter and is not basically quantitative one and are hardly these objectives developed in the literature (Narayanan & Suribabu, 2014). However, when applied to more sophisticated medium and large-scale problems, the MAWA performs poorly and is incapable of discovering global optima. The second way to deal with the conflict between time and cost objectives is through the non-dominated sorting (NDS) concept. Using NDS improves the solution(s) obtained at the end of a MOP process with distinct metaheuristic algorithms such as Teaching Learning Based Optimization (TLBO) (Eirgash et al., 2019; Toğan & Eirgash, 2019b). Since the academic/real field nature of the issue, there is a convincing requirement for the improvement and enhancement of optimization problem-solving techniques, a modified oppositional teaching-learning-based optimization (MOTLBO) model is developed to minimize the deficiencies associated with the traditional MAWA.

Abovementioned studies were restricted to single or bi-objective optimization because probability of discovering the non-dominated solutions decrease exponentially as the number of conflicting objectives increase (Gen & Cheng, 2000). Given the importance of construction quality, many researchers have tried to extend the time-cost trade-off to time-cost-quality trade-off (TCQT).

This study follows the given arrangement: Firstly, it demonstrates the time–cost trade-off formulation. Secondly, it presents the opposition-based learning concept along with the modified oppositional TLBO to solve the TCQTs. The application of MOTLBO in benchmark TCT optimization problems are then investigated to exhibit its effectiveness, and eventually, it provides the results and conclusions of the utilized algorithm. Flowchart of the proposed algorithm is given in Figure 1.

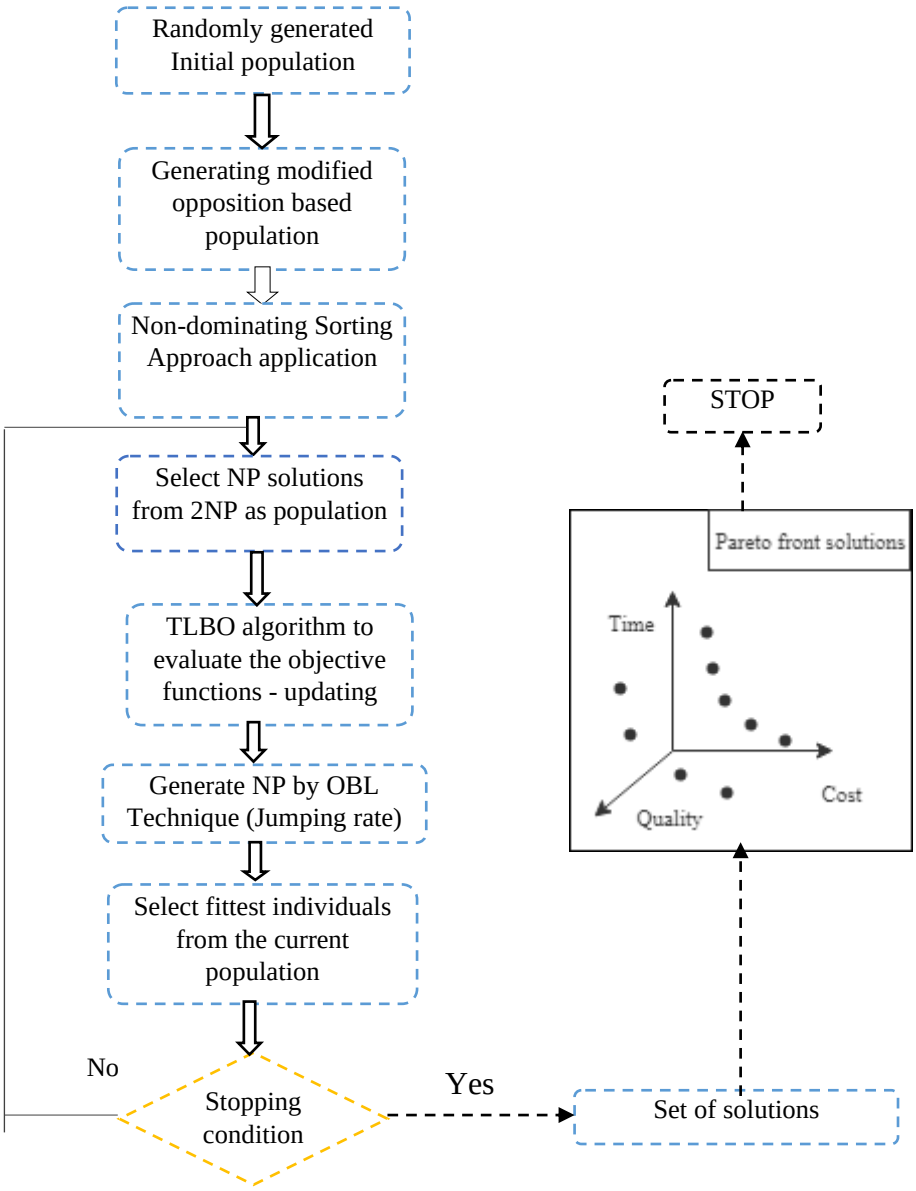

Figure 1: Flowchart of the MOTLBO algorithm for the solution of TCQT.

Problem Formulation

Obtaining the time-cost objectives of a project by selecting suitable options for each activity is done through the TCTP concept. Calculation of the time objective function of a project is operated using Equations (1) to (2).

Activity time (AT), activity cost (AC), and activity quality (AQ) are taken as input for employed TCQT model. This study intends to simultaneously optimize project time (PT), project cost (PC), and project quality index (PQI), all of which are functions of AT, AC, and AQ. Explanations of the three objectives are given as follows:

Objective 1: Minimization of project time (PT)

PT is a crucial construction project parameter that has a significant impact on the successful completion of a project. The precedence diagramming method (PDM) is used to determine PT. PDM is based on activity on node (AON) project networks with critical path (CP). The total number of activities on the critical path of a construction project is equal to PT.

$$\text{PT} = \sum_{A \in CP} AT_A \tag{1}$$

Here PT is the completion of the project duration and ATA is the critical path activity completion time (A).

Objective 2: Minimization of Project Cost (PC)

PC is one of the key factors affecting the success of construction projects. PC is simply the algebraic sum of each activity cost (AC). Whereas AC is the sum of direct cost and indirect cost of activity. Direct cost (D.C) include mainly the cost of labour, material and equipment while indirect cost (I.C) include overhead expenses and outage losses.

$$\text{PC} = \sum\nolimits_A D.C + \text{I.C per day} \times \text{PT in days} \tag{2}$$

Where PC is project completion cost, $\sum_A D.C$ is sum of direct cost of each activity. Indirect cost of construction project is simply estimated by multiplying the PT and indirect cost of project per day.

Objective 3: Maximize Project Quality Index (PQI) or Minimize 1/PQI

Since the project quality (PQI) is of paramount importance objective of construction project, to measure the PQ quantitatively is very challenging task. In this paper, PQ is measured in terms of project quality index (PQI), which is estimated by taking the weighted sum of each activity quality (AQ). On the other hand, AQ depends upon three quality indicators i.e. labour, material and equipment. Therefore, AQ can be measured by taking the weighted sum of quality indicators of activity.

$$\text{AQ}=\text{wt}_A.\sum_{k=1}^{k} \text{wt}_{\text{A,k}} . Q_{\text{A,k}}^{m} \tag{3}$$

$$\text{PQI} = \sum\nolimits_{\text{A}=1}^{\text{n}} \text{wt}_{\text{A}} . \sum\nolimits_{\text{k}=1}^{\text{k}} \text{wt}_{\text{A,k}} . \text{Q}_{\text{A,k}}^{\text{m}} \tag{4}$$

Where $Q_{A,k}^{m}$ is performance of quality indicator (k) in activity (A) using alternative (m); $wt_{A,k}$ is weight of quality indicator (k) compared to other indicators in activity (A); and wt_A is weight of activity (A) compared to other activities in the project.

The OBL for Optimization

The basic principle behind opposition-based learning is to employ opposites for better and faster learning in the optimization process. The algorithm's rapid convergence to the ideal solution is related to the point that not far away from it (Rahnamayan et al., 2007). In lack of any prior knowledge, it seems to be challenging to make the best initial estimate. In other words, this approach enables it to carry-out the search for the optimum solution in both directions concurrently (Tizhoosh, 2005).

Opposite number: Let's put x∈ [a; b] a real number and its opposite number $\tilde{x}$ is given $\tilde{x}$ =a+b-x. Likewise, following is the opposition number in N-dimensional space: let's assume X= (x_1; x_2 ;…. x_N) a point in N-dimensional space in which x_1;x_2 ;.....x_N ∈R and xi∈[a_i,b_i] ∀i=1;2;....., N, and its opposite point $\tilde{x} = (\tilde{x}_1, \tilde{x}_2 .... \tilde{x}_N)$ is represented by its elements as $\tilde{x}_i$ = $a_i + b_i - x_i$.

Initialization of OBL Population of Size Npop

For OBL population initialization following simple steps are followed:
Step 1: Initial population (pop) is generated randomly within the upper and lower limits.

$$X_{i,j}{}^{G=0} = Lb_j + x_{i,j} \times (Ub_j - Lb_j) \tag{5}$$

Step 2: Generate opposite population (Opop) as described below.

$$X^o{}_{i,j} = Lb_j + x^o{}_{i,j} \times (Ub_j - Lb_j)(j = 1,\ldots,D; i = 1,\ldots,N_{pop}) \tag{6}$$

$$Opop_{i,j} = a_i + b_j - pop_{i,j} \quad i = 1, 2....Npop \ , \ j = 1, 2.....D \tag{7}$$

Step 3: Select Npop (pop.size) fittest individuals from population (pop) and opposite population (Opop).

Generation Jumping of Opposition Based Learning

In this phase, calculation of generation jumping of the opposition population is performed dynamically on contrary to the initial population process of OBL. Instead of applying variables' pre-defined interval boundaries, based on the min^m and max^m values of the current population for that variable, the opposite of each variable is calculated as equatin (8).

$$X_{i,j}{}^{o,current} = Min_j^p + Max_j^p - x_{i,j}^{current} \ (j = 1,....,D; i = 1,....,N_{pop}) \tag{8}$$

Modified Oppositional Teaching Learning Based Optimization Algorithm

This paper considers the modified oppositional teaching learning-based optimization (MOTLBO) algorithm, which combines the opposition-based learning (OBL) concept with the original teaching learning based optimization (TLBO) approach to solve optimization problems. MOTLBO expedites the convergence rate of the standard TLBO algorithm by employing opposition-based population initialization and generation jumping. The sole TLBO comprises significant weaknesses, such as being caught in local optimal solution, and doesn't

preserve a good convergence rate in relation to the complexity of the problems (Eirgash, 2018). Thereby, the proposed algorithm eliminates these drawbacks using a negative correlation notion of OBL. The size of the initial population required to enhance convergence to the optimal solution can thus be reduced while maintaining diversity. The steps of the modified learning strategy are outlined below:

Step 1: Initial population (pop) of the entire individuals is generated randomly within the upper and lower constraints.
Step 2: Generate modified opposite population (Opop) as described below.

```
for i=1:Pn
for j=1:Dv.size
    opp_no=rand(1);
      if  opp_no<=0.5
        opp_no=-1;
      else
         opp_no=1;
       end
   opp_pop(i,j)=population(i,j)+opp_no;
  end
opp_pop=alt_ust_sinir_kontrolu(opp_pop);
```

Step 3: Value of the objective function of all the individuals of the modified opposite population set are evaluated.
Step 4: Select np (population size) fittest individuals from population (P) and modified opposite population.
Step 5: Apply teaching factor to modify the grade point of each subject of each of the individual student.
Step 6: Through mutual contacts with other students, the grade point of all students in each subject is updated.
Step 7: The feasibility of newly created solutions is verified, and infeasible solutions are substituted with a random subset generated new solutions.
Step 8: The modified opposing population is formed from the feasible population set employing a jumping rate and is explained as follows:

```
for i=1:Pn
for j=1:Dv.size
    lb=1;
    ub=length(eval(['Dv.Ta', num2str(j)]));
   opp_jump_no=rand(1);
      if  opp_jump_no<=0.3
        opp_jump_no=ub+lb-current_population(i,j);
      else
         opp_jump_no= current_population (i,j);
      end
  Opp_jump_population(i,j)=opp_jump_no;
 end
end
```

Step 9: Select np fittest individuals from current population and the modified oppositional population.

Numerical Examples

The proposed algorithm is coded in MATLAB (R2021a) environment compiled on a personal computer having Intel (R) Core (TM) i3 CPU 2.40 GHz and 3GB RAM.

Empirical Example of 7-Activity Project

The example was originally introduced by Feng et al. (1997) and then solved by Zheng et al. (2005) for construction time-cost trade-off analysis and shown in Figure 2. Table 2 includes the related data on different resource utilizations and their corresponding time, cost and quality. Originally the example did not contain the information about quality level of resource utilization options.

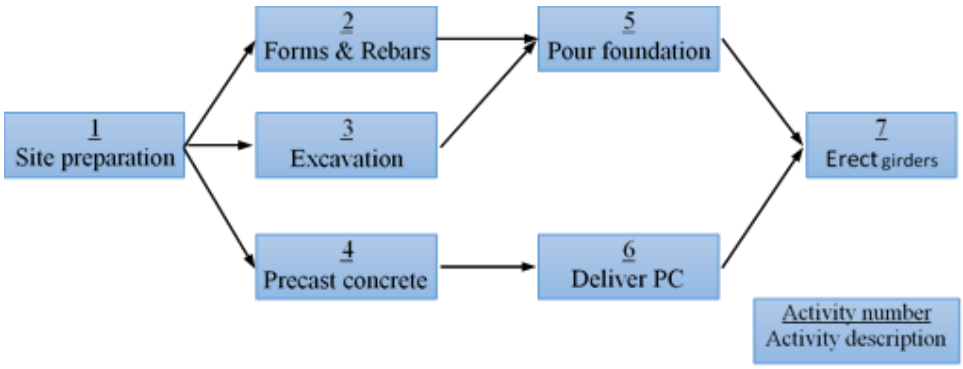

Figure 2: Network configuration of 7-activity test example.

Table 2. Options for 7- activity project for daily indirect cost of $500/day.

Activity Description	Activity number	Precedent activity	Option / Mode	Duration (days)	Direct cost ($)	Activity weight (%)	Quality %

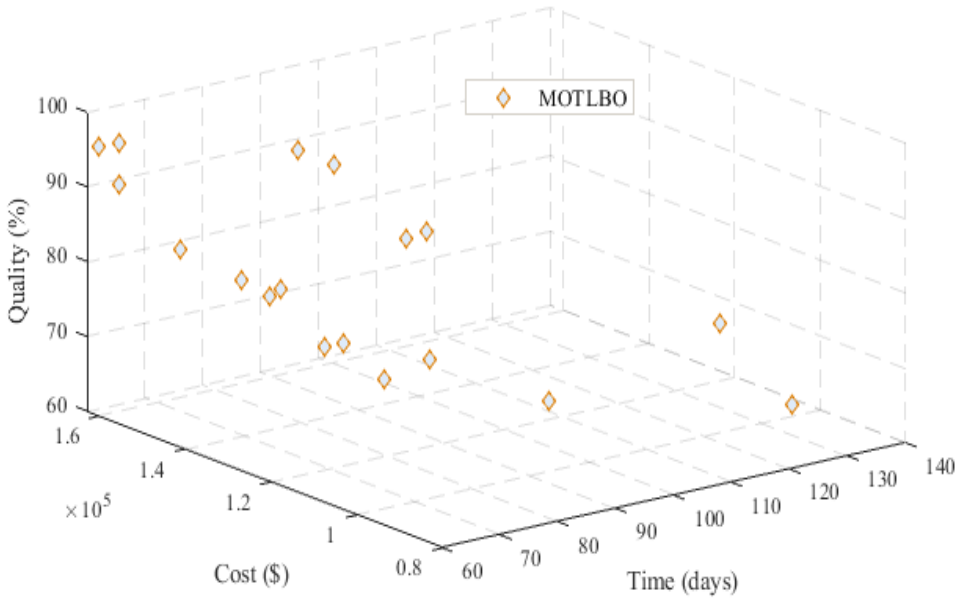

Figure 3: Pareto optimal solutions of time-cost-quality trade-off problem.

Pareto front solutions of the different algorithms considering the different number of function evaluation is given in table 3. It is clear that the MOTLBO has the potential to provide a large number of Pareto optimal solutions with a significantly smaller NFC, implying a faster convergence rate. The graphical representation of the results (Pareto front solutions) obtained by employing MOTLBO is illustrated in Figure 3 while table 4 presents details for the non-dominated solutions.

Empirical Example of 13-Activity Project

In the presented paper, the working of the proposed TCQT model is demonstrated through solving one case study project introduced by Sharma and Trivedi (2020). The case study project with 13 activities of possible alternatives is shown in table 5. Likewise, the three-dimensional plot for obtained PT, PC and PQI values is shown in Figure 4.

Table 5. Details of the case study project.

Table 6 indicates all 25 Pareto optimal solutions with selected activity modes. The Pareto-front obtained using MOTLBO and Kamal and Trivedi (2020)'s modal is compared in table 6. It can be seen from table 6 that MOTLBO obtains identical Pareto solutions, adopting the smaller objective function values.

Table 6. The options selected with the corresponding objectives.

Conclusion

This paper besides examining the effects of the opposition-based learning (OBL) concept to demonstrate the variation of the optimal solutions, presented a multiobjective approach that aims to optimize time cost, and quality simultaneously by utilizing modified oppositional teaching learning-based.To maintain the diversity in the search process, the negative correlation concept of OBL is coupled with the original TLBO. Instead of opposite numbers, here, negative correlated numbers are used for population initialization and also for generation jumping. The proposed modal is successfully tested and implemented in benchmark problems. If the numerical simulation results are observed, the results demonstrate the benefits of MOTLBO compared with the multiobjective ant colony optimization (MOACO), differential evulotion (DE), and RKV-TCQ methods in obtaining satisfactory Pareto-front solutions. This research contributes to improving construction project scheduling and decision-making.

From the results, it is clear that the applied MOTLBO algorithm is proficient of finding optimum solutions for the small 7 activities and 13 activity problems. For the small 7 activities the proposed algorithm is able to achieve Pareto front solutions with an average deviation of %0 from the optimal costs and a smaller number of function evaluation. Similarly, 13 activity problem could provide Pareto front solutions with an average deviation of %0.7 from the optimal solution. Further research can be extended to the optimization model which considers the safety factors along with the new variants of the OBL technique i.e comprehensive learning strategy.

The Importance of Value Engineering in Construction Industry

B. Ozbas and E. Bostancioglu
İstanbul Kultur University, Institute of Graduate Education, İstanbul, Turkey

Abstract

Sustainable development is one of the most important strategies in responding to social, economic and environmental problems. The construction sector is an important sector with social and economic support for national sustainable development due to its great impact on the gross domestic product of both developed and developing countries. In order to provide cost efficiency, improve project performance, improve quality, use new technologies, reduce the use of raw materials, Value Engineering (VE) has been adopted by public and private companies in the construction sector in many countries. In this study, a literature review will be conducted and it will be evaluated by classifying the areas of use of value engineering and the contributions they provide to the construction sector on a country-by-country basis according to the frequency of repetition in the sources in the literature using the content analysis method. Thus, the areas of use of value engineering in the construction sector and the benefits they provide, as well as their weights, will be determined on a country-by-country basis. An assessment will be made by comparing the areas and frequencies of use in Turkey and other countries, taking into account the characteristics of the countries.

Keywords: *construction industry, sustainable development, value engineering.*

Introduction

Increasing competition in the business world, aggravation of economic conditions, reduction of natural resources has caused various searches in the construction sector. For many years, value engineering has been applied to provide innovative ideas and solutions to increase the project value in construction projects around the world. (Masengesho, 2021) Value engineering has been used in public and private sector. It has contributions to reduce costs, improve performance, use the material, labor and time effectively, increase the production capacity, reduce the construction time, and increase the functional utility of design, environmental protection, and the use of new technology.

In the literature review conducted on Web of Science, 67 publications have been accessed in various fields on value engineering applications. 53 publications have been made in China on value engineering applications. There is one publication in the field of Industrial Engineering in Turkey (Web of Science, 2022).

42 of the 67 publications are covered by the construction sector. Figure 1 shows the number of publications related to value engineering applications in construction sector for different

countries. China has 31publications on value engineering applications in construction sector. The USA has 3 publications. Also, The Czech Republic, Iran, Pakistan, Sri Lanka and Saudi Arabia has publications on value engineering applications in construction sector. In the literature review conducted on Web of Science, Turkey has not a publication on value engineering applications in construction sector. Although there are graduate theses related to this subject, there has been no publication within the scope of Web of Science.

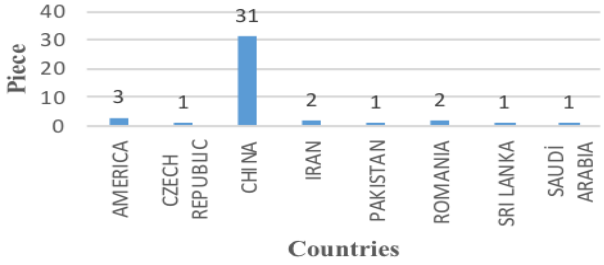

Figure 1: Number of publications on value engineering applications in construction sector for different countries (Source: Web of Science).

As of 1997, Value Engineering has been used extensively in public contracts in the United States with government encouragement and government enactment. The ratio of the profit obtained by Value Engineering to the budget of the entire business is not to be underestimated. Figure 2 shows the ratio of the profit from the application of Value Engineering on highways as of 1997 to the budget of the entire business. The contribution of Value Engineering to reduce costs has been used in highway applications for many years (Save summary report).

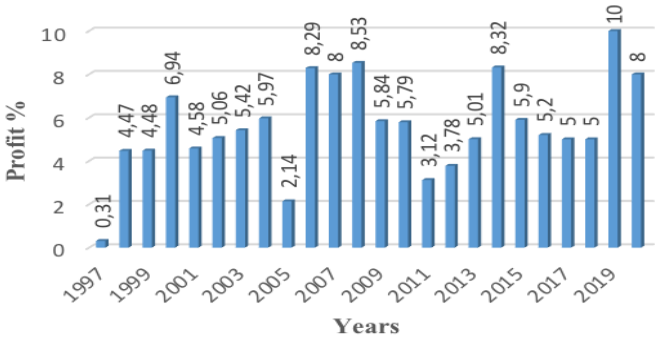

Figure 2: The ratio of the profit obtained from the State-Supported Value Engineering Works of Highways in the United States of America over the years to the budget of the entire business (Source: Save summary report).

It is known that there are various contributions of value engineering applications in developed countries such as Malaysia, Japan, the United Kingdom, and the United States (Wei, 2021). It is aimed to call attention to the contributions of value engineering and to generalize the use of value engineering in Turkey.

Method

After the publications about value engineering applications in construction sector have been scanned on Web of Science, the contributions of value engineering in construction sector will be specified and the contributions will be assessed for different countries. The flowchart of the method is shown in Figure 3.

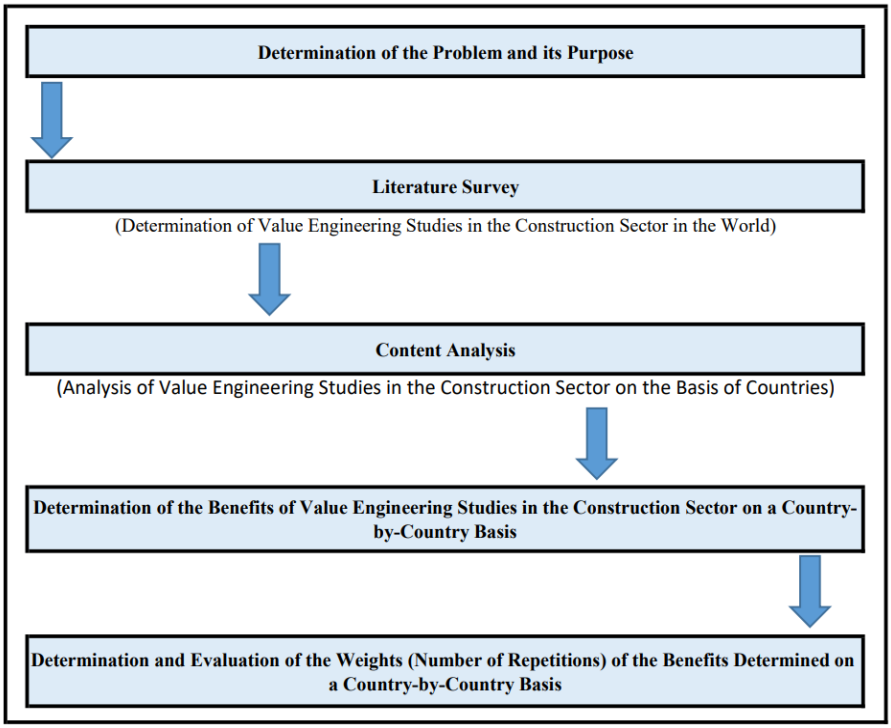

Figure 3: Flow chart of the method.

Content analysis is a method of analyzing written, oral or visual communication messages. (Cole, 1988) It allows the researcher to test theoretical issues to enhance understanding of the data. Through content analysis, it is possible to distil words into fewer content related categories. It is assumed that when classified into the same categories, words, phrases and the like share the same meaning (Cavanagh, 1997) It is the systematic examination of text and field notes by identifying and grouping themes and coding, classifying and developing categories (Jonge et al., 2007) In qualitative content analysis, the results are presented in the form of categories and/or themes. (Graneheim et al., 2017).

Content analysis is an appropriate method that can be used to scan the texts in the literature to classify the contributions of value engineering with specific words. When scanning the relevant literature within the scope of the content analysis method, the frequency of the contributions of value engineering in construction sector will also be revealed.

Determining the Contributions of Value Engineering Applications

The areas and the contributions of value engineering applications the construction sector will be determined by the content analysis method. The frequency of the contributions will be determined on the basis of countries. The steps of the content analysis are described below.

Determination of the Sample

The sample has been selected as the publications about value engineering applications in construction sector. In order to reach the data, the publications on Web of Science have been scanned. There are 42 publications about the value engineering applications in construction sector. 40 of them are articles and 2 of them are books.

Determination of Categories

In content analysis, the determination of the sample is followed by the determination of the categories step. In the analysis carried out; the contributions of value engineering applications in construction sector have been determined from 42 publications. When determining the categories, similar contributions has been collected under a same category. Contribution categories has been determined as “reducing cost”, “improving performance and coverage”, “reducing working time”, “increasing the functional utility of design”, “increasing total value/quality”, “contribution to environmental protection”, “supporting the new technology use". The contribution categories of value engineering in construction sector for different countries are seen in Table 1.

Table 1. The contribution categories of value engineering in construction sector for countries.

	Country	Publication	Contribution Categories

Data Analysis

Identified categories have been assessed on the basis of the 42 publications. Abstracts of the 42 publications have been reviewed and the categories identified have been analyzed based on the words in the abstracts. The countries of publications have been assessed, too. As can be seen from Table 1, multiple contributions of value engineering applications have been discussed in many countries.

Determination of the Counting System

Frequency of the data has been considered as counting system. Data in Table 1 have been assessed and the number of occurrences of categories has been established which then has been demonstrated in a graph in Figure 4. As a result of the analysis, we have found out the number of times categories have been featured in the publications and the most frequently featured categories.

Evaluation of the Findings

The contributions of value engineering applications in construction sector have been analyzed from the literature. The contribution categories of value engineering applications have been assessed in Table 1. Frequency of the contribution categories in terms of countries has been specified and the assessment is seen in Figure 4.

In 42 publications in the literature, “reducing cost” has been repeated 32 times, “improving performance and coverage” has been repeated 23 times. "Reducing cost" is the most important contribution of value engineering applications in every country except Saudi Arabia. The country where the most value engineering studies are carried out in construction sector is China. China has 31 publications on Web of Science. In the 31 publications in China, “reducing costs” has been repeated 23 times, “improving performance and coverage” has been repeated 18 times, “reducing working time” has been repeated 3 times, “increasing the functional utility of design” has been repeated 7 times, “increasing total value/quality” has been repeated 9 times, “contribution to environmental protection” has been repeated 7 times, “supporting the new technology use" has been repeated 5 times. “Reducing cost” has been the most important contribution of value engineering applications in China.

As shown in Table 1 and Figure 4, publications in the United States have focused on the contributions of “reducing costs” and “improving performance and coverage”; while publications in Czech Republic have focused on the contributions of “reducing costs”, “improving performance and coverage” and “reducing working time”. Publications in China have focused on “reducing costs”, “improving performance and coverage”, “reducing working time”, “improving the functional utility of design”, “increasing total value/quality”, “contribution to environmental protection” and “supporting the new technology use". Publications in Iran have focused on the contributions of “reducing cost” and “improving the functional utility of design”, while in Pakistan have focused “reducing cost”, “improving the

functional utility of design", "increasing total value/quality". The contribution of "increasing total value/quality" has only been mentioned in publications of China and Pakistan. "Contribution to environmental protection" category has been discussed in publications of China and Sri Lanka.

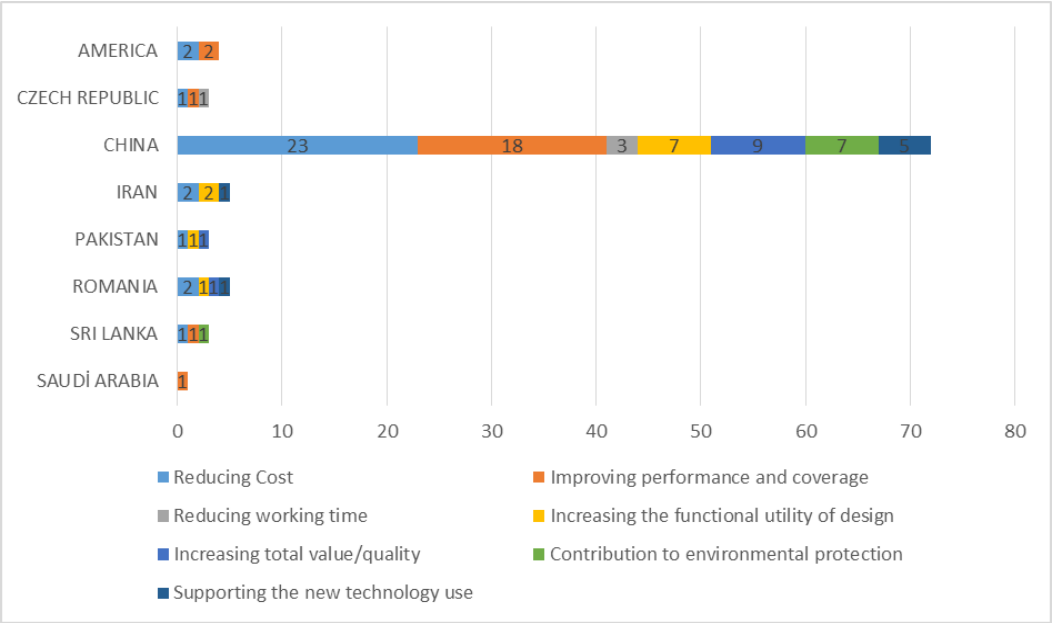

Figure 4: Frequency of contribution categories of value engineering applications in terms of countries.

The publication about value engineering applications of Turkey on Web of Science has been about mass production. The study conducted in the field of Industrial Engineering was published in 2022. In this study, the contributions of value engineering such as "reducing cost" and "improving the functional utility of design" have been emphasized. Although there are no publications on value engineering applications in construction sector of Turkey on Web of Science, there are 8 graduate theses about this subject. These studies were conducted between 1994 and 2021 (YOK Thesis Center).

As shown in Figure 5, 6 of the 8 theses focus on the contribution of "reducing cost", while 5 of them focus "increasing total value/quality". The contribution category of "improving performance and coverage" has not been mentioned in graduate theses of Turkey.

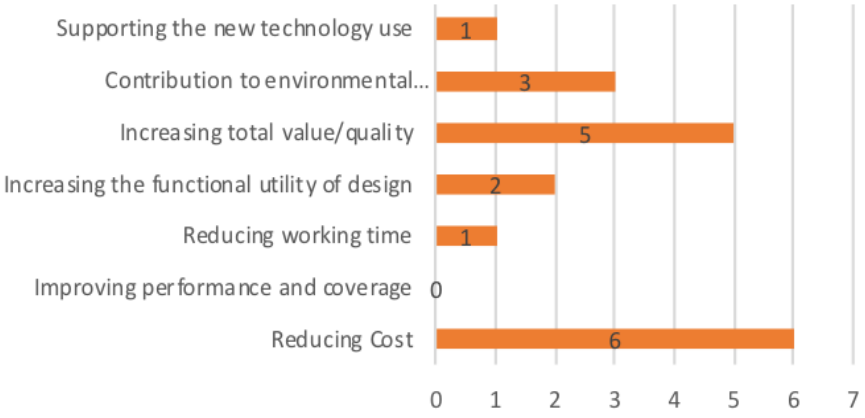

Figure 5: Contributions of value engineering applications in construction sector of Turkey (Source: YÖK Thesis Center).

It has been observed that the most contribution of value engineering applications in construction sector is "reducing cost" in the publications of Turkey like the other countries. Although the contribution of "improving performance and coverage" has been mentioned in the publications of USA, Czech Republic, China, Sri Lanka and Saudi Arabia; this contribution has not been emphasized in graduate theses of Turkey. The contribution of "improving performance and coverage" has been the only mentioned category in publications in Saudi Arabia. "Increasing total value /quality" contribution has been discussed in the publications of China, Pakistan and Romania like Turkey.

Conclusion and Recommendations

As a result of the content analysis, 42 of the 67 publications related to value engineering applications in the literature belong to the construction sector. China has 31 publications on value engineering in construction sector. In publications of China, the most important contribution of value engineering is "reducing costs", while the second place is focused on "improving performance and coverage". The most repeated contribution in all publications is "reducing cost". It shows the impact of the economy on the construction sector on a global basis. Publications in all countries except Saudi Arabia have focused on the contribution of "reducing cost". The problems in the economy have caused the studies to focus on this issue.

After the assessment of the contributions of value engineering applications in the construction sector, it is seen that the aim of the value engineering application differs depending on the level of development and economic situation of countries. There is no publication on Web of Science examining the contributions of value engineering in construction sector of Turkey. Developed and developing countries has provided different contributions from value engineering applications in construction sector. Turkey can provide contributions from value engineering applications in public and private organizations.

Abstract

Construction equipment plays an important role in construction projects. It is commonly acknowledged that decisions regarding the type of equipment to use on a construction project have a significant impact on the success of a construction project. Even though researchers have generated quite a volume of academic studies on selection of the type of equipment to use on a construction project, a limited number of studies focus on the selection of a spare parts supplier. The selection of a spare parts supplier is as important as the selection of the type of equipment to use because the production may stop when the construction equipment breaks down. At this point, the equipment starts only costing money to its owner rather than providing a benefit. Therefore, this study proposes an integrated multi-criteria-decision-making (MCDM) model that will assist decision makers to select the most appropriate spare parts supplier. The proposed model consists of two stages: (1) the criteria weights are calculated using Decision Making Trial and Evaluation Laboratory (DEMATEL), (2) the ranks of the suppliers are determined via Technique for Order Preference by Similarity to Ideal Solution (TOPSIS). It is expected that the proposed model will provide a beneficial framework for the selection of spare parts suppliers.

Keywords: *construction equipment, spare parts supplier, decision making.*

Introduction

In the construction industry, contractors perform several types of construction activities which may require different types of construction equipment. The use of construction equipment is essential in completing construction projects whether it is a residential construction project or an infrastructure construction project. In other words, construction equipment is widely used in construction projects (Uzun, 2012). For example, in Turkey, according to values taken from, a total of 88,000 new construction equipment has been sold in Turkey in 67 years (T.C. Ministry of Industry and Technology, 2009). According to the report published by IMDER (Turkey Construction Equipment Distributors & Manufacturers Association) in 2018, the quantity of construction equipment sales increased from 4.400 to 12.030 from 2009 to 2017. Hence, it is no wonder then that the equipment usage is as important as other factors that may have an impact on the success of a construction project (Day & Benjamin, 1991). Therefore, researchers have conducted numerous studies and proposed many different models to select most appropriate construction equipment in construction projects. However, in the literature, the

studies that focus on selecting spare parts supplier are limited. The selection of a spare parts supplier is as important as the selection of the type of equipment to use because the production may stop when the construction equipment breaks down. For that reason, the purpose of this study is determined to develop an integrated multi-criteria-decision-making (MCDM) model that will assist decision makers to select the most appropriate spare parts supplier. For this purpose, first, a literature review was performed. In addition, interviews were conducted with participants (purchasers, site managers, construction equipment renters) of supplier decision processes to determine the criteria which are directly or indirectly related to spare parts supplier selection. Then, an integrated multi-criteria-decision-making (MCDM) model is proposed to assist decision makers to select the most appropriate spare parts supplier in construction projects. The proposed model uses Decision Making Trial and Evaluation Laboratory (DEMATEL) and Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) methods. While DEMATEL method is used to determine the criteria weights, the spare parts suppliers are ranked due to their appearances and criteria weights with the help of TOPSIS method. A case study was carried out to illustrate how the proposed model can be applied in a real-life case.

The Proposed Model

The proposed model is developed thorough several steps. First, the spare parts supplier selection problem is defined. Identification of the decision-making group responsible for the spare parts supplier selection process is the second step. The main and sub-criteria of the spare parts supplier selection problem are determined by this decision-making group. In addition, the hierarchy and direct-influence matrices of the spare parts supplier selection problem are formed by the decision-making group. This step is followed by the step of calculating the weights of the main and sub-criteria by DEMATEL method.

After that, the computation steps of TOPSIS method are followed to develop the model. First, the decision matrix which shows the evaluations of the decision-making group on spare parts supplier alternatives is constructed. In the following step, the weighted normalized decision matrix is constituted via using the weights of main and sub-criteria that are calculated by DEMATEL method. Then, positive and negative ideal solutions for criteria and the distances of the supplier alternatives to these solutions are computed. In the final step, these distances to positive and negative ideal solutions are used to rank the spare parts supplier alternatives in descending order.

The DEMATEL method was introduced by the Geneva Research Centre of the Battelle Memorial Institute with the purpose of analyzing multifaceted connections between matrixes (Gabus & Fontela, 1972). It is commonly claimed that DEMATEL method is strongly beneficial to identify the connections between reasons and outcomes (Si et al., 2018). A review of the recent literature reveals that the DEMATEL method is used in development of several decision-making models. Moreover, the studies conducted to improve the DEMATEL method have expanded the variety of fields in which it can be used (Si et al., 2018). According to Celik and Akyuz (2015), the DEMATEL method consists of the following stages:

Stage 1: Constructing the direct-relation matrix (A) using a scale of 0 to 4 (see Table 1).
Stage 2: Determining the normalized direct-relation matrix (X).
Stage 3: Obtaining the total influence matrix (T) with derivations.
Stage 4: Computing the threshold value (a).

Stage 5: Constructing the casual diagram.

Table 1. The linguistic scale.

Linguistic Terms	Influence Score
No influence	0
Very low influence	1
Low influence	2
High influence	3
Very high influence	4

The TOPSIS method was firstly presented by Hwang and Yoon (1981). Researchers consider this method as one of the most important MADM methods. It is mainly based on finding the best option via identifying the shortest geometric distance from the positive ideal solution (PIS) and the longest geometric distance from the negative ideal solution (NIS) (Assari et al., 2012). According to Çam et al. (2015), the calculation stages of the TOPSIS method consists of the following stages:

Stage 1: Formation of the decision matrix with n alternatives and m criteria
Stage 2: Formation of the normalized decision matrix.
Stage 3: Formation of the weighted normalization matrix.
Stage 4: Determination of Positive Ideal Solution (A^+) and Negative Ideal Solution (A^-).
Stage 5: Calculation of the distances between alternatives.
Stage 6: Determination of relative margins from ideal solution.
Stage 7: Ranking the alternatives.

In this study, the DEMATEL method is used for calculating the weights of given criteria and the TOPSIS method is used for determining the best spare parts supplier alternative.

Case Study: Spare Parts Supplier Selection Using the Proposed Model

The illustration of the proposed model can be best demonstrated by a case study. This case study focuses on a procurement problem of a company that performs geotechnical construction. This company is specialized in mini-piling, bored piling, anchoring and jet grouting. The use of construction equipment is very common in activities related to geotechnical construction. The geotechnical construction companies may maximize their profit and productivity, if they maintain their construction equipment carefully. Spare parts play a critical role in these maintenance stages. Therefore, the case of a spare parts supplier selection problem of a geotechnical company is used in this study.

In this study, the main criteria and sub-criteria are identified via a comprehensive literature review and conducting interviews with professional who are involved in decision making process of spare parts supplier selection. There are five main criteria used in this study, namely, (1) Financial, (2) Supplier, (3) Delivery, (4) Service, and (5) Quality. The first main criterion (i.e., Financial) has three sub-criteria, namely, (1) product price, (2) payment terms, and (3) quantity discount. There are four sub-criteria of the second main criterion (i.e., Supplier), namely, (1) number of employees, (2) reputation, (3) production capacity, and (4) financial capability. Another main criterion “Delivery” also has four sub-criteria, namely, (1) lead time, (2) percentage of on-time delivery, (3) percentage of order fulfillment, and (4) geographical

location. The fourth main criterion (i.e., Service) has four sub-criteria, namely, (1) communication ability, (2) response speed, (3) buyer-supplier relationship, and (4) after-sales services. If one takes a closer look at the fifth main criterion (i.e., Quality), one will notice that it has three sub-criteria, namely, (1) percent of rejections, (2) duration of use, and (3) insurance/warranty. In this case study, the geotechnical construction company has six different spare parts supplier alternatives which are named as Supplier 1, Supplier 2, Supplier 3, Supplier 4, Supplier 5 and Supplier 6. The decision hierarchy of the spare parts supplier selection problem is presented below (Figure 1).

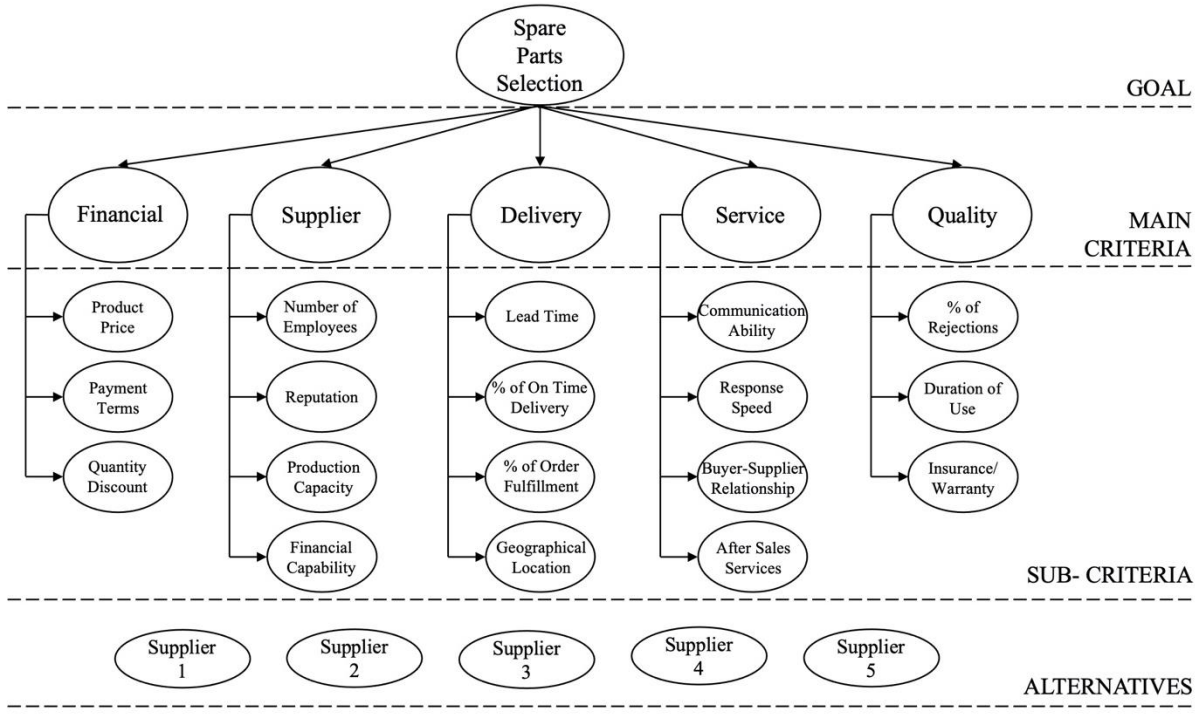

Figure 1: Hierarchy of the spare parts supplier selection problem.

Following the development of the decision hierarchy of the spare parts supplier selection problem, the weights of the main criteria and sub-criteria must be calculated via utilizing DEMATEL method. To calculate these weights, the proposed model needs pairwise comparison matrices of the main criteria and sub-criteria. These pairwise comparison matrices are formed by three decision-makers. Since there is a need of making a group decision, three pairwise comparison matrices are aggregated using the arithmetic means of each preference. Thus, the weights of the criteria of spare parts supplier selection problem are computed via the DEMTAEL method (Table 2).

Table 2. Aggregated pairwise matrix of criteria for the spare parts supplier selection problem.

Criterion	Product Price	Payment Terms	Quantity Discount	No. Of Employees	Reputation	Production Capacity	Financial Capability	Lead Time	% of on time Delivery	% of Order Fulfillment	Geographical Location	Communication Ability	Response Speed	Relationship	After-Sales Service	Percent of Rejections	Duration of Use	Insurance/Warranty	**Weights**

The findings of the study reveals that the “Product Price” criterion has the greatest weight (i.e., 0,110) among the criteria. Since the product price is commonly a game changer in a procurement process, it is no surprise that it has the greatest weight. On the other hand, the second and third greatest weight belong to “Reputation” and “Relationship” criteria, respectively. These results can be interpreted as an expression of that decision makers attach more importance to trust and social factors when the product price is determined. The fourth and fifth highest ranked criteria were “Payment terms” and “Quantity discount”, respectively. However, some professionals state that these criteria may have more importance in unstable economies. The “Percentage of rejections” criterion has the lowest weight among the spare parts supplier selection criteria.

In the second phase of the proposed model, TOPSIS method is employed to determine the ranking of the spare parts supplier alternatives. Decision makers evaluated six spare parts suppliers by considering 18 different sub-criteria. Several significant measurements were used for these evaluations. Product price is a cost criterion which is measured in terms of dollars. Payment terms, reputation and communication ability were measured on a scale of 1-9 where a greater number is desirable. For quantity discount, percentage of on-time delivery, percentage of order fullfillment and percentage of rejections were determined in percentages. Number of employees and buyer-supplier relationship were measured in numbers. On the other hand, response speed, lead time and duration of use were measured in days. For lead time and response speed criteria, a lower number is preferable where a greater number is preferable for duration of use criterion. Production capacity is the amount of goods which the supplier can manufacture monthly and financial capability is the yearly endorsement of the supplier companies which defined with dollars. Geographical location criterion was measured in kilometers by considering the distance between the company and supplier. After-sales services and insurance/warranty were measured in terms of presence/absence (i.e., 0 for absence and 1 for presence). The initial decision matrix of evaluation criteria for spare parts supplier alternatives is given in Table 3.

Table 3. Initial decision matrix of evaluation criteria for six spare parts supplier alternatives.

Criteria	Measurement Unit	Supp. 1	Supp. 2	Supp. 3	Supp. 4	Supp. 5	Supp. 6	Sum
Product price	**k $**	6.25	6.68	7.35	6.4	6.65	6.55	16.303
Payment terms	**1-9 scale**	5.31	5.65	4.64	5.94	5.94	7	14.189
Quan. Discount	**%**	6	5	4	2	7	4	12.083
# of Employees		4	4	6	5	3	4	10.863
Reputation	**1-9 scale**	7.65	6.32	6.32	7.65	7.65	7.32	17.578
Prod. Cap.		400	350	300	250	450	450	916.51
Fin. Cap.	**k $**	300	200	250	150	125	280	555.9
Lead time	**day**	2	2	1.5	1	2	1,5	4.183
% of on-time delivery	**%**	95	92	90	95	91	90	225.821
% of order fullfillment	**%**	85	80	90	90	90	95	216.679
Geog. location	**km**	5	3.5	8	6	13	9,5	19.912
Comm. Ability	**1-9 scale**	6.32	6.65	7.32	6.32	6.65	7.27	16.572
Response speed	**day**	1.15	1.65	1.65	1	0.63	1	3.026

Buyer-supplier rel.		4.76	3.48	5.09	2.62	8	3.04	11.865
After-sales services	**0-1**	0	1	1	0	0	1	1.732
% of rejections	**%**	5.5	3.5	5	4.5	5	5	11.737
Duration of use	**day**	250	200	300	300	200	400	694.62
Insurance/Warranty	**0-1**	1	1	0	1	0	1	2

After forming initial decision matrix of evaluation criteria for spare parts supplier alternatives, the items of it were normalized. Following this step, the weighted normalized decision matrix was developed. Then, the Positive Ideal Solution (A^+) and Negative Ideal Solution (A^-) were determined. Afterwards, the distances of spare parts supplier alternatives from these ideal solutions were calculated. After completing the mathematical calculations of TOPSIS method, the proposed model ranks the spare parts supplier alternatives (Table 4).

Table 4. The result matrix of TOPSIS method.

Alternatives	Si+	Si-	Ci	**Ranking**
SUPPLIER 1	0.042	0.042	0.504	3
SUPPLIER 2	0.042	0.045	0.512	2
SUPPLIER 3	0.041	0.040	0.495	5
SUPPLIER 4	0.055	0.033	0.375	6
SUPPLIER 5	0.048	0.048	0.497	4
SUPPLIER 6	0.040	0.046	0.538	1

According to the findings obtained in this study, SUPPLIER 6 is the best alternative as it has the maximum value for the relative closeness. On the other hand, when one reviews the values of relative closeness for the other alternatives, one will observe that SUPPLIER 2 and SUPPLIER 1 are the second and third most appropriate alternative, respectively.

Conclusion

In the construction industry, it is commonly acknowledged that decisions regarding the type of equipment have an impact on the success of a construction project. If one reviews the literature, one will notice that there are several studies on selection of the type of equipment to use on a construction project. However, there is a limited number of studies that focus on the selection of a spare parts supplier. The selection of a spare parts supplier is as important as the selection of the type of equipment to use because the production may stop when the construction equipment breaks down. This kind of importance makes the selection of spare parts suppliers a compelling task for decision makers. The study presented in this paper is initiated as a response to the lack of an integrated multi-criteria-decision-making (MCDM) model that will assist decision makers to select the most appropriate spare parts supplier. The illustration of the proposed model is demonstrated by a case study. DEMATEL method is employed to calculate the weights of the main and sub-criteria in the first stage of the proposed model. After that, TOPSIS method is used to determine the ranking of 6 spare parts supplier alternatives. The

findings of the study reveal that the Supplier 6 is the most appropriate alternative. The results also show that the proposed model is beneficial and appliable in selection of spare parts supplier in the construction industry. Future can consider using different MADM techniques in order to make comparisons.

Abstract

Information search is a research area under the cognitive sciences to study decision making and judgement processes: It focuses to understand information acquisition and cognitive insights of decisions and judgements by using several process training approaches such as information boards, eye fixation, active information search, thinking aloud protocols, etc. Information search has been the focus of interest in the several research areas in the literature such as marketing, business management, psychology, legal and healthcare issues. Yet the impact of information search has not yet revealed in the construction management studies. This research aims to introduce the use "Active Information Search" as a research method to the construction management literature. The proposed research method could lead to the use of information search in the construction management literature to derive inferences about decision making processes by analyzing changing variables such as content, context and time, cognitive and heuristics backgrounds as well as uncertainty and subjectivity effects. A research design based on "Active Information Search" is to be presented to illustrate its application protocols and also the utility of the method.

Keywords: *active information search, construction management, decision making, research methods.*

Introduction

Cognitive science focuses on information acquisition and cognitive representation studies by using different process training methods that explore the cognitive processes and the tools and techniques of decision-making processes (Kühberger et al., 2011). Basically, these methods focus on the fields of information acquisition, integration, evaluation and the psychological and neurological insights of cognitive processes through a two-step analysis approach that includes indicating cognitive attributes and collecting data for hypothesis testing. Various methods under each field of study have been developed to analyze decision making processes such as information boards, eye fixation, Active Information Search (AIS) is located the under information acquisition; thinking aloud protocols, structured response dictation under information integration and evaluation; and final reaction time, Galvanic skin conductance,

Pupil dilation and eye-tracking, and neural techniques of the location under cognitive process analysis (Kühberger et al., 2011).

In this study, Active Information Search (AIS) method is analyzed in detail and its potential contribution to the construction industry will be presented. The main reason to focus on AIS method is that it allows to analyze decision makers' attitudes and interests under risky decision-making processes that includes subjectivity and probabilities (Huber et al., 2011). Some research areas that attach importance to stakeholders' decisions in construction industry practice such as design and group decision making processes, user/consumer pattern analyses, marketing, work environment improvements and entrepreneur management, etc. in order to take the advantage of AIS method and other information search methods by detail analyzing risky, uncertainty, subjectivity, heuristic, explanatory insights of decisions (Schulz-Hardt et al., 2000; Dhami & Harries, 2010; Urbany et al., 1989; Ozanne et al., 1992; Loibl & Hira, 2009; Cooper et al., 1995). Within the framework of this paper, methodological background of the AIS method will be summarized, and a research design is illustrated to indicate its application protocols and also the utility of the method in the construction industry.

Active Information Search as a Decision Analysis Method

Active Information Search (AIS) method has been developed to analyze risky decisions with respect to the subjective values and the probabilities of decision makers (Huber et al., 1997; Huber & Seiser, 2001; Huber et al., 2009; Huber et al., 2011). With the AIS method, information search, justification pressures and risk defusing operators (RDOs) in risky and natural decision-making processes can be evaluated. Justification with respect to explaining and believing reason of choosing is shaped by justification pressures that are mainly externally sourced. With the AIS method, the justification pressures ending up with risk defusing operators (RDOs) are developed by decision-makers to defuse or decrease risk in decisions (Huber & Seiser, 2001; Huber et al., 2009; Huber & Huber, 2008).

The analysis of decision of AIS method begins with presenting decision tasks/scenarios to subjects (participants or experiments). Subjects ask questions about the proposed tasks to understand the details of task. Analyzers consider this process as a pilot study to reconsider decision tasks and constituting coding schemas that are used in question phase and verbal protocols. Coding schemas can be prepared by considering the approach of subjects on indicated protocols such as the protocol based on probability, evaluation, new alternatives, worst-case planning, control, long-term plans, decisions, irrelevant and not categorical categories (Huber et al., 1997; Huber & Seiser, 2001; Huber et al., 2009; Huber et al., 2011). After this process, analyzer ask for the decisions of subjects in written or verbal formats to begin to analyze cognitive representation of their decisions (Huber et al., 2009). Qualitative data derived from the process of question and answer are transformed into quantitative data by using coding schemas. After that statistical analyses are applied to understand decision making patterns (Huber et al., 1997; Huber et al., 2009). The table below summarizes phases of the AIS method (Table 1) (Huber et al., 2011).

Table 1. Phases of active information search method (Source: Huber et al., 2011).

Phases and Components of Active Information Search Method	
The phase of Information Acquisition and Coding	
Reading	-giving quasi-realistic scenarios -explicitly mention the possibility of the negative outcome -no probability provided
Questions	-participant asking questions to obtain more information -the question coded by the experimenter (code is recorded)
Answers	-for each question, the experimenter presenting an answer in printed or computer (for standardization purposes and avoiding non-verbal influences)
Decision	-after having sufficient information, a decision is given by the participant
The phase of Construction of AIS Scenarios and Categorization of Questions	
Selection of Topic	-should be interesting -the participant should not know much knowledge about the topic for preventing external search -testing topic by informally interviewing a few participants of the same population -can be used for both expert and non-expert decision making analysis
The first version of Basic Description and Preparation of Answers	-including the role of the participant and a short description of the decision situation -description of alternatives -brainstorming for indicating possible questions to answer -generating appropriate answers -during the application, only the code of answer is recorded (*in the basic type of AIS)
Optimization of Task Description and Answers	-modifications for indicating the dominance of alternative, the implausibility of fact and rich description of the task -thinking aloud procedure (can be costly and time-consuming, post-experimental interviews, testing task description by generating a list of questions can be helpful methods to use
Categorization of Questions	-required for the information acquisition process -coding scheme to capture the category of question and test model comprehensibility
Problems in Coding Scheme	-considering additional issues during the construction of questions and answers as well as coding during the process
-construction of answer	-considerations; type of questions and its order, proposing RDO that are actions to choose an alternative to minimize risk and its applicability, negative event identification, the scale used for answers, existence and probabilities of RDOs, answering new alternative options
-procedural issues	-problems; asking more questions for the same alternative, asking for facts that are already described, repeated questions for positive and negative consequences -has to be standardized -asking for more precise and reformulated questions -comparing the importance
-reliability of the coding scheme	-required for questions and answers and validity of research -inter-rater reliability (Cohen's Kappa) of the coding system should be tested in pre and final processes
Statistical Analyses	Raw data analyzed in different ways; -quantity of information in total and specific coding category -the sequential aspect of information search; Parametric analysis for several questions analyzed Mann-U and Wilcoxon tests for biased means due to repeated and 0 questions Logit analysis for concurrent analysis of several factors varied between subjects by fitting them in a hierarchy of logic model for identification of effective factors Sign and Cochran Q tests for factors varied within sub-headings

In the task/scenario preparation, two different perspectives can be considered both in (1) design and (2) application phases. In task design, (1a) descriptive and (1b) empirical approaches are considered. In descriptive approach, decisions can be design two ways that are choice and judgement. While choice focuses on preferable outcomes, judgment considers subjective values in the decisions. In empirical perspective, two ways of process design that are outcome and process oriented are considered. While the outcome-oriented process design emphasizes on radical and specific decisions, process oriented analyzes pre and post decisional phases (Huber & Seiser, 2001). The application of AIS method can be also differentiated with respect to (2a) process and (2b) behavior dominated. The process dominated is designed to make a decision based on monetary aspects whereas the behavior dominated analyzes risk with respect to utility and subjective probabilities.

The presentation of information may also vary (Huber et al., 1997). Accordingly, information can be presented completely and administered by the task giver. In the administered option, two main types of AIS procedures that are basic and list type are summarized in the below table with respect to advantages and disadvantages (Table 2) (Huber et al., 2011).

Table 2. Types of presenting AIS method (Huber et al., 2011).

Types of AIS procedure	
Basic Type	**List Type**
Advantages: -**does not push information** to the participant	**Advantages:** -questions are designed and presented to participants that can **ask more questions** -questions do not have to be coded during experimental sessions; **practical advantages** -behavior coded that **eases implementation** of alternative attribute matrix in computer -**alerting participant about risk diffusing operators** -can be used in **Internet experiments**; chatrooms, e-mail; sending questions, responding and answering and web-based processes
Disadvantages: -questions **administered during the experiment** -questions are **coded during the experiment** -**no structure** for information search -participant may **not be aware of RDOs** -applied **only face-to-face**	**Disadvantages:** -**computerized AIS application**, WebDib (ability to judge text is low that may result in unexpected results) -**cost of information** in monetary and computational aspects in terms of the number of questions and their choice by the participant, indicating several questions and type of information

In the literature different scenarios/tasks are applied to conduct AIS method. Some of them are listed as;

- Post office task: Evaluating the pros and cons of renting/not renting the hall by the post office manager in the village that is resulted deciding whether to be appointed to the permanent position at the end of the decision made by post office manager (Huber et al., 1997),
- Machine task: Buying decision of a small factory owner between two machines that have different advantages and disadvantages to fulfil orders (Huber et al., 1997),

- Choice of head for corrective home: Decision of a member of the board of directors to be head of corrective home for criminal adolescents from a group of different personal characteristics having different importance (Huber & Seiser, 2001),
- Virus task: Evaluating the situation of two alternative treatments that can be applied for your spouse who has a lethal virus during the trip and deciding on the type of treatment (Huber et al., 2009),
- Gamble task: Conservation program manager's decision to place the endangered lemur species in one of eight alternatives (Huber et al., 2011).
- Maki task: Selection of a gambling alternative according to the possible wins and losses of the two gambling alternatives consisting of their selection from different tasks (Huber et al., 2011).
- Turtle task: To choose between a coast or an island that offers different living conditions in order to determine the natural habitats of the endangered turtle species (Huber et al., 2011).

As it is seen in the applied task/scenarios, stories include several risks or options to make decisions that are also affected on risky results. This circumstance can be seen almost any phase of design and construction practices. To give some examples.

- Any decision making on scope and schedule about the projects may have impact on the cost of project,
- Any decision making on the prequalification process may influence communication and stakeholder relationships,
- Any design decision may have impact on the social, the physical, the cultural characteristics of the existing physical environment,
- Any managerial decision may have influence on psychology and motivation of workers,
- Any decision making on resources and/or materials may have effect on health and safety issues and/or user/client contentment, etc.

Applying AIS method in construction practice may help to decision-makers to foresee possible risks and opportunities before they are making their final decisions. In this way, possible risks, uncertainties, problems occurring by subjectivity or heuristics can be minimized. In construction industry, organizational resilience can be improved by developing decision-makers' ability to adapt in different risky circumstances. In addition, as a natural risky situation, possible consequences of natural disasters that effect construction project in variable aspects can be studied with AIS method to develop preventive measures. Accordingly, this study aims to propose a research design that guide decision makers in the construction industry to imply AIS method more effectively.

Research Design

AIS method is begun with a decision task. Developing tasks are crucial for achieving effective conclusions to achieve a general idea about decision-makers' intentions. This research design deeply investigates decision tasks used in AIS method with the elements of Storytelling method. Storytelling is research method used for analyzing complex social interactions that allows to analyze cultural, social, natural, personal, managerial actions in a more comprehensive way to define strategic purposes of decision makers (Boje, 2006; Their, 2018; Machiavelli, 1950; Forman, 2013). The elements of story are important for revealing the

different influences of stories and achieving effective storytelling analysis. There are seven headings for defining the elements of stories that are *plot, character, theme, dialogue, melody, décor and spectacle* (Aristotle, 1954). Table 3 summarizes characteristics for each element of storytelling.

Table 3. Elements of storytelling.

Elements of Storytelling	
Plot	Indicating the **actions of characters** Actions mainly on overcoming struggles and challenges The aim is to improve positively their actions
Character	Indicating actors and their **personalities** Personalities based on emotions, needs, backgrounds The aim is to develop empathy on motivations
Theme	Indicating the **goal of the story** Focus of story
Dialogue	Indicating **what and how people talking** and not wanting to talk Emphasizing feelings
Melody/Chorus	Indicating the **ability of the storyteller** to use his/her emotions to better understand the theme
Décor	Indicating **the environment** How the environment affects teller actions and behaviours
Spectacle	The part **listening story**, remembering it and proposing discussion and ideas

This research design aims to develop a layout/canvas/template to improve the potential effects of stories that increase the power of narrative techniques. Accordingly, decision tasks applied with AIS method in the literature are systematically analyzed with the elements of storytelling. In this way, the potential of each element to influence decision-maker can be figured out and decisions tasks can be applied in different contexts (Table 4).

Table 4. AIS tasks and storytelling elements.

Reference	**Task name**	**Elements of Storytelling**						
		Plot	Character	Theme	Decor	Melody /Chorus	Dialogue	Spectacle
Huber, Wider and Huber 1997	Post office	✓	✓	✓	✓	X	X	X
Huber, Wider and Huber 1997	Machine task	✓	✓	✓	✓	X	X	X
Huber and Seiser 2001	Choice of head of a corrective home	✓	✓	✓	✓	X	X	X
Huber, Bär and Huber 2009	Virus task	✓	✓	✓	✓	✓	X	X
Huber, Huber and Bär 2011	Gamble task	✓	✓	✓	✓	✓	X	X
Huber, Huber and Bär 2011	Maki task	✓	✓	✓	✓	X	X	X
Huber, Huber, and Schulte-Mecklenbeck 2011	Turtle task	✓	✓	✓	✓	X	X	X

As it can be seen in the table above, some elements of the stories in the AIS tasks are used, while some were never used. To examine in more detail, tasks always are begun with defining the characters and environmental conditions of the story, and then emphasizing the subject of the story. After defining these, it explains the actions of decision makers and the environment in more detail and presents all the details to the decision maker. In some tasks, thoughts of storyteller are generally not presented. Apart from this, the ideas of listener and the dialogues

among characters are not included in the tasks. Table 5 presents some of the examples from the elements of stories used in the AIS method.

Table 5. Examples of storytelling elements used in AIS tasks.

Plot	**Post office task:** deciding whether the provisional manager becomes the permanent manager or not training its middle management **Machine task:** buying an additional high-capacity machine for production to meet the demand **Head of corrective home task:** selecting criteria on the base of their average importance measured in preexperiment **Virus task:** deciding on the treatment, imagining travelling on an island **Gamble task:** assigning moderate possible gains, asking questions **Maki task:** protecting an endangered maki species **Tuttle task:** turtle living in the southern pacific is acutely threatened by extinction.
Character	**Post office task:** New provisional manager, superiors, village administration, applicants **Machine task:** Owner of factory **Head of corrective home task:** Members of executive board, head of corrective home, criminal adolescents **Virus task:** Partners, participants of pilot experiments **Gamble task:** participants **Maki task:** Manager of preservation program **Tuttle task:** Head of program, marine biologists
Theme	**Post office task:** to decide whether to rent the hall or not **Machine task:** to assume the role of the owner of a small factory that produces weatherproof credit cards for ski lifts and to buy an additional high-capacity machine for production to meet the demand. **Head of corrective home task:** to choose the head of a corrective home for criminal adolescents. **Virus task:** to decide on the treatment instead of the partner. **Gamble task:** four gambles choice tasks with two versus eight gambles as alternatives. **Maki task:** decide which one of x possible areas **Tuttle task:** to protect turtles
Décor	**Post office task:** Village h, post office, local meeting hall **Machine task:** Machine A and B **Head of corrective home task:** Corrective home for adolescents **Virus task:** Island, Treatment A and B **Gamble task:** Alternatives **Maki task:** Areas **Tuttle task:** Beach and island
Melody/Chorus	**Virus task: "**It should be noted that participants in the pilot experiments considered the disorder of the immune system as more dangerous and undesirable than the symptoms of paralysis." **Gamble task: "**We used the AIS variant that was employed in Experiment 1, with questions for positive and for negative consequences presented on cards (randomized order)."
Dialogue	Not exist
Spectacle	Not exist

After deeply examining the elements of story in the tasks, some elements are required to be existed to explain tasks in detail such as, character, plot, and theme. While character defines roles of decisions makers, plot indicates the main aim in the task and theme highlights the subjects of task. Décor is also important for decisions-makers to achieve details about existing circumstances. Melody/chorus can be used for giving details about the task that are not always required to known by the decision-maker. Dialogue and spectacle elements are not observed in the existing tasks, but dialogue may be included if decision task is related about the

relationship among decision-makers and spectacle may be included if decision task is including also community opinion.

Figure 1 presents both the elements of story used in the AIS method and also the examples for the related elements that can be used to design tasks in the constructions industry (Figure 1). Accordingly, construction activities, stakeholders and subject of story, environmental factors related with the task, personal opinions of storyteller, dialogue among stakeholders and other stakeholders that are as the observer of story can be carefully designed for adapting AIS tasks to analyze decision making process in the construction industry. In this way, tasks designed for construction industry can be effectively designed to achieve appropriate decisions used for analyses.

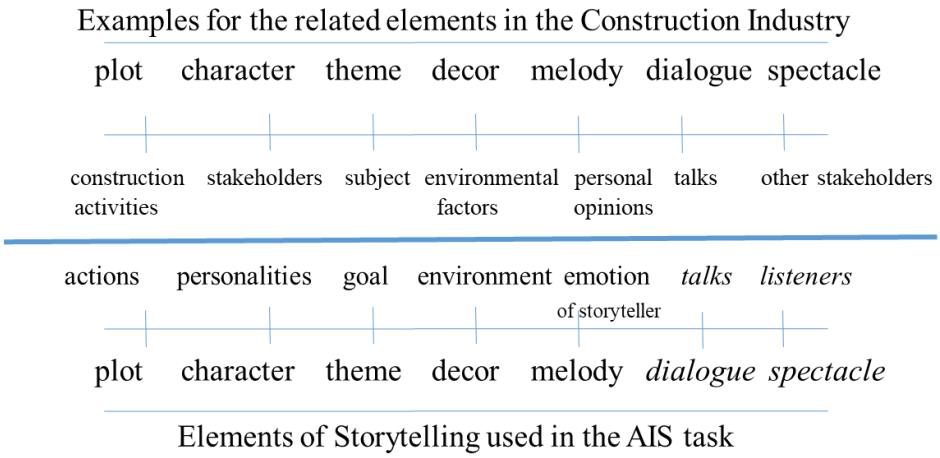

Figure 1: An outline for adapting task to construction industry.

This research design aims to provide an outline for the user of AIS method in the phase of task design. In construction industry, almost all elements of story can have important circumstances in the tasks to give information to decision-makers. In the stories written to carefully design the elements of the story, a lot of information can be obtained about the content, context and time, cognitive and heuristics backgrounds, the way the decision maker thinks and what the decisions will be. This information will be a guide for the evaluation of decision-making processes in the sub-fields of construction management both socially, physically and cognitively.

Conclusion

In this study, the possible benefits of Active Information Search (AIS) method, which is used as an information search method, in construction management studies are presented. In addition, the task part, which is the first stage of the AIS method, has been examined in detail, and a research design has been presented by examining its interaction with the elements of storytelling method in depth. In the light of the information obtained, the effects of storytelling elements used in AIS tasks on decision-making processes of the construction management were discussed and their possible benefits were emphasized.

Abstract

Building restoration is a complex process with a high level of uncertainty. It differs from many construction projects in terms of the need for research-based practices to define scope, planning, scheduling, design, supervision, decision-making, material use, construction methods, and also the legal environment. Restoration professionals can significantly benefit from the well-established discipline of project management to achieve their targets; however, available evidence shows that the use of the project management body of knowledge in restoration projects is far from the desired level. Although there are some bylaws and guides that are followed, peculiarities of the restoration projects with a project management lens are yet to be explored. This paper argues that a contemporary perspective which utilizes project management tools and techniques can contribute to the conservation of architectural heritage in line with the universal conservation principles. Following a literature review, the paper clarifies the knowledge gap regarding the management of restoration projects and identifies the key areas of concern and challenges for future research.

Keywords: *architectural heritage, conservation, project management, restoration projects.*

Introduction

Project management is a well-established professional discipline which has tools and processes that can be successfully implemented when understood; however, the situation is somewhat complicated when it comes to the management of restoration projects, because each restoration project has its own peculiarities and processes that are difficult to standardize, and most importantly, has considerable uncertainties due to the potential to contain very different techniques, materials and periods below the visible building layers (Perovic, 2015; LeBlanc, 2006; Prudon, 1986). Not all of these are easily foreseeable in the project initiation phase, and instant solutions are often required to respond to emerging situations. Moreover, restoration projects have various additional challenges regarding legislation and procedures, scope definition, tender and procurement, decision making, time and budget management, lack of information about the structure, and managing a large number of stakeholders with varying expectations. Accordingly, there is a need to question

the available project management methodologies, tools and techniques for the case of restoration projects to achieve better results in (Perovic, 2015). Although there are some sporadic studies at the intersection of “project management” and “building restoration” subjects which focus on the problems of building restoration projects, importance of project management methodologies, integration of Building Information Modeling (BIM) to these projects, or site management practices; to best of authors’ knowledge, no comprehensive study has yet investigated the management of building restoration projects in detail or proposed management model for these specific type of projects. A quick search of the academic publication databases also reveals that there is a significant knowledge gap regarding management of building restoration projects (Figure 1).

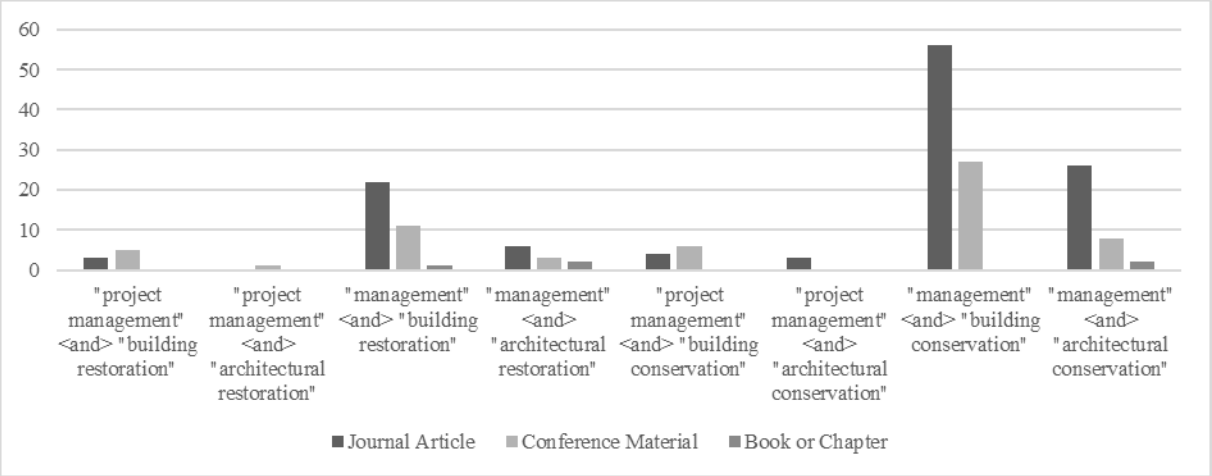

Figure 1: Search results from academic publication databases.
Sources: Scopus and Web of Science (as of June 2022)

As part of a broader research project which aims to develop a comprehensive project management model that considers the peculiarities of the building restoration projects, this paper clarifies the knowledge gap in the literature regarding the management of restoration projects and identifies the key areas of concern and challenges for future research. Following sections briefly review the literature on conservation and restoration and compare the typical new construction projects and restoration projects, before focusing on the relationship between restoration projects and project management body of knowledge.

Conservation and Restoration

There are various but parallel definitions of conservation made by different organizations (ICOMOS, 1964; UNESCO, 1972; Republic of Turkey Ministry of Culture, 1983; Australia ICOMOS Burra Charter, 2013) and researchers (Hasol, 1976; Duguay, 1992a; Earl, 2003; Burden, 2004; Ahunbay, 2007; Orbaşlı, 2008; Zakar & Eyüpgiller, 2018). Conservation can be defined in the shortest and most comprehensive way as all efforts designed to understand cultural heritage, know its history and meaning, ensure its material safeguard and as required, its presentation, restoration and enhancement (ICOMOS The Nara Document on Authenticity, 1994). It is often used with the prefix "architectural" when conservation relates to the built environment (Duguay, 1992a). The basic principles of conservation can be summarized as protecting as it is, minimum intervention, similar repair, reversible repair, distinguishable repair, self-respect and record keeping. Conservation includes physical intervention, when

necessary, where minimum is ideal, and relating strategies vary according to the degree of physical intervention (Table 1).

Table 1. Architectural conservation strategies (Duguay, 1992b).

</table>

In general, conservation can be summarized as all the processes that must be carried out in order for the building to survive without deteriorating and losing its importance, and it is essential that the conservation action is continuous. While restoration means a direct study of a piece, and even the replacement of that piece, any intervention is always under strict technical-scientific and historical-critical control (Carbonara, 2012). The main principle is to protect the originality of the building and building materials with evidence-based interventions. Since this paper approaches mainly the process based on physical interventions for architectural heritage structures, the main framework and terminology are set up as management of ‘restoration’ projects, instead of ‘conservation’ projects.

Challenges of Building Restoration Projects Compared to Typical New Construction Projects

Although there are a limited number of studies (most notables are Perovic, 2015; Duguay, 1992b; Prudon, 1986) that directly compare building restoration projects to typical new construction projects, a considerable number of studies deal with the peculiar characteristics and challenges of restoration projects in terms of practices and management. The most important aspects that stand out in the literature are as follows.

Planning and Research

Restoration projects require intensive historical and architectural research and analysis of existing conditions like survey, measurement, analytical survey, field and laboratory tests and material and structural analysis to gain an understanding of the building before the design begins, compared to a typical new construction project (Duguay, 1992b; Prudon, 1986). The planning phase is longer and more intense; moreover, the need for consultation is higher relative to new construction projects (Perovic, 2015). This phase includes the most fundamental and complex tasks for restoration projects. (Causevic et al., 2012). Searching for original drawings and records is probably one of the most important differences between a restoration practice and a new construction practice. (Prudon, 1986).

Scope Definition

Scope definition is the most difficult task for the restoration projects that are subject to uncertainty, as it is not always easy to determine the current state of the building in such projects, unlike typical new construction projects where the scope can be relatively more easily determined. (Perovic, 2015; Roy & Kalidindi, 2017). Although it is theoretically possible to reduce uncertainty by examining the building by taking samples from all materials, conducting field and laboratory tests, conducting a thorough field survey and making detailed application research; such efforts require time and budget. As a result, there is often a trade-off in this regard, and restoration projects often require decisions based on uncertainty in scope.

Stakeholders

Restoration projects have a greater number and types of stakeholders that are not typically found in new construction projects. (Perovic, 2015). According to ICOMOS Turkey Architectural Heritage Conservation Charter (2013), professionals from different disciplines specialized in the field of conservation, central and local governments, conservation boards, practitioners, property owners, universities, non-governmental organizations, the public, users, professional chambers and media organs are the main actors in the of architectural heritage. Restoration projects attract much more public, media and political attention than typical new construction projects (Roy & Kalidindi, 2017). Therefore, keeping the public's pulse right, establishing the right communication and interaction with the media and political stakeholders, and keeping open exchange of ideas with these stakeholders, when necessary, especially in buildings with monumental value, is critical for restoration projects. Ultimately, restoration projects are more likely to be successful when the decisions taken are adopted by all stakeholders (Perovic, 2015). Therefore, a consensus model should be developed with the contribution and participation of all stakeholders to manage their expectations correctly. In addition, the Conservation Boards, an external stakeholder that is not involved in new construction projects, play a decisive role in restoration projects. Conservation Boards are involved in the process at early stages such as design and even planning to determine and approve the acceptable level of intervention.

Risks

Due to the age, physical condition, qualities, and unfamiliarity with the construction techniques and materials of these structures, it is very difficult to evaluate from the beginning what will be encountered during the construction phase. Even when the research and analysis

are done in detail at the planning stage, there is always the possibility of encountering hidden layers and latent situations during the construction phase that cannot be foreseen at the beginning. In this respect, construction risks are quite high compared to new construction projects (Perovic, 2015).

Legislation

The laws, regulations and procedures to which restoration projects are more diverse and stricter than new construction projects. While customer requests are the focal point in new construction projects, the principles and procedures to be followed in restoration projects form the main basis (Perovic, 2015). This difference in legislation requires relatively longer and bureaucratic approval processes relative to new construction projects (Zolkafli et al., 2012). For a smooth and uninterrupted flow, the project process must be planned by considering these legal processes.

Freedom on Design

Unlike new construction projects, there is an understanding of taking care to preserve the existing architectural texture and to make changes in a minimum way in the restoration projects. There are severe restrictions on design freedom in restoration projects compared to typical new construction projects (Perovic, 2015).

Documentation

Although restoration projects are more demanding in terms of details, buildings that are subject of restoration are usually not fully documented, which makes it difficult to understand the relevant conditions (Prudon, 1986; Zolkafli et al., 2012; Roy & Kalidindi, 2017). The information about the building is usually in the archives and the archival information is either incomplete or does not reflect the latest situation; there is not always enough time and budget for the research, or the researcher's competence in restoration is weak; therefore, restoration projects often face the problem of managing unknown factors (Perovic, 2015). Every new finding that emerges has the possibility to pause the project and cause design and detail changes (Prudon, 1986). In addition to the need for historical documentation, restoration projects are also very demanding in terms of appropriate and adequate documentation of the intervention made. If qualified documentation cannot be produced during the planning and design phases, the frequency of returns that may slow down or even stop the work during the implementation phase is relatively higher than typical new construction projects.

Expertise and Original Materials

Some materials and production methods used in restoration projects, each involving unique situations, will be extinct, rare or unknown, and it will be difficult to work with stakeholders who are experienced in the relevant application and can meet the appropriate production quality as usually expert practitioners pool is quite narrow for restoration projects (Roy & Kalidindi, 2017; Harun, 2011; Prudon, 1986). The need for qualified people applies not only to the implementation but also to the stakeholders and team members who will participate in the project. The lack of skilled people is one of the most common problems of restoration projects (Hirsenberger et al., 2018; UNESCO, 1972). In addition, budgeting will be difficult in restoration projects compared to new construction projects, since there will be no data or similar building information to compare rare materials and techniques (Zolkafli et al., 2012).

Hidden Layers

Restoration projects have hidden layers, a feature that is almost never found in typical new construction projects (Perovic, 2015; Roy & Kalidindi, 2017; Lee et al., 2006). In other words, restoration projects have the potential to host very different techniques, materials and periods below the visible layers (Prudon, 1986). When a new hidden layer emerges, it is necessary to re-design, price, agree on methodology and intervention, and have it re-approved by the authorities. Therefore, considerable savings in time and cost can be achieved if these hidden layers can be identified before the application begins, although there is always a trade-off regarding this situation.

Scheduling

Due to the nature of the restoration work, one of the most obvious differences between a typical restoration project and a typical new building project is seen in the construction schedule. In general, restoration work is done piecemeal; that is, the work is not carried out completely, but only in the necessary parts of the building; meaning, location is determined, started, work completed, cleaned and moved to the next location. As a result, the restoration process will be more labor-intensive and time-consuming than the new construction (Prudon, 1986).

Project Success

Although there is no unique set of success criteria that clearly differentiates restoration projects from new construction projects in the literature, according to Shenhar and Dvir (2007), two criteria are appropriate for measuring the success of restoration projects: *project efficiency*, in terms of meeting planned targets according to time, budget, quality and scope, and the *impact on the client*, which can be measured by meeting major stakeholders' expectations, prolonging the useful life and recognition. In addition to these, preserving the aesthetic quality, identity, historical/social importance and universal heritage value of the buildings are often considered as success criteria (Mason, 2005; Provins et al., 2008; Roders & Oers, 2011).

Project Lifecycle

According to ICOMOS Turkey Architectural Heritage Conservation Charter (2013), conservation of an architectural heritage consists of documentation, research, analysis, interpretation, identification and determination of the conservation approach, definition of intervention, implementation and monitoring respectively. Considering that each cultural property has its peculiar characteristics, problems and potentials; studies aimed at examining, documenting and evaluating this heritage and defining conservation interventions should be specific to that structure and must comply with universal principles. Although there are some minor differences in practice of different countries, the restoration life cycle generally follows a similar pattern across countries (RIBA Plan of Work, 2020; ICOMOS Turkey Architectural Heritage Conservation Charter, 2013; Carbonara, 2012; Harun, 2011; Duguay, 1992b). While the basic structure remains the same when comparing a typical new construction project life cycle to that of a typical restoration project, particular attention should be paid to the preliminary assessment and research phases of restoration projects, as these phases differ significantly from the inception and feasibility phases of a new construction. In the restoration, much more research and analysis of existing conditions such as bibliographic and

archival research, a comprehensive survey, historical study based on direct analysis of the monument, material and structural analyses to determine the deterioration of the building in order to determine the appropriate intervention method and etc. must be done before the design begins. (Carbonara, 2012; Harun, 2011). During the implementation (design and construction) phases, these two project life-cycles are almost the same except for some minor differences from the project management lens, but the role of the architect is usually greater during the restoration (Duguay, 1992b). More attention should be paid to the initial phases of the conservation projects, which are highly interdisciplinary in nature and an area in which a wide variety of professionals from different fields participate (Cassar et al., 2001).

Building Restoration Projects and Project Management

Architectural conservation and restoration projects are particularly problematic in complying with time and cost constraints (Perovic, 2015). Major support for this proposition is the observation made by Reyers and Mansfield (2001) that conservation projects are more prone to go over-budget (62%) than new construction projects, and any conservation project over £10,000 is most likely will need a time extension based on RIBA reports. In addition, these projects contain more technical and economic risks compared to new construction projects (Dann & Cantell, 2007) and have a high number of varied challenging components which do not exist in typical new construction projects (Perovic, 2015). Looking at the bylaws and guides followed on restoration projects in the world (*such as charters of ICOMOS and UNESCO; the Venice Charter; Carta del Restauro; The Burra Charter; Conservation Principles, Policies and Guidance of English Heritage; BS7913:2013: Guide to the Conservation of Historic Buildings; RIBA Plan of Work; U.S. Department of The Interior's Standards for the Treatment of Historic Properties with Guidelines for Preserving, Rehabilitating, Restoring and Reconstructing Historic Buildings; Federal Heritage Buildings Review Office's Standards and Guidelines for the Conservation of Historic Places in Canada; Central Public Works Department of India's Handbook of Conservation of Heritage Buildings; Law No. 2863 on the Protection of Cultural and Natural Assets of Turkey; Resolution 660 of the Supreme Council of Monuments of Turkey, etc.*); while they define the basic principles and procedures of restoration projects, none of them relies on a comprehensive project management knowledge and not recommend any project management method specific to restoration projects. Despite the development of various principles, policies and guidelines, there are still many problems affecting the management of restoration projects underpinning the need to research and adapt project management tools and techniques specifically to conservation and restoration projects for better performance (Perovic, 2015; Harun, 2011).

There are many project management frameworks and tools that have been transferred to the construction industry to carry out projects for various types of structures. Some of them are: PRINCE 2 (is widely used in projects of various scales that are publicly funded by the UK government and has also been adopted by Australia), CIOB's Code of Practice for Project Management for Construction and Development (is a guide to construction project management principles and practices, regardless of project size, nature or complexity), RIBA's Outline Plan of Work (provides a model framework for project management in the UK construction industry) and PMI's Project Management Body of Knowledge (is an internationally and widely recognized guide to project management, with an appendix specific to construction projects). None of them are yet extensively adopted by industry to apply in restoration projects. Considering its widespread and valid use, comprehensive and systematic

definition, having advanced tools and techniques, and the potential to be applied in projects with high uncertainty such as restoration projects, it was deemed appropriate to examine the management of restoration projects through the PMI's project management knowledge areas lens in this study when identifying key areas of concern.

Key Areas of Concern When Managing Building Restoration Projects

Architectural heritage buildings are mostly unique in the techniques and materials used and reflect the time in which they were built. One common challenging aspect of these projects is that they face uncertainties resulting in many and major changes that cause these projects to exceed time and budget during the implementation phase (Perovic, 2015). One of the main reasons for this is that project tasks cannot be pre-determined accurately in terms of specification, scope, time and cost (Reyers & Mansfield, 2001), although inadequate or incorrect scope definition is one of the leading causes of project failure and can lead to numerous causal relationships that can arise problems during the project (Dumont et al., 1997). In addition, while managing a project within the scope is difficult in most construction projects, this situation is even more difficult for restoration projects that involve higher levels of uncertainty over their life cycle (Zwikael & Smyrk, 2011). When the restoration life cycle is examined; a poor project brief will lead to problematic scope definition and possibly problematic design; a problematic design will lead to un-coordination with other disciplines, and this will create insufficient or wrong information about the structure. Insufficient or wrong information will lead to unnecessary amount of site queries, as a result, the desired project objectives will not be achieved, which means that lack of foresight in the scope definition in the early stages will complicate the next steps (RIBA Plan of Work, 2020). That is, ***scope management*** is the first key area of concern identified in terms of the management of restoration projects.

The importance of stakeholders for the planning, development and execution of successful projects has been acknowledged by many researchers (Frooman, 2010; Bourne & Walker, 2005; Newcombe, 2003; Freeman & McVea, 2001). As mentioned earlier, restoration projects have a greater number of stakeholders than typical new building projects and a variety of stakeholders that are not usually present in typical new building projects, such as the public, media, political parties and conservation boards. Managing the conflicting expectations of all these stakeholders is a critical challenge to address, and there is no contractual relationship with most stakeholders in general. When stakeholders are the main source of uncertainty in projects (Ward & Chapman, 2008), it is very difficult to predict, manage and respond to a wide variety of opinions and demands. Especially when the large number of stakeholders are involved in the process with conflicting expectations, goals and needs of these stakeholders add to the uncertainty and complexity of the restoration project life cycle, which result in deviations from the project goals (Alallafa & Torreb, 2010). Therefore, a proper stakeholder management strategy will help to clarify who the key stakeholders are, determine how they will be managed, manage the flow of information, and determine how to manage constraints or risks (RIBA Plan of Work, 2020). That is, another key area of concern in terms of the management of restoration projects has been identified as ***stakeholder management***.

Many of the relevant stakeholders lack sufficient knowledge and skills on conservation and restoration issues, especially in terms of materials, methods and processes (Perovic, 2015; Prudon, 1986; UNESCO, 1972). Proper communication and documentation are highly important for any type of project especially for projects involving stakeholders with

conflicting skills and perspectives. This need becomes even more important in large and complex activities where key decisions need to be made collectively; when different actors are engaged in different aspects of the project independently; critical errors that are often not noticed until it's too late and repetitive discussions are made to resolve the same problems repeatedly (Alallafa & Torreb, 2010). When documentation and communication systems are not detailed enough, information requests become an almost daily procedure and take up a significant amount of the project's time (Perovic, 2015). Consequently, these problems lead to time and budget overruns. In addition, agile project environments that are subject to various uncertainties and changes, such as restoration projects, require the frequent and quick communication of evolving and emerging details. This can be achieved by facilitating team members' access to information, frequent team checkpoints and bringing team members together as much as possible, and by publishing project documents transparently, conducting regular stakeholder reviews and encouraging stakeholder communication (Project Management Institute, 2017). Proper documentation of principles and activities is also a fundamental requirement for restoration projects (Hajialikhani, 2010). Accordingly, ***communications management*** based on innovative information and communication tools and methods is amongst the key areas of concern for restoration projects.

Another challenge arising from the inadequate knowledge and skills of stakeholders especially in terms of materials, methods and processes is the quality assurance in restoration projects. Some materials and production methods used in restoration projects, each of which contains unique problems, will be lost or not known enough, and it will sometimes not be possible to work with stakeholders who are experienced in the relevant application and can meet the appropriate production quality (Perovic, 2015). Likewise, this lack of necessary skills and knowledge is addressed in the Australian Environment Committee's 2016 report as the continued decline in the availability of specialist practitioners, the lack of training opportunities and the growing lack of skills are putting enormous pressures on the conservation of architectural heritage. For these reasons, ***quality management*** is identified as one of the key areas of concern for restoration projects, as it is one of the important challenges to meet the project targets defined by international organizations such as ICOMOS and local legislations.

As mentioned before, it is very difficult and challenging to evaluate what will be encountered during the construction phase due to the age, physical condition, qualities and familiarity of the construction techniques and materials of the buildings subject to restoration. Although research and surveying could be carried out extensively in the planning phase, there is always a possibility of latent situations to arise due to the building's condition. In this respect, construction risks are quite higher in restoration projects compared to new construction projects (Perovic, 2015). That’s why, another key area of concern in terms of the management of restoration projects has been identified as ***risk management.***

Although the above-mentioned areas of concern have utmost importance in terms of the management of restoration projects, other challenges related to project management knowledge areas should not be ignored including ***integration management*** in coordinating actions and changes to be carried out as a result of new findings; ***cost management*** to keep the project within budget targets; ***time management*** to minimize deviation from time targets; ***resource management*** in making it possible to work with the right people with sufficient knowledge and skills in restoration which plays a critical role in restoration projects that require advanced expertise not only in contractors but also in subcontractors; ***supply management*** in ensuring the trouble-free supply of disappeared, rare or unknown materials

and their equipment and workforce that will be required for restoration; ***health, safety and environmental management*** considering the fact that the buildings subject to restoration are generally old and sometimes contain physical risks and their effects on the environment are taken into account; and ***financial management*** since the majority of restoration projects are subject to large budgets and large cash flows (Perovic, 2015; Hajialikhani, 2010; Prudon, 1986).

Conclusion

Peculiarities of the building restoration projects such as the need for research-based practices to define scope, planning, scheduling, design, supervision, decision-making, material use, construction methods, latent conditions, stakeholders, information flow, the legal environment, etc. significantly complicate the project management efforts and raises the need to treat them with an unconventional approach. Although some guidelines, standards and by-laws that define the fundamental principles and procedures of building restoration projects are available, additional research is needed to exploit the opportunities of project management discipline through its well-established processes, tools and techniques. A contemporary perspective which uses project management tools and techniques can contribute to the conservation of architectural heritage in line with the universal conservation principles. Collaboration with professionals who have practical experience in the field is essential to address the peculiar requirements of the restoration field. The project management body of knowledge should be specifically examined for the case of building restoration projects and the possibility of adapting specialized methods should be explored to propose a management model that considers the peculiarities of such projects.

Abstract

Construction projects involve complex processes by nature with many uncertainties. Despite these uncertainties, many construction processes are repetitive. Identifying and modelling repetitive processes leads to efficient use of all kinds of repetitive materials, manpower, and machinery in construction. Lean thinking focuses on examining processes with the objectives of improving resource flow to minimize waste and increase efficiency. Repetitive construction processes can be efficiently modelled, analysed, and planned from a practical point of view using simulation, a tool that supports lean thinking. It is important to encourage the use of Simulation in the construction industry, which is one of the most traditional and change-resistant industries. The development of the CYCLONE modelling elements by Halpin, a pioneer in the use of simulation in construction processes, increased the interest in simulation and many simulation tools were developed. Simulation systems provide a quantitative way to observe, plan, analyse and control construction processes and operations, thereby significantly reducing complexity in construction processes, increasing efficiency, and balancing resources. Therefore, in this research, a comprehensive literature review on lean construction and simulation was conducted and repetitive work operation on a surveyed construction site was simulated using the EZStrobe modelling system which is based on STROBOSCOPE software.

Keywords: *EZStrobe, lean construction, simulation, STROBOSCOPE.*

Introduction

The lean approach aims to minimize waste, simplify the process, and increase value and efficiency (Mao & Zhang, 2008). The basis of this approach is to be clear, simple, and plain. With the implementation of the lean approach, activities that do not add value are identified and these are reduced, resources are used efficiently, more output is obtained with less effort, and the customer receives the best quality service at the most affordable price. This reduces production cycle time and cost, improves processes, and increases quality, value, and efficiency. The application of the lean approach in the manufacturing sector has resulted in success. This success has encouraged other sectors, including the construction sector, to adopt this approach (Koskela, 2000; Koskela et al., 2002; Abbasian-Hosseini et al., 2014; Bajjou et al., 2017).

Lean construction aims for excellence by maximizing value and efficiency and minimizing waste (Bajjou & Chafi, 2020). The application of lean principles in construction processes is effective in increasing performance. However, there is no practical guide for the application of these principles in the construction industry. The success achieved in lean applications in the manufacturing sector may not be achieved in the construction sector because of the uniqueness of the construction processes. Before these principles are applied in construction processes, they should be tested and their performance measured (Mao & Zhang, 2008). A simulation is an appropriate tool that makes this possible (Halpin & Kueckmann, 2002). Construction processes consist of repetitive processes (Alkoc & Erbatur, 1997). These processes can be efficiently modelled, analysed, and evaluated through simulation before they are applied in the real world (Abbasian-Hosseini et al., 2014). Thus, resources such as material, manpower, and construction equipment are used efficiently, potential problems are determined in advance and precautions are taken before they encounter them in the field, trial and error costs are eliminated, and productivity increases. Many researchers state that the use of simulation is an excellent complement to the application of the lean approach to construction processes (Goienetxea Uriarte et al., 2020). Halpin and Kueckmann (2002) state that simulation is a part of lean construction. Improving the flow and reducing waste are principles of lean thinking, and simulation uses these principles to increase productivity and gain performance (Pollesch et al., 2017).

Complex processes are difficult to analyse using standard mathematical methods, but the simulation tool can be used in all construction processes ranging from very simple to complex (Martinez, 1996). Halpin developed the Cyclic Operations Network (CYCLONE) simulation tool in the 1970s to encourage the use of simulation in construction processes (Halpin & Kueckmann, 2002). CYCLONE is an easy-to-learn, effective and simple system that is widely used in simple construction processes (Martinez & Ioannou, 1999). Inspired by CYCLONE simulation, advanced simulation software used in complex construction processes such as STROBOSCOPE or many construction simulation tools used in simple processes such as EZStrobe have been developed (Wang & Halpin, 2004; Bajjou & Chafi, 2020).

This study aims to simulate a repetitive construction operation at a construction site and evaluate the outputs by focusing on the relationship between lean construction and simulation. The construction operation chosen for this purpose is "dry batch delivery and concrete placement operations". To simulate this process, the EZStrobe simulation tool which is based on STROBOSCOPE software, and is capable of modelling moderately complex processes, is used instead of advanced simulation tools.

Lean

The term “lean” was coined to reflect the nature of the Toyota manufacturing system to reduce waste and increase productivity (Womack et al., 2007; Aziz & Hafez, 2013). Lean concepts have emerged with inspiration from the early work of Deming, Juran, Crosby, Feigenbaum, Ishikawa, and other researchers focusing on quality in the manufacturing industry. The Total Quality Management (TQM) approach ensures that waste of resources is prevented by increasing quality, better products and services are obtained by improving the process, costs are reduced, a more competitive position is achieved, and employees are happier and more productive (Deming, 2014). Although the Lean concept is inspired by TQM objectives such as avoiding waste that does not add value, continuous improvement, communication, and coordination among stakeholders (Aziz & Hafez, 2013), Lean manufacturing originates from

the Toyota production system (TPS), which focuses on production based on customer satisfaction (Bajjou & Chafi, 2020). Thus, lean manufacturing became a universal term beyond the manufacturing industry, suppressing the principles of Taylorism, Fordism, and Post-Fordism that dominated the manufacturing industry, respectively (Aziz & Hafez, 2013; Bajjou & Chafi, 2020). Lean manufacturing, which replaces the traditional manufacturing process, encompasses many ideas based on TPS, such as continuous improvement, elimination of waste, team coordination, efficient use of resources, and improvement of quality and safety (Agha et al., 2010). Lean manufacturing uses half of the generally required resources such as materials, labour, and equipment (Gao & Low, 2014; Bajjou & Chafi, 2020).

The lean approach is not a set of rules or tools, it covers the entire process and is a shared system of thought and behavior throughout the value stream (Diekmann et al., 2004; Bajjou & Chafi, 2020). The starting point of lean thinking is that Womack and Jones published "Lean Thinking" in their book "The Machine That Changed the World" to answer the question asked about how lean manufacturing methods are applied (Halpin & Kueckmann, 2002). Lean is a management philosophy behind lean production that aims at maximizing the value offered to the customer, minimizing waste, and excellence (Ohno, 1988; Womack & Jones, 1997). Womack and Jones (1997) present five principles for embracing lean thinking; value, value stream, continuous flow, pull, and excellence. The starting point of lean thinking is value and value must be defined correctly. Even if the producer creates the value, the customer determines the value, so the satisfaction of internal and external customers is important (Ohno, 1988). With the value stream, activities that do not add value are identified and waste is prevented. By providing a continuous flow of value-creating actions, activities that cause unnecessary waste are eliminated. The pull principle allows the customer to pull the product they need instead of pushing the undesired product to the customer. Excellence symbolizes the ideal situation that can never be reached in practice, and zero error is aimed at continuous improvement (Ohno, 1988; Womack & Jones, 1997). The most important principle of lean thinking is to identify and eliminate all kinds of waste in the process. There are three Japanese concepts to express waste in the terminology of TPS: muda, mura, muri (Ohno, 1988). Muda is waste that does not create value but wastes resources. Mura is waste that expresses irregularities such as unbalanced loading of resources. Muri is waste caused by unreasonable overloads (Womack & Jones, 1997). Waste is activities that do not create value but consume resources or the results of these activities. There are eight types of waste; unnecessary transportation, excess stock, unnecessary movement, unnecessary waiting, overproduction, over processing, errors and fixes, and unused capabilities (Ohno, 1988; Liker, 2004; Bajjou et al., 2017).

Lean Construction

The success of the lean manufacturing system in manufacturing has led to the spread of the lean approach to new areas such as customized manufacturing, services, management, and product development. This approach has also been applied in the construction industry since 1992 in order to reduce waste and increase efficiency (Koskela, 2000; Aziz & Hafez, 2013; Bajjou et al., 2017). Lean construction ensures minimizing waste, improving processes, increasing efficiency, listening to the voice of the customer, providing a full understanding of the customer, and coordination among stakeholders. Lean construction is a way of designing systems that will minimize any waste to maximize value (Koskela et al., 2002; Aziz & Hafez, 2013).

Lean construction has changed the traditional transformation perspective and embraced the concept of flow and value creation (Aziz & Hafez, 2013). Construction has traditionally been managed from a transformation perspective (Koskela, 2000). Halpin and Kueckmann (2002) liken the transform to a "black box" with inputs on one side and desired output on the other. In this black box are the construction processes. In the transformation perspective, the value of the output and the cost of the overall process depends only on the value and cost of the inputs (Halpin & Kueckmann, 2002; Abdel-Razek et el., 2007). The concepts of value creation and flow are largely ignored as attention is directed to inputs (Bajjou & Chafi, 2020). This trend leads to a mismatch of processes, loss of value, inefficiency, and massive waste (Koskela, 1992; Koskela, 2000; Halpin & Kueckmann, 2002; Abdel-Razek et el., 2007). The smooth running of the process impacts the productivity of high quality and value. The lean perspective focuses on processes to completely rebuild or create new processes (Halpin & Kueckmann, 2002). Lean construction emphasizes the consideration of flow and value, not just transformational steps, in the design of construction processes (Aziz & Hafez, 2013; Bajjou & Chafi, 2020). Therefore, it is important to adopt the concept of lean construction in the construction industry to reduce waste, cycle time, and variability and increase efficiency and value (Aziz & Hafez, 2013).

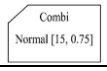
Simulation and Lean Construction

Simulation is defined as the construction of a mathematical and logical model of a real-world system or process in a virtual world (Goienetxea Uriarte et al., 2020). Simulation is an efficient method that improves planning in construction projects (Sacks et al., 2007). Many researchers have benefited from simulation in construction processes. For example, Balbontin-Bravo (1998), used simulation in the manufacture of precast elements to increase efficiency, reduce costs, and obtain various working alternatives and achieved great cost savings in many operations through simulation. Simulation for studying construction operations was first proposed and developed by Halpin (Wang & Halpin, 2004). Halpin developed the Cyclic Operations Network (CYCLONE), one of the first simulation tools to simplify the simulation modelling process for modelling construction operations, and then, a computer program called MICRO-CYCLONE based on CYCLONE modelling elements (Wang & Halpin, 2004). This simulation tool has been used in many studies, as an example is, Alkoc and Erbatur (1997), used MicroCYCLONE simulation software for the design and optimization of the pouring process and concrete delivery to increase the productivity of the concreting operations. Thus, inspired by the benefits of simulation, many construction simulation programs have been developed based on CYCLONE modelling elements such as STROBOSCOPE, SIMPHONY, and ARENA (Wang & Halpin, 2004; Bajjou & Chafi, 2020).

Halpin and Kueckmann (2002) state that lean thinking and simulation are linked. Lean thinking provides a format that improves processes, simulation provides a methodology that evaluates processes (Halpin & Kueckmann, 2002). In a controllable environment, processes can be efficiently modelled, analysed, and improved using simulation, without the waste of trial and error in the real world (Halpin & Kueckmann, 2002; Wang & Halpin, 2004; Abbasian-Hosseini et al., 2014). Simulation of construction operations enables analysis of all construction processes, from very simple to complex, in an experimental environment that does not require many data entries (Martinez, 1996; Halpin & Martinez, 1999; Abbasian-Hosseini et al., 2014). Simulation created with the information of the process provides an inexpensive, fast and effective method to evaluate more than one alternative action and choose the best course of action and produces outputs such as cycle time, daily throughput, productivity, resource and crew utilization (Halpin & Kueckmann, 2002; Sacks et al., 2007; Bajjou & Chafi, 2020). Thus,

time and cost savings are achieved, productivity is increased, non-value-adding activities are identified, and lean construction waste can be measured and avoided (Balbontin-Bravo, 1998; Halpin & Kueckmann, 2002; Wang & Halpin, 2004). With these benefits of simulation, lean construction concepts can be tested and validated before being implemented in the field (Halpin & Kueckmann, 2002; Abbasian-Hosseini et al., 2014).

Previous researches show simulation as a useful tool for modelling and analysing the applicability of lean construction principles in construction processes (Tommelein, 1998; Halpin & Kueckmann, 2002; Sacks et al., 2007; Mao & Zhang, 2008; Wang et al., 2009; Abbasian-Hosseini et al., 2014; Bajjou & Chafi, 2020). Tommelein (1998), evaluates the pipe-spool installation process using STROBOSCOPE simulation software to compare push-driven and pull-driven processes, and states that the simulation improves the performance of the pull technique in material delivery. Halpin and Kueckmann (2002) used simulation as a tool to evaluate the benefit of using lean construction techniques for the wall erection and concrete forming construction processes and noted that the relationship between lean construction and simulation provides operational gains such as increased productivity, reduced the idle times of the crews, and reduced overall cycle time. Sacks et al. (2007), evaluated the benefits of the lean approach by using the simulation technique for the execution of fine works in high-rise apartment buildings with personalized apartment designs and stated that using STROBOSCOPE simulation increased efficiency, improved cash flow, and reduced apartment delivery cycle time. Mao and Zhang (2008) developed a construction process reengineering framework that integrates lean principles and computer simulation techniques, and with a case study of the tunnel project, they indicated that this framework can be applied in construction processes for improved productivity, efficiency, and cost-effectiveness. Wang et al. (2009), used simulation to apply lean production principles and flow production to shop fabrication and demonstrate that the simulation-based lean approach improves the performance of a spool fabrication system. Abbasian-Hosseini et al. (2014), discovered the potential impact of lean construction using simulation in the bricklaying process. This discovery revealed a 27% increase in operational efficiency, a more than 40% increase in productivity, and a 41% decrease in cycle time. Bajjou and Chafi (2020), evaluated the impact of lean construction principles on the performance of reinforcement operations using a discrete-event simulation approach and stated that this approach was effective in increasing its performance by presenting a 41% improvement in process productivity, 14% enhancement in process efficiency and 17% reduction in cycle time in performance measurements.



STROBOSCOPE and EZStrobe

STROBOSCOPE is a programming language designed for the simulation of construction processes (Martinez & Ioannou, 1999). General-purpose simulation systems cannot easily model the multi-source requirements and dynamic complexity of construction processes. The STROBOSCOPE simulation software makes these models possible (Martinez, 1996). Martinez and Ioannou (1999) describe the STROBOSCOPE as "a programmable and extensible simulation system designed to model complex construction operations in detail and develop special-purpose simulation tools". STROBOSCOPE is an acronym for "STate and ResOurce Based Simulation of COnstruction ProcEsses" (Martinez, 1996). Stroboscope is an efficient and effective simulation system (Martinez & Ioannou, 1994). The STROBOSCOPE dynamically accesses the properties of sources and with this access, is sensitive to properties of sources such as size, weight, and cost. Besides, this software can dynamically choose the routing of resources and the order of operations (Martinez, 1996). STROBOSCOPE is designed for advanced

modelling tasks. Therefore, the simpler and easier to learn EZStrobe was developed to model easy to moderately complex problems (Martinez, 2001).

EZStrobe is based on extended and annotated Activity Cycle Diagrams (ACD) (Martinez, 2001). This simulation tool is powerful, easy to learn and use, and does not require direct knowledge or use of STROBOSCOPE. EZStrobe is a discrete-event simulation system with capabilities such as drag-and-drop model building, visual network-based logic, and ACD network animation. EZStrobe shows the movement of resources and interaction with activities with ACD network animation and uses simple modelling elements such as the Queue, Combi, Normal, Fork, and Link to illustrate this animation. (Ioannou, 2020). Table 1 shows the basic EZStrobe modelling elements (Martinez, 2001).

Table 1. The basic EZStrobe modelling elements.

Elements	Function	Parameter	Description
Queue	holds idle resource until used	Queue name number of resources	
Combi	constrained activity, starts when required resources are available	Combi name probability distribution density function	
Normal	not constrained activity starts when a previous activity is completed	Normal name probability distribution density function	
Fork	probabilistic element to randomly select the path to follow		
Link	Connects different activities and queues	condition necessary for the successors activity start, number of resources to be consumed	

Methodology

Aim. This research aims to simulate a repetitive construction operation at a construction site and evaluate the outputs, using simulation as a tool for applying lean construction principles to construction processes.

Scope. In this research, the dry batch delivery and concrete placement construction operation of a completed construction project was examined.

Method. The method of this study is to evaluate the simulation outputs by comparing them with real-world data. Data is collected from field workers and to simulate this process, the EZStrobe simulation tool based on STROBOSCOPE software is used.

Project description. The project is the construction of a facility where the modernization training of military aircraft in the fleet of a country of great strategic importance in the Middle East will be given. Within the scope of the project, the facilities including the mosque, cafeteria, training classes, water tank, apron, and hangars, with a closed area of approximately 40,000 m2, including sports and technical training areas, were completed and put into use between 2015 and 2017 with a cost of approximately 150 million USD.

Description of dry batch delivery and concrete placement operation. In the works completed within the scope of the facility, 2,200 tons of reinforcement, 38,500 m^3 of structural concrete, 30,000 m2 of apron taxiway works, approximately 3,000 m of clean water line, 9,000 m of facade panel works are within the scope of some works completed within the scope of the project.

For the concrete works within the scope of the project, it is aimed to complete the works within the scope by establishing a concrete batching plant at a distance of approximately 7 km from the project site. In this context, although the situation that the construction site has sufficient space for the concrete plant installation was not included at the beginning of the project, it will also be examined from this perspective in the simulation study.

Model development. The activities and cycles in the model simulated in Figure 1 are as follows;

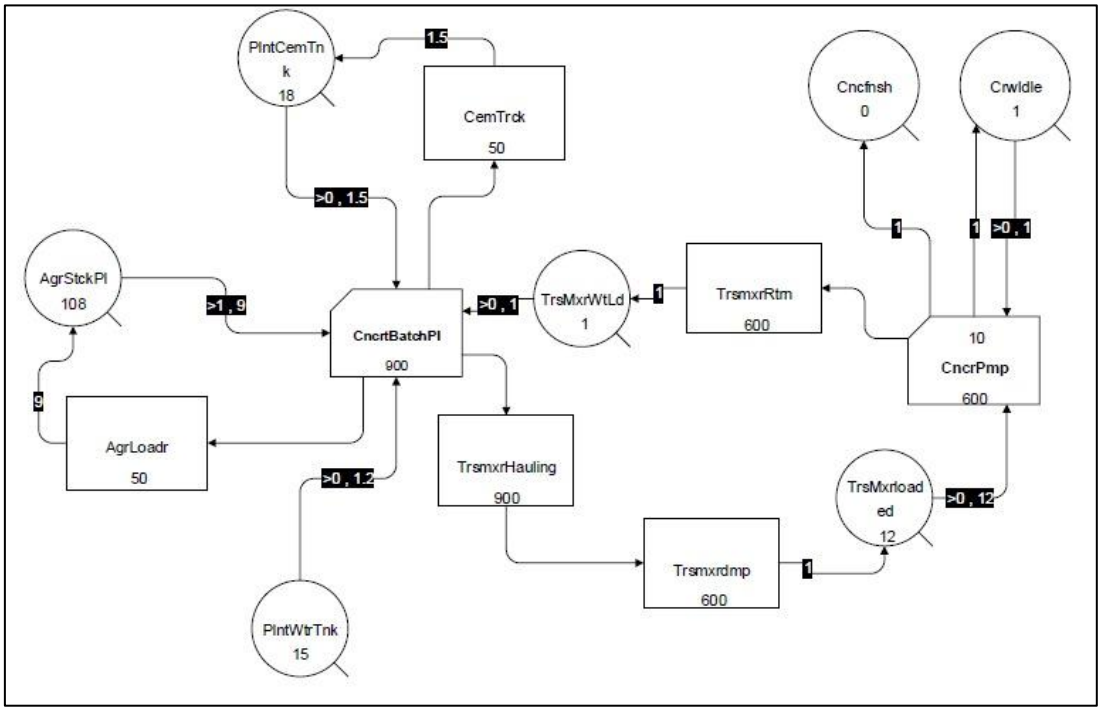


Figure 1: Activity cycle diagram for dry batch and delivery placement.

The batch plant area will be set up on land 7 km away from the project site. The batch plant is set up as shown in Figure 2. Concrete mix materials that form aggregates are transported to the factory site and delivered are stocked in factory site stockpiles. During the concrete mix producing materials, are loaded to the plant with a wheel loader. The batch plant has a cement tank and water tank system that is integrated with the batch plant. Cement and water are stocked in the tank as per their use. The water tank is used for the project's other parts. The cement trailer is organized as per demand and stocked remained amount on the cement tank. A weighbridge is installed in the batch plant area for controlling and checking delivered materials and the aggregate stockyard is controlled using survey equipment.

The trans-mixer is loaded at the plant and goes to the concrete site until the concrete pump arrives. The trans-mixer discharges the concrete mix into the concrete pump until it is completely empty, and then returns for reloading. The discharged concrete is evenly distributed on the floor by the concrete pump, and then the spreading process begins. The trans-mixer is

loaded at the plant and goes to the concrete site until the concrete pump arrives. The trans-mixer discharges the concrete mix into the concrete pump until it is completely empty, and then returns for reloading. The discharged concrete is evenly distributed on the floor by the concrete pump, and then the spreading process begins. After the concrete placement, the finishing process begins. The Queue element controls the termination of the model. For this particular model, the total concrete quantity installed during a 1.5-h work period was 72 m^3.

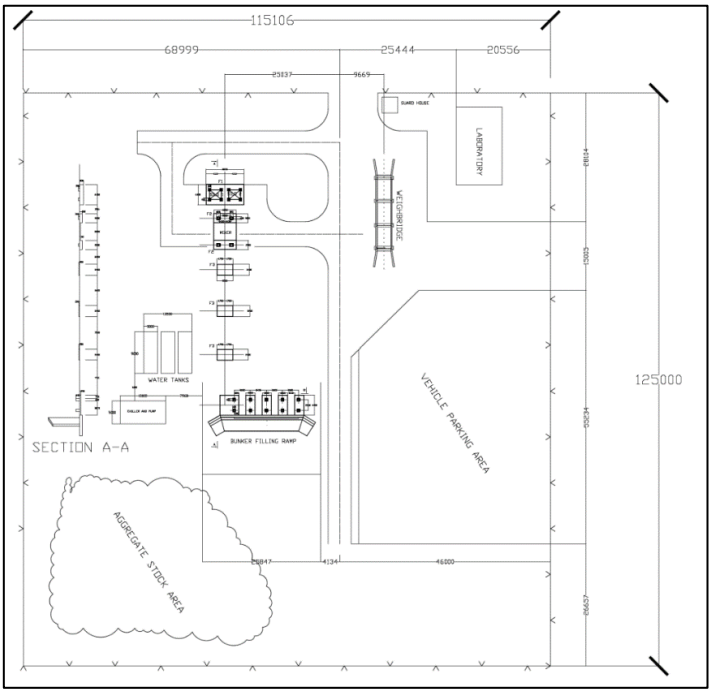

Figure 2: The plan of this dry batch and delivery placement.

Results

As shown in Table 2, two different simulations were performed. The first simulation was carried about with the option concrete batch plant has been constructed 7 km away from the construction site. Another simulation was carried out with the option concrete batch plant has been constructed in the construction area, which is the same as the project area and that will be the same until project completion. The simulation results are shown in Figures 4 and 5. After that, simulation results were compared with each other.

Table 2. Parameters of two different simulations.

Parameters	First Simulation	Second Simulation
Mixers Number	4	3
Load Mixer	15 min / 12 m^3	15 min / 12 m^3
Loaded Trans-mixer Time	15 min	5 min

Figure 4: Second simulation results.

Discussion

In this research, simulation was used as a tool to present the application of lean construction principles in construction work processes. For this purpose, a work operation of a completed construction project was simulated in two different ways. Two different simulations were carried out by using different parameters for changing the place of the batch plant, the distance between the construction site and the concrete batch plant area, and reducing the transmixer number. The first simulation has been run with the option, that is concrete batch plant is operating 7 km away from the construction site. In this way, the simulation time was calculated as 170 minutes. The second simulation has been run with different parameters which have been shown above related parameters' table. In this way, simulation time was calculated as 169

minutes with less equipment as compared with the first simulation. Thus, positive improvements were achieved in project activities by shortening the distance of the concrete plant from the construction site. With the installation of the concrete plant on the construction site, the full mixer transfer time was reduced from 15 minutes to 5 minutes, and the empty mixer turnaround time was reduced from 10 minutes to 3 minutes. In this direction, the number of mixers has been reduced and the same work has been completed in less time with fewer resources. When evaluated with these results, the concrete transfer work done with 4 mixers in simulation 1 was completed in less time with 3 mixers within the same time limits, and the efficiency was increased by increasing the usage period of the resources from 6 to 8. In this case, the number of mixers has been reduced, and the same work has been completed with % 25 fewer resources. Besides, hourly cost savings have been achieved, due to the distance change and use of less resources. As a result, it has been determined that construction operations can be implemented with less resources, low cost, and high efficiency with simulation models.

Conclusion

This research aims to present that simulation can be used as a tool to apply lean construction principles. To achieve this goal, a repetitive operation in a completed construction project is simulated in two different ways using the EZStrobe simulation tool which is based on STROBOSCOPE software, and the outputs are evaluated. As a result of these evaluations, the study presents the following; real-time projects can be simulated with different parameters at the beginning project to evaluate the productivity of resources; in projects that have started and/or are in progress and/or will begin, by using the simulation system, resources can be used correctly and efficiently to minimize waste, or the most appropriate decisions can be made about their use; construction operations can be implemented with less resources, low cost and cycle time, and high productivity with simulation models; the objectives (minimize waste, simplify the process, increase value and efficiency) of the lean construction approach can be achieved; previous studies state that simulation is a tool for the adoption of lean principles in the construction industry are supported. Future research can encourage the adoption of lean construction principles in the construction industry through simulation, using simulation tools in different construction operations.

Abstract

Project duration and project cost are the main factors of the project in construction management. Most of the conflicts between contracting parties are based on incorrect time management and delays. For contractors, although the cost is at the forefront, especially in public projects, the duration of the project is also very important. Contractors who fail to complete the project on time may face penalties for delay. It is necessary to analyze schedule delays and cost overruns, and research the most significant causes of delay and cost overruns in construction projects to avoid or minimize their adverse impacts on the project and project participants.

Since the Turkish construction industry is a labor-intensive industry, it has been greatly affected by Covid-19 during the pandemic period. This has led to serious time and cost overruns, especially in large construction projects.

In this study, firstly, the causes of delays and cost overruns in large-scale construction projects in Türkiye were determined based on previous academic research, surveys and interviews with experts. Then, delay analysis and cost overrun analysis were performed on the data collected from an ongoing public construction project using MS Project software. Subsequently, the results were interpreted.

Keywords: *case-study, construction projects in Türkiye, cost overrun, pandemic, delay analysis, MS Project.*

Introduction

The construction industry plays a vital role in developing countries' economies. Construction projects provide many investment opportunities across various related sectors. Therefore, the

construction sector is an important economic indicator for developing countries like Türkiye. Although the Turkish construction industry has the potential to reach an international level, the construction management subjects have not been fully adopted by our companies yet.

For a construction project to be considered successful, it must be completed within the planned time/budget, in accordance with the relevant drawings and specifications, and to the satisfaction of the project stakeholders. Unfortunately, in developing countries like Türkiye, most construction projects face time and cost overruns due to a large number of uncertainties in the construction industry (Vyas & Birajdar, 2016).

Delays in construction can cause a number of changes in a project such as late completion, lost productivity, acceleration, increased costs, and contract termination. The party experiencing damages from delay needs to be able to recognize the delays and the parties responsible for them in order to recover time and cost. However, in general, delay situations are complex in nature. A delay in an activity may not result in the same amount of project delay. A delay caused by a party may or may not affect the project completion date and may or may not cause damage to another party. A delay can be caused by more than one party; however, it can also be caused by none of the parties (such as unusually severe weather conditions). A delay may occur concurrently with other delays and all of them may impact the project completion date. A delay may sometimes contribute to the formation of other delays. In construction contracts, schedule delay analysis is commonly conducted to demonstrate cause and effect relationships of time-related disputes. Schedule delay analysis makes use of the as-planned schedule, the as-built schedule, and schedule updates (Mohammed & Jafer, 2011).

Cost overrun can be defined as when the project objectives have not been achieved within the estimated budget (Avotos, 1983). Cost overrun is a very frequent phenomenon and is almost associated with nearly all projects in the construction industry. This trend is more severe in developing countries where these overruns sometimes exceed 100% of the anticipated cost of the project. Cost overruns are a major problem in both developed and developing countries (Angelo & Reina, 2002). Therefore, the problem of cost overruns is critical and needs to be studied to alleviate this issue in the future. In developing countries, the trend is more severe where the cost overruns sometimes exceed 100% of the estimated cost of the project. The reason for those overruns is poor management of the resources such as man, materials, and money.

There are several factors that are responsible for construction schedule delays and cost overruns. This paper attempts to identify the major factors of schedule delay and cost overrun in the construction sector of Türkiye and can serve as the way forward for future work in coping with these overruns. The literature, work experiences and expert opinions were used to determine the factors causing schedule delays and cost overruns.

In this study, first, some information is given about schedule delay and cost overrun subjects. Then a literature review has been presented on these topics. Within the scope of this study, the schedule delay and cost overrun analysis was applied to a real construction project data, and the results were interpreted with a case study. A G+5 reinforced construction building is selected for analysis as a case study. Later, Microsoft Project has been used for planning, scheduling and for delay analysis As Planned As Built technique has been used. The schedule delay and cost overrun analysis were done over some clusters of activities related to the construction project. Finally, the analysis results are interpreted.

Schedule Delay

Schedule delay is defined as the extension of time beyond the planned completion date specified in the contract or beyond the date that parties agreed upon for delivery of the project (Subramani et al., 2014). Delays are incidents that impact a project's progress and postpone project activities, delay causing incidents may include weather delays, unavailability of resources, design delays, etc. In general, project delays occur as a result of project activities that have both external and internal cause-and-effect relationships (Vidalis et al., 2002). Ameh and Osegbo (2011) describe schedule delay as the time during which some part of the construction project is completed beyond the project completion date or not performed as planned due to an unanticipated circumstance. Choudhry (2014) defined the schedule delay as the difference between the actual completion time and the estimated completion time.

Causes of Schedule Delay

Construction projects, which have a complex structure and require large investments, are faced with unexpected delays for many reasons. In order to be able to describe the schedule delays in the project as a whole, first of all, it is necessary to identify the delay elements that occur during the process. For this, both local and international studies on the subject have been examined and two important studies that examined delay causes in Turkish construction projects are given below.

Arditi et al. (1985) investigated the causes of delay in publicly funded construction projects in Türkiye between 1970 and 1980. They explained the reasons for the delay with 23 items. The reasons for delay according to the findings; are shortage of materials (e.g. iron and cement), difficulties in getting payments from stakeholders (e.g. not making payments on time, not making advances, expensive bail bonds, the insufficient budget of public enterprises), contractor difficulties (e.g. shortage of liquid funds, difficulty in collecting debts, obtaining loans' difficulty), organizational characteristics of contractor companies and public institutions (e.g. defined task and responsibility problems, lack of authority of the field manager, insufficient and slow decision-making mechanism, an abundance of bureaucratic obstacles, multitude of transformations of technical personnel).

Kazaz et al. (2012) have a detailed study on the causes of delays in construction projects in Türkiye. According to this study, 34 factors that cause time overruns in construction projects were gathered under 7 factor groups.

These classified factor groups are as follows.

- Environmental factors
- Financial factors
- Labor-based factors
- Managerial factors
- Owner-based factors
- Project-based factors
- Resource-based factors

Considering the views of participants, the most predominant ten causes of time overruns out of 34 factors were determined as can be seen in Table 1. The first five factors were described as "very important", alerting the industry considerably against to the time extension threat. Three

of them belong to financial factors, and this shows that the main notion behind the endemic timing problem in the sector depends largely on the economic conditions of owners and contractors. Overall, the most significant factor was found to be “design and material changes”, followed by “delay of payments”, “cash flow problems”, “contractor’s financial problems”, and “poor labor productivity”, respectively (Kazaz et al., 2012).

Table 1. The top ten causes of schedule delay (Kazaz et al., 2012).

Factor Groups	Factors	Rank	Importance Level
Managerial factors	Design and material changes	1	Very important
Financial factors	Delay of payments	2	Very important
Financial factors	Cash flow problems	3	Very important
Financial factors	Contractor’s financial problems	4	Very important
Labor-based factors	Poor labor productivity	5	Very important
Managerial factors	Estimation problems	6	Important
Project-based factors	Lack of feasibility studies	7	Important
Labor-based factors	Construction defects	8	Important
Labor-based factors	Unbalanced number of workers	9	Important
Financial factors	Fluctuation in material prices	10	Important

Cost Overrun

The notion of “cost overruns” is defined in a variety of ways in the literature. For example, Hinze et al. (1992) suggested that cost overrun is the difference between the original contract value and cost at practical completion. Derakhshanalavijeh (2017) described project cost overrun as the positive difference between the actual cost upon project completion and the agreed estimation of the project budget. Flyvbjerg et al. (2002) and Odeck (2004) interpreted cost overrun as the difference between forecasted and actual construction costs.

According to Zhu et al (2021), cost overrun is defined as the excess of actual cost over budget. Cost overrun is also sometimes called “cost escalation,” “cost increase,” or “budget overrun.” (Al-Najjar, 2008). Choudhry (2004) defined cost overrun as the difference between the original cost estimate of the project and the actual construction cost on completion of works of a commercial sector constriction project.

Cost overrun is defined as an instance in which the provision of contracted goods or services are claimed to require more financial resources than was originally agreed between a project sponsor and a contractor (Nega, 2008). Wideman (1992) defined cost overrun as the amount by which actual costs exceed the baseline or approved costs.

Cost Overrun= (Final Contract Amount – Original Contract Amount)/(Original Contract Amount)

Causes of Cost Overruns

The literature shows that there are various reasons for cost overruns in construction projects. Ameh, et al. (2011) identified 42 reasons for cost overrun and found that the main major factor causing cost overrun in Nigeria are inexperienced contractors, price of material, variation of

material prices, changes in design, economic stability, and high-interest rates charged by banks on loans. Al-Kharashi and Skitmore (2009) mentioned ten (10) out forty-two (42) identified factors resulting in cost overrun in Gaza construction projects, these factors are the increase of materials prices due to border closures, slowness in construction supply of raw materials and equipment by contractor, changes in the prices of building materials, unsettlement of local currency in relation to dollar value, monopoly of the project materials by some suppliers, design changes, and insufficient quantity take off.

Methodology

Delay Analysis Methods

There are four methods often mentioned in the literature that are professionally acceptable (Mohammed & Jafer, 2011).

They include:
• As-planned versus as-built schedule analysis method,
• Impact as-planned schedule analysis method,
• Collapsed as-built schedule analysis method, and
• Window analysis method, and they are known by different terminologies among practitioners.

The as-planned vs. as-built method is the observation of the difference between an as-planned schedule and an as-built schedule. The method identifies the as-built critical activities, compares these activities with the activities on the as-planned schedule, assesses the impact of delays on the project, identifies the sequences which actually define the duration of the project, and determines the causation and responsibility of delays that impact project completion. (Mohammed & Jafer, 2011).

The impact as-planned method uses only an as-planned or baseline schedule for delay analysis. It is based on the theory that the earliest date by which a project is completed can be determined by adding the delays into the as-planned schedule. New activities that represent delays, disruptions, and suspensions are added to the as-planned schedule and are used to demonstrate the reason why the project was completed later than planned. Contractors, who submit claims that involve a time extension, add only owner-caused delays to the as-planned schedule in the appropriate sequence to document the total project delay caused by the owner. (Mohammed & Jafer, 2011).

The collapsed as-built method is also referred to as the ‘‘but-for’’ schedule method. This analysis is popular in claim presentations because it is easily understood. Society of Construction Law (SCL) defines it as a method where the effects of delays are ‘‘subtracted’’ from an as-built schedule to determine what would have occurred but for those events (Society of Construction Law, 2002). This approach is a method of choice when a contractor lacks an acceptable schedule during the project, or when no as-planned schedule was required in the contract.

The window analysis method breaks the construction period into discrete time increments called “window” and examines the effects of the delays attributable to each of the project

participants as the delays occur. It adopts the as-planned schedule as its baseline, but the as-planned schedule is periodically updated at the end of each planned time period. The windows analysis method is distinguished from the impact as planned and collapsed as-built analyses in the fact that it incorporates both party delays into the analysis. In addition to this advantage, window analysis also provides a disciplined basis for the contractual parties to keep a project schedule up-to-date and properly adjusted. The majority of the viewpoints reviewed in the literature agree that windows analysis yields the most reliable results. In spite of its advantages, this method still has limitations which are summarized as follows:

• Window size can have a significant impact on the results of the analysis.
• Windows analysis has no mechanism for considering owner directed versus contractor acceleration.
• Windows analysis procedures do not include a systematic approach for calculating the responsibility for delays when multiple baseline updates have been used at different construction stages.
• Windows analysis does not consider the impact of resource over-allocation resulting from delays caused by various parties. (Mohammed & Jafer, 2011).

Case Study

In this study, a six-storeyed (G+5) university administrative building construction project which is in progress in Istanbul was selected as a case study. One of the authors is working as a technical office chief on the related project and the data were collected by him. The project's original duration is 785 days and the budgeted cost is ₺ 103,159,000,00. Construction, electrical and mechanical disciplines are included in the project planning.
The relevant project schedule program was prepared in MS Project software and the schedule is updated every month. In this study, the most important project schedule delay and cost overruns are given and the results are interpreted.

Scheduling in Ms. Project:

First of all, all project activities were determined. The activities were grouped under different groups. The Work Breakdown Structure (WBS) was established. Critical Path Method is the project scheduling method used in MS Project to link all the activities. The total baseline duration of the project was found to be 785 days.

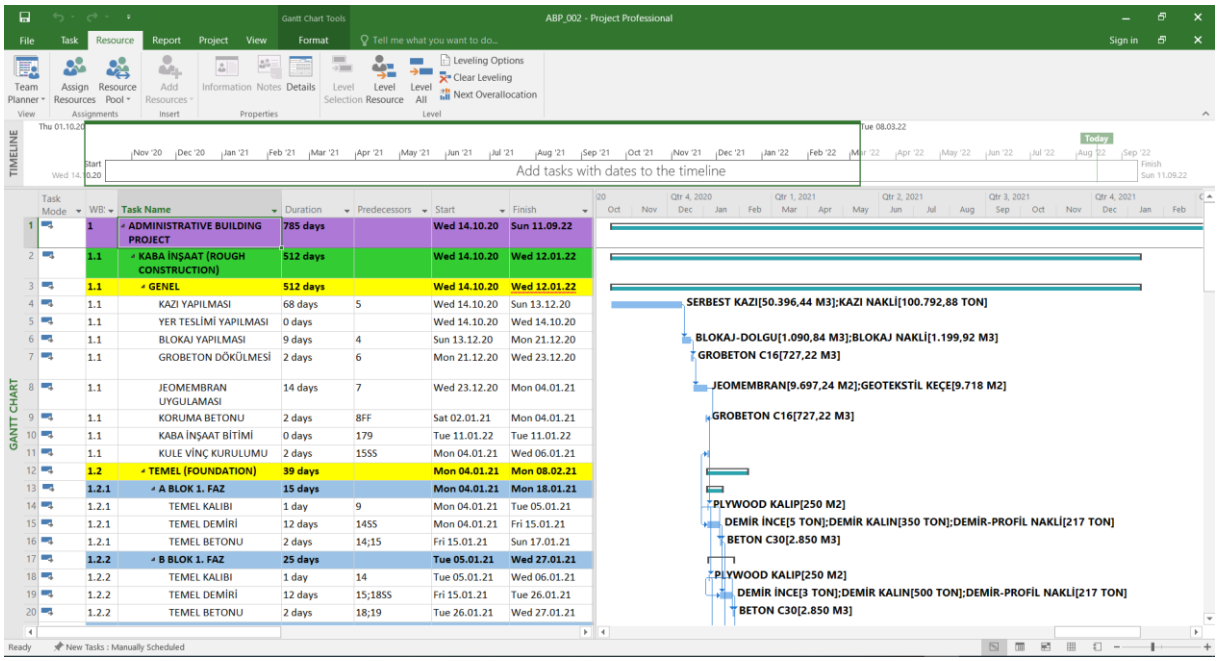

Figure 1: The project schedule and Gantt graphic.

Then, the quantity of each activity was calculated, and the man-hour calculation was made for each activity. Resources entries were made in the Ms project and the project baseline was saved.

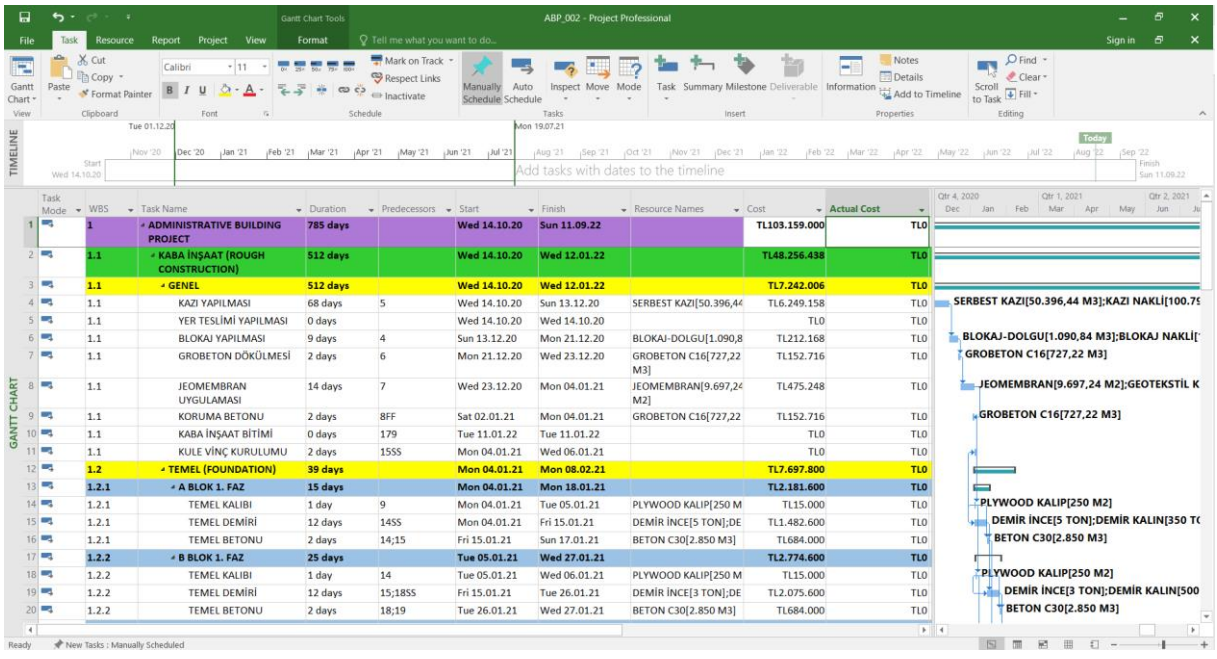

Figure 2: Activities with baseline.

Results

Examining The Duration and Cost Calculation of the Project

In this study, the most important schedule update results are given below;

WBS	Task Name	Duration	Finish Slack	Cost	Cost Variance
1.1	ROUGH CONSTRUCTION	512 days	-160 days	TL48.256.438	-TL12.626.363
1.1	GENERAL	512 days	-160 days	TL7.242.006	-TL1.665.661
1.2	FOUNDATION	39 days	0 days	TL7.697.800	-TL1.770.494
1.3	2nd Basement Floor	58 days	0 days	TL7.328.360	-TL1.312.890
1.4	1st Basement Floor	62 days	-20 days	TL7.049.532	-TL1.248.759
1.5	Ground Floor	62 days	-30 days	TL4.877.440	-TL1.707.104
1.6	1st Floor	62 days	-110 days	TL4.800.200	-TL1.680.070
1.7	2nd Floor	62 days	-110 days	TL4.814.500	-TL1.685.075
1.8	3rd Floor	62 days	-110 days	TL4.446.600	-TL1.556.310

Figure 3: Project schedule delays and cost overruns.

The project was delayed for 2 months due to project revision, 10 days due to bad weather conditions, 1 month due to leaving work of a subcontractor and the start of the new sub-contractor, 2 months due to the lack of allowance of the administration, thus160 days in total.

Conclusions

The contractor must properly manage his own financial resources in order to complete the work on time and on budget. It should distribute the progress payments from the owner in a planned manner for the payments to be made to the subcontractors and suppliers. In other words, it should provide control of cash flow. Site management and inspection are vital issues in order to ensure that the project is completed within the desired time and at the desired quality. This can be done with a sufficient number and qualified administrative and technical personnel selected by the contractor. In addition, the employer/administration must be faithful to the allowances specified in the contract and pay the progress payment to the contractor on time. In the current construction market, material prices increase more than the price difference given by the government to the contractor, this puts the contractors in a difficult situation and even causes them to go bankrupt.

Delays caused by stakeholders, namely individuals, can actually be minimized by corrective actions. But in some cases like unforeseen natural disasters, pandemics, civil war, conflicts, etc. delays are inevitable. For example, a work schedule can be prepared according to the number of rainy days by looking at the last 10-year average of the weather conditions, but no one can guarantee that the number of rainy days will be below or above the average in that year. Unforeseen external factors cause delays. In such cases, there may not be a way to follow other than taking action to accelerate the work.

Abstract

Construction, as a leading sector in Turkey's economical perspective, an industry challenging with time and cost overruns related to construction wastes. As a consequence, total quality of the project is not provided as expected at the initial phases of the project life cycle. In recent years, some lean tools have been used to deal with this problem. Due to the variety of tools used in lean approaches, it becomes a critical issue which tool could be used. This study aims to classify the tools used in lean approaches in the construction industry, based on their participation in academic studies with a bibliometric study review. The study is limited with the articles written in time of 2013-2022 in Scopus database. According to the frequency of tools based on articles, availability of tools in implementation process in construction projects is examined.

Keywords: *construction, construction industry, lean, lean management, lean tools analysis.*

Introduction

Lean construction theory is the application of lean production principles in the construction industry, by eliminating all kind of waste, reducing variability in projects, and increasing quality for customer satisfaction. On transferability of lean principles into the construction industry, all the consultants and the contractors admitted that it would be possible to transfer the principles of lean to the construction industry. Transferability of lean principles into the construction industry can help to change current practices such as the generation of excessive waste and sub-standard products (Can &Tas, 2018). Lean approaches have been gained an importance internationally, with their benefits such as preventing time and cost losses and increasing total quality in construction projects. Different lean construction tools which originated from lean manufacturing approaches are used in different construction projects. Therefore, it is a critical issue to decide which lean tool to use in a specific project. At the same time, academic research focusing on lean tools in the construction industry shows a great tendency and analyzing the existing studies is complicated.

Defining the lean tools used and searched in the construction industry is important to improve application areas of these tools in an effective way in that industry. So, this study aims to highlight the most subjected lean construction tool in academic studies with a bibliometric analysis. Due to high numbers of studies focusing on the subject, Vos Viewer, a software tool for constructing and viewing bibliometric map is used to analyze the existing research. By this way, a searching pathway will be conducted for future studies in the subject of lean construction tools.

Methodology and Data Collection

In this study, Scopus search engine, which has a large source, was used to classify the last ten year's research (2013-2022) on lean tools and construction. Then, Vos Viewer software tool was used to analyse links between lean tools and to determine the most used lean tool in academic studies. The bibliometric study is limited with articles and conference papers written in the English language in engineering area. This study was composed by four main steps as below:

1. Step:

- Keyword search in the Scopus database using the keyword "Lean tools"
- Due to the high number of studies, 1123 documents, containing the subjects other than construction (like lean production, lean management strategies etc.); limiting the search with keywords of "Lean tools" and "Construction"
- Selection of articles and conference papers in English language, in engineering area between 2013- 2022.
- Exporting the data of 144 documents, with CSV format to analyse in the Vos Viewer software tool.

2. Step:

- Developing a map of links and analysis of clusters in the Vos Viewer software tool, containing the data of selected 144 documents.
- Analysing the findings on occurrence of all keywords.
- Listing of lean construction tools which have the most strength links with selected articles and conference papers.
- In accordance with the bibliometric analysis findings, selection of 4 most focused lean construction tool, to make more detailed analysis.

3. Step:

- Keyword search of most researched lean construction tools, which have been obtained with second step, in the Scopus database in addition to "Lean tools" and "Construction"
- Limiting the studies with articles written in English language in engineering area between 2013- 2022 by one by for each lean construction tool.

4. Step:

- Listing the articles about the most focused lean construction tool with descriptive information of authors, country, publication date, research methodology etc.
- General review of articles in the context of lean construction tools.

Analysis of Findings

Lean construction strategies, which take their origins from lean production management, show some common goals and tools like lean production system. Therefore, at the beginning of this research, lean tools keyword is searched in the Scopus database. The search is limited with articles and conference papers, written in English language in engineering area between 2013-2022. 1123 documents are analysed in Vos Viewer software tool and Figure 1 is derived.

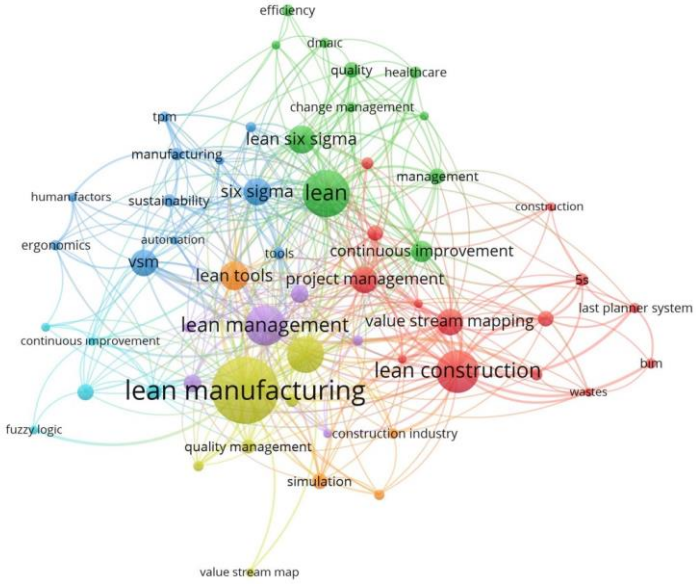

Figure 1: Lean tools occurrence keyword occurrence map in Vos Viewer software tool.

It shows that, 'lean manufacturing' issue has a greater impact on lean tools than lean construction. But the scope of this research is to analyse the lean construction tools; the search is redone with keywords of 'lean tools' and 'construction' within the same limitations. Figure 2 is derived. The lean construction tools in the keywords shown with links in the figure is chosen according to 40 lean construction tools in the thesis of Can (2020). The most impactful lean tools are listed as following.

- Last planner system
- Visual management
- Value stream mapping
- Building Information Modelling (BIM)

In the following step, the most occurred 4 lean construction tools in academic studies are researched in Scopus database again. Each tool is researched one by one with the keywords of

'lean tools' and 'construction'. For this step, only the articles are chosen written in English language in engineering area between 2013- 2022. The numbers of studies about each tool as follows:

- Last planner system- 26 articles
- Visual management- 7 articles
- Value stream mapping- 18 articles
- Building Information Modelling (BIM)- 20 articles

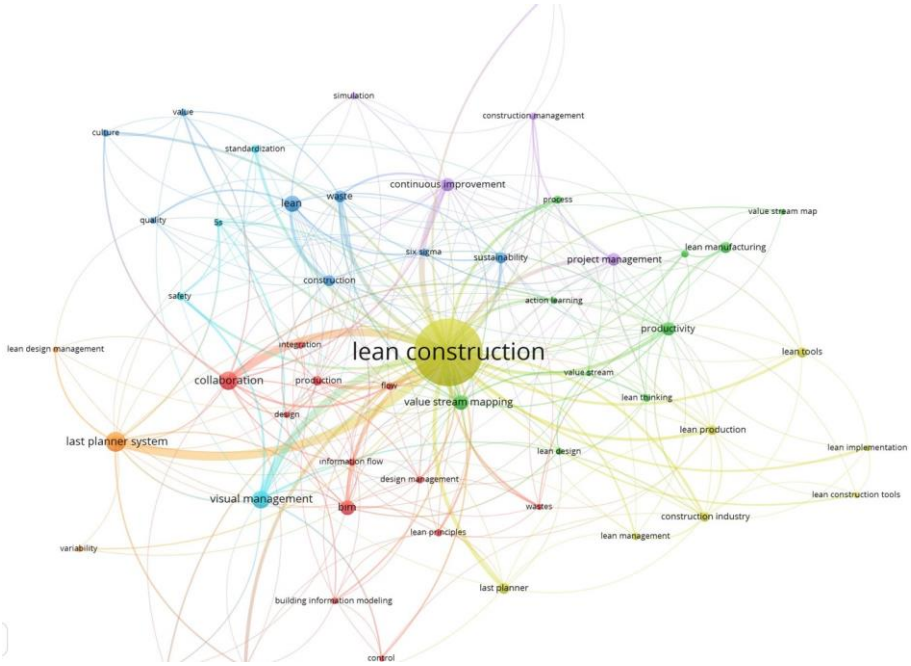

Figure 2: Lean tools and construction keyword occurrence map in Vos Viewer software tool.

According to the numbers of articles about lean construction tools, it is seen that 'Last Planner System' shows a majority than the other tools in the context of academic studies. So as a next step, 26 articles written about Last planner system is listed and analysed descriptively (Table 1). In the conclusion the data derived from the articles are evaluated and discussed.

Evaluation of Findings

The Last Planner System is a lean construction tool based on production control by dividing the project process into stages and preparing separate programs for each stage (Aydın, 2019). It helps to increase reliability of work plans, improve workflow, and improve the coordination and collaboration between construction industry actors by controlling the productivity in construction process. In accordance with the analysis of bibliometric study about lean construction tools, ‘Last Planner System (LPS)’ is the most emphasized research topic in academic studies. In 26 articles about LPS; it is focused on integration of LPS tool to ongoing construction projects, to avoid time and cost losses. In researched articles, the challenges of using LPS as well as its benefits have been explored. According to the articles, LPS tool is handled with the other lean construction tools rather than alone. According to keywords of 26 articles; the mostly dealt lean tools with LPS are Building Information Modelling (BIM), Visual Management, Value Stream Mapping, 5S, Earned Value Management etc. In most of articles, the availability, and benefits of using these lean construction tools integrated with LPS are tested with case studies, observations and measurements of cost and timeline data in real projects. So, the efficiency of the LPS tool is examined. In research, new lean construction models are built to increase the productivity of projects and decrease construction wastes related to construction risks in projects. So, in articles, LPS tool is emphasized as a lean management tool. Some articles emphasize on the supply chain management with the use of lean construction tools as LPS. Autonomy and visualization of project data are other related factors with lean construction tools in studies. Additionally, the comparison of project efficiency in the context of time, budget, and quality limits in addition, in the studies, comparisons in the context of time, budget and quality factors are made on how LPS is applied or not in the projects.

Conclusion

Construction industry is growing at a rapid pace. Along with this growth, the industry is facing numerous challenges that are making delivery of projects inefficient. At that point, lean principles that increase project efficiency and productivity come to prominence. So, in this study, it is aimed to analyze the studies of last 10 years about lean construction tools with a bibliometric study. Although many lean tools have emerged in the lean construction industry, the Last Planner System (LPS) is one of the most important. According to analysis of

bibliometric study, 26 articles about LPS within the research scope are evaluated and discussed in the context of; keywords, research topics and aims of the studies. According to articles, the implementation of LPS with other lean construction tools in construction projects is one of the most emphasized subjects. Benefits of LPS implementation by increasing reliability of work plans, smoothing workflow, and strengthening the communication and collaboration between project actors, challenges faced during the implementation of LPS tool and comparison of LPS tool with traditional management models are other most researched subjects. By analyzing the LPS related research, this study aimed to draw a research pathway about implementation of lean tools like LPS in the construction industry for further studies.

Abstract

The most critical issue faced by companies during the tender preparation process, especially in public construction tenders, is to give an exact bidding price. The calculation of bidding price for public tenders is a comprehensive and detailed process for Tender Management teams in construction companies. The performances of these tender teams are categorized as two key performance indicator (KPI) "Competitive" and "Not Too Low" depending on the bidding value given in the tender process. "Competitive" as a KPI score shows whether the offered price is within the standard deviations of all the offers given in tender process; whereas "Not Too Low" as a KPI calculates whether the offered price falls over the lowest limit decided by the local authority. It is important to meet those two KPI's targets to be included in bargaining process, instead of a firm that is eliminated due to too low or too high bidding prices. Therefore, it is beneficial to have decision support system that guides them in estimation process of the bidding price for tender teams.

Being able to give an exact bidding price to the tenders depends on the variety and accuracy of the datasets available regarding the contract during the tender preparation phase. Because of these prerequisites, the publicly available tenders of European public procurements were selected, and the detailed data sets and explanations needed for analysis were driven from European public procurement. Critical data sets in deciding the right bidding price were determined by multiple regression analyzes. Regression analysis results, to estimate winning bidding price for construction sector, were validated by European publicly shared sample tenders.

Keywords: *estimate winning bidding price, too low KPI, competitive KPI score, classification of construction contracts, regression analysis, decision support systems for construction business.*

Introduction

Tender preparation phase for construction companies, is a detailed and comprehensive process to work on. Since most of the public tenders heavily rely on infrastructure jobs, tender

teams need to make analysis through field visits and technical drawings. However, during the preparation phase of tenders, they do not have enough consultancy to guide them through finding the winning bidding price for an offer. Mostly, previous similar tenders are analyzed and people with similar project experience are used as a support. This research aim is to create a decision support system for tender teams, by using the public procurements results by regression analysis using machine learning algorithms developed in python.

To develop the proposed decision support system, detailed information about the tenders and its results should be accessible. Especially since it is important to have a relationship between the bidding prices offered and the actual contract values, the European Public Procurements were selected. Especially in developing countries, it is common to encounter tenders where there is a high difference between the estimate and actuals prices of projects and high variance between offers given by participant firms.

After the target region is decided and CSV notice results downloaded, all parameters received from the data set and codebook is studied. All data were cleaned by removing unnecessary or unusable information regarding the estimation process. After the dataset is analyzed and data cleaning is applied, the second task is to make feature selection. If there is irrelevant and redundant information such as noisy or unreliable data, then the training phase of models would be much more inefficient (Karagiannopoulos M., Anyfantis D., Kotsiantis S.B., Pintelas P.E., 2004). For this reason, a detailed feature selection control is applied in this study with three alternatives; "SelectKBest", "Recursive Feature Elimination" and "SelectFromModel" method alternatives are used.

Those selected parameters coming from the feature selection phase is trained and tested with "GradientBoostingRegressor" and "RandomForestRegressor" algorithms, which are two most common tree-based algorithms used for regression analysis.

The results from the two models are analyzed by comparing the estimated bidding prices in respect to winning bidding price values. The model results will be compared by checking their "Root Mean Squared Error (RMSE)" and "Mean Absolute Error (MAE)" result, as these two measures of error methods are useful in contrasting paired observations. The following figure presents the research framework of this study.

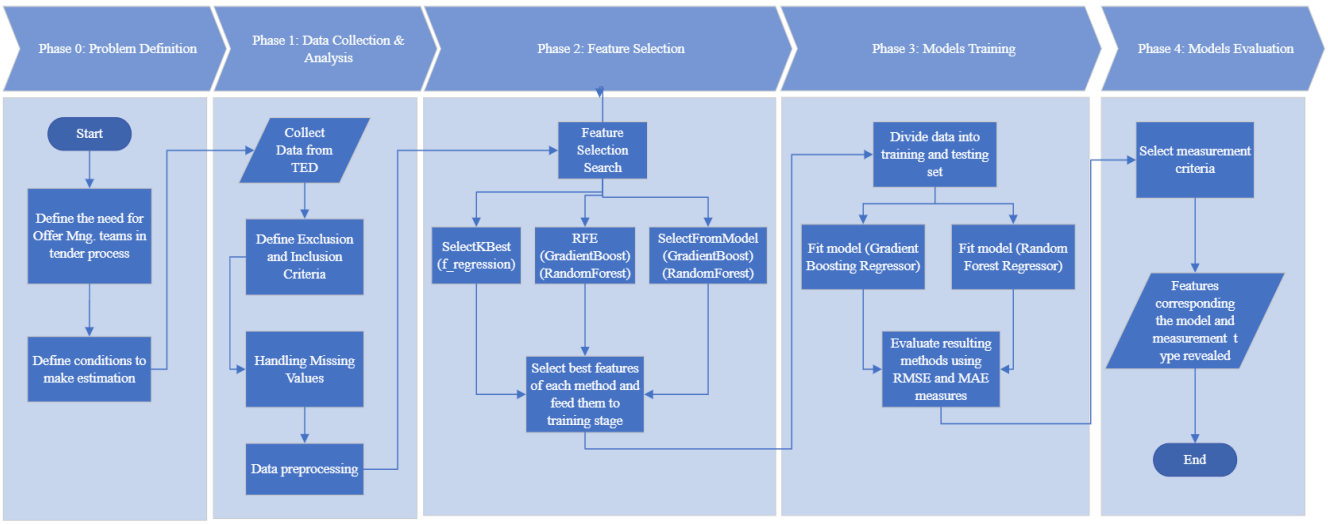

Figure 1: Research framework.

Literature Review

There are numerous studies on factors that affect cost and bidding prices in construction projects, however only a few of them is about estimating the bidding price through the analysis of tenders.

In Petrusava et al. (2016)'s study, authors have developed a model for predicting bidding price for construction projects in Skopje, Republic of Macedonia. In this research, they have used Support Vector Machine instead of linear regression models and reached a very high accuracy of prediction. Although, the research aims forecasting of parameters in construction sector overall, it is only focused on 26 signed agreements in Skopje; therefore, this study stays local and hard to implement to tenders outside Macedonia.

In another research (Stiti & Yape, 2019), authors have written a thesis on public procurements in Sweden, aiming to stream and digitize public procurement sector in general. The first contribution of project is looking at the factors affecting the bid/no bid and pricing decision of bidders, rather than giving an estimation on winning bidding price.

Data Collection & Analysis

The Tenders Electronic Daily (TED) comma separated value (CSV) open data, covering public procurement for the European Economic Area, Switzerland, and the Republic of North Macedonia, and the codebook that includes details of parameters were downloaded from the website "https://data.europa.eu/euodp/en/data/dataset/ted-csv" . Total of 75 parameters were analyzed, the following parameters were found relevant and usable for machine learning for model prediction (Petrusava et al., 2016)

Table 1. European public procurement feature analysis.

YEAR	It is the year of publication of the offer results. Since in TED (Tenders Electronic Daily dedicated to European public procurement) site, only result from 2007 to 2019 are shared; these years are used for training the dataset.
CANCELLED	The notices which were published before but cancelled afterwards are marked as *CANCELLED* value by 1.
B_MULTIPLE_CAE	This value shows if there is more than one contracting authority or not. This value is converted into a Boolean data type.
B_ON_BEHALF	It is a Boolean feature that shows if there is a central purchasing body or several buyers buying together. Since this parameter is a result of contract notice, this parameter should be filled as an estimate value.
B_INVOLVES_JOINT_PROCUREMENT	It is a Boolean feature that shows if the contract involves any joint procurement. Since this parameter is a result of contract notice, this parameter should be filled as an estimate value.
B_AWARDED_BY_CENTRAL_BODY	It is a Boolean feature that shows if contract is awarded by a central purchasing body. Since this parameter is a result of contract notice, this parameter should be filled as an estimate value.
B_FRA_AGREEMENT	It is a Boolean feature that shows if the notice involves the establishment of a framework agreement. Since this parameter is a result of contract notice, this parameter should be filled as an estimate value.

B_FRA_CONTRACT	It is a Boolean feature that shows this notice is probably about specific contracts within a framework agreement.
B_DYN_PURCH_SYST	It is a Boolean feature that shows if the notice involves contract is based on a dynamic purchasing system.
B_GPA	It is a Boolean feature that shows if the contract is covered by the Government Procurement Agreement.
B_EU_FUNDS	It is a Boolean feature that shows if the contract is related to a project and / or programme financed by European Union funds
B_ACCELERATED	It is a Boolean feature that shows if the option to accelerate the procedure has been used.
B_ELECTRONIC_AUCTION	It is a Boolean feature that shows if an electronic auction has been used.
B_AWARDED_TO_A_GROUP	It is a Boolean feature that shows if the contract has been awarded to a group of economic operators. Since this parameter is a result of contract notice, this parameter should be filled as an estimate value.
ISO_COUNTRY_CODE	It shows the country code of the first listed authority. There are about 33 country codes listed in a total of 13-year span.
CAE_TYPE	It shows the type of contracting authority. The possible values are listed as below: 1 “Ministry or any other national or federal authority, including their regional of local subdivisions” 3 “Regional or local authority” 4 “Water, energy, transport and telecommunications sectors” 5 "European Union institution/agency" 5A "other international organization" 6 "Body governed by public law" 8 "Other" N "National or federal Agency / Office" R "Regional or local Agency / Office" Z “Not specified" This parameter is defined as a categorical feature.
EU_INST_CODE	Type of EU Institution. For this value to be active, CAE_TYPE value must be 5. Below are possible values: AG "agencies" BC "European Central Bank" BI "European Investment Bank" BR "European Bank for Reconstruction and Development" CA "European Court of Auditors" CJ "Court of Justice of the European Union" CL "Council of the European Union" CR "European Committee of the Regions" EA "European External Action Service" EC "European Commission" ES "European Economic and Social Committee" FI "European Investment Fund" OB "European Patent Office" OP "Publications office of the European Union" PA "European Parliament"
TYPE_OF_CON	This a categorical feature that shows the type of contract. This is an

TRACT	important feature that differentiate contract types. Below are possible values: W "Works" U "Supplies" S "Services"
FRA_ESTIMATED	This is a categorical feature that shows whether there are indications that this notice is about a framework agreement that depends on *B_FRA_AGGREMENT* parameter. If this parameter values are "Y", then below are possible values: (These parameter combinations are available also) K "The keyword `framework', in the appropriate language, was found in the title or description of the notice." A "Multiple awards were given per one lot, which is legally admissible only in case of framework agreements, dynamic purchasing systems, innovation partnerships, and qualification systems." C "Consistency across notices: the contract notices which preceded this notice was marked as a framework agreement."
CPV	Common procurement vocabulary (CPV) establishes a single classification system for public procurement aimed at standardizing the references used by contracting authorities and entities to describe procurement contracts. ➢ The first two digits of CPV is identified as divisions (XX000000-Y). ➢ The first three digits identify the groups (XXX00000-Y), ➢ The first four digits identify the classes (XXXX0000-Y), ➢ The first five digits identify the categories (XXXXX000-Y).
TOP_TYPE	Type of procedure feature (Categorical feature): ➢ AWP: award without prior publication of a contract notice ➢ COD: competitive dialogue ➢ NOC/NOP: negotiated without a call for competition ➢ NIC/NIP: negotiated with a call for competition ➢ OPE: open ➢ RES: restricted ➢ INP: innovative partnership
OUT_OF_DIRECTIVES	It is a Boolean feature that shows if the procurement falls outside the scope of application of the directive. This feature is available if TOP_TYPE value is either NOC/NOP or AWP.
NUMBER_OFFERS	Number of tenders received for the contract notice. Since this parameter is a result of contract notice, this parameter should be filled as an estimate value.
NUMBER_TENDERS_SME	Number of tenders received from SMEs. Since this parameter is a result of contract notice, this parameter should be filled as an estimate value.
NUMBER_TENDERS_OTHER_EU	Number of tenders received from tenderers from other EU Member States. Since this parameter is a result of contract notice, this parameter should be filled as an estimate value.
NUMBER_TENDERS_NON_EU	Number of tenders received from tenderers from non-EU countries. Since this parameter is a result of contract notice, this parameter should be filled as an estimate value.

AWARD_EST_VALUE_EURO	Estimated Contract value in EUR, without VAT. This is the most critical parameter in estimating new contracts.
AWARD_VALUE_EURO	It is the winning bidding price in contract in EUR, without VAT. This is the parameters that our estimation model tries to predict.

Above parameters are worked on from the data received between 2007 and 2019. There are in total 7.347.867 entries in total; for these all records below data cleaning actions are taken:

➢ *AWARD_VALUE_EURO* and *AWARD_EST_VALUE_EURO* are two most important features to consider in estimation. *AWARD_VALUE_EURO* is the contract price that is the value to be estimated in our model. *AWARD_EST_VALUE_EURO* is the estimated contract value, which has the highest correlation with the contract price and critical in making prediction. For those reasons, entries with missing contract and estimated contract value are omitted from estimation process.

➢ Cancelled contracts are also withdrawn from estimation process as there are also a lot of intersection with *AWARD_VALUE_EURO* and *AWARD_EST_VALUE_EURO* empty fields. Cancelled notices (Value of 1) are withdrawn from the training data.

➢ Since the paper is about predicting the bidding price in construction sector, a filter is applied on *TYPE_OF_CONTRACT* feature. Only contracts with "W" (Works category) are considered in the prediction process, which means contracts of Supplies and Services are withdrawn from the data. From the total of 2,464,816 entities, the status of the contract type is examined, the distribution is presented below (This is the distribution after 1st and 2nd controls are applied)

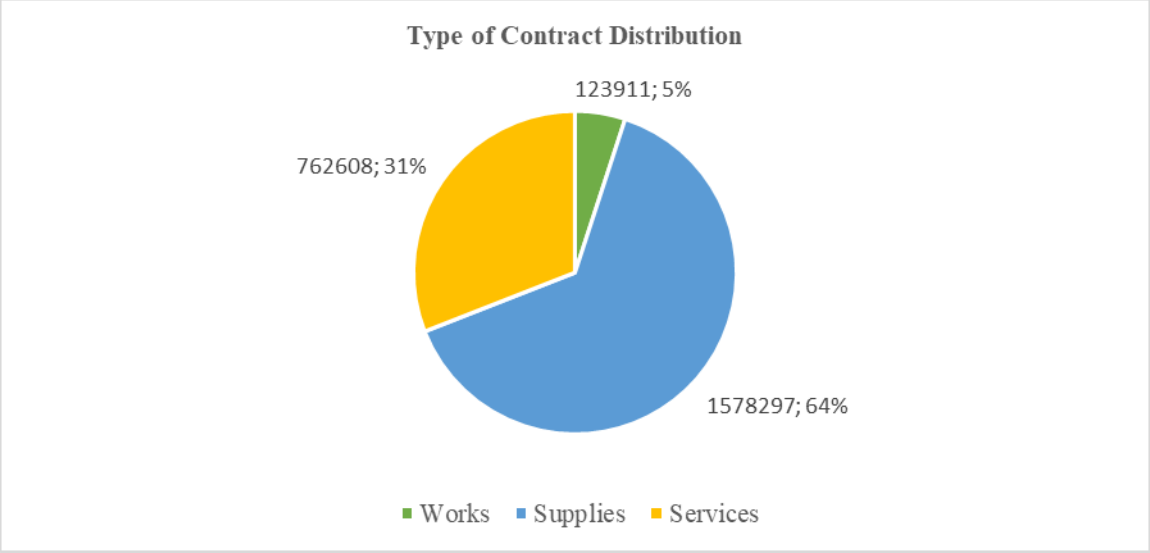

Figure 2: Type of contract distribution for contracts between 2007-2019.

Works category has in total 123911 entities; this is also normal as "Works" contracts are less in quantity, but high in budget.

➢ A new feature named "*CPV_DIVISON*" is created from the existing *CPV* feature. Because *CPV* value by itself is not helpful in the estimation process with unnecessary

separation of sample with detailed information. From the existing options, it has been decided to use the “Division” identifier as it is helpful in distinguishing the type of projects.

When all data is investigated, there are possible of 68 divisions available. The other options are excluded, because those options are more detailed definitions and there are not many samples to make estimation for each option.

➢ The entities with null values on Boolean features are assigned to values “N” (No), to be used in the estimation model.

➢ Missing *FRA_ESTIMATED* entities are updated as “K” which means the keyword `framework', in the appropriate language, was found in the title or description of the notice.

➢ Missing *TOP_TYPE* entities are update “OPE”, since this is an open procedure procurement which is the most common style public tenders.

➢ Missing GPA_COVERAGE entities are updates as “2” which is equivalent to entity not covered by GPA.

➢ Missing *NUMBER_OFFERS, NUMBER_TENDERS_NON_EU, NUMBER_TENDERS_OTHER_EU, NUMBER_TENDERS_SME* entities are updated with their corresponding arithmetic means. Basically, missing *NUMBER_OFFERS* values are updated with the arithmetic mean of all projects NUMBER_OFFER parameter.

Mean values are calculated as below:

- *NUMBER_OFFERS* = 6.49
- *NUMBER_TENDERS_NON_EU = 0.024*
- *NUMBER_TENDERS_OTHER_EU = 0.14*
- *NUMBER_TENDERS_SME = 3.36*

➢ A new parameter named as “price_ratio” is defined, which is calculated from the division of Estimated Contract Value to Award Contract Value (*AWARD_EST_VALUE_EURO/ AWARD_VALUE_EURO*). This new parameter is defined to check the relationship between the estimations and realizations of contract values and to detect outlier contracts with unrelated (high/low) contract values. Below is the figure that shows the data density of Price Ratio value:

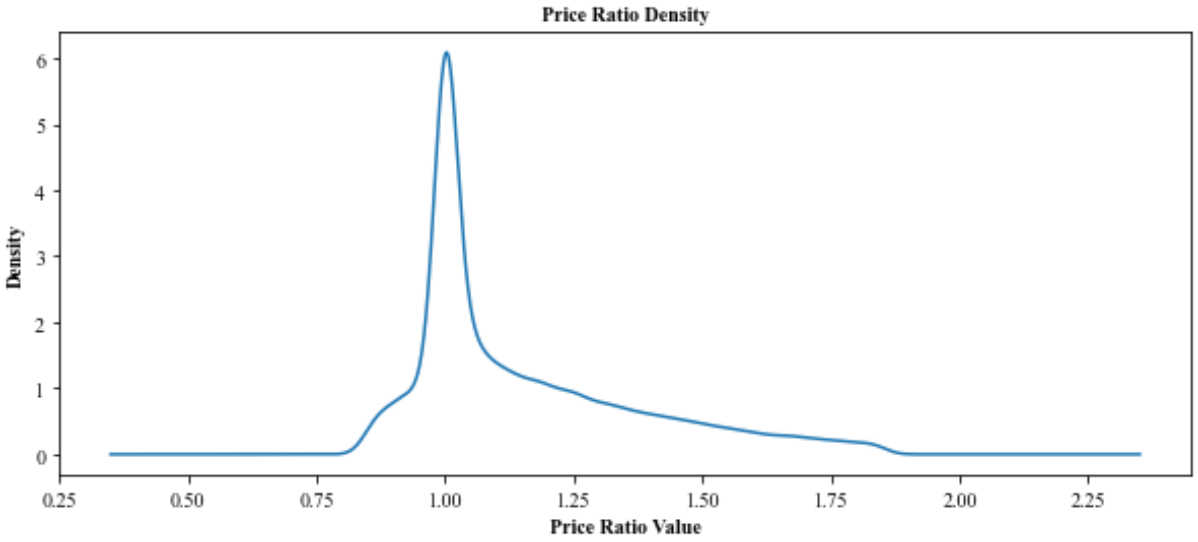

Figure 3: Data density of price ratio value.

As it can be checked from the figure, most of the contracts have a price ratio value close to 1 and the data is skewed. For this reason, Tukey's method (Boxplot) rule is applied on Outlier detection and treatment. Tukey introduced the rule to screen outliers which practices on quartiles instead of means or standard deviations (Saleem et al., 2021). Since most of the contract award notice price ratio values are concentrated around value 1 and extreme price ratio values are rare cases; the extreme observations that stays out of inner fences (Interval with 1.5 Interquartile range) are omitted from the estimation process.

For IQR rule, below operations are applied.

1) The data for price_ratio is sorted in ascending order.

2) The first quartile of price_ratio is calculated (Q1-%25)

3) The third quartile of price_ratio is calculated (Q3-%75)

4) IQR value is calculated which is equal to $Q3 - Q1$.

5) The lower range is calculated as $Q1 - (1.5 * IQR)$

6) The upper range is calculated as $Q3 + (1.5 * IQR)$

From the 123911 entries found, *Upper Limit* value is calculated as 1.85 and *Lower Limit* value is calculated as 0.83. After upper and lower limit are found; contracts with outlier price_ratio values are eliminated from the data, which cause 12801 entries to be removed from the model data.

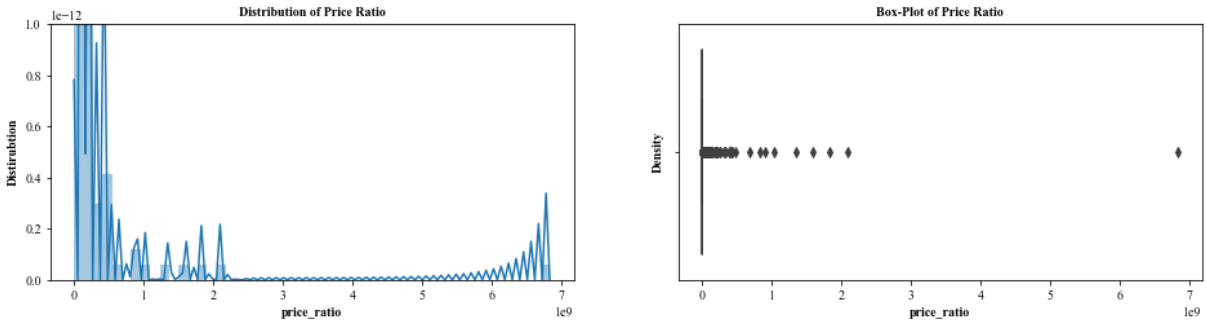

Figure 4: Density plots of price ratio value.

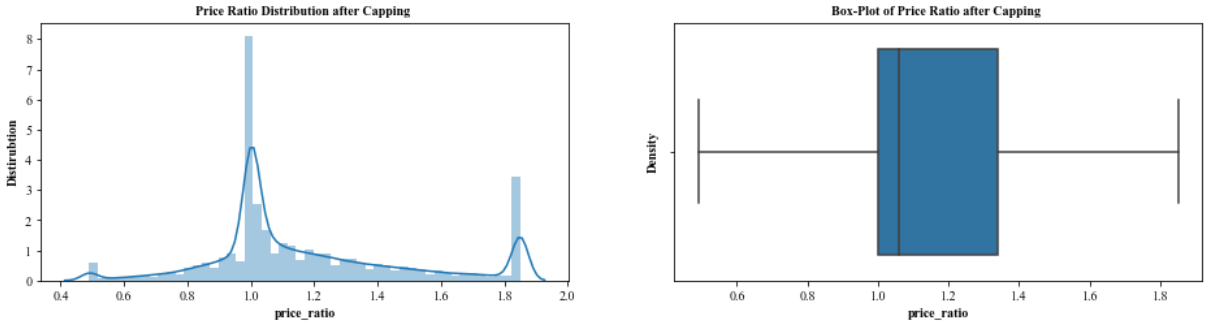

Figure 5: Density plots of price ratio value after capping data.

Correlation Feature Selection

At this stage, a work is done on which features to be selected and check the correlation of each with contract winning price value. These parameters selected from multiple correlation feature selection methods, then were used in model training stage. As stated in Blum and Langley (1997), as Machine Learning aims to address larger and more complex tasks, the importance of working with relevant information has become increasingly important. Since as the features and the number of constructions works increases, it is also important for the estimation of construction bidding prices. From the total of 75 features available; after data cleaning operation was completed, the number of features to be worked on estimation process is gathered to 23 features. Null values and categorical values were handled and prepared for estimation process.

To filter which features to exclude in the training phase of model, correlation of features in respect to winning bidding price (*AWARD_VALUE_EURO*) are checked. In correlation analysis check, "AWARD_EST_VALUE_EURO" (Estimated bidding price value by local authority) is excluded because this is the highest correlated value to winning bidding price and it is added to estimation model immediately. To extract other most relevant features, below methods are used:

- All Features
- SelectKBest method with f_regression
- Recursive Feature Elimination (RFE)
- SelectFromModel

SelectKBest with score_func option “f_regression” is commonly used for regression analysis, which combines p-values and F-test scores to evaluate the performance of parameters, making the method statistically robust (Otchere et al., 2022). Below is the bar chart showing the importance scores of those inputs. According to results received from SelectKBest; features with a correlation higher than 0.5 (CAE_TYPE with a value 0.78 is the lowest relevant) are received from the analysis result. Below 5 features are added in the estimation process.

- *B_FRA_AGGREMENT, B_FRA_CONTRACT, B_EU_FUNDS, B_GPA, CAE_TYPE*

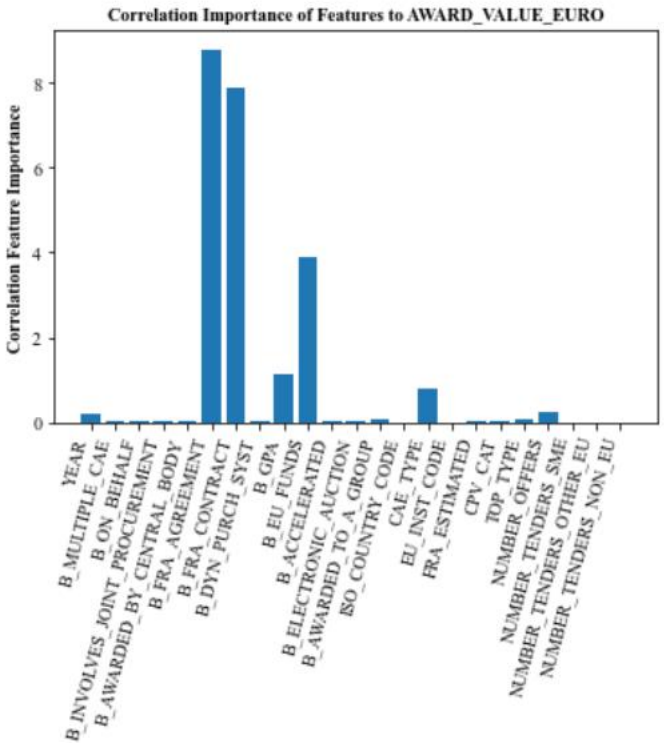

Figure 6: Correlation importance of features in respect to winning bidding price.

Recursive Feature Elimination (RFE) trains the model with full parameters at the beginning and ranks the importance of features. The same process is applied to smaller subsets and finally the features that belong to best model is revealed (Feng et al., 2017). The main parameter in RFE is the “estimator” and both “GradientBoostingRegressor” and “RandomForestRegressor” algorithms are used. Another important parameter is “n_features_to_select” which requires the number of features to be selected from the method. In our study, half of the parameters are tried which is equal to 11 parameters. Below is the list of 11 parameters:

- Gradient Boost Regressor: *B_FRA_AGGREMENT, B_FRA_CONTRACT, B_GPA, CAE_TYPE, YEAR, ISO_COUNTRY_CODE, FRA_ESTIMATED, CPV_CAT, TOP_TYPE, NUMBER_OFFERS, NUMBER_TENDERS_SME*
- *Random Forest Regressor: NUMBER_OFFERS, NUMBER_TENDERS_SME, YEAR, B_FRA_CONTRACT, B_FRA_AGREEMENT, TOP_TYPE, FRA_ESTIMATED, ISO_COUNTRY_CODE, B_GPA, CAE_TYPE, CPV_CAT*

SELECTFROMMODEL method starts with training the model with all parameters as well. In a backward way, least significant features are removed from the model until there is no

improvement observed on model performance (Badrouchi et al., 2021). Just like in RFE, this method requires "estimator" parameter as well. From this method, there are 2 critical attribute values received. One of them is the "threshold" value which shows the value used for feature selection and other is the list of features that are selected. From this method, below features are added to estimation process.

- Gradient Boost Regressor: *B_FRA_CONTRACT, CAE_TYPE, B_EU_FUNDS, B_FRA_AGREEMENT, NUMBER_OFFERS, YEAR*
- Random Forest Regressor: *B_FRA_CONTRACT, CAE_TYPE, YEAR, ISO_COUNTRY_CODE, NUMBER_OFFERS*

Training the Algorithms

After feature selection phase, the next step is to train and test the algorithms with corresponding features. At the end of this stage, it will be decided which regression algorithm presents the best estimation for public tenders in European Public Procurements. This study focusses on two tree-based regression algorithms that have ensemble learning techniques coming from linear regression model, to make more accurate predictions.

Gradient Boosting Regressor is an iterative collection of sequentially arranged tree models in which the model predictions are improved from the error of former models (Otchere et al., 2022). At each node, a regression tree is fit on the negative gradient of the loss function calculated.

Random forest is an algorithm that is built on two mechanisms "Bagging" and "Feature Sampling". Each tree in Random Forest is pre-built from sample data sets and at each node, variables are sampled as candidates at each split. The best split point is then for this random set variable. This process continues until all trees in random forest are fully grown (Callens et al., 2020).

Table 2. Algorithm results.

	Gradient Boost Regressor		Random Forest Regressor	
	RMSE	MAE	RMSE	MAE
All Features	22.068.217	1.511.664	32.012.699	1.009.447
SelectKBest	20.424.446	1.490.968	32.926.380	1.201.329
Recursive	20.762.825	1.488.853	30.072.299	990.801
SelectFromModel	19.496.648	1.470.041	21.121.527	876.450

As a result of our analysis, for RMSE, Gradient Boost gave better results compared to Random Forest, both in the set where all the features are applied, and in the sets where the SelectKBest, Recursive, SelectFromModel methods are applied. Random Forest, on the other hand, did better for MAE on all sets. The best value for RMSE was the SelectFromModel method with Gradient Boost as estimator and model, while the best value for MAE was obtained with SelectFromModel method again but with Random Forest estimator this time. Our best score is 19,496,648 for RMSE and 876,450 for MAE.

Models Evaluation

In this final model comparison stage, the results received from the two algorithms were compared in respect to "Root mean square error (RMSE)" and "Mean absolute error (MAE)" calculations. MAE calculation is done by averaging the absolute values of total errors, whereas RMSE is the standard deviation of prediction errors. In RMSE, since the calculation is done by squaring the errors first, it penalizes the variance as it gives errors with larger absolute values more weight than errors with smaller absolute values. On the other hand, same weight is given to all errors at MAE evaluation. (Chai & Draxler, 2014). From these two statistical evaluation methods, there are different opinions to count on.

According to Cort and Kenji, RMSE do not describe average error alone as it is not possible discern to what extent RMSE reflects average error and the variability within the distribution of squared errors (Willmott & Matsuura, 2005).

On the contrary, a study made by Chai and Draxler argue against this notion. According to this study, RMSE is more appropriate to use than MAE when there is normal distribution. If some of the outliers are examined and leave out the estimation process, the effect of penalization to large errors would be minimized (Chai & Draxler, 2014).

In this study, since outlier contracts are eliminated and it is not desirable to have high variance over estimated and actual bidding price, RMSE is selected as the critical evaluation method on control. For this reason, it is decided to proceed with the "Gradient Boost Regressor" algorithm and features selected from the "SelectFromModel" class with "GradientBoostingRegressor" estimator used.

Conclusion

Tender preparation phase for construction companies is an exhaustive stage which requires detailed work and analysis; for this reason, it is beneficial for them to have any decision support system in assisting their decision on final bidding price. The previous researches on this topic are mainly focused on local regions, whereas in this study, it is aimed to come up with a solution that includes multiple regions.

The results of this work will be used for Dogus Construction and the model created with "GradientBoostingRegressor" estimator, will be implemented to Offer Management system. The below declared features will be required for projects occurring in the region of European Union and the estimated bidding price value is going to be shared with Offer Team as a decision support system.

The features that are selected for the selected method can be summarized as:

- Estimated price value of contract (*AWARD_EST_VALUE_EURO*)
- Number of tenders received for the contract notice (*NUMBER_OFFERS*). This value should be filled as an estimate value by the estimating firm.
- Year of the contract notice (*YEAR*)
- If notice is probably about specific contracts within a framework agreement (*B_FRA_CONTRACT*)

- If the notice involves the establishment of a framework agreement (*B_FRA_AGREEMENT*)
- If the contract is related to a project and / or programme financed by European Union funds (*B_EU_FUNDS*)
- Type of contracting authority (*CAE_TYPE*)

Although the model is created based on the gathered from European Union public procurements, the same work can be applied to regions with similar characteristics (United States, Canada…etc.) and results (selection of parameters and model) received from those can be compared with the ones in this research.

Total Construction Duration Calculation of TOKI Housing Projects: A Case Study

H. Tirataci and H. Yaman
Istanbul Technical University, Department of Architecture, Istanbul, Turkey
htirataci@ itu.edu.tr, yamanhak@itu.edu.tr

Abstract

In modern project management principles, accurate estimations for construction duration are significant to successfully complete projects on time. However, in accordance with literature review and Supreme Court decisions, it was determined that considerable number of housing projects were delayed in Turkey. TOKI (Housing Development Administration of Republic of Turkey), as an authorized public entity, has been major client to build housing projects in Turkey. Therefore, it was decided to study the construction delays for TOKI housing projects in this case study. The objective of this study was to reveal the difference between calculated construction durations by TOKI's own calculation method and durations indicated in official construction contracts between TOKI as client and awarded contractors. This research was adopted as a case study methodology involving semi-structured interviews with TOKI personnel. The datasheet showing detailed project information about 2800 completed TOKI projects was obtained. Interviews also showed that TOKI has been using three factors, namely number of houses, type of project drawings utilized in tendering process, and non-working days to calculate total construction duration. Findings of the study showed that calculated construction durations by TOKI were way higher than of those indicated within official construction contracts. Study revealed that TOKI was significantly shortened the calculated durations while transferring to contract durations officially which ultimately resulted in considerable number of housing projects delayed.

Keywords: *case study, construction duration, planning in construction, project management, TOKI.*

Introduction

Planning and programming in tender phase were regulated by relevant laws and authorized organizations (FIDIC, 2017). However, it was observed that it is not the case for public construction sector in Turkey (Yitmen & Dikbas, 2002; Birgonul et al., 2007; Koktas et al., 2009; Akkaynak, 2013; Erbas & Ciraci, 2013; Usta, 2014) due legal regulations reckon without planning but prioritize only the lowest tender price (Public Procurement Law no. 4734 dated 04.01.2002, article 40) and this situation needs to be improved (Turesoy, 1989; Demirci, 2001; Karapinar, 2005; Tokalakoglu, 2010; Sevim, 2011; Kaplan, 2012). There are also studies in which project duration is considered as one of the least important factors (Walraven & de Vries, 2009; Shokri-Ghasabeh & Chileshe, 2016). It is emphasized that lower costs should not be the only basis for choosing contractors, but also time and performance factors should be considered

(Obodo et al., 2021). According to these findings, it is understood that construction duration was not studied much in researches although many factors are considered in different studies. Moreover, better tender system and effective planning specified in the Development Plans have not been fully implemented (DPT, 2001; DPT, 2007; Turkish Republic Presidency of Strategy and Budget, 2019).

The most significant factor affecting the project duration was cost and many factors affecting the project duration were not considered (Odabasi, 2009). Similar with the interviews with TOKI personnel, Baltaci (2012) observed that market experience and job efficacy of the contractor and environmental impacts are also considered and no findings regarding time planning were found. Sonmez (2019) emphasized that the total construction duration in time-cost relationship for TOKI housing cannot be done with a single mathematical equation and there were time planning failures due to own characteristics of each construction project. For these reasons, it has been shown that a dynamic system is needed in accordance with the complex structure of TOKI projects. Turhan (2006) confirms delays in TOKI construction projects.

On the other hand Supreme Court case law indicates that there are legal disputes due to timely delays related to housing projects tendered by TOKI in Turkey (Supreme Court Office, 2010, 2011, 2013, 2014, 2015). Literature also indicates the same findings (Al-Khalil & Al-Ghafly, 1999; Aibinu & Jagboro, 2002; Odabasi, 2009), suggesting that TOKI shall use modern planning and programming techniques rather than utilizing data from previously completed projects.

The purpose of this paper to introduce the findings of the case studies searching the reasons and results of construction delays in housing projects in Turkey. The research is the initial part of a PhD thesis that aims to determine ideal construction duration for housing projects by considering factors affecting total construction duration by proposing a novel model where the findings of this research constitute such requirement. At the beginning of the research it is aimed to analyze the state-of-the-art and reveal the gap between construction duration calculated with Construction Documents or with only Schematic Design by TOKI and official contract durations.

Background

The project management is principally based on planning and programming (PMI, 2021). Construction projects are considered successful if they are completed on time within budget in specified quality (Majid, 2006). During the tender phase, effective planning and programming leads success in construction phase (Luu et al., 2009; Ismail, 2013; Tunc & Ozsarac, 2015). The most important factor affecting time, cost and quality in construction projects is insufficient planning and programming (Elinwa & Joshua, 2001; Ibironke & Elamah, 2011).

TOKI (Directorate of Public Housing and Partnership Administration) is a kind of pioneer in the public construction sector in terms of the purpose of establishment and it is authorized to build housing projects as client. TOKI primarily operates within the scope of the Public Housing Law No. 2886, No.2985, No. 4966 and No. 5162 (Turkish Republic Official Gazette, 1983, 1984, 2004; Baltacı, 2012). The project budgets are determined annually and the project is suspended in case there are not enough funds at the beginning of the year. This causes the project delivery date to be exceeded (Solak, 2013).

In planning and programming for tender phase, Department of Tender Affairs of TOKI prepares cost estimations of construction projects and job descriptions in the contracts. Odabasi (2009) observed that contractor selection method was single stage. In other words, a tender process is used that allows the bid was awarded directly to the eligible bidder for the jobs described in the tender requests. In this process, the work is given to the contractor with the lowest bid. The contractor is examined and analyzed by technical committee of TOKI, and the construction firms that previously worked with the chosen contractor are also asked about the contractor. If the TOKI committee is convinced that the contractor is suitable for the job, they decide to give project to the contractor. If the committee is not convinced about it, the same procedure is applied to other contractors (Odabasi, 2009). From this perspective, it is suggested that the contracts are based on cost and precedent projects of the contractor to persuade the TOKI committee. In practice, there is no evidence related to an official calculation method for total construction time.

Literature findings indicated that case studies are necessary for analysis of status and problems of calculating construction duration along with a proposed model utilizing factors affecting the construction duration (Lee et al., 2009; Jin et al., 2016; Yeom et al., 2018). Moreover, two case studies were performed to propose construction duration models while one case study was used to validate a proposed model. Since project duration was defined by the Client or suggested by contractor (Jin et al., 2016; Bayram, 2017), the construction duration computational model utilized by the Client during tender phase should be a specialized standard for Turkish housing projects. Therefore, it was concluded that case study approach is more appropriate for conducting this kind of research.

Methodology

This study was adopted as a case study methodology. According to Yin (2003), the case study can be exploratory to create new knowledge, constructive to solve some problems, or confirmatory to test a hypothesis with empirical evidence. The purpose of this case study was to analyze the state-of-the-art of TOKI housing projects. Baseline Construction Durations (BCD) were calculated for 1530 housing projects within "TOKI Projects Status Table" by using below equation which is extracted from the calculation method used by TOKI to estimate total construction duration for housing projects;

Baseline Construction Duration (BCD) (days) = (Number of working days in Factor #2a: "Duration with Construction Documents (DCD)" *corresponding to Factor #1:* "Number of Flats"*) + (50 working days in case use of Factor #2b:* "Duration with Schematic Design (DSD)"*) + (Factor #3: "Number of non-working days")* (1)

After that these durations were compared with the official contract durations. Duration with Construction Documents (DCD) and Duration with Schematic Design (DSD) were calculated separately and Contract Duration (CD) data were used to reveal the gap between Baseline Construction Durations and Contract Durations.

In the case studies either primary data (the researcher collects the data) or secondary data (the researcher uses someone else's data) can be used. Two case studies were implemented according to the tender processes of TOKI;

Case 1 – Calculation Duration with Construction Documents (DCD)
Case 2 – Calculation Duration with only Schematic Design (DSD)

Each case study was carried out with the intent to present a valid comparison of DCD/DSD versus Contract Duration (CD). Both cases are based on 1530 housing projects. Analysis, in line with the objective of this case study shows not only comparison of DCD/DSD versus Contract Duration, but also compares with Delay Time (DT) for housing projects. The phases of case study are as below;

Phase 1: Identification of Construction Duration by Literature Review.

Phase 2: Identification of Construction Duration Factors which TOKI used via Literature Review, Semi-Structured Individual Interviews with TOKI officials, case study observations, Supreme Court case law and TOKI documents (TOKI Projects Status Table).

Phase 3: Identification of Contract Durations and Delay Times from TOKI Projects Status Table.

Phase 4: Calculation of Baseline Construction Duration with Construction Documents and with only Schematic Design by Numerical Analysis.

Phase 5: Implementation and Validation of the Case Study by comparing Phase 4 values vs. Phase 3 values.

The scope of this case study was limited to TOKI housing projects, planning and programming activities in the tender phase, bidding processes defined and indicated within Public Procurement Law No. 4734, Public Housing Law No. 2985, No. 4966 and No. 5162, TOKI Standard Contract for Construction, Regulation on the Use of TOKI Resources (2002) and the Regulation on Construction Tenders Implementation (2009). Descriptive data is limited with TOKI projects' datasheet extracted from TOKI Project Status Table.

TOKI documents were scrutinized to determine the number of delayed projects and delay times for all projects. Delay in construction projects is defined as exceeding of time beyond the completion date specified in contract or the date agreed by the parties for the delivery of a project (Shahsavand et al., 2017). Analysis of the "TOKI projects' datasheet" showed that most delays occurred in housing projects.

Project information includes but not limited to the following: "project description", "project location", "contract date", "contract duration", "start and finish dates" on TOKI Projects' datasheet. Data analysis were conducted by percentage and frequency statistics. Total number of projects were 3500 and 700 ongoing projects were eliminated and 2800 projects were remained where 1530 of them was housing projects. The minority data which has insufficient information was also eliminated.

Approximate construction duration in this research refers to the total construction duration from the beginning to the end of the construction during the construction phase, which is estimated in the project planning phase. In order to understand the existing situation in better way, semi-structured interviews were conducted with TOKI officials in Ankara on 22-23 December 2015 and in Istanbul on 24-25 December 2015. Verbal information obtained from the TOKI authorities was noted. No audio recordings were allowed by TOKI in the data collection.

Documents such as periodical and non-periodical TOKI publications were obtained. During the interviews, objectives and scope of this case study were explained. Current implementations for planning and programming in tender phase, time allocated by TOKI personnel for completed projects and factors used to calculate total construction duration were asked. Findings from interviews and observations were suggested that total construction duration was not calculated in line with modern project management principles. Instead, duration estimations were based on data of previously completed projects. Also, it is observed that TOKI officials directly decide construction duration without using any tool or software.

Furthermore, Supreme Court cases were examined to reveal whether disputes were arisen due to delays of construction duration. Many conflicts were generally arisen from delays in project delivery dates specified on the contracts. Claims showed that houses were not delivered to the beneficiaries on the contract date.

Results

Findings of this study primarily involved the analysis of all types of projects constructed by TOKI within "TOKI Projects Status Table" and later focused on housing projects. Descriptive statistics for 2800 TOKI projects in. There were 22 different types of projects and most of them were 1530 housing projects. It was followed by hospital projects (347 units) and school projects (327 units). Most of the TOKI projects were executed in Central Anatolia Region with 590 units and the least were in the Mediterranean Region with 238 units.

As primary focus, analysis of the housing projects constructed by TOKI was revealed that 720 out of 1530 housing projects were delayed. The ratio of delayed TOKI housing projects to total number of TOKI construction projects (720/2800=0.2571) was 25.71%. The number of delayed housing projects out of 1530 TOKI housing projects was calculated as 720 and the delay rate (720/1530=0.4706) was 47.06%.

Table 1. Number of delayed TOKI construction projects and (%) percentages according to geographical regions.

Geographical Regions	Number of Delayed Projects	Total Number of Projects	Percentage 1* (%)	Percentage 2** (%)
Mediterranean	130	238	54.62%	8.50%
Eastern Anatolia	253	536	47.20%	19.14%
Aegean	121	260	46.54%	9.29%
Southeastern Anatolia	152	301	50.50%	10.75%
Central Anatolia	305	590	51.69%	21.07%
Black Sea	177	385	45.97%	13.75%
Marmara	229	490	46.73%	17.50%
Total	1367	2800	48.82%	

In Table1, Geographical regional distribution of projects, Percentage 1 and Percentage 2 ratios were used. 1367 out of 2800 construction projects in Turkey were delayed and 48.82% of the projects carried out by TOKI are not completed on time.

Percentage 1*: Number of delayed project in the region/ Total number of projects in the region.

Percentage 2**: Total number of project in the region / Total number of projects in Turkey.

Geographical regional distribution of Percentage 1 showed that the most delays occurred in the Mediterranean region (54.62%) and this was followed by Central Anatolia (51.69%), Southeast (50.50%) and Eastern Anatolian Region (47.20%), respectively. The Black Sea and Aegean regions had the highest number of projects completed on time. Geographical regional distribution of Percentage 2 showed that most of TOKI projects were executed in Central Anatolia Region (21.07%) and least in Mediterranean Region (8.50%).

Table 2. Number of TOKI construction projects with time extension according to geographical regions and (%) percentages.

Geographical Regions	Number of projects with time extension				Total (Nos)	Percentages (%)
	1	2	3	4		
Mediterranean	107	16	4	3	130	9.51%
Eastern Anatolia	209	33	8	3	253	18.51%
Aegean	102	13	3	3	121	8.85%
Southeastern Anatolia	119	23	8	2	152	11.12%
Central Anatolia	279	18	6	2	305	22.31%
Black Sea	162	10	2	3	177	12.95%
Marmara	197	22	6	4	229	16.75%
Totals	1175	135	37	20	1367	100.00%

In Table 2, Number of projects without time extension was (2800-1367) equal to 1433, with time extension only once was 1175, with second time extension was 135, with third time extension was 37 and with fourth time extension was 20. 130 of the 1367 delayed projects was in Mediterranean Region, 253 in Eastern Anatolia, 121 in the Aegean, 152 in Southeast Anatolia, 305 in Central Anatolia, 177 in the Black Sea and 229 in the Marmara Region.

The city with the most project delays in the Central Anatolia Region was Ankara with 142 projects, Istanbul with 110 projects in Marmara Region, Trabzon with 29 projects in the Black Sea Region, Van with 46 projects in the Eastern Anatolian Region, Izmir with 26 projects in the Aegean Region and Diyarbakir with 27 projects in the Southeastern Anatolia Region.

Central Anatolia Region ranks first with 181 housing projects without any time extension. However, it was determined that the same region had the highest number of housing projects with one time extension compared to other regions. Marmara Region had the highest number of housing projects with 12 projects having second time extension. The Eastern Anatolia Region is the only region without having third of fourth time extensions. It was also observed that the total number of housing projects with one time extension to second time extension dropped

from 654 to 47 drastically. From the perspective of cities, Ankara ranks first with 87 delays, followed by Istanbul with 59 and both Bursa and Adana with 18 delayed housing projects.

Table 3. Number and average delay times of delayed housing projects by geographical region.

Geographical Regions	Average construction duration of housing projects (days)	Number of housing projects (Nos)	Number of delayed housing projects (Nos)	Percentage of delayed housing projects (%)
Mediterranean	450	106	60	56.60%
Eastern Anatolia	446	271	96	35.42%
Aegean	445	142	64	45.07%
Southeastern Anatolia	484	139	69	49.64%
Central Anatolia	508	370	189	51.08%
Black Sea	474	220	104	47.27%
Marmara	541	282	138	48.94%
Totals	486	1530	720	

In Table 3, Average construction duration for a housing project was 486 days. Marmara Region was above Turkey's average construction duration with 541 days and the Central Anatolia Region with 508 days. The Southeastern Anatolia Region also had an average construction duration of 484 days, closer to the Turkey's average. Other regions showed durations below the average.

60 out of 720 delayed housing projects were in Mediterranean region, 64 in the Aegean Region, 69 in the Southeastern Anatolia Region, 96 in the Eastern Anatolia Region, 104 in the Black Sea Region, 138 in the Marmara Region and 189 in the Central Anatolia Region. The ratio of delayed housing projects to total delayed housing projects was 56.60% in the Mediterranean Region, 35.42% in the Eastern Anatolia Region, 45.07% in the Aegean Region, 49.64% in the Southeastern Anatolia Region, 51.08% in the Central Anatolia Region, 47.27% in the Black Sea Region and 48.94% in the Marmara Region. It is a significant result that almost half of housing projects in all regions have delays with approximately 50%.

Case 1: Calculation Duration with Construction Documents (DCD)

In the last phase of this case study, Baseline Construction Duration with Construction Documents and Schematic Design were compared with contract durations and delay times for housing projects.

Table 4. Comparisons of DCD, CD and DT.

	Durations	Values (%)
Comparisons of DCD with CD	DCD-CD<0 (Negative)	37.29
	DCD-CD>0 (Positive)	62.71

Comparison of (DCD-CD) with DT	(DCD-CD)-DT<0 (Negative)	28.66
	(DCD-CD)-DT>0 (Positive)	71.34

In Table 4, the differences were found positive for 62.71% of the housing projects by subtraction of CD from DCD. The results equal to zero were negligible due having no significant meaning in view of the study. The positive value indicates that the DCD values are higher than CD values for majority of housing projects. In this case, it was determined that DCD obtained from total construction duration calculated by TOKI was usually longer than CD duration and it showed that TOKI was greatly shortened the total construction duration in official contracts. In other words, total construction durations have been proven to be shorter than they should be for almost 63 projects out of 100 housing projects.

Firstly, CD values were subtracted from DCD values in Table 4. This difference showed how much TOKI authorities were shortened the construction duration and used in the construction contracts. Second, the contract date was subtracted from the project completion (finish) dates to find delay time (DT). Third, (DCD-CD) values were subtracted from the DT value, resulting in 71.34% positive values. Positive value for 71.34% of housing projects indicated that shortening of total construction durations by TOKI officials was higher than the delays. In other words, the magnitude of the duration shortened was generally much higher than delay times in housing projects. Even if delay margins were added to the contract duration for a housing project, DCD value could not be reached at this case. This showed how major the shortenings were made by TOKI during the tender phase. This major difference means that the contract duration determined by TOKI have low reliability. It is clear that delays in total construction duration will lead more prosecutions against contractors rather than TOKI.

Case 2: Calculation Duration with Schematic Design (DSD)

In order to calculate DSD, DCD was firstly determined according to the number of flats in Equation 1. Afterwards, 50 days were added to DCD value and DSD was calculated and then the non-working days were also added and consequently final DSD values were reached according to the location of the project.

Table 5. Comparisons of DSD, CD and DT.

	Durations	Values (%)
Comparisons of DSD with CD	DSD-CD<0 (Negative)	23.20
	DSD-CD>0 (Positive)	76.80
Comparison of (DCD-CD) with DT	(DSD-CD)-DT<0 (Negative)	24.61
	(DSD-CD)-DT>0 (Positive)	75.39

In Table 5, the differences were found positive for 76.80% of housing projects by subtraction of CD from DSD. The results equal to zero were negligible due having no significant meaning in view of the study The positive value indicated that the DSD values were higher than CD values for majority of housing projects. In this case, it was determined that DSD obtained from total construction duration calculated by TOKI was usually longer than CD duration and it showed that TOKI was greatly shortened the total construction duration in official contracts. In other words, total construction durations have been proven to be shorter than they should be for almost 77 projects out of 100 housing projects.

Firstly, CD values were subtracted from DSD values in Table 5. This difference showed how much the TOKI authorities shortened the construction duration and used in construction contracts. Second, the contract date was subtracted from the project completion (finish) dates to find delay time (DT). Third, (DSD-CD) values were subtracted from the DT value, resulting in 75.39% positive values. Positive value indicated that shortening of total construction durations by TOKI officials was higher than the delays for 75.39% of housing projects. In other words, the magnitude of the duration shortened was generally much higher than the delay times in housing projects, similar to those DSD's. Even if delay margins were added to the contract duration for a housing project, DSD value could not be reached at this case. This showed how major the shortenings were made by TOKI during the tender phase. This major difference also means that the contract duration determined by TOKI have low reliability. It is obvious that delays in total construction duration will lead more prosecutions against contractors rather than TOKI.

Conclusion

This study revealed that 720 housing projects were delayed with a rate of 47.06% among 1530 housing projects. The ratio of delayed housing projects in all TOKI projects was 25.71%. Results from case study analysis for TOKI housing projects showed that DCD values were evidently higher than CD values. Thus, it was determined that CD values were greatly shortened by TOKI for the calculation of total construction duration. Similarly, as a result of comparison of (DCD-CD) with DT, positive values were obtained in excess amount of TOKI projects and it was observed that the magnitude of shortened duration was generally higher than the delays in housing projects. These findings suggested that the shortening of contract duration was considerably high. Greater contract duration shortenings also caused contractors to deliver projects more delayed to the stakeholders.

In conclusion, it is shown that three factors used by TOKI to calculate the total construction duration were not sufficient. TOKI officials determine the official contract duration by significantly shortening the Baseline Construction Duration through discernment other than these three factors. The study found that this shortening gap were excess where there were many housing projects delayed, and delays led to time and cost losses for all project stakeholders. Therefore, it became clear to propose a model which shall calculate ideal construction duration and consider additional factors affecting total construction duration.

A Proposed Model for Estimation of Ideal Construction Duration in Housing Projects

H. Tirataci and H. Yaman
Istanbul Technical University, Department of Architecture, Istanbul, Turkey
htirataci@ itu.edu.tr, yamanhak@itu.edu.tr

Abstract

There are various factors affecting construction duration such as number of flats, drawing type, priority of project and complexity, financial risks, location, and climatic factors. Estimation models for construction duration with various factors have been used by previous researches to estimate construction durations. Despite these models, only a few studies applied in tender phase and less in housing projects. Moreover, research related to construction duration in Turkey showed that there were considerable delays occurred in housing projects. For this reason, it was decided to investigate the factors affecting construction duration only for housing projects to propose a novel model to achieve "Ideal Construction Duration". Data was obtained from Housing Development Administration of Republic of Turkey (TOKI) which has been major client to build housing projects in Turkey. Statistical data analysis was performed by multiple regression analysis, CHAID and CART. Findings shown that several factors were significantly affected the Ideal Construction Duration for each statistical method. The cut-offs and standard errors were calculated to test the validity statistical methods. Testing of model was conducted with regression equation. After testing of model, it was observed that the delays in housing projects were significantly decreased.

Keywords: *CHAID and CART analysis, construction duration estimation, factors affecting construction duration, planning in construction, project management, regression analysis.*

Introduction

Construction project is regarded as successful if it is completed on time with other criterion such as cost, quality and stakeholder satisfaction (Chan & Kumaraswamy, 2002; Majid, 2006). Estimation of "Ideal Construction Duration" is necessary due to common delays, efficiency of organizations and benchmarking performance of a project in construction industry (Chan & Kumaraswamy, 2002; Mensah et al., 2017). Effective planning and programming prevents delays and provides enhanced construction project performance which results in time- and cost-savings (Gibson et al., 2006; Luu et al., 2009; Ismail, 2013; Lines et al., 2014; Tunç & Özsaraç, 2015). Poor planning and programming has negative impacts on Client, contractor and owner (Ndekugri et al., 2008). However, literature on planning and programming for construction duration during tender phase is limited.

Although time planning and programming in tender phase were regulated by relevant laws and authorized organizations (FIDIC, 2017), it was observed that it is not the case for public construction industry in Turkey (Yitmen & Dikbas, 2002; Birgonul et al., 2007; Koktas et al., 2009; Akkaynak, 2013; Erbas & Ciraci, 2013; Usta, 2014) due legal regulations reckon without planning but prioritize only the lowest tender price (Türesoy, 1989; Karapinar, 2005; Tokalakoglu, 2010; Sevim, 2011; Kaplan, 2012). It is emphasized that lower costs should not be the only basis for choosing contractors, but also time and performance factors should be taken into account (Obodo et al., 2021). Moreover, better tender system and effective planning specified in the Development Plans have not been implemented (DPT, 2001; DPT, 2007; Turkish Republic Presidency of Strategy and Budget, 2019). Although stakeholders of construction industry are aware of the importance of construction duration, it was determined that many contracts had not met requirements (Lin et al., 2011). According to these findings, it is evident that construction project completion on time is a prevailing issue and projects in Turkey are lacking of time planning and programming.

In Turkey, the most significant factor affecting housing project duration is cost and many other factors are not taken into account (Odabasi, 2009; Baltaci, 2012; Sonmez, 2019). In practice, most estimation methods for construction duration depends on the "subjective skill and cognition of the estimators and planners, rather than on objective assessment" (Lin et al., 2001). On the other hand, Supreme Court case law indicates that there are legal disputes due to timely delays related to housing projects in Turkey (Supreme Court 13. Law Office, 2010, 2011, 2013, 2014, 2015). Literature also indicates the same findings (Al-Khalil & Al-Ghafly, 1999; Aibinu & Jagboro, 2002; Odabasi, 2009), suggesting that clients shall use modern planning and programming techniques rather than utilizing data from previously completed housing projects. For these reasons, a reliable estimation tool is needed in accordance with the complex nature of housing projects.

As mentioned above, there is a potential gap for a research on modelling construction duration in tender phase for housing projects. In order to fill this research gap, it is necessary to develop, validate, and test a model calculating Ideal Construction Duration by utilizing necessary factors affecting construction duration from both literature and TOKI along with evaluation criterion to prevent delays in TOKI housing projects. Model should be also compatible with the existing bidding system and user-friendly, thus preventing cost and time losses. Therefore, this article proposes a model that can help Ideal Construction Duration for housing projects in tender phase. The model is based on data collected from TOKI regarding construction durations. Findings of this study are expected to allow all project stakeholders to estimate Ideal Construction Duration for housing projects during tender phase. This study is ultimately intended to contribute decision making processes for the project managers.

Background

The construction duration has been considered as one of the main criteria for performance of housing projects in the construction industry (Bromilow, 1969; Chan & Chan, 2004; Aibinu & Odeyinka, 2006; Ting et al., 2021). However, the delay of housing projects is still a common problem (Lin et al., 2011; Bromilow, 1969; Al-Khalil & Al-Ghafly, 1999; Blyth et al., 2004; Iyer & Jha, 2006).

Construction duration of projects are often overlooked by assumptions or comparisons and are not considered early stages of construction projects (Elinwa & Joshua, 2001; Walraven & de

Vries, 2009; Ibironke & Elamah, 2011; Shokri-Ghasabeh & Chileshe, 2016; Oyedele, 2013; Oyedele et al., 2015; Obodo et al., 2021). At the tender phase of construction project, stakeholders seek a reliable estimation of project duration (Qiao et al., 2019; Thing, 2006; Jin et al., 2016; Wang et al., 2012).

There were a wide variety of factors affecting construction durations (Oo et al., 2022). Although project costs are largely dependent on project duration, it was determined that complexity and size of the projects, rate of return and cash flow, type of contract, priority of projects, previous experiences and geographical area are given more importance across globe (Ahmad & Minkarah, 1988; Shash, 1993; Fayek et al., 1998; Fayek et al., 1999; Hillebrandt, 2000; Bageis & Fortune, 2009; Jarkas et al., 2013; Alsaedi et al., 2019). Researches for estimating construction duration were mainly focused on financial and economic factors (Turesoy, 1989; Wa'el Alaghbari, 2005; Shane et al., 2009; Musarat et al., 2021), climatic, geographical and topographic factors (Ellag et al., 2005; Shane et al., 2009; Cheng, 2014; IAEA, 2018), complexity and size of projects (Singh, 1984; Kerzner, 1991; Chevallier & Russell, 2001), priority of project (Yang et al., 2014), supply and logistic conditions of the project region (Asnaashari et al., 2009; Ramli et al., 2018; Tunji-Olayeni et al., 2018; Nayak, 2019), social and cultural factors (Imbert, 1990; Assaf & Al-Hejji, 2006; Salleh, 2009; Al-Sabah et al., 2014). Despite several factors are considered in different studies, literature findings showed that construction duration is mostly ignored.

Several construction duration estimation models have been developed from these factors. To predict duration, many researchers demonstrated the applicability of regression analysis in duration estimation in early phases of a project (Khosrowshahi & Kaka, 1996; Lin et al., 2011). Simulations model were also used to estimate construction duration. Sanni-Anibire et al. (2021) developed a machine learning model including Multi-Linear Regression Analysis (MLRA), k-Nearest Neighbors (KNN), Artificial Neural Networks (ANN), Support Vector Machines (SVM), and Ensemble Methods for tall building projects (Fan et al., 2021). Yogesh and Rao (2021) developed a system to estimate road construction durations by using Delphi analysis. Yaseen et al. (2020) used hybrid artificial intelligence model. Lines et al. (2014) demonstrated that time planning model during tender phase results in cost and time reduction, as 44.0% and 44.9%, respectively. Another study by Lines et al. (2015) determined that the planning model at the tender stage reduced the cost and duration by 54% and 70%, respectively.

Decision tree algorithms, namely classification and regression tree (CART) and chi-squared automatic interaction detection (CHAID) are also used for duration estimation (Godinho & Costa, 2004). However, few researchers have used CART and CHAID in construction industry. Lin and Fan (2019) used CHAID and CART to identify defects in public construction projects to reduce adverse effects on completion duration. Pospieszny (2015) used CHAID for estimation of effort and duration of software projects. A hybrid software cost estimation approach was also developed by using CHAID and CART (Papatheocharous & Andreau, 2012).

Scope of This Paper

The scope of this paper was limited to TOKI housing projects, planning and programming activities in the tender phase, bidding processes defined and indicated within Public Procurement Law No. 4734, Public Housing Law No. 2985 (1984), No. 4966 and No. 5162 (2004), TOKI Standard Contract for Construction, Regulation on the Use of TOKI Resources (2002) and the Regulation on Construction Tenders Implementation (2009) in Turkish Republic

Official Gazette. During data collection from TOKI interviews, TOKI Projects Status Table was obtained. In addition, approximate construction duration in this research refers to the total construction duration from the beginning to the end of the construction during the construction phase, which is estimated in the project planning phase. The scope of quantitative methods involve regression, CHAID and CART by using SPSS 26.0 (Statistical Package for the Social Sciences) software.

Methodology

This research was adopted quantitative methodology. Research method and procedure was included four phases: Preparation phase, development phase, validation phase, testing phase of model. The research method steps were explained in Figure 1.

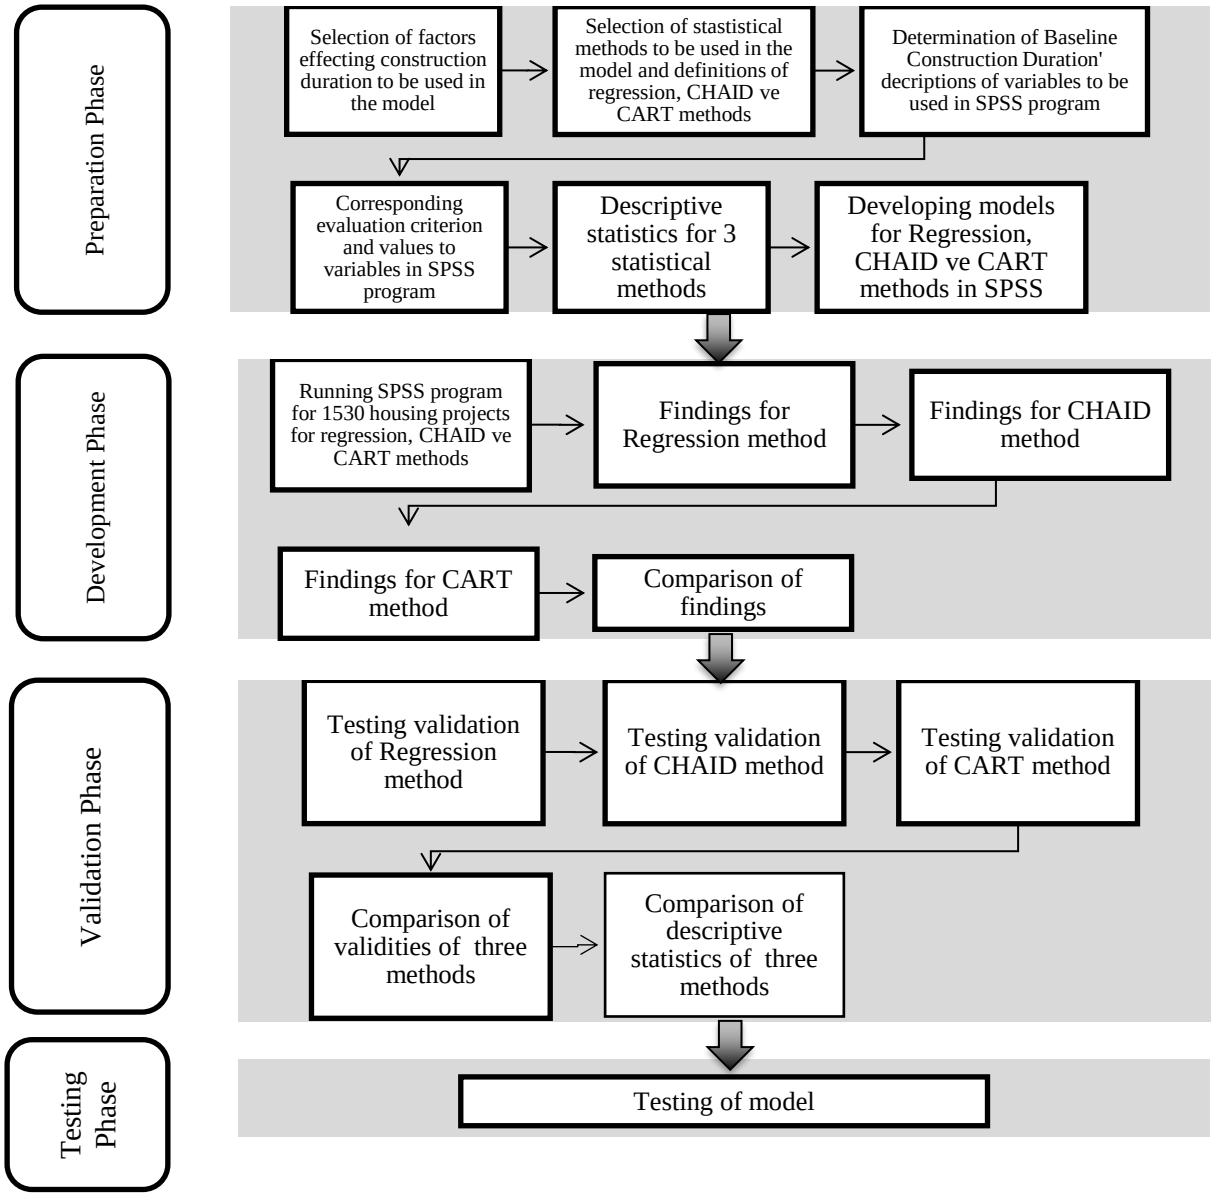

Figure 1: Flow chart for research method and procedures.

Preparation of the Model

Descriptive statistics for 2800 TOKI projects were determined by using the data in the "TOKI Projects Status Table" where descriptive data is limited with TOKI projects' datasheet extracted from TOKI Project Status Table.

There were 22 different types of projects and most of them were 1530 housing projects. Average construction duration of housing projects were 486 days. The housing projects corresponded to 25.71% of 2800 TOKI projects. 1367 out of 2800 construction projects in Turkey were delayed and approximately 49% of the projects carried out by TOKI are not completed on time. 720 out of 1530 housing projects were delayed. The ratio of delayed TOKI housing projects to total number of TOKI construction projects (720/2800=0.2571) was 25.71%. The number of delayed housing projects out of 1530 TOKI housing projects was calculated as 720 and the delay rate (720/1530=0.4706) was 47.06%. It was determined that number of delayed projects among TOKI projects was the highest for housing projects by 25.71%. Therefore, it was decided to establish the model with only housing projects.

In order to select the factors affecting construction duration, 56 factors were obtained from literature review and 11 factors selected to be used in the model were given in Table 1.

Table 1. Description of factors.

Factor No.	Description of Factors	Variable Type
F1+F2+F3 (standardized)	Baseline Construction Duration	Independent Variables
F4	Priority of Project	
F5	Complexity of Project	
F6	Special Request for Project	
F7	Difficulty of Project	
F8	Financial Risk of Project	
F9	Logistic Conditions of Project Region	
F10	Climatic Conditions of Project Region	
F11	Seismicity of Project Region	
Y	Ideal Duration (Days)	Dependent Variable

The determination of magnitude of effect on construction duration for each variable, evaluation criterion and values were used. For the first eight factors, evaluation criteria values were coded as "0, 1, 2" where 0 represents "no effect" on duration, 1 represents "reduce" the duration and 2 represents "increase" the duration. For F9 and F10, evaluation criteria values were coded as categorical from 1 to 7 where as the value increases, the effect on duration also increases. For F11, evaluation criteria values were coded as categorical from 1 to 5 where as the value increases, the effect on duration also decreases.

The purpose of this paper was to analyze the state-of-the-art of TOKI housing projects. Baseline Construction Durations (BCD) were calculated for 1530 housing projects within "TOKI Projects Status Table" by using below equation which is extracted from the calculation method used by TOKI to estimate total construction duration for housing projects.

Baseline Construction Duration (BCD)(days) = (Number of working days in Factor #2a: "Duration with Construction Documents (DCD)" *corresponding to Factor #1:* "Number of Flats"*) + (50 working days in case use of Factor #2b:* "Duration with Schematic Design (DSD)"*) +(Factor #3: "Number of non-working days")* (1)

Multiple linear regression analysis with backward elimination method and non-parametric CHAID and CART analysis were used to determine the factors affecting the Ideal Construction Duration. Chi-squared Automatic Interaction Detection (CHAID) is used for the identification and analysis of classified dependent variables. Classification and regression tree (CART) is a non-parametric statistical method to estimate categorical or continuous dependent variables is also used. Data analyses were performed by using SPSS 26.0. p-value less than 0.05 indicates that findings should be significant at least 95% level.

Results

Descriptive statistics in the study were shown in Table 2. The average Ideal Construction Duration was 679 days for regression analysis, 704 days for CHAID and 706 days for CART analysis respectively.

Table 2. Results of descriptive analysis for regression, CHAID ve CART analysis.

Method Used in Model	Ideal Construction Duration				
	N	Average	Std. Dev.	Min.	Max.
Regression Analysis	1530	679.16	133.20	387	1355
CHAID	1530	704.38	113.13	635	1051
CART	1530	705.98	109.50	640	926

The comparison of descriptive statistics implied that average Ideal Construction Duration was slightly higher in CHAID and CART methods with lower standard deviations. Minimum and maximum values of Ideal Construction Duration were considerably different.

Table 3. Results of regression analysis.

Variables	R^2	β	t	p	VIF
Constant	0,356	663630	21009	.000***	
Standardized Baseline Construction Duration (F1+F2+F3)		146447	27833	.000***	1.160
Priority of Project (F4)		-48437	-3733	.000***	1.341
Complexity of Project (F5)		-47053	-4057	.000***	1.402
Special Request for Project (F6)		-.029	-1249	.212	1.279
Difficulty of Project (F7)		43870	3800	.000***	1.047
Financial Risk of Project (F8)		-18510	-2326	.020*	1.011
Logistic Conditions of Project Region (F9)		-3953	-1716	.086	1.088
Climatic Conditions of Project Region (F10)		-13676	-4768	.000***	1.045
Seismicity of Project Region (F11)		-.024	-1205	.228	1.115

*p≤0.05, **p≤0.01, ***p≤0.001

In Table 3, Ideal Construction Duration was significantly affected by Baseline Construction Duration (F1+F2+F3), Priority of Project (F4), Complexity of Project (F5), Difficulty of Project (F7), Financial Risk of Project (F8) and Climatic Conditions of Project Region (F10). A one-day increase in the Ideal Construction Duration would increase the Baseline Construction Duration by 146 days, Complexity of Project by 47 days, Priority of Projects by 48 days, Difficulty of Project by 43 days, Financial Risk of Project by 18.5 days and Climatic Conditions of Project Region by 14 days. Baseline Construction Duration (F1+F2+F3) had a major impact on Ideal Construction Duration.

The root node at the top of the CHAID tree diagram was divided into six groups at the first tree depth in terms of Baseline Construction Duration. The root node at the top of the CART tree diagram was divided into two groups at the first tree depth in terms of Baseline Construction Duration and both results given in Table 4.

Table 4. Significant variables for all three methods.

Variables	Regression Method	CHAID Method	CART Method
Standardized Baseline Construction Duration (F1+F2+F3)	Significant	Significant	Significant
Priority of Project (F4)	Significant	Significant	Significant
Complexity of Project (F5)	Significant	-	-
Difficulty of Project (F7)	Significant	-	-
Financial Risk of Project (F8)	Significant	-	-
Logistic Conditions of Project Region (F9)	-	Significant	Significant
Climatic Conditions of Project Region (F10)	Significant	Significant	-
Seismicity of Project Region (F11)	-	Significant	-
Special Request for Project (F6)	-	-	-

Among the 11 factors affecting Baseline Construction Duration, eight, seven, and five factors were found significant in regression, CHAID and CART analysis, respectively. The first three factors were counted as one variable, as the Baseline Construction Duration was standardized. In this case, it was determined that six variables were significant for the regression method, five variables for the CHAID method, and three variables for the CART method.

The model equation, consisting significant variables in the regression method was obtained as follows:

*Ideal Construction Duration(Y) = 663.630 + 146,447*Std. Baseline Construction Duration - 48,437* Priority of Project (F4)-47.053*Complexity of Project (F5) +43.870* Difficulty of Project (F7)-18.510*Financial Risk of the Project (F8)-13.676*Climatic Conditions of the Project Region (F10)* (2)

Contrary to the regression method, Logistics Conditions of the Project Region (F9) showed significance in the CART and CHAID methods. Contrary to the regression and CART methods, the Seismicity of the Project Area (F11) was determined as a significant factor in the CHAID method. Special Request for Project (F6) was not significant in all three methods. While Logistics Conditions of the Project Region (F9) in the CHAID method showed significance, the Priority of Project (F4) in the CART method was found significant on the Ideal Construction Duration. CHAID and CART analysis provided the most suitable solution for the model by

using decision trees for all independent variables. The regression method did not categorize the effects of independent variables but evaluated them as numerical outcomes in the form of a model equation. The main and common purpose of all three methods was to estimate the Ideal Construction Duration in the most suitable way.

Validation Phase

The validity of CHAID and CART methods was obtained through 10-fold cross-validation, 70/30 training and test sets, and standard error values for estimations. Enter and Stepwise methods were used for the validation of regression method.

Validation of the regression method. Collinearity exists if the tolerance is less than 0.1 or if VIF > 10 (Yeom et al., 2018). In this model, collinearity did not exist because VIF of the construction duration was smaller than 10.

Table 5. Validity of regression method.

	Group 1 (Enter method)			Group 2 (Stepwise method)		
	B	t	p	B	t	p
Constant	696696	18876	.000***	646473	21562	.000***
Standardised Baseline Construction Duration (F1+F2+F3)	146765	27548	.000***	148020	28551	.000***
Priority of Project (F4)	-55102	-3981	.000***	-50401	-3897	.000***
Complexity of Project (F5)	-48665	-4179	.000***	-47116	-4060	.000***
Special Request for Project (F6)	-18039	-1329	.184	-.033	-1431	.153
Difficulty of Project (F7)	43636	3781	.000***	47520	4185	.000***
Financial Risk of Project (F8)	-17,797	-2,231	,026*	-18340	-2304	.021*
Logistic Conditions of Project Region (F9)	-4285	-1800	.072	-.037	-1716	.086
Climatic Conditions of Project Region (F10)	-13893	-4835	.000***	-14443	-5081	.000***
Seismicity of Project Region (F11)	-5978	-1205	.228	-.014	-.680	.496

*p≤0.05, **p≤0.01, ***p≤0.001

Results of regression analysis in Table 5 showed that regression method was valid due that results of enter method and stepwise method are close to each other.

Validation of the CHAID method. In Table 6, Standard error for CHAID method was similar with the one calculated by 10-fold cross validation which secures the validation.

Validation of the CART method. In Table 7, *Standard* error for CART method was similar with the one calculated by 10-fold cross validation which secures the validation. The comparison of validity results implied that regression method indicated more accurate results than CHAID and CART methods as shown in Table 8. Regression method can be used to estimate the Ideal Construction Duration over six factors in future studies. Standard errors of all three methods were similar.

Table 6. Validity of CHAID method.

Method	Estimation	Standard Error
CHAID	37227.186	3109.763
10-fold cross validation	40115.651	3524.340
Training Set (70%)	36616.334	5011.920
Test Set (30%)	42521.916	4823.904

Table 7. Validation of CART method.

Method	Estimation	Standard Error
CHAID	33379.264	3166.306
10 fold cross validation	41092.216	3860.222
Training Set (%70)	43341.801	5111.257
Test Set (%30)	41189.758	5133.594

Table 8. Comparison of validity results of regression, CHAID and CART methods.

Model	Number of Significant Variables	Estimation	Standard Error
Regression	6	36495.932	3039.935
CHAID	5	37227.186	3109.763
CART	3	33379.646	3166.306

The results obtained from decision tree methods showed similarity with the regression method. However, apart from the regression method, CHAID and CART methods can show more significant and more specific results in determining the Ideal Construction Duration.

Testing of Model

The data composed of 40 delayed housing projects that were selected for pilot study to test the model. These housing projects were chosen among 3500 projects listed in "TOKI Project Status Table" by random sampling method. These 40 selected projects consisted of recently completed housing projects with delay. The number of test data was kept above the minimum limit for

normality condition of 30 data (Field, 2009; Cevahir, 2020).

To test the selected data, regression equation was utilized. Variables showing statistical significance in regression method that were used for testing. It was observed that the results obtained for 40 housing projects by utilizing regression equation in the SPSS 26.0 was accurate and convenient. In other words, test results of model were reliable.

Table 9. Testing of model.

	Pre-test	Post-test
Number of Delayed Housing Projects	40	23
Delay Percentage	100%	57.50%
Reduction Amount of Delayed Housing Projects (%)	-	42.50%

As shown in Table 9, it was determined that regression method for test data reduced the number of delayed housing projects by 42.50%. It was also observed that the number of delays in housing projects decreased from 40 to 23. Post-test delay times of 23 delayed housing projects were also reduced.

Conclusion

It was shown that factors used by TOKI to determine Baseline Construction Duration were not sufficient. It was proven that additional factors from literature were required to achieve more accurate durations. Statistical analysis showed that all three statistical models were valid. Regression method indicated more accurate results compared to CHAID and CART. Therefore, the Ideal Construction Duration could be predicted over six factors by utilizing the regression method in the future. Despite CHAID and CART methods had lower performances compared to regression method, it was revealed that Ideal Construction Duration estimations can be achieved by utilizing less factors. Thus, it was proven that the Ideal Construction Durations could be calculated by all three methods. Indeed, it was argued that a factor that shown significancy within any model at least once shall be considered for Ideal Construction Duration estimation.

Testing of model showed that the model reduced number of delayed housing projects and delay times. In this sense, results implied that the model is useful and valid. The model also supports the optimization of total construction duration. It was possible to ensure that TOKI housing projects were completed on time by determining the Ideal Construction Duration, thus preventing delays which consequently will lead better cost management and less dispute among stakeholders.

A more practical and consistent project management tool was developed by the model that ensures the prevention of problems during tender phase and leads less risks during construction phase. In future researches, this proposed model can be transferred into a digital environment and converted into a computer program to increase the number of users, expanding to public and TOKI personnel. Thus, the proposed model can be utilized in a wider range.

Construction Project Manager Selection for Superstructure Projects Using AHP and TOPSIS Multi-Criteria Decision Making Techniques

R. Akbıyıklı, A. Demircan and G. Karaçam
Duzce University, Department of Civil Engineering, Duzce, Turkey
rifatakbiyikli@duzce.edu.tr, anildemircan@gmail.com, gokalpkaracam@gmail.com

Abstract

Construction projects involve very complex processes with the pressure and risks created by the multi-stakeholder structure of the sector due to high quality expectations, limited construction periods and large investment costs. Due to this high-risk nature of the sector, it is of vital significance for the project to keep the risks under constant control for the later stages of the project by foreseeing, organizing and planning them within the framework of a methodological project management. At that point, the project manager is the responsible one who will ensure that the project is completed within the framework of specified quality, budget and time. In this context, the selection of a qualified project manager has gained great significance for the sustainability of projects. In this study, the 5 most important risk factors and their sub-titles, that can be encountered in superstructure projects, has been obtained by expert opinions and grouped in themselves. These risk headings has been planned to be evaluated by 5 project managers to choose the most suitable project manager for the investor. While making the selection, it was aimed to reach the result in the TOPSIS method by weighting the risk factors with AHP (analytical hierarchy method), one of the multi-criteria decision making techniques. Thus, while choosing the project manager, it was aimed to reach a more rational result with a mathematical approach rather than emotionality.

Keywords: *analytical hierarchy, construction project manager, construction risks, manager selection, multi-criteria decision making*.

Introduction

A project is an effort to obtain a unique product or service with clearly defined start and end activities, under budget, time, resource and quality constraints, with well-defined goals and objectives (PMI, 2008). By another definition, a project is a set of activities in which the stages of the task are planned, performed, and all these activities are created to achieve a specific goal.

Project management is defined as the application of all knowledge, skills, methods, tools and techniques to project activities in order to meet project needs (PMI, 2013). It is likely to complete the projects produced in the construction sector by staying within the required time, quality and specific budget with a coordinated work. This coordinated work is formed within the concept of project management. Successful implementation of project management in

construction projects is carried out with the coordination of project management techniques and project management methodologies (Kömürlü and Toltar, 2018).

Project management is a discipline that has certain rules about how to manage projects, and its goal is to complete projects and reach the final point successfully (Newton, 2006).

The person authorized to complete the project successfully is called the project manager. The duties, authorization and responsibilities of project managers in construction projects can be listed as follows (İnşaat Tekniği, 2014);

- Ensuring that the project management policies determined by the senior management are understood by the construction sites connected to the project and that the activities are carried out within this framework

- Preparation, revision and follow-up of work schedules, master plans and budgets of the projects/projects for which he/she is responsible

- To ensure that the necessary measures are taken by detecting possible disruptions with labor, financing needs and projections in parallel with the reports prepared during the construction of projects

- Preparation of the 'Project Management Plan' and execution of the project within this plan

- Selection and approval of subcontractors, preparation of their contracts, management and performance monitoring

- Ensuring flow of information by establishing an effective communication and coordination network between the project and the central units

- Selection, approval, preparation of contracts and performance monitoring of suppliers

- Planning of project cash flow

- Preparation, control and approval of progress payments and final accounts by the employer in accordance with the contract and company interests

- Ensuring that all support and service units of the construction site work in accordance with the workflow

- Carrying out the occupational safety in accordance with the procedures by taking all precautions and controlling the activities.

- Representing the company in the best way by developing good relations with the employer, employer representatives, partners, site workers, union representatives, official institutions and the surrounding community.

- Conducting, coordinating and finalizing all the works related to the project delivery, such as temporary acceptance, final acceptance, with the employer/employer representative and central units.

- To take an active part in resolving disputes in cooperation with domestic/international technical consultants and lawyers

People undertaking the project management should have some technical and non-technical characteristics in order to fulfill all these authorities and responsibilities properly. The most important non-technical features of the project manager are; leadership, empathy, referral, management and orientation ability, follow-up, coordination, responding to customer expectations and being understood (Atabey, 2020).

Construction projects involve very complex processes due to the pressure and risks created by the multi-stakeholder structure of the sector, as well as high quality expectations, limited construction times and large investment costs. Due to this high-risk nature of the sector, it is of vital significance for the project to keep the risks under constant control for the later stages of the project by foreseeing, organizing and planning them within the framework of a methodological project management.

At that point, the project manager is the person who will ensure that the project is completed in the quality, budget and time desired by the investor by evaluating and managing every negative element that may occur in the project and will take the responsibility. In this context, the selection of a qualified project manager has gained great significance for the sustainability of the projects.

Personnel selection, which is a part of the principles and practices of human resources management, is an issue that should be emphasized in the construction sector, where labor is intense, as in other sectors (Anbarcı & Manisalı, 2012). Employees are the most significant key resource in an organization that determines the success of that organization today with their knowledge, ability and motivation (Karabesevic et al., 2018). The decisions to be made about hiring a person are very important for the sustainability and success of the organization. (Afshari et al., 2014). Selecting talented, ambitious and skilled candidates helps businesses achieve the success (Demirci & Kılıç, 2019). The purpose of the personnel selection process is to benefit from the techniques necessary to meet the personnel needs of the enterprise in the most accurate way and to provide sufficient number and quality personnel in a timely manner (İçigen & Çetin, 2018). Personel selection is a strategic issue for organizations, and it is necessary to use imprecise and uncertain data in the decision-making process (Dağdeviren, 2007). Organizations make use of many traditional or modern methods during personnel selection. Some of these techniques are interview and test methods. The training, skills and personality characteristics of the candidates are evaluated together by the company officials participating in the interview using the interview method, which is considered the most appropriate technique for selecting personnel. In this case, the evaluation results may differ depending on the authorities of the company performing the evaluation. In addition, there is no generally accepted scale for the characteristics to be evaluated. Therefore, the solution of the problem with known arithmetic operations may not be very healthy here (Anbarcı & Öz, 2015). Another method used to identify the right candidates with the qualifications and abilities to meet the needs of the business is MCDM methods (Ilgaz, 2018). The need to measure qualitative variables along with quantitative variables has made the data richness and the use of numerical techniques a necessity (Özdemir, 2015). More effective and efficient supportive decision-making tools that will contribute to the individual skills of decisionmakers in complex decision-making processes are a necessity (Yıldırım & Önder, 2015).

In addition to intuitions, experiences and limited information, an analytical evaluation of the decision process is required for rational decisions (Can, 2015).

Working conditions, which are constantly changing and getting harder over time, condition people, institutions and businesses to choose the good and successful ones in decision making (Forman & Gass, 2001). Numerical methods or decision technologies (decision analysis, models, algorithms and theories) have a positive effect on the decision making process (Carlson & Fuller, 1996).

The use of Multi-Criteria Decision Making (MCDM) methods in the decision-making phase helps managers evaluate alternatives and ensures more efficient use of business resources. MCDM methods are an analytical method that provides the opportunity to evaluate many strategic and operational factors that can be measured and not measured at the same time, and that can include many people in the decision-making process (Dağdeviren et al., 2005). MCDM method, such as group decision (Chu et al., 2007; Opricovic & Tzeng, 2007), quality (Tong et al., 2007), engineering (Liu & Yan, 2007) and enterprise resource planning (Büyüközkan & Ruan, 2008) used in various fields.

Multi-Criteria Decision Making; It consists of two main parts, namely Multi-Objective Decision Making and Multi-Attribute Decision Making (Phua & Minowa, 2005). MultiAttribute Decision Making method is used to solve problems consisting of more than one criterion. In this method, **AHP** (Analytic Hierarchy Process), **ANP** (Analytic Network Process), **TOPSIS** (Technique for Order Preference by Similarity to Ideal Solution), **PROMETHEE** (Preference Ranking Organization Method for Enrichment Evaluation) and **ELECTRE** (Elimination and Choice Translating Reality) are the most preferred methods (Timor, 2011).

In his study, Dağdeviren (2007) proposed an algorithm for solving the personnel selection problem with the Fuzzy Analytical Hierarchy Process (FAHP) method. The proposed algorithm was used to determine the personnel to be promoted in a business and priority values were determined for the candidate personnel. In the application of the proposed model, the factors and sub-factors in the decision-making process were decided by using fuzzy numbers, and in this way, the uncertainties in the process were evaluated more easily by the decision makers.

Samanlıoğlu et al. (2008) proposed a framework for the evaluation and selection of personnel for an information technology department. Personnel evaluation is a complex and multicriteria decision-making problem involving many qualitative and quantitative criteria. Due to the ambiguous and imprecise nature of the evaluation and criteria, an integrated AHP-TOPSIS method, in which the decision makers' decisions are expressed with fuzzy numbers, is determined here to rank the different information technology experts. After determining the weights obtained from fuzzy AHP by scope analysis, alternatives were listed with fuzzy TOPSIS.

Doğan and Önder (2014), in their study, aimed to present a model in which the most suitable candidate(s) can be selected by using multi-criteria decision making techniques in the human resources procurement and selection process. For this purpose, the qualifications of the candidates were obtained from the expert opinions, job advertisements of the companies and the literature. Then, the degree of importance of the characteristics that the candidates should have was analyzed with the Analytical Hierarchy Process (AHP) with the survey data obtained from the experts and faculty members. In line with the order of importance determined as a

result of the analysis, 10 experimental candidates were evaluated with the TOPSIS method and the most suitable person(s) was selected.

Koyuncu and Özcan (2014) re-evaluated six engineers who were hired in the last one year in the position of production manager of a manufacturing company, in line with the recruitment criteria. The personnel selection process in the company has been discussed with the AHP and TOPSIS methods, which are among the multi-criteria decision-making methods in the literature. The rankings obtained from the AHP and TOPSIS results were compared with the performance results of these individuals after at least 6 months of employment. AHP and TOPSIS methods gave the same ranking in the ranking, and the performance evaluation result observed that the first and last ranked candidates were consistent with these results.

In his study, Ilgaz (2018) used AHP and TOPSIS methods together for the selection of the operation personnel needed by a business operating in the logistics sector. In the study, five alternative candidates were evaluated according to thirteen criteria. The criterion weights were calculated by the AHP method. The ranking of the alternatives was made using the TOPSIS method and the most suitable candidate for the enterprise was determined.

İçigen and Çetin (2018) used AHP and TOPSIS methods for personnel selection of a five-star accommodation business. In the study, ten candidate personnel were evaluated according to fifteen criteria. The criterion weights were calculated using the AHP method. The ranking of the candidates was made using the TOPSIS method and the most suitable personnel were selected.

Widianta et al. (2018) conducted a comparison to discover how well each of the AHP, SAW, TOPSIS and PROMETHEE methods performed in solving the problem of evaluating employees and to place them in the position where they can play best according to their qualifications. These authors show that TOPSIS and PROMETHEE give more accurate results than some rankings conducted by recruiters earlier.

Nabeeh et al. (2019) integrated a neutrosophic AHP approach with TOPSIS through a case study to evaluate and select a number of candidates to fulfill a manager position in an Egyptian technology park.

Özdemir and Nalbant (2020) used the integrated fuzzy preference relations-fuzzy AHP method for the engineer selection problem of a company in Turkey. In the study, seventeen alternative candidates were evaluated according to twenty-two criteria under five sub-criteria. Alternatives were ranked according to the results of the integrated method and the most suitable candidate was determined.

Taş and Karataş (2021) used the neutrophisophic AHP and neutrophisophic TOPSIS methods for project manager selection in a software company. In the study, four alternative personnel were evaluated according to five criteria. Criterion weights were calculated using the neutrophilic AHP method. Alternatives were listed according to the results of the neutrophic TOPSIS method and the most suitable one was determined.

Material and Method

In our study, the 5 most important risk factors and their 23 sub-titles, that can be encountered in superstructure projects, has been obtained by expert opinions and detailed literature review and grouped in themselves. These risk headings has been planned to be evaluated by 5 project managers to choose the most suitable project manager for the investor. While making the selection, it was aimed to reach the result in the TOPSIS method by weighting the risk factors with AHP (Analytical Hierarchy Process), one of the multi criteria decision making techniques. Thus, while choosing the project manager, it was aimed to reach a more rational result with a mathematical approach rather than emotionality.

The AHP and TOPSIS methods have been preferred in this study as the TOPSIS shows that the closest alternative to the ideal solution and the farthest alternative to the negative ideal solution is the best alternative. One advantage of TOPSIS is that each alternative takes its own value. Therefore, it is possible to get a good view of the differences between the alternatives and how the criteria differ from each other (Spee, 2005).

In addition to this, AHP is concerned with the judgments people make on their feelings and intuitions as well as their thoughts. AHP relies on simple elaborated hierarchical structures to represent decision problems. With such an appropriate representation, it can deal with risk, conflict and forecasting problems. People find AHP easy and are often influenced by the method rather than being alienated (Saaty, 1994).

AHP (Analytical Hierarchy Process) Method

AHP, which is a quantitative and qualitative method developed by Thomas Saaty in 1977, performs the ranking of the important criteria and decision alternatives with pairwise comparisons of the effective criteria in decision making by including the knowledge, experience and intuitions of the decision maker in MADM problems under uncertainty (Chena & Wang, 2010). The following steps are used when making comparisons in the AHP method;

Step 1: The problems are determined and the main and sub-criteria to be used in the solution of the problem are determined.

Step 2: The hierarchical structure of the main and sub-criteria to be used is created.

Step 3: After the hierarchical structure is established, the relative importance of each criterion is calculated (Chandran et al., 2005). The relative importance of the criteria can only be found by making a pairwise comparison, that is, by comparing the two criteria with each other (Sharma et al., 2008). Pairwise comparison is based on the experience and knowledge of the decision maker (Chandran et al., 2005). Therefore, at this point, the decision maker is asked to create binary decision matrices by comparing the main and sub-criteria.

After the hierarchy is created, it is necessary to calculate how many times more important the criteria are (relative importance degrees) against each other. The decision maker determines the degree of importance between the criteria based on the 1-9 scale. The importance scale seen in Table 2, created by Saaty, is used when making a pairwise comparison.

Table 1. Creating a pairwise comparison matrix for criteria (Saaty, 1990; Chandran et al., 2005).

	Criterion 1	Criterion 2	Criterion ……..	Criterion j
Criterion 1	W_1/W_1	W_1/W_2	……	W_1/W_j
Criterion 2	W_2/W_1	W_2/W_2	……	W_2/W_j
Criterion ….	……..	…….	……	……..
Criterion i	W_i/W_1	W_i/W_2	……	W_i/W_j

Table 2. Saaty comparison scale (Saaty, 1990).

Importance	Definiton
1	Equally important
3	A little more important
5	Strongly important
7	Very strongly important
9	Absolutely important
2,4,6,8	Intermediate values

Step 4: This is the phase of checking the consistency of the pairwise comparison made in the previous step. After creating the comparison matrix and giving the numerical values to the criteria with the help of the scale in Table 2, it is necessary to calculate the relative importance levels. The best way to calculate relative importance in a pairwise comparison matrix is Saaty's eigenvector method (Hurley, 2001). The eigenvector is calculated by the formula (Ramadhan et al., 1999);

$$\mathbf{w_i} = \frac{\mathbf{1}}{\mathbf{n}} \sum_{\mathbf{j=1}}^{\mathbf{n}} \frac{\mathbf{a_{ij}}}{\sum_{\mathbf{j=1}}^{\mathbf{n}} \mathbf{a_{ij}}} \qquad (1)$$

Step 5: After calculating the eigenvector and determining the relative importance of the criteria, the consistency (CR) of the comparison matrix is calculated (Hafeez et al., 2007) (Zhou & Shi, 2009). CR= Consitency Ratio, CI= Consistency Index, RI= Randomness Index.

$$\mathbf{CI} = \frac{\boldsymbol{\lambda}_{\mathbf{max}} - \mathbf{n}}{\mathbf{n} - \mathbf{1}} \qquad (2)$$

$$\mathbf{CR} = \frac{\mathbf{CI}}{\mathbf{RI}} \qquad (3)$$

While calculating CI, the maximum eigenvalue (λmax) in the formula is calculated as follows (Peng & Dai, 2009);

$$\lambda_{max} = \frac{1}{n}\sum_{i=1}^{n}\frac{(AW)_i}{W_i} \qquad (4)$$

In order to calculate λmax, the "All Priorities Matrix" is obtained by multiplying the comparison matrix with the weights and priority vector found in the previous stages. All the elements of the calculated priorities matrix are divided by the priority vector values. The result obtained by taking the average of the obtained values is determined as λmax (Uzun et al., 2016).

Step 6: The RI values determined by Saaty are taken from Table 3 in order to find the consistency ratios.

Table 3. Random indicators (Saaty, 1994).

n	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
RI	0	0	0,58	0,90	1,12	1,24	1,32	1,41	1,45	1,49	1,51	1,54	1,56	1,57	1,59

The purpose of calculating CR is to determine whether the decision maker acts consistently when comparing criteria. The upper limit of the Consistency Ratio (RO) is evaluated as 0.10. If the calculated consistency ratio is greater than 0.10, the criteria are considered to be inconsistent and the decision maker should reconsider the values entered in the matrix (Donegan et al., 1992; Stain & Mizzi, 2007). That is, the closer the CR is to zero, the higher the consistency of the decision matrix (Jian-Zhong et al., 2008).

TOPSIS (Technique for Order Preferences by Similarity to Ideal Solution) Method

TOPSIS is a method added to multi-criteria decision making techniques by Hwang and Yoon (1981). The main rule in this method is to find the best option among the alternatives by measuring the shortest distance to the ideal solution and the longest distance to the negative ideal solution (Dumanoğlu & Ergül, 2010).

The main reasons for the active use of the TOPSIS method are that it can be applied directly over numerical data and has a very limited subjectivity. The only subjective point in the method is the weights given to the criteria.

The stages used in the TOPSIS method are listed below (Ahi et al., 2008);

Step 1: Determination of decision matrices.

Step 2: Determination of normalized decision matrices by means of the following formula.

$$r_{ij} = \frac{x_{ij}}{\sqrt{\sum_{i=1}^{m} x_{ij}^2}} \qquad i = 1, 2, \ldots m; \;\; j = 1, 2, \ldots . n. \qquad (5)$$

Step 3: Determine the weighted normalized decision matrices by the formula given below.

$$v_{ij} = w_j * r_{ij} \quad (6)$$

Step 4: Determining the distances to the positive and negative solution by measuring the separation by means of the formulas given below.

$$S_i^+ = \sqrt{\sum_j \left(v_{ij} - v_j^*\right)^2} \quad i = 1, 2, \ldots, m \quad (7)$$

$$S_i^- = \sqrt{\sum_j \left(v_{ij} - v_j^*\right)^2} \quad i = 1, 2, \ldots, m \quad (8)$$

Step 5: Calculating the closeness to the ideal solution using the formula given below.

$$C_i^* = \frac{S_i^-}{(S_i^- + S_i^+)} \quad i = 1, 2, 3, .., m \;\; 0 \leq C_i^* \leq 1 \quad (9)$$

The C_i^* value must be between $0 \leq C_i^* \leq 1$. The solutions obtained are sorted by their relative closeness (C_i^*) to the ideal solution and the most suitable option is determined (Azimifard et al., 2018).

Application

In this study, the choice of project manager, which is a very significant subject in the construction sector, was determined by means of 5 main risk factors and 23 sub-risk factors. The weights of the risk factors were calculated using the AHP method with the evaluations taken from the experts. The weights of the risk factors obtained with AHP were solved with TOPSIS. It is very difficult to evaluate which of the project managers, who are close to each other in terms of experience, age, expertise, education etc., are suitable for the company and the project. The 23 sub-risk factors were evaluated according to the order of importance that the project managers resolved and the order of importance given to the problems of the company and the project. Sub-risk factors of the **'Management/Organizational Structure Based'** main risk factor are; **1a)** Financial and operational management of the company, **1b)** Not established or non-operative communication, coordination and reporting lines, **1c)** Delays in investigations made by the employer, **1d)** Delays in payments and progress payments, **1e)** Reputation and reliability problems. Sub-risk factors of the **'Planning Based'** main risk factor are; **2a)** Deviation of material supply time predictions, **2b)** Failure to keep up with the work schedule during the construction process, **2c)** The risk of change in the amount of workquantity, **2d)** The ability of the project team to understand the scope of the project in planning. Sub-risk factors of the **'Design Based'** main risk factor are; **3a)** Insufficient architectural and engineering designs, **3b)** Insufficient communication between the customer representative and the project supplier, **3c)** The risk of the designer not being able to complete the necessary design stages on time, **3d)** Deficiencies in the design documents. Sub-risk factors of the **'Construction Based'**

main risk factor are; **4a)** Delays in employer decisions, **4b)** Experience in construction technique and applicability of technological developments, **4c)** Construction method not suitable for design, **4d)** Starting work at the construction site without obtaining work approval in accordance with the technical specifications and requirements of the employer, **4e)** Insufficient capacity of materials and equipment to be used in production. Sub-risk factors of **'Finance & Economics Based'** main risk factor are; **5a)** The effects of inflation/speculative movements in the country's economy, **5b)** Insufficient project financing, **5c)** Cash flow deviations, **5d)** Exceeding the project budget specified in the contract, **5e)** Exchange rate fluctuations.

The main risk factors presented to the project managers and the sub-risk factors among the main risk factors were asked to be ranked between 1 and 5 (best - 5, worst - 1). It was aimed to select the most suitable project manager for the company's ideas by using the TOPSIS method, based on the answers received from the candidate project managers consisting of 5 people.

Table 4. Weight calculations of sub-risk factors with AHP.

Main Risk Factors	Sub-Factors	w	General Weights
Management/Organizational Structure Based (w= 0,272)	1a)	0,100	0,0272
	1b)	0,176	0,0479
	1c)	0,077	0,0209
	1d)	0,353	0,0960
	1e)	0,295	0,0802
	CR Value = 0,059 (OK)		w=0,272

	3b)	0,090	0,0067
	3c)	0,199	0,0147
	3d)	0,287	0,0212
	CR Value = 0,039 (OK)		w= 0,074
Construction Based (w= 0,174)	4a)	0,283	0,0492
	4b)	0,068	0,0118
	4c)	0,382	0,0665
	4d)	0,171	0,0298
	4e)	0,097	0,0169
	CR Value = 0,046 (OK)		w=0,174

Finance & Economic Based (w= 0,360)	5a)	0,299	0,1076
	5b)	0,356	0,1282
	5c)	0,091	0,0328
	5d)	0,108	0,0389
	5e)	0,146	0,0526
	CR Value = 0,054 (OK)		w=0,360

As seen in Table 4, pairwise comparisons were made for the main risk factors and sub-risk factors using the AHP method. At this stage, expert opinions were used. Using the obtained data, the weights of the sub-factors were calculated and data were obtained for the TOPSIS method. Among the 5 main factors, the 'Finance and Economy Based' risk factor emerged as the most important factor with w=0.360. In the second place, the risk factor 'Management/Organizational Structure Based' came to the fore with w=0.272.

After the decision matrix was created in the TOPSIS method, normalized decision matrices were created. The weighted normalized decision matrix was obtained by multiplying the calculated normalized decision matrix with the importance weights of the criteria.

Positive and negative ideal solution values, which are the next stage of the TOPSIS method, were calculated.

Table 11. Distance from the positive ideal solution

	TOTAL	Si^{*+}
A	0,0045421	0,067395
B	0,0061343	0,078322
C	0,0034152	0,05844
D	0,0018558	0,04308
E	0,0055983	0,074821

Table 12. The distance from the negative ideal solution.

	TOTAL	Si^{*-}
A	0,0042978	0,065558
B	0,0034477	0,058717
C	0,0049508	0,070362
D	0,0067335	0,082058
E	0,0034519	0,058753

After calculating the distances from the positive and negative ideal solution, the relative distance value C_1^* from the ideal solution was calculated.

C_1^* is obtained by dividing the distance from the negative ideal solution by the sum of the distance from the positive and negative ideal solution.

Table 13. Relative distance values to the ideal solution.

CONCLUSION	Si*(+)	Si*(-)	Ci*
Person A	0,06739509	0,06555751	0,49308932
Person B	0,07832153	0,05871672	0,42846957
Person C	0,05843955	0,07036195	0,54628207
Person D	0,04307952	0,08205794	0,65574240
Person E	0,07482150	0,05875263	0,43985036

After calculating their relative distances to the ideal solution, the selection stage was made among the project managers consisting of 5 people. Person D, with the highest relative distance to the ideal solution, stands out as a suitable project manager for a company doing business in housing projects with Ci* = 0.65574240. Person C took the second place with Ci* = 0.54628207. Person B took the last place with the value Ci* = 0.42846957.

Conclusion

In this study, it has been aimed to reach a solution by using multi-criteria decision-making techniques in the selection of the project manager, which is one of the most significant issues in the construction industry. In the system created using expert opinions and literature review with 5 main risk factors and a total of 23 sub-risk factors, the importance weights of the criteria were determined by the AHP method. Candidate project managers were asked to rank the main and sub-risk factors in order of importance. Using the TOPSIS method with the sequencing data obtained, it was investigated which project manager the company would be suitable to work with.

Among the 5 main factors, the 'Finance & Economics Based' risk factor came to the fore with the highest importance. While the 'Management/Organizational Structure Based' factor came to the fore in the second place, the 'Design Based' risk factor took the last place with a weight of w=0.074. Among the sub-risk factors, the factor of 'Insufficient financing of the project' took the first place with the weight of w=0.1282. The second place was taken by the factor of 'The effects of inflation/speculative movements in the country's economy' with a weight of w=0.1076.

It has been seen that the multi-criteria decision-making methods used to solve complex events and choices that may involve emotions using mathematical expressions could also be used while selecting the project manager in construction projects. Not only the age, experience and education of the project manager, but also the suitability of the company to the target and ideas that the company wants to achieve can be evaluated by means of a questionnaire that can measure the ideas of the project managers.

The survey results obtained as a result of the answers given by the A, B, C, D and E project manager candidates has been evaluated. Persons **C and D** took **the first two places** due to the importance weights of their answers obtained by the AHP method. The project manager candidate who does not match the ideas of the employer who will choose the project manager is the **B** candidate.

In the analyzes obtained using the TOPSIS method, it has been seen that '**Person D'** ranks the criteria **5a** and **5b**, **which have a high degree of importance, as the highest value**. It stands out as the project manager that the company may want, with the high values it gives to the criteria with high importance in the importance weights of the risk factors created by using expert opinions.

It is easy to make a choice by using multi-criteria decision making methods, which are widely used today. As a result of the analysis, it has been seen that it would be more consistent to move away from emotionality and make a choice with a mathematical approach.

emre.isil@alumni.metu.edu.tr, salar.ahmadisheykhsarmast@metu.edu.tr, rsonmez@metu.edu.tr

Abstract

Public procurement investments attract many private companies due to its huge market volume. This results a huge competition among companies in the world and in Turkey during public procurement tenders. Given the notable competition, the fact that investments are made with taxes paid by citizens, and the involvement of government officials and politicians in the process, almost all countries have public procurement regulations. Obviously, Turkey is one of the countries with a public procurement law for the regulations to be followed by the government institutions for public procurement. Consequently, tenderers must cultivate strategies by calculating the probability of winning a contract within this public procurement law due to its competitive nature of the industry. In this study, tenderer's potential winning strategy under Turkish Public Procurement Law open procedure is examined by means of proposing a simulation model for probability calculation with the restrictions of relevant regulations of Turkish Public Procurement Law no. 4734, tenderer's perceived market conditions and their cost structure against various probability distribution to support tenderers in decision making under uncertainty prior to tenders.

Keywords: *decision support, probability distribution, public procurement, simulation model.*

Introduction

Public goods such as public infrastructure or national defense are the commodities in which users' individual consumption has no effect on the quantity or quality of the product or service obtainable by others (non-rival) and individual use of the commodity cannot prevent other's consumption (non-excludable) (Sloman et al., 2016). Consequently, this results no motive for private market to make public goods available for people due to lack of profit opportunity and, therefore, this is government's responsibility to provide these goods or services for resident's use by means of collected taxes from citizens. Similar to public goods, governments are also providing merit goods such as health and education despite the fact that those could be supplied privately (Fiorito & Kollintzas, 2004). While those commodities, public or merit goods, are being provided or invested by governments or state-owned enterprises for people's use, private market is the one who delivers the goods, services or works for the realization of those enormous volume of projects. Hence, public procurement (or government procurement) which

is the process of procurement of goods, services and works on behalf of public authorities from private market is inevitable.

As conveyed by Organization for Economic Co-operation and Development (OECD) (2017), general government procurement as a percentage of Gross Domestic Product (GDP) varies between 10-15% of a state economy in average. Whilst this percentage has increased as a result of COVID 19 response and overall falling of GDP due to economic crisis after 2019, public procurement compared to non-procurement government expenditures decreased in 2020 due to direct support packages by government (Organization for Economic Co-operation and Development (OECD), 2021). According to the estimate done by Open Contracting Partnership and Spend Network (2020), the size of global procurement market is 13 trillion USD per annum.

Given enormous volume of global public procurement and its share in state economies, source of this investments' being taxes collected by citizens and probable connection of government officials and representatives in the process, public procurement has to be and is regulated by law almost in all countries. By means of those regulations under the procurement law of states or international institutions, transparency, competition, equal treatment, reliability, confidentiality, public supervision, and fulfilment of needs appropriately, promptly, and efficient use of resources are tried to be promoted. One of the countries who offers a public procurement law to be complied by the government institutions and tenderers during public procurement is Turkey. The current public procurement act (Law No. 4734) was published in Turkey on 22 January 2002 (Republic of Turkey Public Procurement Authority, 2020). Under this act, open procedure (where all tenderers can submit a quotation), restricted procedure (only invited tenderers who are qualified following a prequalification procedure can submit their quotation) and negotiated procedure (to be used under special circumstances) are provided under article 18.

In this study, determination of the probability for achieving a maximum tender price score in Turkish Public Procurement Law Open Procedure is discussed. In order to determine the probability, a simulation model is proposed by taking into consideration, (i) the restrictions of Law no. 4734 with relevant regulations, (ii) assumption of tenderer's perceived market conditions, iii) tenderer's assumption on probability distribution and iv) tenderer's own quotation. It is assumed that the outcomes of the simulation model will provide a decision support to the tenderer whether to enter the bid or not or revise its quotation. Therefore, in coming section of this study, tendering procedure under Law no. 4734 with relevant regulations is summarized, then, in next section, simulation model is developed. Finally, outcomes with past tenders are tested with the proposed simulation model.

Open Procedure under Law no. 4734

Following steps under Turkish Public Procurement Law are provided for open procedure type of tenders in Figure 1

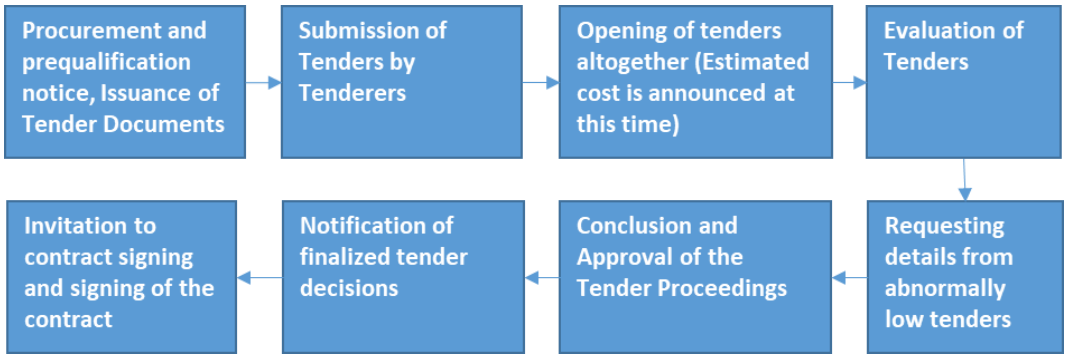

Figure 1: Steps for open procedure type of tenders.

Upon tender submission and evaluation by tender commission, the tenderer who submitted the *Economically Most Advantageous Tender* would be awarded by the contract. As conveyed under article 40 of Turkish Procurement Law, either only price base or the price base and non-price factors as cost of operation and maintenance, productivity, quality and technical aspects are defined as *Economically Most Advantageous Tender* (Republic of Turkey Public Procurement Authority, 2020). In this study, only price base score is taken into account for *Economically Most Advantageous Tender* for the proposed mathematical model. Article 45 (Identification of Limit and Abnormally low tenders) of Public Procurement General Notice published on 22 August 2009 determines the best tender price scored tender with the formulation given below:

T_n (Valid Offer): $(EC * 40\ \%) < T_n < (EC * 120\ \%)$ (1)

where *Estimated Cost (EC)* is the cost calculation undertaken by the contracting authority which is announced at the time of tender opening.

T_{ort1} : Valid offers (T_n) mean value ($T_{ort1} = \frac{\sum T_n}{n}$) (2)

σ : Valid offers standard deviation ($\sigma = \sqrt{\frac{\sum (T_n - T_{ort1})^2}{(n-1)}}$) (3)

σ is included to mean and deducted from mean.

$T_{ort1} - \sigma$

$T_{ort1} + \sigma$

The second arithmetic mean is determined by obtaining the average of the tenders within the zone of one standard deviation below and one standard deviation above the arithmetic mean value.

T_i : Tenders inside one standard deviation: T_i: $(T_{ort1} - \sigma \leq T_i \leq T_{ort1} + \sigma)$ (4)

T_{ort2} : Mean of Tenders inside one standard deviation: $(T_{ort2} = \frac{\sum T_i}{n})$ (5)

A value (C) is determined by dividing the second calculated mean by the estimated cost (EC).

C : T_{ort2}/EC (6)

A (K) value is found by substituting the value of (C) in the relevant one of the following equations.

If;

$C < 0.60 \rightarrow$ $K = C$ (7)

$0.60 \leq C \leq 1.00 \rightarrow$ $K = \frac{(3.2\ C - C^2 - 0.6)}{(C+1)}$

$C > 1.00 \rightarrow$ $K = \frac{(C^2 - 0.8\ C + 1.4)}{(C+1)}$

The limit value is found in the following equation:

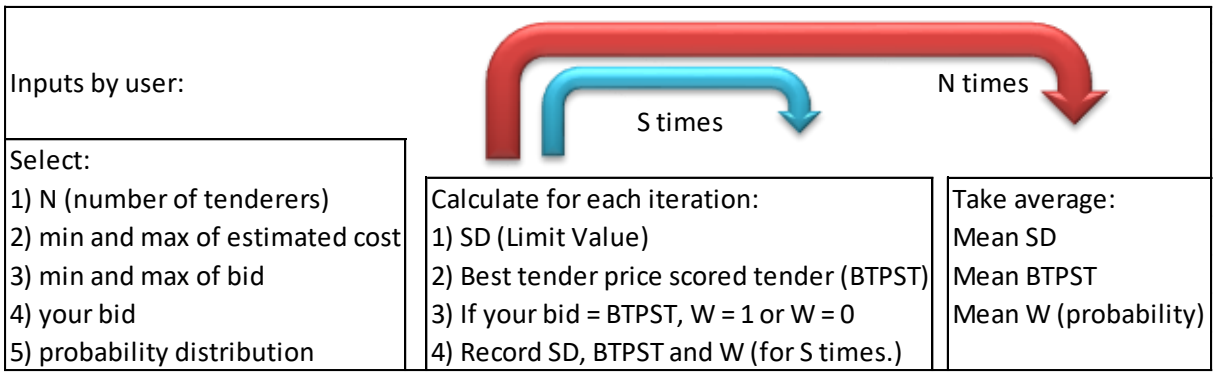
$$\text{SD (Limit Value)} = \frac{K \times T_{ort2}}{C \times N} \quad (8)$$

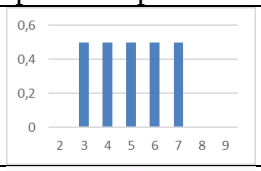
Upon obtaining SD (Limit Value) with the formulation given above, the first offer, which is just above SD is the best tender price scored tender. While tenders given below SD is called *Abnormally Low Tenders*, other tenders above SD have price scores calculated proportionally. In this study, the main target of the proposed model is to find out the probability of getting the best tender price score of the given offer.

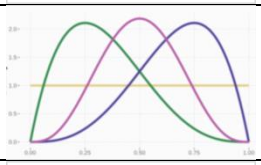
Model Development

The proposed model is based on acquiring average outcomes from randomly selected input variables among tenderer defined ranges through a number of iterations with respect to several probability distribution. In each iteration, outcome through above given formula is calculated and recorded. The possible results of those records are the mean of SD (Limit Value) and the mean of the best tender price scored tender. In addition, the value of user's tender price can be checked against the value of the best tender price scored tender in each iteration. If user's tender price match with the best tender price scored tender, it means the user's tender price wins and recorded as a win. Otherwise, it would be recorded as lost in that iteration. Hence, the mean value of total number of those wins against the number of all iterations gives us the probability value of the assumptions made by the user for this tender session.

In the model, the inputs assured to be known by the tenderer are number of tenderers (N) giving quotation to the tender including the bidder itself, range of estimated cost (min_cost and max_cost), range of quotation to be given by the tenderer (min_bid and max_bid), your bid (own_bid), probability distribution of the tender (dist) and the number of iterations (S). In each iteration, SD (limit value), best tender price scored tender (BTPST) and whether your bid wins or not (W) are found with respect to the randomly selected inputs as per the chosen probability distribution. Consequently, this sequence is repeated with the given number of iterations up to maximum number of tenderers (N) (Figure 2).







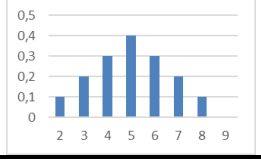


Figure 2: Steps of proposed model.

Proposed Probability Distribution

Although estimated cost is selected randomly according to a uniform distribution between user defined minimum and maximum of estimated cost, bids of each tenderer for N number of tenderers are selected randomly by means of an user defined probability distribution. The proposed probability distributions for bids are discrete uniform distribution, beta distribution and symmetric triangular distribution (Sinharay, 2010) as shown in Table 1. In discrete uniform probability distribution, all integers in a range of variables have equal probability. That is, all the bids have the same probability in the given tender. In symmetric discrete triangular distribution, integers in the range do not have equal probability and probability density function is shaped like a triangle. Lastly, we preferred beta distribution option with various parameter values in our model. Using two parameters of beta distribution function, the shape of the distribution can be controlled by the user.

The reason why those probability distributions are chosen is to support decision making to see different scenarios if all bids have equally likely outcomes (discrete uniform probability distribution), if all of the tenderers would have tendency to bid lower or higher bids compared to other bidders (beta distribution with different α and β parameters) or if all of the tenderers would like to bid around the mean value of the market conditions (symmetric triangular distribution). Although it is very hard to estimate which probability distribution is appropriate to use, the user would have a chance to compare and check the previous similar bids so that they would use this estimation for future tenders.

Table 1. Summary of probability proposed distribution.

Probability Distribution	Function	Graphical Representation
Discrete uniform probability distribution	f(x) = 1/k where k = the number of values the random variable may assume	
Beta distribution	$f(x,\alpha,\beta)$ = constant * $x^{\alpha-1}(1-x)^{\beta-1}$ where $\alpha,\beta > 0$	
Symmetric Triangular distribution	$f(x) = ((b-c)-abs(c-x))/(b-c)^2$ where b is max bid and c is the mean bid	

In our model, for Beta distribution, α & β coefficients from 1.5 to 5 are used in order to cover all distribution options for randomly selected bids of each tenderer as shown in Figure 3.

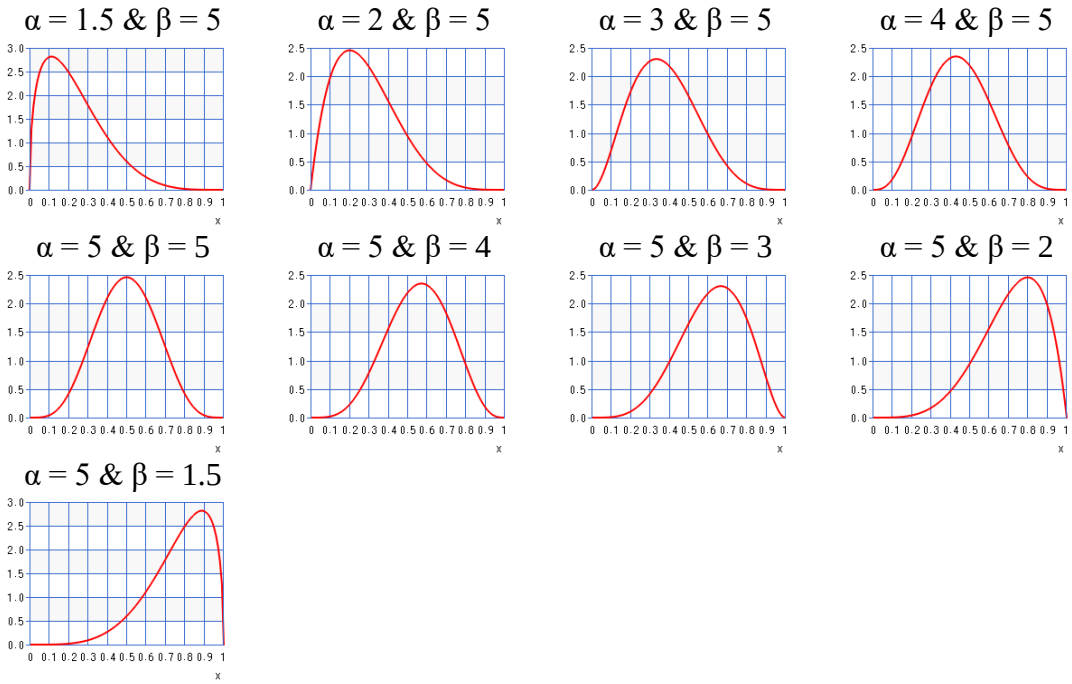

Figure 3: Beta distribution coefficients used in the model.

Detailed Model Steps

The proposed model includes fifteen steps as follows:

1: Set min_cost, max_cost, min_bid, max_bid, own_bid, S, dist

2: For n = 3 to N do

3: For i =1 to S do

4: bids = sample (n-1) number between min_bid; max_bid uniformly at chosen dist

5: cost = sample one number between min_cost; max_cost uniformly at random

6: valid bids = bids in the zone (greater or equal to cost*0.4 and smaller and equal to cost*1.2)

7: if number of valid bids < 2, stop and do next iteration

8: calculate T_{ort1}, σ, $_{Tort1}$+ σ, T_{ort1}- σ, T_i, T_{ort2}, K, C and **SD**

9: calculate BTPST = min (valid bids>SD) and record BTPST, cost and SD on list of "records" dataframe for n

10: If own_bid = BTPST, W =1, else W = 0 and record W on the list of "records" dataframe for n

11: End for.

12: Mean_BTPST = mean (records of BTPST), Mean_SD = mean (records of SD), Mean_Cost = mean(records of cost), Mean_W = mean (records of W)

13: End for.

14: Plot the data of Mean_BTPST vs N

15: Plot the data of Mean_W vs N

Using the steps given above, we tried a simulation with the assumptions: min_cost = 2,000,000 ₺, max_cost = 2,200,000 ₺, min_bid = 1,000,000₺, max_bid = 2,400,000₺, own_bid = 1,500,000 ₺, S = 2000, dist = uniform distribution and N is from 3 to 20. The results are shown in Fig. 4.

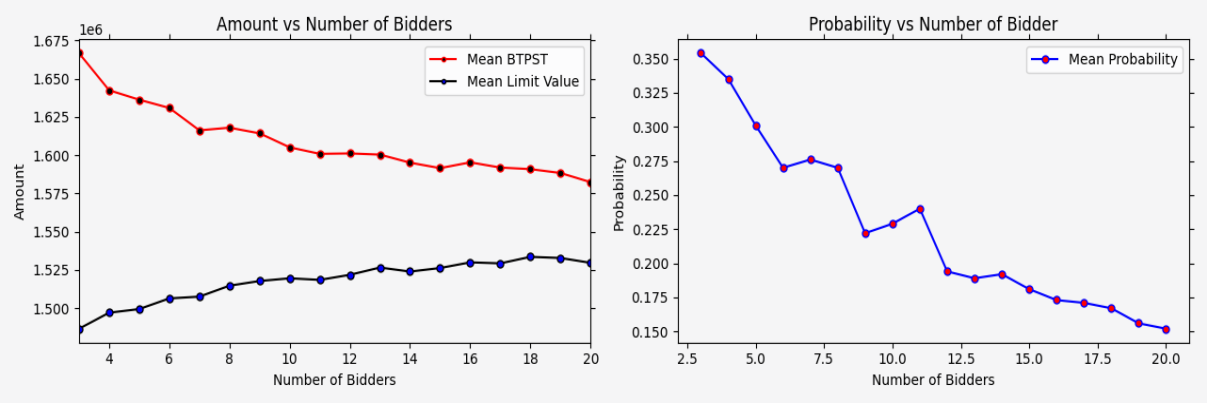

Figure 4: Estimated values and probability against number of bidders.

It is not astonishing that while the number of bidders increases, the mean BTPST is falling as a result of rivalry between bidders. Yet, the mean limit value is growing so that the abnormally low tenders can be disregarded. On the other hand, with the increase of the number of bidders, the mean probability of our own bid of being the best price scored tender is getting lower and lower. This is also not surprising. However, what is surprising in here, as the number of bidders is increasing, in order to increase the probability of getting a higher score, the bidder should increase their quotation. Notwithstanding, it is limited with other bidders' quotations. Therefore, estimating the correct number of bidders to enter to the bid is also vital.

Results of Simulation of Proposed Model

While the model is tested with above mentioned assumptions, we also tested the model with 30 actual tenders. In order to observe the error between simulations and the actual tenders, we used the Mean Absolute Percentage Error (MAPE) [11] approach as;

$$\mathrm{M} = \frac{1}{n}\sum_{t=1}^{n}\left|\frac{A_t - F_t}{A_t}\right| \tag{9}$$

In order to form the results table given in the Annex -1 by means of a software program coded in Python using the algorithm given above, probability with various probability distribution is tested to determine the highest probability against that probability distribution. After filtering the highest probability values for the corresponding distribution, the Absolute Percentage Error for Limit Value and BTSPT for each tender is calculated so that the overall MAPE can be demonstrated. Here, while actual minimum & maximum bid values, BTPST and Limit Values observed in each tender are used as input for the simulation, for estimation of interval of minimum and maximum estimated costs, 95% and 105% of tender's estimated cost are used as model inputs for minimum and maximum estimated cost. For all tender simulations, number of iterations (S) are taken as 2000 iterations. Consequently, models provided results are BTPST, Limit Value and probability. Therefore, using actual and model results of Limit Value, absolute percentage error is calculated.

Once the results table formed by using the assumptions and actual tender inputs, it is demonstrated that the mean probability of estimation of the best tender price scored tender of those 30 actual tenders with our model is 20.39 %. As seen in Fig. 5, it is not surprising that as the number of bidders are increasing the probability of having the BTPST is decreasing since the competition among companies are increasing.

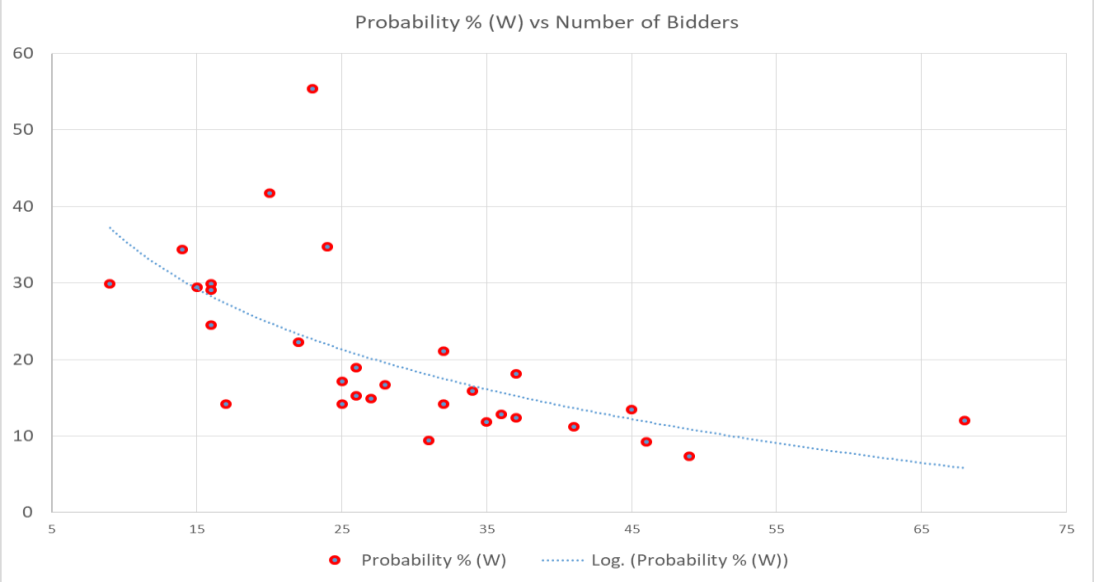

Figure 5: Probability vs number of bidders.

Among those 30 actual tenders, the results table shows that no probability distribution dominates against the number of bidders. Although it is found that 8 out of 30 observations (27%) is beta distribution with $\alpha = 3$ & $\beta = 5$ parameters and no triangular distribution is used in the table, we trust that the distribution is unique for each and every tender. Maybe, one may use previous tenders to estimate the correct parameters and distribution. However, it is sure that there is a room for further studies where the probability distribution can be estimated more precisely.

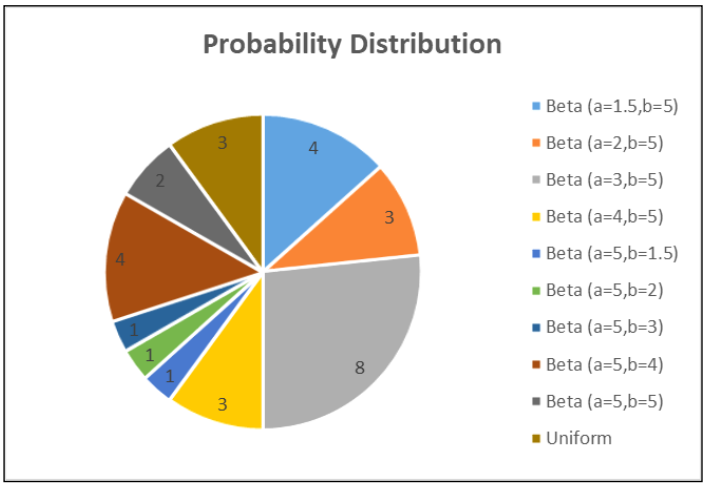

Figure 6: Probability distribution.

Lastly, the MAPE of Limit Value and BTPST are found as 1.01% and 0.93% respectively. Although those percentages seem very less, considering the huge volumes of the projects which are over millions of Turkish Liras, these may cause significant number of differences in certain cases. Even, those would impact who would be the winner. Notwithstanding, it should be noted that probability to getting the highest score require *minimum error* in estimation of Limit Value.

Conclusion

Trying to achieve a maximum tender price score in Turkish public procurement law open procedure is a problem of decision making under uncertainty. The model given in this study is developed in order to support the decision makers prior to submission of their tenders for the bids announced under Public Procurement Law of Turkey open procedure. By means of the proposed model, tenderers have the chance to see the probability of their bids to get the maximum tender price score. However, the proposed model requires that the inputs have high certainty so that outputs can be accurate. Although estimated cost to be given by the contracting authority can be estimated with the calculation of project quantities and possible unit costs in a certain extent, number of bidders to give quotation, their minimum and maximum bid values and possible probability distribution could be difficult to guess. Hence, there is a big room for further studies to develop methods to obtain more accurate inputs into the model so that maximum probability can be targeted.

Data Scraping for Corporate Identity Evaluation: A Stakeholder Engagement and Management Perspective

A. T. İlter
Istanbul Technical University, Informatics Institute, Istanbul, Turkey
iltert@itu.edu.tr

Abstract

Stakeholder management is one of the vital topics of project management which is recently separated from communications management, forming the tenth knowledge area of project management discipline. The communication in-between all stakeholders and the organization as an entity is subject to this knowledge area, and include a wide range of forms, that can be written or verbal, as well as formal or informal. Different communication technologies can be used in this context, and there is a shift towards informal communication methods in construction industry, just as many others. One of the informal-written communication mediums is social networking site (SNS) with an increasing popularity. SNSs offer an interactive communication space that accommodates valuable information for the organization, and the information on these networks are open to the public to an extent. Considering corporate SNS accounts as a formation of corporate identity (CI), and SNS users as stakeholders, this paper tries to create a framework where publicly available data on an SNS is extracted using data scraping techniques and the extracted data set is used to evaluate the CI strategy by mining this data. This framework is expected to be assistive for providing valuable information how AEC firms build, develop and manage CI on social networks, to improve their CI strategies.

Keywords: *AEC, big data, data scraping, SNS, stakeholder engagement management*.

Introduction

In the construction industry, strategy can be defined as degree of diversification and geographic expansion, and how an organization adapts to environmental changes (Dikmen & Birgönül, 2003). These environmental changes refer to the conditions related to the competitive business environment the companies are in. However, that limited perspective considering company profits above all are being questioned more than ever due to the climate change and environmental catastrophes caused by the economic activities of human kind. For the construction industry, this means a challenge for a project based environment to look beyond the project environment and consider more about the ongoing effects of the built environment and the footprints that we leave behind for the next generations. Being one of the leading energy consuming, waste producing and carbon dioxide emitting industries, construction industry needs a change.

This inevitable shift in the line of sight appears in company activities and applies to a wider ground of public as stakeholders. Companies are showing their responsibilities not only for their shareholders and other parties in their projects from a close proximity, but also for the public as a stakeholder from a broader perspective. Corporate social responsibility (CSR) activities are widened with the emphasis on the topic of environment, and corporate social and environmental responsibility (CSER) activities and reports are assembled under the topic sustainability. On corporate web sites, sustainability statements became an essential part of the corporate identity, such as mission and vision statements. As sustainability becomes a core competency in strategic management framework, its existence and approval by the public domain becomes a key issue for corporate strategy, and core competencies cannot be measured in terms of dollars and market share (Chinowsky & Meredith, 2000).

Regarding these notions, this article tries to develop a theoretical framework in order to identify the position and effect of SNSs on corporate identity (CI), and its place in the strategic management of AEC firms. In this regard, concepts that form the theoretical framework of corporate identity evaluation through SNS activity are examined followed by a proposed model for using social media data for corporate ID evaluation. The paper then discusses the model and propose future research recommendations.

Theoretical Framework

Developments in IT are deeply affecting all the industries, forcing companies to invest, adapt and innovate new processes in their business environment, while the boundaries between business and private life is getting blurred by the SNSs. People are becoming increasingly aware of the relevance of environmental issues in their daily lives (Bartels & Hoogendam, 2011). Social media (SM) have completely redefined the interaction between companies, customers and all the stakeholders, creating a social network that enables instant communication. The availability of digital technologies, and the extent of available data are essential elements for exploiting innovative opportunities (Russo et al., 2022). However, companies' attempts to differentiate themselves using these technologies frequently fail due to the lack of integration with their corporate strategies (Dikmen & Birgönül, 2003). This lack of integration puts forward the importance of understanding key concepts and the need for more research to use these technologies to strengthen strategic perspectives.

Corporate Identity

Companies have a strategic perspective just as the personality of individuals, that is independent from its intentionally planned extent and this perspective is crucial for paving the way through competitive advantage (Dikmen & Birgönül, 2003). In a broad definition, corporate identity is how an organization reveals its philosophy and strategy through behavior, communication and symbolism (Leuthesser & Kohli, 1997).

While discussing the corporate identity, other phrases like corporate reputation or corporate image also come to mind. While image and reputation can be regarded as representing the same concept, the main difference between identity and image can be simplified as different perspectives depending on the side we are observing the organization from. From the internal perspective, the term corporate identity should be understood as its personality, and it refers to the essential features that differentiate the organization, meaning the behaviors a company

chooses to present itself to all the stakeholders, as well as the public (Dutot et al., 2016). Instead, company image is how customers or external stakeholders define the impression of the company, and, is more subjective. Moreover, executive managers' reputation accounts for a large extent of the company. This amount is 50% in US, and 63% in Germany according to the CEO magazine (Everett, 2017). On the other hand, the image that a firm creates on their stakeholders, depending on the information the firm disseminates on its internet based digital mediums is called e-reputation, which is also coined as digital reputation (Dutot et al., 2016). Although the means of expression for corporate identity are various in different mediums, leading categories are mission statements of the firms and annual reports that form a visible communication with stakeholders. These reports are also a good source for summarizing corporate image (Leuthesser & Kohli, 1997). Dikmen and Birgönül (2003) indicate that one of the most important objectives of construction companies that operate internationally is building a positive company image.

Corporate Social (&Environmental) Responsibility Reports

In the recent years, the concept of corporate social responsibility (CSR) or with its extended name, corporate social and environmental responsibility (CSER), increased in importance. Harvard Business School reports that 90% of the S&P 500 index companies published CSR reports in 2019, up from 75% in 2014, and 20% in 2011 (Cote, 2021). Although there is not a universally agreed definition of CSR, the European Commission mentions it as social and environmental factors taken into account by stakeholders, in contact with relevant other stakeholders on a voluntary basis (EU, 2001). Zhao et al. (2012) embraces a definition that distinguishes the firm's consideration and response towards issues beyond a narrow economic, technical and legal requirements of the company to accomplish social and environmental benefits balancing the concerns of various stakeholder, adding that CSR reports are an emerging component of corporate performance since the mid 1990's (Zhao et al., 2012). Tekçe (2014) links the emergence of CSR reports to the public demand in parallel to the progress of the sustainability concept and examines their presence in large scale, international construction companies. Research also shows that, leading motivations for releasing CSR reports are reputation and brand identity. The given messages in these reports can be classified under four main topics: benefits, values, focus, and self-image (Leuthesser & Kohli, 1997).

However, current progress in sustainability agenda seems to transform CSR reports a step further that goes beyond the target of opinion formers like pressure groups, politicians and media, towards the whole value chain from an enlarged stakeholder perspective. This progressive report type is called "sustainability report". Despite this focus change, CSR and sustainability are closely linked, and they are often considered as equivalent concepts (Rameshwar et al., 2020). Whether it is a CSR or Sustainability report, SM show a significant contribution to the construction of company's identity than the management of analytical aspects of sustainability performance (Russo et al., 2022).

Previous research suggests that, corporate culture featuring obligation towards social and ethical values are better in attracting best talent, increase productivity and maintain better connections with their stakeholders, also attracting more interest from investors (Moneva et al., 2007). Similarly, Zhao et al. (2012) indicate that CSR is increasingly valued in construction industry for its contribution on sustainable business development, and corporations develop CSR reports to maintain a positive corporate image (Zhao et al., 2012).

In order to achieve this, a firm should integrate its concerns on environmental, social, human or labor related issues with its strategy and policy by a voluntary commitment (Dutot et al., 2016).

Strategic Management Process

A typical management process consists initiation, planning, execution, monitoring and control, and strategic management process fits into this scheme within the same perspective. One of the most intact and cited model for strategic management is shown in Figure 1. In David's model (David, 1989), the initiation and planning stages are considered as 'strategy/formulation', where, the identity of the company is born and matured. As the process is cyclical and multi-dimensional, different stages and components, as well as the results of monitoring and control stage of strategy evaluation gives feedback to the other stages throughout the process lifecycle.

Figure 1. David's Model of the Strategic Management's Process

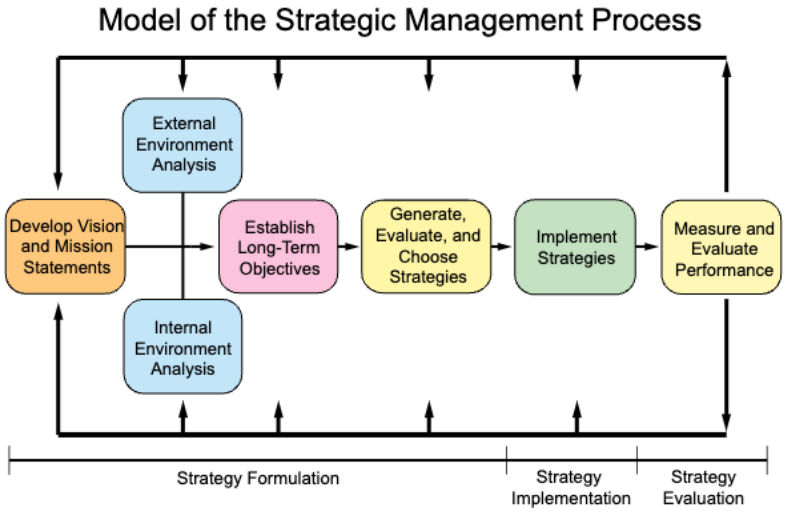

Figure 1: David's 'Strategic Management Process' model.

This model puts forward that, every kind of activity performed by a firm is a product of its strategic perspective, and rooted from its very own identity. Hence, it is also possible to 'reverse-engineer' the process and find out clues about the firms identity from its footprints, and try to understand the strategic management components. Identifying these components can help improve the process according to its objectives or make a company reassess the objectives itself.

Stakeholder (Engagement) Management

In the first instance, it may seem precarious to assess the public as a stakeholder, as the concept derived from the word 'stockholder'. The public may seem to be out of the managerial influence area, and far from administrative discussions. Some of the earliest work

about stakeholder management concepts suggested a narrow definition such as “the groups that enable the existence of the organization (Ackermann & Eden, 2011). However, the sustainability agenda changed such definitions and developed a definition that emphasize a mutual relationship between the two sides. Broadening the concept of strategic management afar from its economic roots, stakeholder can be defined as “any group or individual who is affected by an organization’s objectives as well as parties who can affect it (Freeman et al., 2005). After decades long discussions, it is inevitable to consider each economic activity with its impact on our environment and all the living habitat. In this perspective, the influence of public over corporate institutions cannot be ignored. Ramananda et al. (2020) underlines that public pressure effects corporate disclosure and companies voluntarily release CSR information in social media to respond various social and economic issues and to impress their stakeholders. Environmental issues are receiving an increasing public attention and they dominate the SM based disclosure (Akbas & Canikli, 2014).

Project managers spend a substantial amount of their time, more than 75%, for communication (Alten et al., 2020) and it is a critical part of project management (Turkulainen, 2015). On the other hand, previous research show that top level management teams find dealing with stakeholders problematic, both because of its difficulties as well as its ethically compelling sides (Ackermann & Eden, 2011). At this point, the legitimacy of stakeholder management rise to the surface, and the stakeholder versus stakeholder engagement management discussion emerges. Although these two phrases are being used interchangeably, there are slight differences between the two. As Association for Project Management defines it, stakeholder management approach depends on the prediction that stakeholder actions and behaviors can be predicted and in a way be manipulated, while stakeholder engagement approach focuses on relationship building for the practice of various outcomes through the project life-cycle (APM, 2022). Therefore, it is critical to consider these differences in order to set the aim of a research and adopt the findings from strategic management perspective.

What to Expect from SNS Data

As Feher (2015) indicates, all the companies and their employees, as well as all their partners and stakeholders are leaving digital footprints behind, on the internet. SNSs are not exempt from these digital footprints, and although they give an impression to be on the personal side, corporate presence on social networks is increasing exponentially. Besides, when the employee is considered as the main risk factor for the company’s reputation and safety (Feher, 2015), borders of the personal and corporate area of influence are getting blurred. Chinowsky and Meredith (2000) defined the business change and underlined the importance of the information access more than two decades ago. With the help of IT innovations, the boundaries in front of organizations that they had to place themselves in certain markets have changed drastically. Today any organization regardless of its size and geographical location can bid, design and even operate anywhere around the globe. Knowledge workers, new markets, and IT are part of everyday business life for AEC firms as well as other industries. Dutot et al. (2016) emphasize that the internet presence of companies has increased to such an extent that, it has become a fundamental pillar in communication strategy with its ubiquitous presence and attractive nature for the market, the ability to boost brand reputation with reduced costs, its capacity to offer real-time and easy to cross-check metrics (Dutot et al., 2016; Soydaş Çakır & Levent, 2021).

On the company side, the whole social media profile of the firm and its possible different uses should be managed by the management team distinctively according to different stakeholder profile and expectations. If this strategic process is considered as a simple exitance of a SM profile, companies will lose the opportunity to interact with their stakeholders and enhance their sustainability performance (Russo et al., 2022). SM can be considered more as simple texts and media like photographs or movie clips. Using photographs may help express ideas and experiences in different ways that words cannot and they have the power to influence the observers emotions. Also, it is not uncommon that, companies use images to create biased perceptions in their annual reports such as CSER which may lead to 'greenwashing' (Chong et al., 2019). However, SM presence of the firm creates a more open and traceable environment that is constantly in public eye, and enables verifications by performing crosschecks. In this context, Thompson (2018) positions SNS activities over the 'engagement' and 'connectivity' zones in her 'conceptual framework for the interaction of social media with the practice of project management' (Thompson, 2018).

According to a survey that questioned children in US, UK, and China, the percentage of children who want to be a 'YouTuber' is three times the number of children who wanted to be astronauts, a decade ago (Overstreet, 2022). In the era of content creators and influencers, it is quite appealing to think about a possible rise of 'architecture influencers'. As a medium with increasing importance, the data it produces is vast and available online.

A Data Scraping Model Proposal

Web scraping is a tool used to create structured data sets from unstructured data such as SNSs provide. Besides its popularity for SM research, it can be considered as a tool for collecting, storing and validating data from the internet for many reasons, such as online price comparison. Application Programming Interfaces (API) that many social media developers provide or custom made tools developed by programming languages like Python are being used for collecting data. Under the light of the theoretical framework of this research, two data scraping models are proposed aiming to evaluate the corporate identity of AEC companies from a stakeholder engagement and management perspective.

Data

Data used for firm selection and scraping are open to consideration depending on the framework researcher wants to use. Different databases can be considered as the data released by professional associations, academic institutions, media outlets, or blogs. These company databases should be selected depending on the aim of the particular research considering AEC industry. This research aims to develop a general data scraping model that can be applied for contractors, architectural design companies, or similar. For the trial runs, an international architecture company with active presence in Instagram, as noted by the media outlets is used.

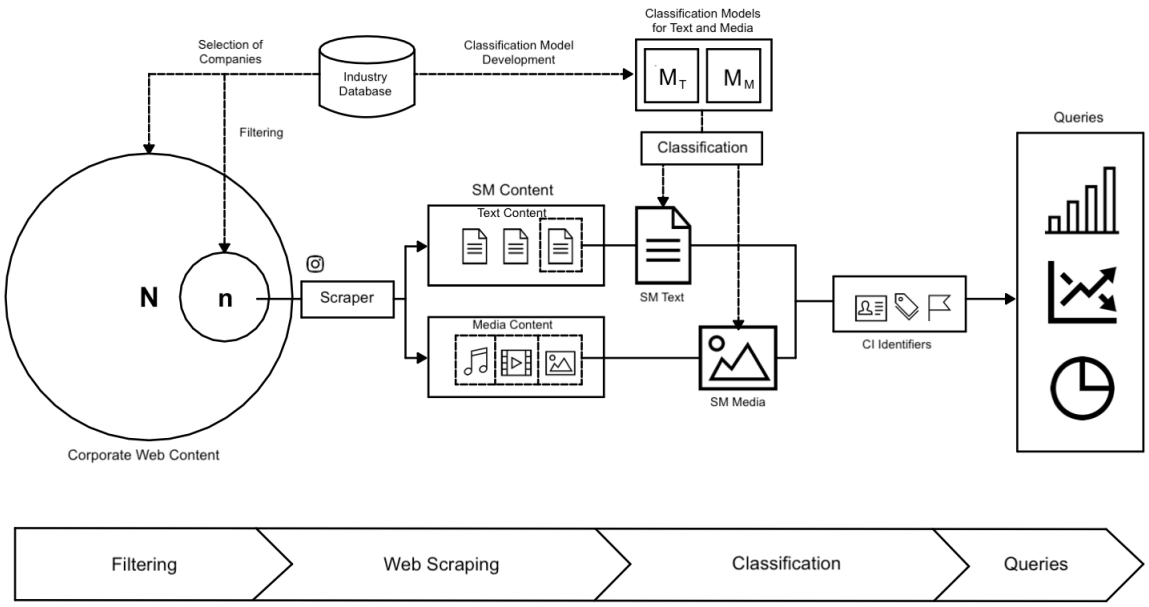

Figure 2: Proposed data scraping model for SNS activities.

Methods

The methodology for data scraping and classification methodology is adapted from (Kinne & Resch, 2018), and presented in Figure 2. In their research, Kinne and Resch (2018) discuss web scraping to obtain innovation indicators for manufacturing firms that are registered in an industrial database, preparing a Phyton programming language based tool, to map geographical locations of innovative firms at a predetermined location. Nevertheless, this research discusses a general SNS scraping model for SM posts, which will develop its own classification models for the text and media files obtained, in order to identify the characteristic items that help form their corporate identity. The model is adaptable to use with different databases, SNS types and uses a freeware, web-based scraping tool obtained from apify.com. The process starts after the database selection and proceeds as follows: (1) filtering the SNS accounts of the companies that will be scanned from the chosen database; (2) scraping the SNS activities form the corporate SM account; (3) Developing classification models for text and media data depending on the used industry database selected; (4) Querying the data for CI evaluation.

Moving further, this research proposes a second model that aims to identify the CI evaluation in comparison to the CSER documentation from corporate web sites of AEC firms. As the literature review suggests many clues about the CSER reports and corporate reputation (Dutot et al., 2016; Leuthesser & Kohli, 1997; Russo et al., 2022; Tekçe, 2014; Zhao et al., 2012), this second model intends to disintegrate text and image used in the reports and classify them using the proposed classification models, in order to both evaluate the CI further but also compare the consistency of these two different sets of data. This second model shown in Figure 3, has a similar workflow with the first model. However, at the web scraping stage, along the SNS data, CSR reports of companies are also scraped. At the classification stage they are dissected into text and pictures, and classified with the developed model. This two-way flow demands necessary adaptations for classifications models that will help reveal the CI identifiers.

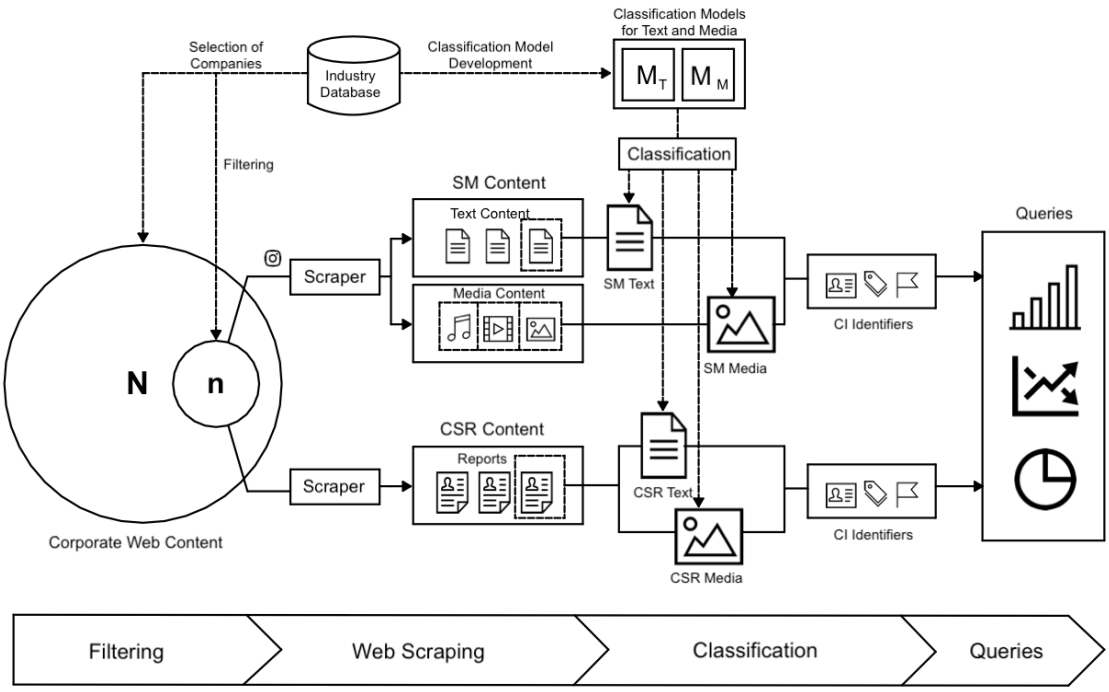

Figure 3: Proposed data scraping model with CSR report module.

Discussion and Conclusion

Stakeholder engagement and management process consists a vast majority of communication practice that are constantly shifting towards informal ways of engagement. As today's highflier of informal communication, SM is an under examined yet powerful tool that can enable big impacts in quite a short time. As business enterprises are paying more attention and trying to secure their position on SM, each SNS activity leaves traces of the firm's corporate identity, that forms a corporate reputation from the stakeholder's perspective. With its possible impacts, SNS activities deserve exploring as a strategic management tool. Different kinds of stakeholders should be considered for SM activities. However, with the rising environmental sustainability concerns, the public became one of the major stakeholders, for the companies who share a common vision for the planet, and want to utilize innovations of IT for their competitive advantage.

This research tries to set the theoretical framework for further research. These two models proposed in this research are developed in order to evaluate corporate identity characteristics of AEC companies that are actively present in SNSs. An SNS scraping process is completed for two major design firms. Further research is being planned for developing the necessary classification models in the near future. Both models will be subject to application for an extensive research that will put forward the corporate identity characteristics of the firms, while testing and developing the models further. Although there are obvious limitations, further research will be utilized to minimize them.

Optimum Solution of Resource Leveling Problem

T. Erzurum and Ö. H. Bettemir
Inonu University, Department of Civil Engineering, Malatya, Turkey
tugbaerzrm@gmail.com, onder.bettemir@inonu.edu.tr

Abstract

The reduction of the fluctuations observed in the resource histogram to the possible minimum level without any delay in the completion time of the construction project is called the resource leveling problem (RLP). The objective of the resource leveling process is to keep the resource utilization rates constant to ensure that the change in resource demand is kept at the minimum throughout the project. Moreover the activities are scheduled in order to ensure that the project completion time does not exceed the one obtained by the early start time of the activities. In this study, software is developed in Visual Basic which generates the construction schedule with the minimum resource fluctuations for small scale construction projects. The software solves the RLP by evaluating all of the scheduling options. Minimum moment resource fluctuation metric is utilized to measure the amount of fluctuations in the resource distribution throughout the construction project. The algorithm evaluates all of the possible scheduling alternatives and records the schedule which gives the minimum resource fluctuation. The executable file is tested to solve the resource leveling problem of a two story construction project. The problem is solved within one hour of computation time. The case study showed that the developed executable file can be implemented by the small scale contractors for the optimum solution RLP.

Keywords: *complete enumeration, optimization, resource leveling problem.*

Introduction

Construction projects may consist of large number of activities, may request large volume of resource use, and may provide high financial turnover. However highly competitive business environment makes impossible to compete without effectively managing the utilization of the resources. In order to manage projects properly in competitive conditions, project managers need to prepare a plan that foresees how resources will be used. In construction works, this planning is usually based on construction schedules. However, planning by focusing only on time causes the other project goals to be ignored, as well as causes an increase in costs. In planning, the goal is to evaluate the project elements together and to balance all elements effectively to get the maximum benefit from the project. Starting activities at the earliest start times may cause undesirable fluctuations in the resource histogram. These fluctuations affect the total budget of the project. Therefore, resource usage should be organized to have a better resource profile (Hiyassat, 2001, 2002).

One of the resource planning tools in projects is resource leveling. The main goal in resource leveling is to improve the resource usage by reducing the fluctuations of the resource demand and the peak resource demand without changing the project duration. Resource fluctuations may cause financial problems, penal sanctions in contracts, increased costs of temporary facilities-resources, and increased demand for the limited resources (Erzurum & Bettemir, 2021).

Exact methods, heuristics and meta-heuristics are applied to solve the RLP. Heuristic and meta-heuristic methods do not guarantee an optimal solution. Exact methods, on the other hand, can provide the guaranteed optimum solution for small-sized problems of RLP, which is NP-Hard (Rieck & Zimmermann, 2015). The computation time and memory requirement of the exact methods for the solution of RLP increase very rapidly if the number of activities of the project increases (Demeulemeester & Herroelen, 2002). Therefore, mathematical methods are insufficient for large-scale problems. However, it should be noted that it is inevitable that exact solutions are needed for the performance analysis of heuristic and meta-heuristic methods.

Heuristic methods require low computational demand. Because of the mentioned convenience, the solution performance is quite low compared to other methods. Because the main focus of the heuristic methods is to solve the problems in a reasonable time. In the problems solved with heuristic algorithms, it is generally aimed to produce a fast solution knowing that the solution is not guaranteed. Even if these algorithms search for solutions that are close to optimum, they are focused on reducing the solution time. Burgess and Killebrew (1962) proposed one of the first heuristics to solve the resource leveling problem. This method is based on a network-based solution that changes the start dates of non-critical activities by shifting the activities until they find the best result. Much of the later work has also focused on priority-based shifting techniques (Harris, 1978, 1990; Martinez & Ioannou, 1993; Hiyassat, 2000, 2001).

Due to the complex resource relationship and the large number of work items in the construction industry, intuitive solutions have become more and more inadequate in resource leveling in the construction industry. Because of the computational burden and time required by exact methods, researchers mostly turned to meta-heuristic algorithms. Meta-heuristic algorithms can direct the search process in the solution space, they can guide the problems to find the best points, reduce the solution time, and the memory requirement, and the effort to avoid local extreme points. In fact, the basis of all these positive features is the artificial intelligence created in the structure of meta-heuristic algorithms. Some of the most common meta-heuristics algorithms utilized for the solution of RLP are; genetic algorithms, simulation annealing, taboo search, particle swarm optimization, ant colony, petri nets, evolutionary development (Hegazy, 1999; Hegazy & Kassab, 2003; Iranagh & Sonmez; 2012; Son & Skibniewski, 1999; Wang & Zheng, 2001; Zheng et al., 2013; Bettemir, 2009; Ponz-Tienda et al., 2017; Lin & Gen, 2018; Qi et al., 2007; Wang & Qi, 2009; Li et al., 2010; Geng et al., 2011).

The solution space of RLP varies according to the number of activities, activity precedence relationships, and total float durations of the activities. Performances of the meta-heuristic methods are likely to reduce if the search space is too large. To avoid this, a deeper search strategy and effective learning algorithms can be developed and used. This will increase the memory requirement considerably because as the search space grows. In addition to this, population size must increase to obtain a near-optimal solution. With the processors produced

today, this negativity can be reduced. In cases where these negativities cannot be eliminated, precise methods are used, which have a high computational load and a longer solution time compared to other methods. Despite these negativities, it is clear that there is a need for problems that can be solved with exact methods and algorithms to be developed. Some of the exact methods are; dynamic programming, branch and bound algorithm, and linear integer programming (Younis & Saad, 1996; Agin, 1966; Demeulemeester & Herroelen, 1992; Mutlu, 2010; Yeniocak, 2013; Karaa & Nasr, 1986; Easa, 1989; Son & Mattila, 2004; Rieck & Zimmermann, 2015; Gather et al., 2011). The largest problem whose exact solution is obtained in a guaranteed manner is 50 activities.

Due to the limitations of the RLP solution methods currently used in the literature, a new solution method is needed. In this study, a method is developed that determines the search space by delaying the non-critical activities of RLP and obtains the guaranteed optimum result by scanning the entire search space. The second part of the study explains how the entire search space of RLP is determined and scanned. In order to measure the performance of the developed method a two-story building project is analyzed in the case study part, and finally the results are concluded.

Proposed Complete Enumeration Algorithm

The first stage of implementation is to create the network diagram of the project. One of the most common methods used for project planning is the activity on arrow diagrams. After the network is created, forward and backward pass calculations are made to obtain the early and late start times as well as float durations of the activities. In RLP delay of an activity cannot be more than its total float duration. In RLP delay times of the noncritical activities are the variables of the problem. The delays of the activities are assigned from 0 to its total float duration in sequence to execute complete enumeration. At each step only one delay time of an activity is incremented.

The construction schedule is formed after the assignment of the delay times. The start and end times of the activities should not violate the early and late start-finish times. Resource usages of the activities are determined by considering the start and finish times and the resource requirement of the activity. The daily resource demand is computed by summing the all of the resource demands of the activities which are executed on that particular day. The resource histogram is prepared by computing the daily resource usages for all of the project days.

The resource fluctuations are measured by resource leveling metrics which will be the objective function of the optimization process. The choice of objective function is very important in order to obtain a properly leveled resource histogram. The basic principle of the objective function is to measure the fluctuations of the resource usages. Minimum moment metric is used in for the measurement of the resource fluctuations. There have been studies in the literature dealing with the use and comparison of objective functions tried with different methods (Damci & Polat, 2014; Damci et al., 2016; Bettemir & Erzurum, 2019a, 2019b). The preferred objective functions are specific to the examined project. In other words, an objective function that gives a good resource profile in one project may not be efficient in another. Before this study, common metrics used in the critical path method were compared and the MM scale was preferred by evaluating the improvement of the resource profile (Bettemir & Erzurum, 2019a, 2019b). The formulation of the minimum moment scale proposed by Burgess and Killebrew (1962) is presented in Eq. 1.

$$MM = \sum_{i=1}^{S} \sum_{j=1}^{k} w_j r_{i,j}^2 \quad (1)$$

In Eq. 1, s is the project duration, k is the number of different resources, $r_{i,j}$ is the j^{th} resource amount needed on the i^{th} day, and ω_j is the weight value assigned for the j^{th} resource. The daily required amounts of each resource are collected in the construction schedule. Then, the total moment calculation is made by applying the objective function.

All of the feasible schedules are evaluated by implementing Eq. 1 and the obtained minimum moment value and the corresponding construction schedule is recorded. In this way, by trying all possible delay combinations, the entire search space of the resource leveling problem will be scanned and the best solution to the problem will be found.

The proposed method is implemented by software developed with the Visual Basic programming language. The advantage of the developed method is that it obtains the most suitable work program in small and medium-sized projects by scanning the entire search space. The software calculates all possible scheduling alternatives using the minimum resource metric and saves the alternative that gives the minimum resource. The details of the preparation and application can be found in (Erzurum & Bettemir, 2017, 2018, 2021; Erzurum, 2019). The computation details of the search domain are given in the case study part to ensure the completeness of the study.

Case Study

The implementation and the benefits of the developed application are illustrated with an example. The presented example consists of the analysis of a two-story building with 36 activities. In the problem only a single resource is defined. The project is completed in 106 days. Actually, other sources are needed for the activities, but in order to show the recommended practice, a review on a single source was preferred. The arrow diagram of the problem with CPM is shown in Figure 1. The amount of resource requirements are presented in Table 1.

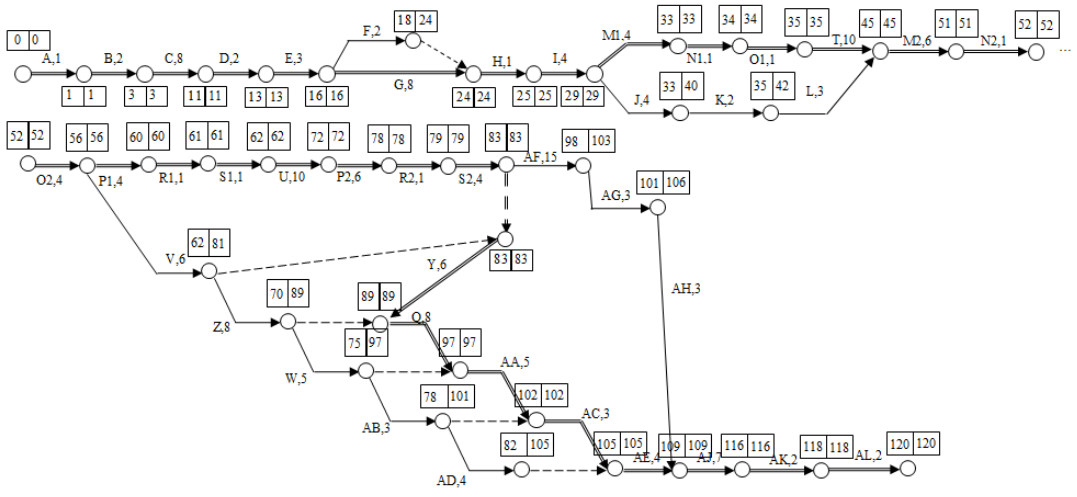

Figure 1: Network diagram of the analyzed two story building construction.

The network diagram shown in Figure 1 consists of 42 activities. The analyzed project is a hypothetical but a realistic construction project of a 2 story building which is constructed by traditional techniques. The building is reinforced concrete but the masonry walls are also load bearing walls. Initially the formworks and reinforcements of the columns are prepared and concreted. The masonry walls are constructed without waiting the final set of the concrete. Then formworks and reinforcements of the beams and the slabs are prepared and then they are

concreted. In this technique, the masonry walls also carry some of the loads on the structure. As a result of this, less bending moments on the beams and columns will occur and less reinforcement is required. This construction technique is slower but more economical than reinforced concrete technique. The same project is analyzed by Erzurum and Bettemir (2021) but with modern construction technique which is constructed in 104 days. However, this time the construction duration is 120 days.

First, the search space of the problem is determined. In order to divide the problem into manageable sizes, the diagram is examined in terms of the paths that constitute the whole diagram. In this problem, apart from the critical path there are 4 noncritical paths which are J-K-L, F, AF-AG-AH and V-Z-W-AB-AD non-critical paths. The details of the number of feasible schedule computations are presented in the Tables 2 to 4.

Table 2 illustrates that if the delay of activity V is kept constant at 0 day, the delay combination of the remaining noncritical activities of the path V-Z-W-AB-AD makes 17495 delay combinations. If the activity V is delayed 1 day then the activity Z has to be delayed by 1 day. In this case 2599 feasible scheduling alternatives are eliminated which makes the number of feasible schedule 14896. If the activity V is delayed 2 days, then the activity Z has to be delayed 2 days. The computation is not shown in Table 2 but in this case the reduction of the feasible schedules will be equal to the sum of the number 276, 253, 231, … , 3 which is equal to 2299. This makes the number of feasible schedule evaluations 12597 when the activity V is delayed 2 days. The total schedule evaluations become 97280 when all of the delay possibilities of the activity V are investigated.

Table 2. Feasible search space of the path V-Z-W-AB-AD.

V	Z	W	AB	AD	Feasible Search Space	
0	0	0	[0,23]	[AB,23]	300	
		1	[1,23]	[AB,23]	276	
		2	[2,23]	[AB,23]	253	
		…	….	….	…	
		22	[22,23]	[AB,23]	3	(2599)
0	1	1	[1,23]	[AB,23]	276

		3	[3,23]	[AB,23]	231	
		…	….	….	…	
		22	[22,23]	[AB,23]	3	(2299)
0	19	19	[19,23]	[AB,23]	15	
		20	[20,23]	[AB,23]	10	
		21	[21,23]	[AB,23]	6	
		22	[22,23]	[AB,23]	3	(34)
Total					17495	

Table 3 illustrates the computation details of the number of schedule evaluation of the path J-K-L. In the first line the activity J is not delayed and the activity K can be delayed from 0 day to 7 days which makes 8 different delay alternatives. The activity L must be delayed at least the delay time of the activity K. Therefore the delay alternatives of the activity L is from delay of K to 7 days. If the activity K is delayed by 0 day the activity L can be delayed from 0 day to 7 days which makes 8 delay alternatives. If the activity K is delayed by 1 day, the activity L can be delayed from 1 day to 7 days which makes 7 delay alternatives. As a result of this the number of delay alternatives becomes the sum of the numbers from 1 to 8 which is 36. This situation is shown in the first line of Table 3. If the activity J is delayed 1 day, the activity K has to be delayed at least 1 day. In this case 8 delay alternatives occurred by the

delay of K activity by 0 day is eliminated and 28 delay alternatives are formed. The rest of the delay alternative computations are given in Table 3 and the total delay alternatives which can be formed from the path K-L-J becomes 120.

Table 3. Feasible search space of the path K-L-J.

J Act	K Act	L Act	Number of Feasible Schedules
0	[0,7]	[K,7]	8 +7 + 6 + 5 + 4 + 3 +2 + 1 = 36
1	[1,7]	[K,7]	7 + 6 + 5 + 4 + 3 +2 + 1 = 28
2	[2,7]	[K,7]	6 + 5 + 4 + 3 +2 + 1 = 21
3	[3,7]	[K,7]	5 + 4 + 3 +2 + 1 = 15

Total			120

Table 4 illustrates the computation of the number of feasible schedules that can be formed by delaying the activities in the path AF-AG-AH without violating the precedence relationships. The path has 5 days total float duration. If the activity AF is delayed 0 day, than the activity AG can be delayed from 0 day to 5 days. The activity AH can be delayed from the delay duration of AG to 5 days. In this case if the activity AG is delayed 0 day, AH can be delayed from 0 day to 5 days which makes 6 delay alternative. If the activity AG is delayed 1 day the activity AH can be delayed from 1 day to 5 day which makes 5 delay alternatives. Finally if the activity AG is delayed 5 days then the activity AH has to be delayed 5 days. This situation makes the number of feasible schedules equal to the sum of the numbers from 1 to 6, which is shown in the first line of the Table 4. If the activity AF is delayed 1 day, then the activities AG and AH have to be delayed at least 1 day. In this case the delay alternatives become from 1 day to 5 and reduce to 5 delay alternatives. In case AF is delayed 1 day, the number of feasible schedules becomes equal to the summation of the numbers from 1 to 5. The mentioned situation is shown in the second row of the Table 4. The rest of the delay situations are shown in Table 4 and 56 feasible schedules can be produced by delaying the activities of the path AF-AG-AH.

Table 4. Feasible search space of the path AF-AG-AH.

AF Act.	AG Act.	AH Act.	Number of Feasible Schedules
0	[0,5]	[AG,5]	6 + 5 + 4 + 3 + 2 + 1 = 21
1	[1,5]	[AG,5]	5 + 4 + 3 + 2 + 1 = 15
2	[2,5]	[AG,5]	4 + 3 + 2 + 1 = 10
3	[3,5]	[AG,5]	3 + 2 + 1 = 6
4	[4,5]	[AG,5]	2 + 1 = 3
5	[5,5]	[AG,5]	1
Total			56

All of the examined paths are not parallel to each other. To illustrate, the path J-K-L are parallel with the critical path so its schedule does not permute with the other paths. On the other hand, paths AF-AG-AH and V-Z-W-AB-AD are parallel and their feasible schedules permute. Therefore the numbers of feasible schedules of the paths AF-AG-AH and V-Z-W-AB-AD are multiplied to compute the number of feasible schedules of the project. The path J-K-L does not permute and examined independently. Therefore, the number of schedule evaluation of path J-K-L is added and the total 5.447.800 schedule evaluation is obtained as shown in Table 5.

Table 5. Computation of total number of feasible schedule.

Paths	Number of Feasible Schedules
J-K-L	120
AF-AG-AH	56
V-Z-W-AB-AD	97280
Total	5.447.680 + 120 =5.447.800

Table 6. Activity delay durations of the optimum solution.

Delay of J	4
Delay of K	4
Delay of L	4
Delay of V	2
Delay of Z	2
Delay of W	6
Delay of AB	6
Delay of AD	6
Delay of AF	5
Delay of AG	5
Delay of AH	5
Early start value	12568
Optimum value	12094

All of the feasible schedule evaluations are examined and the obtained guaranteed optimum result is given in Table 6. The objective function is reduced which means that the fluctuations in the resource usage is minimized. The Gantt diagram of the schedule obtained by the early start of the activities and the Gantt diagram of the optimized schedule are given in Figures 2 and 3 respectively.

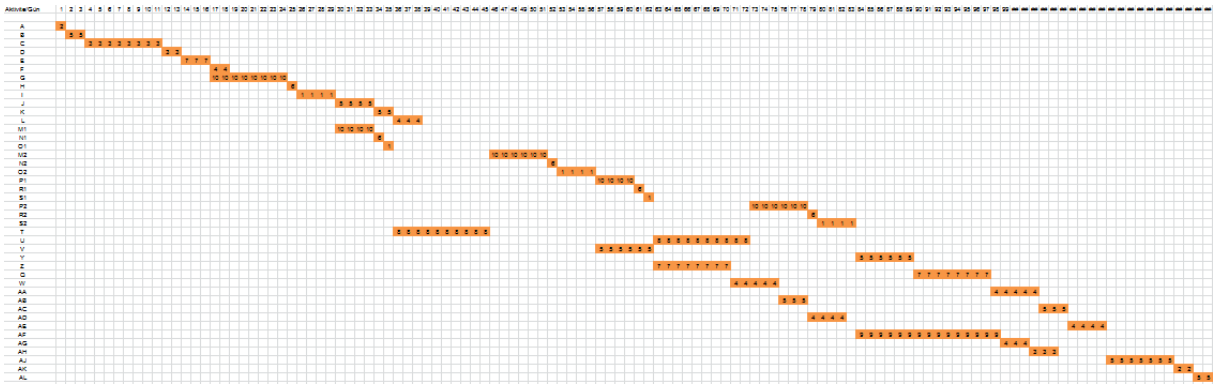

Figure 2: Gantt diagram of the initial schedule.

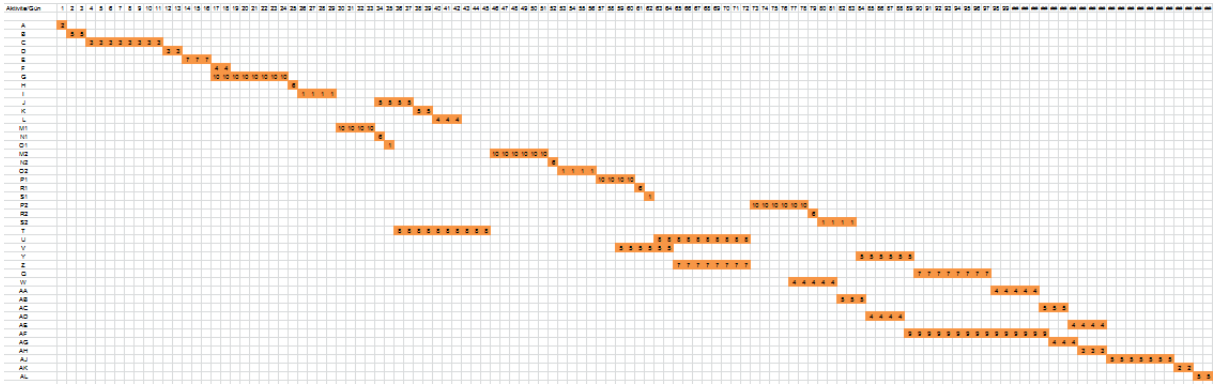

Figure 3: Gantt diagram of the optimized schedule.

The obtained moment values are less than the ones obtained by Erzurum and Bettemir (2021) because the duration of the project elongates without increasing the total man-hour. Therefore the daily resource requirement is reduced and consequently the sum of the square of them also reduced. The obtained schedule is the guaranteed optimum schedule with the minimum moment value because all of the feasible schedule alternatives are tried. Since there is not any feasible untried scheduling alternative it is sure that the optimum solution is achieved.

Conclusion

In this study, construction schedule of a two story building which consists of 42 activities is examined. The examined case problem is the largest project in terms of number of activities. This can be the contribution of this study. The fluctuations of the resources are minimized by utilizing the minimum moment resource distribution metric. The optimization process is handled by exhaustive schedule evaluation. The feasible schedule alternatives are formed by dividing the project into unique path. Each path is examined by adopting the combinatorial analysis and the numbers of different scheduling alternatives are obtained. The paths are combined and the number of the feasible schedule evaluation of the project is obtained and complete enumeration is performed by a Visual Basic code. The obtained solution is guaranteed optimum because all of the schedule evaluations are examined. The computational demand of the implemented technique is high but the computation time can be reduced by parallel computing as future study. The complete enumeration technique can be adopted to obtain the optimum value and the performances of meta-heuristic algorithms can be evaluated by comparing them with the known exact solution.

Heritage Building Information System (HBIM) in Project Management of Cultural Heritage Buildings

P. Karaçar, G. Benli and A. F. Güner
İstanbul Medipol University, Department of Architecture, İstanbul, Turkey
pkaracar@medipol.edu.tr, gbenli@medipol.edu.tr, afguner@medipol.edu.tr

Abstract

Project management is the application of planning, organizing, directing, coordinating and controlling by using project resources to meet the requirements of a project and achieve the project goal and objectives. Companies have systematic efforts aimed at successful completion of projects that gradually become more and more complex in Turkey, just like in the developing countries. The project management system that consists of implementation of the project, time, cost, quality, contract and occupational safety management systems during the project process in a manner complementing each other considerably affects the individual achievement of companies. Project management system is generally associated with the construction sector.
In our country, which is very rich in terms of cultural heritage, there are many conservation project is being carried out for the cultural heritage buildings in the area. Although cultural heritage building information management (HBIM) is a highly studied field, cultural heritage management studies and research on project management processes in the field of conservation projects and applications of heritage buildings are limited. Project management process is well understood, however the concept of project management for architectural heritage projects is different because of uniqueness of every project. When we deal with architectural heritage, historic buildings etc., we need to spend more time and resources to understand what we have and to access its physical condition. In this study, the evaluation of Heritage Building Information System (HBIM) in project management are related with cultural heritage buildings.

Keywords: *construction sector, cultural heritage management, heritage building information management (HBIM), project management.*

Introduction

Cultural heritage management approach, the conservation concept has shifted from technical practice to a factor that increases the quality of life. Therefore, it is possible to perceive cultural heritage management as the most social and public form of conservation action. Cultural heritage management is an integrated conservation approach based on a management mechanism. An integrated conservation process can only be achieved by establishing a management mechanism. There has been an increasing public awareness of cultural assets around the world (Smith, 1999). The cultural heritage management is a complicated and changeable process and it should be modified according to the changes in the political, economic and physical settings (Vacharopoulou, 2005).

Those who work in the field of cultural heritage, are also working on how to manage the cultural heritage, how to research new methods to achieve analysis, how to find the wright material to use collection in order to develop the heritage management. Protection principles are prioritized in determining the methods (Çırak, 2022). Cultural heritage management also include a risk and crisis management plan. At this point, SWOT analyzes and PEST (political, economic, social and technical) auditing and risk assessment should be done. In risk assessment, apart from the period in which the cultural heritage was constructed, all parameters such as the physical environment it is in today, the psychological and sociological conditions of its users, and the economic balances should be considered holistically (Urtene, 2000). Project management can solve the problems of bureaucratic processes, hierarchy within government structures, balances between public and private investments control, creating a cost-benefit balance and risks.

Project Management in Cultural Heritage Buildings

Project management is important for organizing, planning, controlling the project, identifying and clearing issues, managing risks and changes, managing integration and using knowledge. Project management process is well understood, however the concept of project management for architectural heritage projects is different because of uniqueness of every project. However, the implementation of the project management in this area is possible with the facts that, in particular, the project manager is experienced in this area, knows the value of the architectural heritage project, is able to persuade all stakeholders in this regard, knows what needs to be done at each phase of the process; time management, budget updating, risk management, resource management etc., are carried out in the right phases (Güner & Benli, 2019).

In managing cultural heritage values, the qualities of cultural heritage values must be considered. For predictability, the cultural heritage challenges must be assessed so that technologically challenging and costly adjustments or repairs do not arise. Basic project management theory provides that flexibility is generally at its greatest in the early phases of a project, so there is no need to postpone the assessment of cultural heritage in a project (Stendebakken & Olsson, 2018).

The project's front-end phase is when the project exists conceptually, before the final decision about financing the project is made. The most important decisions regarding cultural heritage management are made in this phase. At this stage, the possibility of influencing the final outcome is at its highest (Stendebaken & Olson, 2017).

The main aim of project management is to evaluate the importance of the role of cultural heritage buildings to achieve sustainable refurbishment from the perspective of project managers and team members for the decision-making process, through providing guidance for, first, the flow of work between the stakeholders and, second, the arrangement of the tasks.

The role of project management to make sustainable refurbishment for cultural heritage buildings is important. Therefore, it is essential for the field experts to choose the convenient methods of refurbishment that best suit the situation and reduce the gaps between stakeholders in the management process. This will help the project managers and team members in the decision making process through providing guidance for the flow of work between stakeholders and the arrangement of tasks (Khodeir & Soliman, 2017).

Stakeholders involved in each process/phase of managing sustainable refurbishment for heritage buildings should achieve long-term benefits Guidance for the role of project management on heritage refurbishment (Figure 1). The most appropriate method of protection that cultural heritage experts will use in managing the situation will also guide the conflict between the shareholders. This will help the project managers and team members in the decision making process through providing guidance for the flow of work between stakeholders and the arrangement of tasks (Khaled et al., 2021).

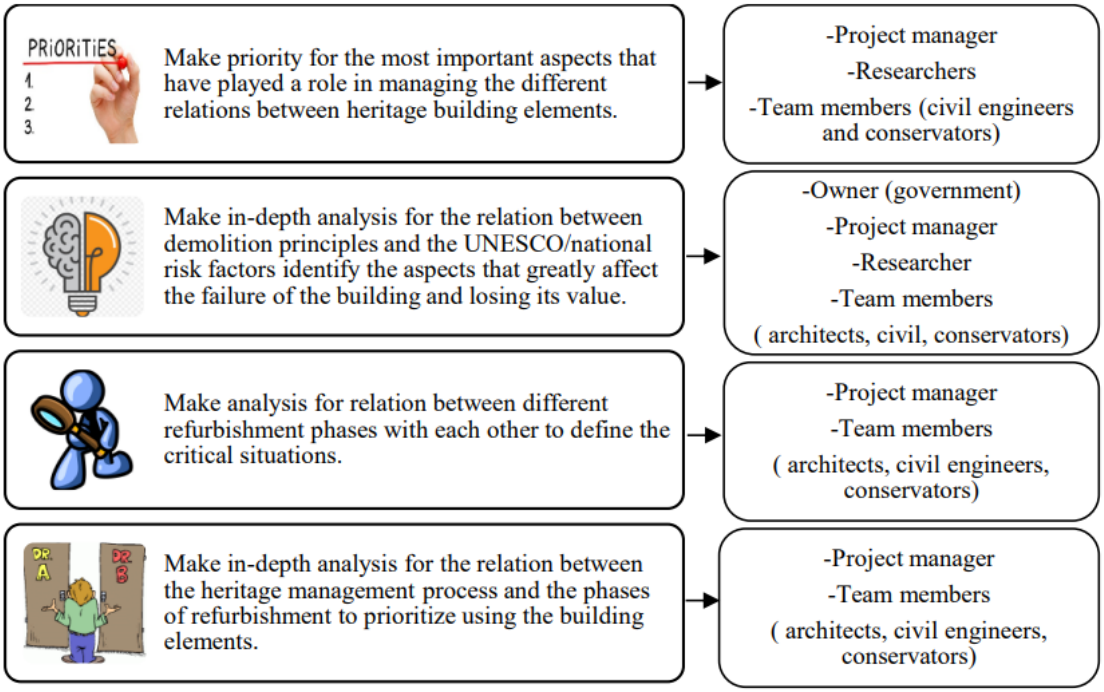

Figure 1: Guidance for the role of project management on heritage refurbishment (Khaled et al., 2021).

Heritage refurbishment aims to maintain and restore the original form of cultural heritage buildings without modernizing them. According to the Sustainable Local Heritage Conservation (2006), a conference was held with the aim of merging Project Management Body of Knowledge (PMBOK) and the National Historic Preservation Act (NHPA). It also recommended more management schemes for cultural heritage projects in terms of operations and resources (Hajialikhani, 2014).

Building information modelling (BIM) within renovation of buildings of significant architectural, historic or cultural values can evaluate the possibilities about renovation or restoration projects of historic buildings can be more demanding, challenging and complex than traditional renovation of for instance within housing. BIM is the tool used for holistic approach on project management and for repetitive data collection, design, simulation and verification processes, and in that sense seen as a tool to use in optimization of this process (Mazzola et al., 2017). As a multidisciplinary design, engineering and project management consultancy have extensive experience of applying BIM and geospatial techniques at all scales, from the restoration of important historical buildings up to major infrastructure projects and cultural landscapes (Kemp, 2014).

In order to improve the framework for 3D modeling, an accurate virtual model of a historic building is digitally constructed, using BIM (Building Information Modeling), where the building is being maintained through its entire lifecycle, including demolition. This integration of heritage recording and BIM is now a method to document and manage historic buildings, in which parametric objects are built, taking into account historical data, and layered-in plug-in libraries representing building components (Dore & Murphy, 2012).

Its integration in environmental design projects is proven to help design teams to make informed decisions from the early design stages and during the whole building life – cycle (Wu, 2010). This dissertation explores the potentials and challenges of BIM application in environmentally sustainable heritage reuse. For that purpose, two aspects are to be explored: applying BIM for heritage management, and applying BIM in environmentally sustainable building projects. Lately, many developments in the BIM field have been established, where the developed technology and methods challenged the cultural heritage community in the documentation framework. BIM has been a growing development within the past decade in the field of cultural heritage documentation, paving the way towards a future in the virtually built environment. In addition, BIM can also enhance the application of sustainable retrofitting of such buildings in particular, as HBIM provides review of the building's exterior and interior, and it also eases the availability to survey renovations and changes that either took place through different time periods or changes that will take place upon applying sustainable retrofit (Logothetis et al., 2015).

Heritage Building Information System (HBIM) in Project Management of Cultural Heritage Buildings

BIM use in the field of cultural heritage documentation. The diversity and complexity of BIM technology is obvious in many different fields; identification of environment, documentation of buildings, examination of construction or structure. (Logothetis et al., 2015). Building Information Modelling (BIM) is progressively being used in managing the complex processes within architecture, engineering and construction industry. Its application for heritage management is called Historic Building Information Modelling, or HBIM (Luggo et al., 2020).

The field of Heritage Building Information Modelling from heritage building management, maintenance and improvement perspectives, including the meaning of conservation, understanding and managing significance, surveys and inspections, energy efficiency and sustainability, building maintenance and repair, managing buildings and project management, managing quality and appropriateness of work and consent applications (Atıcı et al, 2017).

Where work is to be undertaken to an historic building, project management should be integrated with heritage management. This emphasises that understanding and managing significance is essential and needs to be incorporated into the HBIM. Arayıcı describes the situation as follows “There should be a process in place to ensure all people working on the project are aware of the significance of the historic building’’ (Arayıcı et al., 2017).

The interest for adoption of BIM for managing heritage is not on a great level. HBIM usage has demonstrated benefits in managing heritage projects, but the need for further research, and standards of cultural documentation is displayed in the published literature on this subject. It has been found that existing processes to develop our built environment are confusing, poorly

co-ordinated, with design information difficult to find and with many repeated activities, thus raised costs (Brookes, 2017).

In HBIM the parametric objects are built from historic data (surveys, assays and literature) and layered in plug-in libraries aimed to map the elements onto point clouds data and image survey data (Dore & Murphy, 2012). The HBIM process involves a reverse engineering solution whereby parametric objects representing architectural elements are mapped onto laser scan or photogrammetric survey data. The HBIM process generally includes a number of phases, starting with collecting and processing of laser/image survey data, identifying historic details from architectural pattern books, building parametric historic components/objects and finally correlation and mapping of parametric objects onto scan data and the final production of engineering survey drawings and documentation (Murphy et al., 2013).

Creating an as-built BIM is considered the first step of applying the HBIM process. It includes a number of steps as follows: 1. Data collection: in which dense point measurements of the facility are collected using laser scans taken from key locations throughout the facility. The product of the laser scan takes the form of a point cloud that represents the coordinates of the scanned building. 2. Data processing: through this phase of the HBIM process, the sets of point measurements (point clouds) from the collected scans are filtered to remove artefacts and combine into a single point cloud or surface representation in a common coordinate system (Tang & Huber, 2010).

The whole process is clearly represented as HBIM life – cycle diagram, as shown in Figure 2. The starting point of the HBIM process is the survey of the asset. Practically, knowledge and understanding of the historic assets' existing state translates into initial input of information into the HBIM. After the options and detailed surveys are performed, the intervention type is decided so it can be physically performed. When the work is done, the handover and operation phases can be realized, after which the information is stored for the future intervention strategies (Brooks, 2017).

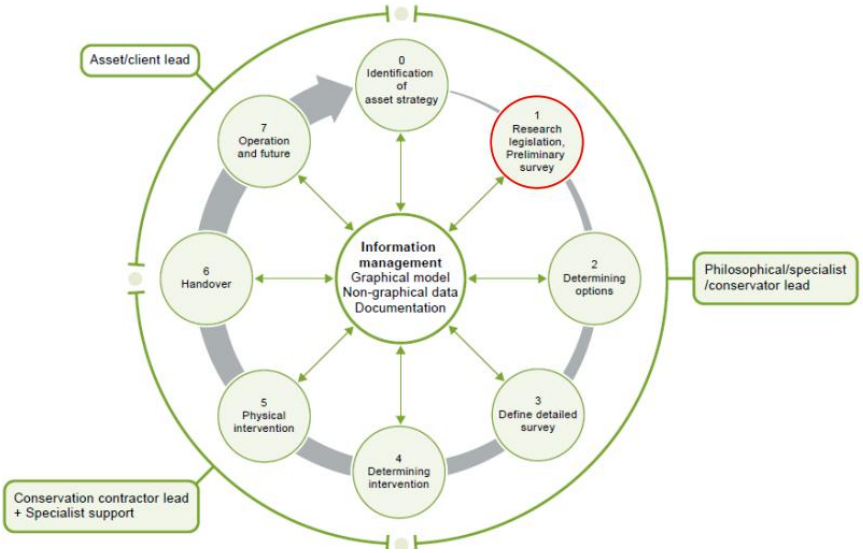

Figure 2: HBIM life – cycle diagram (Brooks, 2017).

Historical building management and planning conservation raise two important issues: the restoration and improvement of historical areas features and adopting a framework of sustainable development in heritage regions. Recently a number of processes have arose to aid in the aforementioned problems, namely the heritage building information modelling (HBIM) and the cyber-physical systems approach (CPS), where the latter is believed to achieve great potentials hereby integrating virtual models and physical construction and enabling bidirectional coordination (Khodeir et al., 2016).

On one hand, HBIM, a plug-in for Building information modeling (BIM) (Khodeir et al., 2016), was introduced as a process for modeling historic buildings from laser scan and photogrammetric data. Thus HBIM is specially tailored to the application on heritage buildings and on the long term management of the built environment (Dore & Murphy, 2012). On the other hand, employing the "cyber-physical systems" approach achieves more potential by integrating virtual models and physical construction, enabling bidirectional coordination (Akanmu et al., 2013). This will serve as a digital archive to help in conserving the heritage buildings and to test future development proposals within the context of these historic buildings.

The present study considers it from different angles by exploring the cyber-physical systems (CPS) approach to innovatively integrate Heritage building information modeling (HBIM) and physical construction (Khodeir et al., 2016).

Introducing Cyber-Physical Systems (CPS) have attempted to link virtual models and the physical construction using different data acquisition technologies (e.g. digital cameras, laser scanners, radio frequency identification tags). However, the existing approaches do not offer opportunities for two-way integration or communication between the virtual models and the physical construction. This two way integration/communication is important for enhancing feedback or controlling the constructed facility. To maintain bi-directional coordination, computational resources are required to tightly integrate the virtual models and the physical construction, such that changes in one environment are automatically reflected in the other. This is termed a cyber-physical systems approach. Cyber-physical systems approach has long been adopted in information systems research, and in other industry sectors (Akanmu et al., 2013). The analysis also proved uncovered the main difference between HBIM and CPS, where the later offers more potential by integrating virtual models and physical construction; achieving bidimensional coordination, enabling better communication between the design and in site teams with accurate documentation of the as-built condition. However convergence is increasingly prevalent for both processes, as for maintaining consistency between the virtual model and physical construction components, enabling preventative maintenance throughout the life cycle of the facility and finally the require of many potential applications in building enclosure and components (Khodeir et al., 2016).

Although HBIM shows a great potential in heritage buildings and in comprehensive preservation approach, as it could achieve the characteristics of resilience and it works as a documentation, visualization, simulation tool for project management of cultural heritage buildings, as shown in Figure 3. However, there is a need for smart tool/software that could be installed in the building to detect any hazards or unsafe actions, then develop reports/mitigation plans to mitigate these clashes automatically, besides ensuring more connection between building and user.

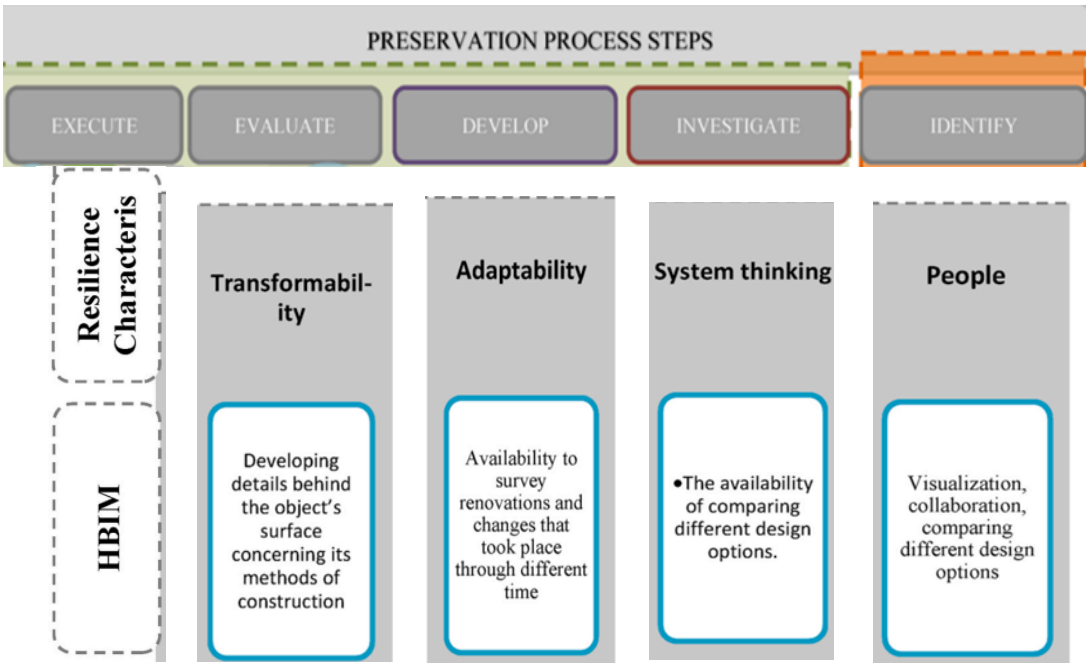

Figure 3: HBIM could achieve the characteristics of resilience and it works as a documentation, visualization, simulation tool with preservation process steps (Elabd et al., 2021).

Conclusion

Overall, BIM implementation workflow requires deep technological skills, precision and discipline from the begining through the whole process of creating the HBIM model. Moreover, economical and time investments need to be made for developing complete custom workflows for the commercial use of the proposed BIM tools. HBIM-based digital model that enables not only to visualize the physical and functional attributes of a building, but also to quickly identify major problems and explore potential issues associated with the conservation/management process of the construction, allowing a priority-based scheduling of maintenance actions and supporting decision-making procedures. Basic project management theory provides that flexibility is generally at its greatest in the early phases of a project, so there is no need to postpone the assessment of cultural heritage in a project.

CPS and HBIM, which could guide decision makers working in the field of heritage buildings management. This analysis showed that HBIM plays an important role in achieving conservation of heritage buildings producing full engineering drawings for the conservation of historic building and environments. Guidance for the role of project management on heritage refurbishment is important for stakeholders involved in each process/phase of managing cultural heritage buildings should achieve long-term benefits.

Abstract

Nowadays, clients in the construction industry are becoming increasingly concerned about the incapacity of executors to complete projects within the specified time and budget. Generally, time and cost variations versus the project's objectives represent the performance of the project. Eventually, to evaluate the project performance and hence the financial risks involved in project execution, it is vital to measure the cost variation in construction projects. Cost variation or overrun which became a typical occurrence throughout the world refers to the deviation between the planned budget and the actual cost of the project. Recently several studies strived to evaluate the causes of cost overruns to explore probable explanations for this phenomenon. One of the commonly adopted methods of withdrawing useful information from the collected data is the application of different statistical tests. However, most of the researchers failed to distinguish between the purpose and applicability of these tests which may lead to inaccurate results and interpretation. Therefore, this study focused on demonstrating the procedure for the selection and application of the aforementioned tests. This study was performed in Iran since the potential of cost overrun occurrence in construction projects in Iran is significantly high. Hence a survey is conducted among different parties including clients, contractors, and consultants who were involved in the construction projects to collect their responses based on probability, impact, and manageability for 38 identified causes of cost overrun. Accordingly, several statistical tests including the Mann-Whitney U test, Kruskal-Wallis H test, and Post hoc test were performed to evaluate the level of agreement between parties from different sectors (Public and Private) as well as different positions (Clients, Contractors, and Consultants). Moreover, Spearman rank-order correlation is adopted to evaluate the ranking of 38 causes of cost overrun based on their probability, impact, and manageability according to the opinion of respondents from different sectors and positions. The results revealed that firstly evaluating the assumptions leads to the selection of non-parametric tests. Secondly, there was a significant agreement between different parties concerning the probability, impact, and manageability of most of the causes of cost overrun except for a few. Finally, the correlation between ranking the causes indicated a strong and positive association between owners and contractors as well as public and private sector respondents in terms of ranking the causes based on their probability and impact.

Keywords: *cost overrun, parametric test, statistical analysis, non-parametric test*

Introduction

Rapid population growth and urbanization development in Iran have created a wide socioeconomic gap. This transformation converts the urban areas into engines of growth and beacons of opportunity and therefore demonstrated immediate construction necessities. Particularly in major urban areas, the construction process accounts for substantial economic output (Alizadeh & Irandoost, 2017). Given the significant development in urban construction projects, cost overrun is one of the major issues that influence construction projects' success dramatically. (Ahady et al., 2017) described cost overruns in the construction industry as a global phenomenon, even though the situation varies from country to country. According to the statistical Center of Iran during the years 2002 to 2012, cost overrun in construction projects was estimated at USD 21 billion (Hamed et al, 2016). Within the area of cost overrun analysis, utilization of statistical tests is considered a common approach. It is because they provide a mechanism for making quantitative decisions about a particular process. Statistical methods are essential for scientific research. In fact, statistical methods dominate scientific research as they include planning, designing, collecting data, analyzing, drawing meaningful interpretations, and reporting research findings. Furthermore, the results acquired from the research project are meaningless raw data unless analyzed with statistical tools. Therefore, executing statistics in research is of utmost necessity to justify research findings. Statistical analysis techniques could provide researchers with several means. Their function could be classified into three major groups descriptive, inferential, and associational statistics. Descriptive statistics is the simplest form of statistical analysis that employs basic mathematical functions such as measures of central tendency, measures of dispersion, and so on to summarize the data from a sample or represent a whole sample in a research population. Inferential statistics on the other hand employs tools such as statistical tests to make inferences or draw conclusions about a larger population based on findings from a sample group within it. Inferential statistics is performed through hypothesis testing to validate generalizations made about a population from a sample due to its ability to account for errors in conclusions made about a segment of a larger group. Finally, Associational statistics is a tool researchers use to make predictions and find causation. It is utilized to find relationships among multiple variables. Associational statistics is the most advanced type of statistical analysis and requires sophisticated software tools for performing high-level mathematical calculations. The analyses in this group are namely regression, structural equation modeling, correlation, and so on. In the area of cost overrun analysis, particularly where the data are collected based on a survey from different respondents' opinions, the aforementioned statistical techniques are widely employed. For instance (Al Hosani et al., 2020; Bekr, 2015; Herrera et al., 2020; Zafar et al., 2016) utilized descriptive statistics to summarize collected data. As far as associational statics are concerned, studies such as (Ahiaga-Dagbui et al., 2017; Asiedu & Ameyaw, 2021; Ubani et al., 2013) utilized causal analysis to explain the direction of association between different causes of cost overrun. In the case of regression analysis as well studies such as (Odeyinka et al., 2006; Zahmak et al., 2020) utilized this technique for assessing the impact of cost overrun causes on the amount of cost overrun in construction projects. Finally, for the case of inferential statistics which is the subject of this study, despite their wide application in cost overrun analysis, through an extensive literature review, common shortcomings are witnessed. Several studies (Akogbe et al., 2013; Cindrela Devi & Ananthanarayanan, 2017; França & Haddad, 2018; Gunduz & Maki, 2018; Rachid et al., 2019; Ramanathan et al., 2012) within the cost overrun analysis are performed statistical tests to generate more detailed insight from their collected data. These statistical tests are normally utilized to withdraw conclusions from different perspectives of respondents. However, the evaluation of the assumptions for the applicability of statistical tests in these

studies is majorly overlooked and subsequently led to inaccurate and unreliable outcome. Therefore, this study intends to demonstrate an appropriate procedure for selection and application of statistical tests to provide more robust outcome for accurate interpretation of the results.

Methodology

This section presented an epitome of the designed methodology for demonstrating the application of required statistical tests to evaluate the level of agreement and ranking correlation between different parties involved as respondents in the survey.

Identification of The Causes

Through an extensive literature review, 20 documents were identified to identify cost overrun causes. From the selected documents, the top 10 factors causing cost overrun were extracted. A total of 200 causes of cost overrun were investigated based on their redundancy, conceptual overlapping, and similarities. Finally, this process resulted in extracting 38 unique causes of cost overrun which according to previous literature influenced urban-related construction projects. Table 1 presents 38 causes of cost overrun that will furthermore have utilized to construct the questionnaire.

Table 1. Cost overrun causes.

S/N	Factors causing cost overrun
1	Variations of clients
2	Change in the foreign exchange rate
3	Change in project design
4	Change in the scope of the project
5	Contract related issues
6	Delay preparation and approval of drawings
7	Delays in the construction schedule
8	Errors or inconsistencies in project documents
9	Errors or omissions in construction work
10	Financial difficulties related to the contractor
11	Financial difficulties related to the owner
12	Improper construction methods
13	Inaccurate project cost estimation and control
14	Inaccurate scheduling and planning
15	Inadequate contractor's experience
16	Incomplete design at the time of tender
17	Insufficient geotechnical investigation
18	Lack of identification of needs
19	Lack of material, equipment availability, or failure
20	Lack of requirement specifications in tender documents
21	Lowest bidding procurement method

22	Material quality change
23	Number and level of competitors
24	Poor financial control on site
25	Poor site management and supervision
26	Project complexity
27	Subcontractor related issues
28	Reworks or additional works during the construction stage
29	Mistakes and defective works in the design and construction stages
30	Lack of preliminary examination before design or tendering
31	The long period between design and time of bidding/tendering
32	Labor productivity-related issues (labor shortage, unskilled labor, etc.)
33	Lack of communication and coordination and agreement between project parties
34	Inflation in prices of (labor, material, equipment, services, land, permissions, and so on)
35	Governmental policies related issues (corruption, legislation, political…)
36	Financial difficulties related to the cash flow (including mode of financing, bonds, and payments)
37	special issues related to unforeseen site conditions, adverse weather conditions, or other unpredicted conditions on the construction site
38	Force Majeure causes include outbreak of war, projectile missile, hostilities, contamination, and other such risks

Questionnaire Development

The preliminary questionnaire was developed and prior to the original survey administration, the contents of the questionnaire were verified through a pilot study. The results from the pilot study demonstrated high relevance and affinity of the questionnaire contents and the final questionnaire was approved based on the expert's opinion. In the final questionnaire along with Socio-demographical information, each respondent requested to score the Probability of occurrence (P), Impact (I), and possible Manageability (M) of each provided cost overrun cause based on a 5-point Likert scale.

Target Population and Sample Size Determination

The target population for the survey decided to be selected from the 3 main construction parties Client, Contractor, and Consultant who participated in urban-related construction projects in Iran. The contractor and consultants' groups were formed of site engineers, cost estimators, quantity surveyors, cost control engineers, construction managers, and project managers. The required sample size for the survey administration was 64 which was determined using Equation 1 (Bartlett et al., 2001):

$$n = \frac{t^2 s^2}{e^2} \quad (1)$$

Where; n = required sample size, t = corresponding statistic based on chosen significant value α, s = Estimate of variance deviation for the data collecting scale, e = margin of error (number of points on the principal scale).

Reliability Test

The reliability of the data collected through the questionnaire will be established through Cronbach's alpha method. Since the questionnaire is supposed to measure the responses for 3 different sub-items as the P, I and, M of each cost overrun cause, therefore, it is advised to perform separate reliability tests for each one of the prospective. In addition, a general reliability test will be performed to ensure the overall questionnaire responses (Gliem & Gliem, 2003). Cronbach's alpha will be calculated by Equation 2 (Bartlett et al., 2001):

$$\alpha = \frac{N \times \bar{c}}{\bar{v} + (N-1) \times \bar{c}} \quad (2)$$

Where: N = the number of items, $\bar{c}$ = average covariance between item pairs and $\bar{v}$ = average variance.

Hypothesis Development

The main objective of this study is the implementation of statistical tests. In this stage, two different types of statistical tests were considered to first measure the level of agreement between the responses from different sectors (public and private) and different positions (contractors, consultants, and owners) in scoring P, I, and M for each cost overrun cause. Eventually, for testing the level of the agreement following hypotheses are developed:

H_1: There is significant agreement among the responses from Public and Private projects concerning the P for each cause of cost overrun.
H_2: There is significant agreement among the responses from Public and Private projects concerning the I of each cause of cost overrun.
H_3: There is significant agreement among the responses from Public and Private projects concerning the M of each cause of cost overrun.
H_4: There is significant agreement among the responses from Owners, Contractors, and consultants concerning the P for each cause of cost overrun.
H_5: There is significant agreement among the responses from Owners, Contractors, and consultants concerning the I of each cause of cost overrun.
H_6: There is significant agreement among the responses from Owners, Contractors, and consultants concerning the M of each cause of cost overrun.
The rule for testing each hypothesis is if the acquired P-value for the selected test > 0.05, then the null hypothesis cannot be rejected which indicates there is a significant agreement between private and public respondents. Secondly, evaluating the strength and direction of association between the respondents' opinions from different positions and sectors regarding ranking cost overrun causes. To perform a correlation test following hypotheses are developed.
H_7: There is no significant relationship among the responses from different pairs of job positions concerning the ranking order of the cost overrun causes based on their P.
H_8: There is no significant relationship among the responses from different pairs of job positions concerning the ranking order of the cost overrun causes based on their I.
H_9: There is no significant relationship among the responses from different pairs of job positions concerning the ranking order of the cost overrun causes based on their M.
H_{10}: There is no significant relationship among the responses from different sectors concerning the ranking order of the cost overrun causes based on their P.

H_{11}: There is no significant relationship among the responses from different sectors concerning the ranking order of the cost overrun causes based on their I.
H_{12}: There is no significant relationship among the responses from different sectors concerning the ranking order of the cost overrun causes based on their M.

The rule of interpretation for the correlation test is, that if the correlation coefficient is negative, it indicates a negative correlation and vice versa. Also, since the correlation coefficient changes between -1 and +1, therefore, closer the correlation coefficient gets to +1 or -1 indicates more correlation strength. For hypothesis testing, when a calculated P-value > 0.05 means, it fails to reject the null hypothesis.

Statistical Tests

Statistical tests in general are categorized into parametric and non-parametric groups. Parametric statistics is a branch of statistics that makes inferences about the parameters based on the assumption that the data came from a certain sort of probability distribution (normal distribution). Once the assumptions verify the applicability of parametric tests, they could yield a more accurate estimate and as a result, they're frequently considered robust (Uchechi, 2020). On the other hand, non-parametric tests are sometimes known as assumption-free or distribution-free tests. It means they could be applied to nominal or ordinal data and also on the scales that don't follow the normal distribution, such as interval or ratio scales (Uchechi, 2020). Regardless of parametric tests' robustness, in comparison to non-parametric tests, they offer other advantages such as adaptability to all sample sizes, applicability on different data types (nominal, interval), and practicability with the dataset including outliers, or data that has been measured imprecisely (Spiegel, 1972). Table 2 presents the most common type of parametric and their equivalent non-parametric tests. It is notable that before implementation of either of the below-mentioned tests a detailed examination of collected data is necessary to verify the test's assumptions. It is due to the fact that violation of any of these assumptions may lead to an erroneous selection of tests and hence, for interpretation or generalization of sample results to the entire population the test produces unreliable or inconsistent outcomes (Lix et al., 1996).

Table 2. Statistical tests' groups.

Parametric Tests	**Non-parametric Tests**
Unpaired T-test	Mann-Whitney Test
Paired T-test	Wilcoxon Signed Rank Test
One sample T-test	Signed-rank test
One-Way ANOVA	Kruskal Wallis Test
Pearson's R	Spearman's R

Statistical Tests Assumptions

As previously mentioned, the evaluation of the assumption for selecting an appropriate test is required. This process should be performed in two stages. In the first stage, the test group should be determined. The most important assumptions for selecting the test from either the parametric or non-parametric group are to identify the data type and data distribution. Parametric tests rely on the assumption that the variables are either ratio or ordinal and

normally distributed. However, once the test group is determined each particular test relies on its assumptions. To test the level of agreement between the responses from different sectors (public and private) the test should be designed for two groups. On the other hand, for the responses from different positions (contractors, consultants, and owners) the test should be designed for more than two groups. Table 3 provides the most important assumption to be examined for each statistical test once the test group is determined (Verma & Abdel-Salam, 2019). After the determination of the required statistical tests, the tests will be performed and accordingly the results will be interpreted.

Table 3. Statistical tests' assumptions.

Aim of the Test	**Required Test**	**Test Group**	**Significant Assumptions**
Level of the agreement for 2 groups	Unpaired T-test	Parametric	Homogeneity of variances
Level of the agreement for 2 groups	Mann-Whitney Test	Non-Parametric	Independence of observation
Level of the agreement for more than 2 groups	One-Way ANOVA	Parametric	Homogeneity of variances, Independence of observation
Level of the agreement for more than 2 groups	Kruskal Wallis Test	Non-Parametric	Independence of observation
Correlation in ranking	Karl Pearson	Parametric	Linearity
Correlation in ranking	Spearman's R	Non-Parametric	Monotonic relationship

Results And Discussion

Reliability Test

Reliability tests were established using Cronbach's alpha approach. As summarized in Table 4, calculated Cronbach's alphas for all perspectives and the overall questionnaire were above 0.9 indicating excellent internal consistency and reliability of the questionnaire.

Table 4. Reliability test results.

Scale	Cronbach's alpha	No of items
P	0.961	38
I	0.970	38
M	0.965	38
Overall	0.987	114

Test Group Selection

The statistical tests in this study were performed using IBM Statistics Version 24. Kolmogorov-Smirnov and Shapiro –Wilk tests were performed to evaluate the normality of all collected responses for the cost overruns causes from their P, I, and M perspective. The

results yield p-values less than 0.05 for all the causes. It means in all the cases the null hypothesis for the normality test which indicated H_0: The population is normally distributed, will be rejected and therefore normality assumption is violated. Hence, violation of this assumption indicates that all the tests should be selected from the non-parametric test group. In conclusion, considering the fact that all the assumption for each particular test is performed, to implement the test for evaluating the level of agreement between the respondents from the public and private sectors Mann-Whitney Test is employed. For evaluating the level of agreement between the respondents from different positions as contractors, consultants, and clients Kruskal Wallis Test along with Dunn's post hoc test is performed. As far as the correlation test was concerned Spearman's ranked order test is performed to evaluate the strength and direction of association for ranking the causes between respondents from public and private sectors as well as the respondents from different positions as contractors, consultants, and clients.

The Level of Agreement for Different Sectors

The results of the Mann-Whitney U test revealed that except for a few cases there is not a significant difference between responses from the public and private sectors for scoring the P, I, and M of the causes of cost overrun. The total numbers of respondents were 89 and from the total for each cause 21 responses were from public project while 68 were from private projects. Table 5 summarizes the results for the only cases of disagreements based on P, I, and M between public and private projects.

Table 5. Sources of disagreement between different sectors.

Disagreement in cost overrun causes based on (P)						
Cause	U	Z	P-value	r	Mean Rank (Public)	Mean Rank (Private)
C1	510.	-2.052	0.04	0.217	35.29	48.00
Disagreement in cost overrun causes based on (I)						
C7	508.5	-2.041	0.041	0.216	54.79	41.98
Disagreement in cost overrun causes based on (M)						
C7	505	-2.082	0.037	0.216	54.95	41.93

The Level of Agreement for Different Positions

The results from the Kruskal-Wallis H test revealed that out of a total of 89 responses 25 responses are from owners while 26 are from consultants and 28 are from contractors. Table 6 summarizes the results for the cases of disagreements based on P, I, and M between owners, contractors, and consultants.

Table 6. Sources of disagreement between different positions.

Disagreement in cost overrun causes based on (P)			
Cause ID	Chi-Square	df	p-value
C2	6.205	2	0.045
C3	9.642	2	0.008
C4	13.561	2	0.001
C7	6.235	2	0.044

C9	7.715	2	0.021
C12	6.143	2	0.046
C16	7.268	2	0.026
C20	6.265	2	0.044
C31	10.248	2	0.006
Disagreement in cost overrun causes based on (I)			
C4	6.788	2	0.034
Disagreement in cost overrun causes based on (M)			
C3	8.250	2	0.016

To identify the source of disagreement, the post hoc test using Dunn's procedure was performed and the results are summarized in Table 7. The adjusted p-value through Bonferroni correction indicates which pair of the three subgroups (owners, contractors, and consultants) had a significant disagreement in the mean ranking of the scores.

Table 7. Post-hoc test results.

Disagreement in cost overrun causes based on (P)		
Cause ID	Sub-groups	Adj.sig
C2	Owner- contractor	0.043
C3	Owner- consultant	0.006
C4	Owner- consultant	0.001
C7	Owner- contractor	0.039
C9	Owner- contractor	0.044
C9	Owner- consultant	0.042
C12	Owner- consultant	0.049
C16	Owner- contractor	0.022
C31	Owner- consultant	0.004
Disagreement in cost overrun causes based on (I)		
C4	Owner- consultant	0.045
Disagreement in cost overrun causes based on (M)		
C3	Owner- consultant	0.017

Testing the Rank-Order Correlation of Different Sectors and Positions

Since the collected data violated the normality assumption eventually the Spearman rank-order correlation was adopted to statistically test the association between ranking the causes of cost overrun based on their P, I, and M perspectives among the respondents from different sectors and positions. The result from the Spearman rank-order correlation as summarized in Table 8 verifies the significant correlation for all the items. That means the obtained p-values concerning H_{10} to H_{12} are less than 0.05, therefore, they should be rejected. It is also indicated that there is a strong positive correlation in ranking the causes between the responses from private and public sectors based on their P (rho = 0.756) and I (rho = 0.656) of the causes. However, according to the result for M (rho = 0.476), there was a medium positive correlation in ranking the causes.

Table 8. Correlation for ranking the causes between different sectors.

		Public		
		P	**I**	**M**
Private	**Spearman rho**	.756**	.656**	.476**
	Sig. (2-tailed)	0.000	0.000	0.000

For different positions, however, the results presented in Table 9 indicated, except for just one case of correlation between consultants and contractors in ranking the causes based on their I (p-value = 0.1) for the rest there is a significant correlation between other pairs. Therefore except for H_8 the rest of hypotheses H_7 and H_9 will be rejected. In terms of the strength of correlation in ranking the causes with respect to probability and impact, owners and contractors demonstrated a strong positive correlation respectively with rho = 0.786 and rho = 0.616. Other correlations as presented in Table 9 are either medium or weak.

Table 9. Correlation for ranking the causes between different positions.

		Owners			Contractors		
		P	**I**	**M**	**P**	**I**	**M**
Contractors	**Spearman rho**	.786**	.616**	.374*			
	Sig. (2-tailed)	0.000	0.000	0.021			
Consultants	**Spearman rho**	.585**	.448**	.540**	.455**	0.271	.389*
	Sig. (2-tailed)	0.000	0.005	0.000	0.004	0.100	0.016

Conclusion

Through an extensive literature review, a major gap regarding statistical assumption evaluation prior to their application in cost overrun analysis is witnessed. The aforementioned issue majorly led to the selection of inappropriate statistical tests which resulted in unreliable outcomes and in certain cases where the assumptions are severely violated the results get completely reversed. Therefore, this study aimed at demonstrating the selection and application of statistical tests for cost overrun analysis. A survey has been conducted among different stakeholders in the Iranian construction industry. Along with their socio-demographical information, the respondents were requested to score using a 5-point Likert scale regarding the probability of occurrence, impact, and manageability of 38 identified cost overrun causes. 89 valid responses are received, and a reliability test validated the responses. The following conclusions are withdrawn from the results:

- Since Likert scale data are considered the ordinal level of measurement also, the normality assumption is violated in all the cases regardless of parametric tests' power the required tests should be selected from the non-parametric tests group.

- Each required statistical test has its own assumptions which must be assessed before application of the test. This study utilized Mann-Whitney Test, Kruskal Wallis Test, and,

Spearman's rank order correlation test hence, before applying of aforementioned tests all assumptions as provided in Table 3 are accurately examined.

- The results indicated that among public and private sectors C1 and C7 were the only sources of disagreement. However, among contractors, consultants, and owners concerning scoring the cost overrun causes based on their probability of occurrences there were significant disagreements in C 2, 3, 4, 7, 9, 12, 16, 20, 31. On the other hand, for scoring the impact and manageability except for C3 and C4 all the parties significantly agreed.

- The results also indicated that in terms of ranking the causes between the public and private sectors as well as contractors, consultants, and owners the highest correlation was belonged to ranking the causes based on their probability of occurrence. It could imply a better comprehension of the concept of probability of occurrence of cost overrun causes in comparison to their impact and manageability among the respondents.

Construction Productivity Improvement: A Case Study of Turkish Republic of Northern Cyprus

A. E. Öztemir and A. Alfghia
Cyprus International University, Department of Civil Engineering, Nicosia, TRNC
aoztemir@ciu.edu.tr, 20156256@student.ciu.edu.tr

Abstract

Productivity in the construction industry cannot be over emphasized, as it is a very essential factor that can contribute to the entire growth of the construction industry. Particularly in Turkish Republic of Northern Cyprus, the benefits of productivity have not been harnessed completely and it falls short in standard as compared to other parts of the world. Therefore, this paper seeks to evaluate productivity problem in T.R. Northern Cyprus, by exploring ways in which productivity can be enhanced using management planning skills and by highlighting the various causes of un-productivity by identifying the key drivers that can cause productivity decline. Data is obtained, by the aid of a questionnaire, which comprise of various sections to collect general information about the respondents, current status of construction industry and Construction productivity in T.R. Northern Cyprus. After which SPSS was used to analyze the result(s). Findings indicate that in T.R. Northern Cyprus there is an extensive delay in construction completions for new projects. Thus, there has to be improvements in the areas of construction labor job security, work conditions and skill retention within the company, along with, improvement of construction methods/procedures and building codes.

Keywords: *construction, Northern Cyprus, productivity improvement.*

Introduction

Construction is a fast-paced work with a plethora of interconnected elements that influence construction procedures and decisions. The construction industry is frequently facing challenges with obstacles to its long-term growth, notably in terms of complexity and uncertainty. It is frequently threatened by lower-than-expected productivity, excessive project costs, and the need to make optimal use of limited resources. This industry is described as a large, dynamic and often times, multifaceted industry which creates processes leading to development of new structures, which includes engineering projects and also all forms of renovations (Celik et al., 2017). It is an industry, which has contributed about 5.9% of the total gross value of European Union member states (Nazarko & Chodakowska, 2015). It plays a major role in the development of any economy including T.R. Northern Cyprus. There was a construction boom after the Annan peace plan which resulted in the emergence of several small companies between the periods of 2004 – 2010 but as a result of no proper regulation of the construction activities, it gave rise to delays, high cost of projects, poor quality of work, low productivity and subsequently inefficiency (Balkiz & Therese, 2014). Therefore, this

paper, as a contribution to existing body of knowledge, seeks to evaluate productivity problem in T.R. Northern Cyprus, by exploring ways in which productivity can be enhanced using management planning skills and by highlighting the various causes of un-productivity by identifying the key drivers that can cause productivity decline.

Literature Review

According to TRNC Statistical Institute's Urban Construction Statistics, between the years of 2015 and 2019-latest year available) total number building construction has increased from 619 (266,560 m^2) to 1306 (650,476 m^2) (Table 1) which means amount of building construction has more than doubled along with an increase in problems related to applicability of current construction methods and standards. A trend that has started after Annan Plan 2004-2007 according to Celikag and Naimi (2011) and continued until 2019.

Table 1. T.R. Northern Cyprus urban construction statistics (Source: TRNC Statistical Inst.).

		2019	2018	2017	2016	2015
Genel Toplam	A	1.306	1.537	964	739	619
General Total	B	650.475	719.598	412.065	411.788	266.560
	C	1.619.724.182	1.618.416.006	922.762.165	635.175.122	370.083.437

A – Number of buildings B- Floor Area (m^2) C – Value (TL)

Also, according to the TRNC Statistical Institute's statistics data, number of people employed in construction companies in T.R. Northern Cyprus was in average 7.5% of the working population (Figure 1), where as in European Union countries, this number was around 3% (Nazarko & Chodakowska, 2017). As a result of the increase in the construction work done and employment by the sector, the success or the failure of the construction projects/industry, as well as the worker productivity, became much more important for the T.R. Northern Cyprus's economy and the livelihood of its residents.

Productivity has been one of the most researched topics in the construction industry in the last few decades where it can be defined in many ways depending on the user (Hanna et al., 2008). According to Hanna et al. (2008) productivity is defined as the ratio between total inputs of resources which include Money, Materials, Machinery, Manpower and Minutes (Time); and the total output of the product within cost, time and specification (Nasirzadeh & Nojedehi, 2013). In general, construction tasks are complex and not easily quantifiable during the assessment and measurement of productivity (Janssen & McLoughlin, 2008). According to (Eriksson & Westerberg, 2011) in many countries, the construction industry attracted criticism for poor quality and low productivity. Towards the improvement of productivity in construction, it is essential to improve the productivity effecting factors in general, like, enhance workers motivation, improve strategic management, and improve procurement management (Rojas & Aramvareekul, 2003). Factors affecting productivity may have a short-term or long-term effect on the project. Various studies in different countries have been carried out to identify the factor affecting construction productivity.

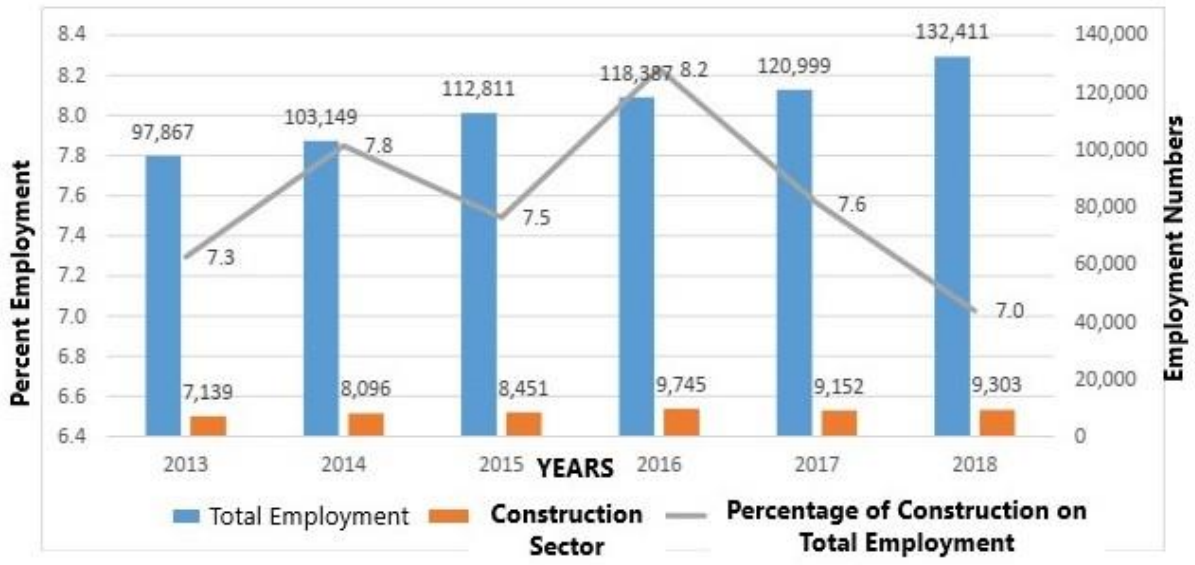

Figure 1: T.R. Northern Cyprus construction employment data (Source: TRNC Statistical Inst.).

One such study done by Shehata and El- Gohary (2011) suggested to group factors that affect labor productivity as Industry related, Management related and Labor related factors (Shehata & El-Gohary, 2011). Some of the factors that affect the construction productivity, which identified through literature review for this research, were grouped into three main areas: Construction Labour productivity, Government Policies/Building codes and applicability of professional Construction Management methods.

Methodology

For this research paper, a quantitative research approach was used to identify the factors influencing the productivity of Construction industry in Northern Cyprus. The data was gathered using Question survey (Convenience sampling). 150 questionnaires were distributed and 110 was gotten back in return, amongst which 100 was valid. All of those responded to the survey had prior experience working on Construction projects. Questions were designed to identify factors and gather data to answer the following main research questions.

RQ1) To what level does the conventional practices affect the productivity in Construction industry of Northern Cyprus?
RQ2) What are the possible effects of, if any, integrating more detailed pre-planning stage in to construction projects to achieve better productivity rates.

Data collection: Design of questionnaire was as following: The questioner was in two sections. First section (A) included questions regarding demographic data about the participant. Second section (B) consisted of close ended question with definite answers. Section B gives options to measure the degree at which a respondent or participant agrees, neutral or disagrees with a point of view. Section A consisted of 10 questions and, Section B consists of 12 questions, making 22 questions in total.

Reliability: The questionnaires were distributed in construction firms around the provinces of T. R. of Northern Cyprus. The received responses by the respondents were summarized in an Excel data sheet and the data analyzed using SPSS software. The reliability of the Section B was examined using Cronbach's alpha if item deleted which represents the scale's Cronbach's alpha reliability coefficient for internal consistency if the individual item is removed from the scale. The reliability of the Section B of this study ranges from .890 to 0.898 (Table 2), which suggest internal consistency.

Table 2. Cronbach's alpha reliability results.

	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item-Total Correlation	Cronbach's Alpha if Item Deleted
QB1	55.35	176.917	.536	.898
QB2	55.10	175.162	.606	.895
QB3	55.19	172.984	.586	.896
QB4	54.79	176.895	.574	.896
QB5	54.64	176.455	.621	.894
QB6	54.97	168.130	.691	.890
QB7	55.05	173.907	.634	.893
QB8	55.16	173.065	.654	.892
QB9	54.90	171.566	.670	.891
QB10	55.32	171.816	.573	.897
QB11	55.25	170.715	.653	.892
QB12	55.27	168.805	.688	.890

Results and Discussion

Results of the survey, from demographic data, shows that 88% of the participants were male and only 12% were female. 73% of the participants were between the ages of 18 and 35, which suggest construction industry is dominated by young work force. 87% of the population had some form of education where 50% had college/university degrees. Also, it can be seen that the ongoing projects are mostly (37%) new construction and 35% were maintenance/renovation of existing buildings. Construction staff size of the ongoing projects were largely concentrated 100-200 staff with 32% and 50-100 staff with 26% where 77% of the survey participants were Managers/Supervisors in these companies/projects. Lastly, 77.0% of the participants have said they worked in a failed construction project where they defined the failed projects as the ones that have spanned 3 to 4yrs over the expected time of completion or abandoned projects.

To answer RQ1 primary data (Table 3) was used (QB2, 4, 5, 8, 9, 10, 11, and 12). Participants (66%) reported that temporary nature of employment (job security), and the working conditions are two major factors that significantly affect the worker productivity. In addition, current T. R. Northern Cyprus Buildings Codes (64%), faulty construction procedures/sub-standard construction methods and materials used (82%) and failure to adhere strictly to specified standards (un-professionalism) (83%) were the three major factors identified that have adverse effect in the successful completion of Construction projects in T. R. Northern Cyprus.

Table 3. Summary of survey results.

QB	Statement	Disagree	Neutral	Agree
2	Transition of acquired skills is limited in the construction industry due to its temporary nature of l aying off workers after every project.	18 (18.0%)	8 (8.0%)	74 (74.0%)
4	Faulty construction procedure is a major challenge in maximizing productivity in North Cyprus.	16 (16.0%)	2 (2.0%)	82 (82.0%)
5	Failure to adhere strictly to specified standards is highly due to un-professionalism	12 (12.0%)	5 (5.0%)	83 (83.0%)
8	The construction procedure for every particular project goes a long way in minimizing waste and enhancing efficiency on site.	20 (20.0%)	8 (8.0%)	72 (72.0%)
9	Productivity on site is largely dependent to the main site supervisor in charge of the project.	17 (17.0%)	8 (8.0%)	75 (75.0%)
10	There will be a significant boost in productivityif the workers have a certain level of job security?	27 (27.0%)	7 (7.0%)	66 (66.0%)
11	The working condition of the workers goes along way in determining the efficiency of the project?	25 (25.0%)	9 (9.0%)	66 (66.0%)
12	A review on North Cyprus building code with the aim to update and regulate it according to new standards will go a long way in ensuring productivity	25 (25.0%)	11 (11.0%)	64 (64.0%)

Table 4. Anova analysis (dependent var.: QB1 & independent var.: QB3, QB6, QB7).

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	95.0% Confidence Interval for B	
		B	Std. Error	Beta			Lower Bound	Upper Bound
QB1								
	QB3	.457	.087	.485	5.275	.000	.285	.630
	QB6	-.016	.091	-.017	-.175	.861	-.197	.165
	QB7	.190	.103	.184	1.842	.069	-.015	.395

To answer RQ2, statistical significance was tested (Table 4), using ANOVA analysis, where QB1 (Integration of pre-planning as a key part of Management method) was dependent factor, QB3 (Effect of integrating pre-planning on construction productivity) was statistically significant (B = .485, t = 5.275; p = .000 <.05), QB6 (Effect of better Government policies on

construction productivity) was not statistically significant (B = -.017, t = -.175; p = .861 > .05) and QB7 (Effect of better integration of advanced management techniques on construction productivity) was also not statistically significant (B = .184, t = 1.842; p = .069 > .05). Therefore based on the participant replies, in Northern Cyprus, improved government policies and application of advanced management techniques will not necessary have a positive effect on construction productivity.

Conclusion and Recommendations

The current study identifies the impact of significant factors on construction productivity and successful project completion in the Turkish Republic of Northern Cyprus using a structured questionnaire survey approach. The Northern Cyprus authorities, like the Ministry of Works and Housing, the Engineering professional, the Cypriot Contractors Union and the other concerned authorities are recommended to promote and encourage contractors to improve their standards and organizational system of working. In addition, these authorities should put in place necessary rules and regulations that will aid in the development of local contractors capabilities, which will eventually reflect higher percentage of productivity/successful completion in local construction sector.

The Need for Stakeholder Management and Engagement in Projects

A. Z. Aziz
University of South Africa, Department of Operations Management, Pretoria, South Africa
azizz@unisa.ac.za

Abstract

The focus of this study was to investigate the influence of project communications and project stakeholder management on the success of projects. The study aimed to highlight some of the areas in project communications and project stakeholders' processes that increase project success, utilizing the case example of Gauteng's SANRAL e-toll project. To achieve its goals and objectives, the study exploited the body of knowledge developed in the field of project management and used communications and stakeholder management in combination with a number of complementary theories. The research design of this correlational and exploratory study entailed a positivist research philosophy using a deductive approach. This implied the need for both narrative and numeric data. The so-called quantitative research was conducted by means of a survey questionnaire which was designed and used to determine the level of influence of communication to stakeholders in the case example of Gauteng's SANRAL e-toll project. The qualitative part of the research was conducted by means of a semi-structured interview. Notable findings of this study include the significant link between communications and stakeholder management on the outcome of a project, specifically with reference to Gauteng's SANRAL e-toll project, and the need for organizations to value the importance of communication to stakeholders in determining the success of a project according to the PMBOK ® (Project Management Body of Knowledge).

Keywords: *communication management, failure, PMBOK, project management, project success, stakeholder management.*

Introduction

The discipline of project management is on the rise. Projects increasingly play a crucial role as the innovation engines, value creation and strategic change tools of the future in both project driven and non-project driven organizations (Killen et al., 2012). Some cases of project failure, reported over decades (Serrador, 2009; Nicholas & Steyn, 2012), relate to project communication, while many problems relating to stakeholder issues have also been observed (Dalcher, 2009). The stake and scope of projects imply the constant need for understanding the causes of project failure, as well as the need for realizing how important variables like project communications and project stakeholder management affect project success (Davis, 2014).

The problem statement therefore focuses on the project communication phenomenon, the need for effective project communication and the specific research gap that needs to be addressed. The Gauteng e-toll project by SANRAL was used as the specific case in this research project. It was selected due to the importance of project communication and the specific media reports and public common knowledge of the controversies surrounding the e-toll project. Although the project had been a technical success, various reports indicated severe complaints, dissatisfaction and grievances voiced about the communication barriers between the e-toll project and its stakeholders (Rennie, 2013). Several aspects of the Gauteng e-toll project by SANRAL were problematic (Clarke & Duvenage, 2014) and led to widespread public disapproval of the project (Rennie, 2013). The author illustrates this as an important aspect, central to project success (Nicholas & Steyn, 2012), noting that successful projects are characterized by good communication and high-quality information sharing and exchange.

It was anticipated that the findings of the study would contribute valuable information to the knowledge base for project managers and professionals working in the field of project communications and stakeholder management by increasing their awareness of the issues that may have caused complications (such as the non – payment of users in the SANRAL e-toll project in Gauteng). Nicholas and Steyn (2012) lists inadequate project communication as a level three cause for project failure due to factors related to inadequate information quality and inadequate information distribution. The author illustrates this as an important aspect as mentioned above (Nicholas & Steyn, 2012). Thus, the researcher's contribution through this article is the provision of project management strategies for improving the link between project communication, stakeholder management and project success through the case example of the Gauteng e-toll project by SANRAL.

The Importance of Stakeholders in a Project

Too many projects fail due to a misconception of projects and the type of management approach they require. The definition offered by PMI® states that a project is "a temporary group activity designed to produce a unique product, service or result" and that project management is the "application of knowledge, skills, tools and techniques to project activities to meet the project requirements" (PMI, 2017). Nicholas and Steyn (2012) indicate the following ways in which the introduction of project management should benefit any organization:

- increase the likelihood that the desired outcome of the project will be attained;
- ensure the best use of the resource allocation;
- meet the needs of the stakeholders associated with the organization; and
- comply with the trends in the global market to ensure a competitive advantage for the organization in question.

The major causes of project failure are ineffective stakeholder management, poor project communications between the project manager and the stakeholders, and a lack of participation on the part of the project stakeholders (Eskerod & Jepsen, 2013). In the majority of project scenarios, the correct stakeholders are not included in the necessary phases of the project, particularly during the early stages. In such cases, the end users are approached only once the project has been implemented and they are then forced simply to accept and use the finished product. However, this may cause major resistance to the project implementation and may even result in the organization concerned suffering major financial losses and a loss of

turnaround time (Chou & Yang, 2012). Evidently, the communication process is important. According to the PMBOK® Guide (PMI, 2013), effective communication serves as the bedrock for business

Organizations that are effective in communication perform well, with 80% of them reaching their goals (Joslin & Müller, 2014). Leading authorities such as Cleland and Kerzner (1985), Larson and Gray (2018), Nicholas and Steyn (2012) and Slack, Chambers and Johnston (2010) define project management as the art of directing, coordinating and integrating human and other resources throughout the unique life cycle of a project. The importance of project communication is therefore evident as critical to project success. It is included as a separate knowledge area of the PMBOK® because it is one of the primary roles of the project manager. By using a project management methodology, one is better equipped (guided) to provide continuous communication to acquire project requirements and to identify and handle the scope of the project. This helps in laying out expectations and early identification and engagement of stakeholders. Through incorporation of the ability to produce realistic project estimates & activity schedules with effective risk and problem management, one now has the ability to handle project constraints (Rowe, 2015).

The different phases of a project can be distinguished in various ways. Kerzner (2013) states that each phase has certain deliverables that need to be completed before the next phase commences. He also states that in some projects, phases tend to overlap. Baars (2006) identifies six different phases of a project, namely the definition phase, design phase, developmental phase, implementation phase and follow-up phase.

Nicholas and Steyn (2012) provide a useful summary of the integration role of the project manager in terms of providing direction (leadership), decision making, being an entrepreneur, being an evangelist (conveying faith in the project), and being the project communication hub.

Nicholas and Steyn (2012) lists inadequate project communication as a level three cause for project failure due to factors related to inadequate information quality and inadequate information distribution. The author illustrates this important aspect as central to project success (Nicholas & Steyn, 2012), noting that successful projects are characterized by good communication and high-quality information sharing and exchange. The project manager will therefore need several communication mechanisms for effectively integrating the efforts of all project participants (and stakeholders) for facilitating the entire project life cycle process. These multiple mechanisms include formal meetings, informal review meetings, frequent ‘teach-ins’, hard copy reports, and electronic updates, among others.

Project stakeholders are often mentioned as essential players in projects (Cleland, 1985; Miller & Olleros, 2001; Office of Government Commerce (OGC), 2003; Olander & Landin, 2005). Cleland (1985) introduces stakeholders and stakeholder management processes to the project management umbrella by highlighting the importance of stakeholder identification, classification, analysis, and management approach formulation. In Table 1, a list of various definitions of stakeholders is compiled which have been analyzed from various articles.

Table 1: Definitions of stakeholders (Littau et al., 2010).

Author	**Definition**
Cleland (1985)	Stakeholders “have a vested interest in the outcome of the project”
Cleland (1989)	“Stakeholders are those persons or organisations that have, or claim

	to have an interest or share in the project undertaking."
Dinsmore (1990)	A stakeholder is someone "who has a stake in project outcome?"
Wright (1997)	"Stakeholders are any individuals who have an interest in the outcome of the project."
McElroy & Mills (2000)	"A project stakeholder is a person or group of people who have a vested interest in the success of a project and the environment within which the project operates."
Freeman (2002)	Stakeholders are "groups or individuals who can affect or are affected by the accomplishment of an organisation's mission."
PMBOK® Guide (2013)	Stakeholders are "individuals and organisations that are actively involved in the project or whose interest may be affected as a result of project execution or project completion."
Boddy & Paton (2004)	"Stakeholders are individuals, groups or institutions with an interest in the project, and who can affect the outcome."
Andersen (2008)	Stakeholders are defined as "a person or a group of persons, who are influenced by or able to influence the project."
Bourne & Walker (2006)	"Stakeholders are individuals or groups who have an interest or some aspect of rights or ownership in the project, and can contribute to, or be impacted by, the outcomes of the project."
Olander (2007)	"A person or group of people who has a vested interest in the success of a project and the environment within which the project operates."
Walker et al., 2008)	"Stakeholders are individuals or groups who have an interest or some aspect of rights or ownership in the project, and can contribute to, or be impacted by, either the work or the outcomes of the project."
Edum-Fotwe & Price (2009)	Stakeholders are "individuals or groups who are directly and/or indirectly involved in the selected scales and beyond and whose lives, environment or business are affected by the three spatial scales and beyond the adopted constructs."
Couillard et al., 2009)	Stakeholders are "entities or persons who are or will be influenced by or exert an influence directly or indirectly on the project."

After considering the definitions of stakeholders and their importance, the definition of stakeholders can be summarized below which the one is adopted in this study:

"Effective stakeholder engagement necessitates an understanding of dealing with host communities and key stakeholders, particularly those who represent a perceived threat to a project, in both the planning and implementation phases. Establishing dialogue and building strong and genuine relationships with local communities and other stakeholders is now recognized as a vitally important part of any project. From large-scale resource projects and transport infrastructure to the development of local community facilities, stakeholders matter. In terms of stakeholder classification, a stakeholder analysis should also be conducted to evaluate the expectations of the stakeholders in order to understand what they expect to gain from a project and, thereby, to understand how to influence the stakeholders to ensure that they support and contribute fully to the project (Yang et al., 2009). There are various systems available to assist in this regard."

Several scholars affirm that the success or failure of a project depends primarily on the management of the project (Chou & Yang, 2012; Kloppenborg et al., 2014; Mohan & Paila, 2013). According to Ó Conchúir (2012), it is essential that the project leader or manager possesses the following project management skills in order to manage projects successfully:

- negotiation skills to reach agreement on the necessary resources and the resolution of conflicting demands for such resources;
- skills to produce the envisaged end results with the available resources and in accordance with the prescribed performance requirements;
- leadership skills so as to direct the project efforts; and
- decision-making skills for the crucial strategic decisions that will lead the project towards a successful end.

It is incumbent on project managers to identify the project stakeholders, determine their requirements and expectations, and manage their influence over the requirements and outcomes of the project to ensure the success of a project. Thus, according to Beringer et al. (2012), the behavior of stakeholders and the techniques of stakeholder management are key factors in either the success or failure of a project. Long et al. (2004) group projects into four principal components, namely comfort, competence, commitment and communication. They argue that the comfort component emphasizes a monetary and leadership resource for the project to run smoothly. This needs to be balanced with stakeholder involvement. The component of competence emphasizes the need for a capable work force to carry out the tasks in the project if success is to be attained ultimately. The component of commitment points to the fact that all stakeholders should be interested in the goals of the project

Project failure is deemed to have occurred when projects do not achieve their intended scope within the predetermined budget and time frame, or else, while implemented within budget and on time, they are not embraced by the end users and/or project stakeholders (McLeod et al., 2012). Thus, if a project is not embraced by an end user/project stakeholders a project failure has occurred.

The South African National Road Agency Limited (SANRAL) Gauteng e-toll project was launched in 2013. It involves an electronic process to collect the tolls. This project is subject to the SANRAL Act 27 of 1998 (South Africa, 1998). One of the often-utilised claims made by the government and its agencies to 'entice' other stakeholders, was that e-tolling needed to be accepted (S.A. Department of Transport, 2012), because:

"The improvements have been made and the benefits of these improvements are being enjoyed by road users. […] Therefore, the funding of this project through the "user-pay" principle is required. This is an equitable way of funding the project, since the benefits will be enjoyed by those who pay for it."

It was therefore necessary to include the e-toll system for the entire e-toll project to be implemented. SANRAL attempted to appease Gauteng motorists using e-tolls by offering discounts on e-tagging fees. However, this strategy was not successful. In fact, SANRAL has been reluctant to reveal the amount of revenue it has collected using the 60% discount scheme. This highlights the lack of stakeholder engagement in the project (Fin24, 2018b).

It was necessary to ensure the definite engagement of SANRAL, the e-toll project managers and government leadership in order to overcome the moral and the ethical disengagement of the stakeholders involved at the time of the launch of the project. Communicating the prior estimation of the cost of the e-tolling to the decision-makers would have enabled an ongoing research process that would have assisted the progress of the project. Another problem associated with the execution of the project related to the definite measuring points installed on the freeways and the lack of alternative routes for users. As pointed out by Matsiliza

(2016), alternative routes for those motorists who are either not able to pay the high toll fees, or who are unwilling to do so, is a requirement.

As mentioned, the e-toll system was expected to ease the traffic flow in South Africa, and this would have been beneficial to the movement of both people and goods. In other words, it was anticipated that SANRAL's e-toll project would stimulate the urban economy by facilitating the easy movement of traffic in Gauteng, the urban hub of the country. On the contrary, the automatic e-toll revenue collection has been found to constitute a significant obstacle to the movement of goods. The Chief Executive Officer (CEO) of SANRAL has stated that there was a stringent plan for collecting e-toll payment from motorists who are refusing to pay their tolls (BusinessTech, 2016). Matsiliza (2016) asserts that the billing system needs to be revised with the help of a competitive pricing model. It is incumbent on SANRAL to involve the stakeholders in instituting various grades of payment to ensure that the users are satisfied with the billing system. With such stakeholder engagement, the project could have been successful in the field of e-tolls (Matsiliza, 2016).

Research Methodology

A mixed methods approach was followed in this research. Additionally, in order to further assist the researcher, a convergent parallel mixed methods design was followed. With this approach, the researcher collects both quantitative and qualitative data, analyses the data separately, and then compares the results to determine if the findings confirm or disconfirm the data sets (Creswell, 2018; McKim, 2017).

According to Bush (2016), a target population is the overall number of people from which insightful responses can be collected. SANRAL e-toll went live in Gauteng on December 3, 2013, when the province had some 3.5 million registered vehicles (Matsiliza, 2016). The target population for this research was therefore the Gauteng motorists as well as the project manager, in this case referred to as SANRAL (SANRAL - Northern region).

Various techniques that were considered in this study under the probability sampling technique (Creswell, 2018). These are simple random, systematic, cluster and stratified random sampling. To select the research respondents that were to fill in the questionnaires, the simple random technique was used. The sample size for those who filled the questionnaire was 400.

In this research, a questionnaire was the data collection method, with its content guided by the literature review. Assistance from the Statistics Department at the University of South Africa was sought, particularly to get advice with regard to the validity of items for statistical purposes. The questionnaire, which was comprised of structured questions was administered to 400 Gauteng road users. Questionnaires were handed to the respondents when they filled up with fuel at Engen garages situated on the national highways of Gauteng.

Semi-structured interviews were used in this research to obtain narrative data to be thematically analyzed. Interviews were planned with the project sponsor (i.e. SANRAL – Northern region) based on the availability of the project managers. An interview schedule was compiled in which the interview questions were outlined.

To obtain the narrative data through a structured interview involved interaction between the researcher and the respondents, which needed to be documented. The interviews were therefore recorded, and the researcher took notes at the same time. After the interviews, the recordings were sent to a data transcriber to develop a content analysis. The recordings and notes are kept as records for future reference.

In brief, the process to obtain numeric data through questionnaires entailed the following process: Questionnaires were distributed at each Engen garage on the N1 (south and north), M1 (south and north), and R21 (south and north). Field workers assisted in distributing the questionnaires to the respondents. The supervisor and another academic colleague were observers at the R21 (south) Engen garage.

From the above it is evident that mixed, integrated or combined methodologies have many advantages. Many authors tend to move away from the conventional approaches.

Discussion of Results and Findings

Thematic analysis was conducted as the essential information gathering strategy to recognise, analyze and distinguish subjects inside the information set. This approach was used because it "permitted the analyst to sort out and portray the information in rich detail to arrange and decipher the numerous viewpoints of the investigated subject" (Braun & Clarke, 2006). The themes were:

- Meeting stakeholder expectations: The expectations of all stakeholders should be determined early in the project through consultations to ensure that they are met at the end.
- Stakeholder engagement in project decision making: Stakeholders are vital when decisions are being made throughout the project in order to achieve a successful outcome.
- Stakeholder identification throughout the project life cycle: The severity of influence of a stakeholder largely depends on the type of stakeholder, which has to be identified, along with ensuring that the right stakeholders are identified at all stages of a project.
- Stakeholder involvement and commitment: Stakeholders need to be involved throughout the process and all stakeholders need to be on board.
- Lack of communication in the project: The soft skill of communication is usually neglected in projects; a lack of communication emerged as the biggest shortfall in project success.

The findings of the interviews confirm that an organization must consider all groups or individuals who can influence business activities, and that the organization must concentrate on bringing in value for stakeholders, as also suggested by Freeman (2004). The themes identified are in line with the idea, which implies that stakeholders are crucial for the existence of any organization (Eskerod & Jepsen, 2013). Overall, the outcomes of the interviews seem to suggest that in order to achieve a successful outcome, stakeholder consultation and communication is required at every stage of the project life cycle.

A value of +1 signifies a perfect positive linear correlation, which means that two variables are precisely related, and as the value of the one variable increases, so does the value of the other. This also means that a value of -1 signifies a perfect negative linear correlation, which means that two variables are precisely related, but as the values of one variable increases, the

values of the other decreases. Spearman's correlation (Cohen, 1990) was used to reflect the correlations between all the significant statements in the questionnaire and the variables of the three scales. Of the twenty statements in the questionnaire, the following were related to stakeholder management:

- Gauteng motorists were involved during the initiation of the project (Statement 4). The majority of the respondents indicated that they were not involved during the initiation of the project.
- The needs of the stakeholders were assessed during the project initiation (Statement 5). The majority of the respondents indicated that their needs were not taken into consideration during the initiation of the project.
- The stakeholders/community had an opportunity to give inputs and make suggestions during the project (Statement 6) The majority of the respondent indicated that the stakeholders/community were not allowed to provide an input during the project.
- The government was involved during the initiation of the project (Statement 7) the majority of the respondents agreed that the government was involved during the initiation of the project.
- The government was involved during the planning of the project (Statement 8). The majority of the respondents agreed that the government was involved during the planning of the project.
- When there were challenges, the government was involved in addressing the challenges (Statement 9). The majority of the respondents indicated that the government did not play a role in addressing the challenges of the e-toll project.
- The e-toll project misled the stakeholders due to a lack of communication with the stakeholders (Statement 10). The majority of the respondents agreed that there was a lack of communication about the e-toll project.

In summary, the twelve statistically significant correlations described above (whether positive or negative) seem to suggest that relationships do exist between project stakeholder management on the one hand, and project communications management and project success on the other hand, as demonstrated in the case of the SANRAL Gauteng e-toll project.

This research finding is in line with previous research by Mawela et al. (2015), mentioned previously, that there were numerous stakeholders related to the SANRAL e-toll project and all of those stakeholders were crucial in the project. Further, according to Achterkamp and Vos (2008), "salience is described as the degree to which managers give priority to competing stakeholder claims".

Secondary research sources are very direct and specific about this issue. Bond-Barnd (2017), Steyn and Fletcher (2015), for instance, argue that the quality of communication triggers the process of achieving success, trust and collaboration. They further indicate that communication sustains the process as it is the only factor identified in the literature that is required as a direct input/predictor of the level of trust, degree of collaboration and success achieved (Bond-Barnard et al., 2015). Bond-Barnard (2017) and Butt and Savolainen (2016) put forward the view that any project must have three levels of success, namely project success, project management success and constant project success. Yet, to achieve these three levels of success, Davis (2014), Joslin and Müller (2014), Goetsch and Davis (2016) and Rose (2013) found that effective communication is necessary to enhance all the links between the various relationships that exist within a project management set-up to satisfy the needs of stakeholders. Stakeholders are individuals and organizations who are actively involved in the project directly or indirectly, and whose interest may be positively or negatively affected

because of project execution or successful project completion (Zulch, 2014). Yang et al. (2014) add that assessing both the attributes and behaviors of stakeholders are critical success factors in a project. They emphasize that important practices in the successful management of a project comprise engaging the stakeholders, communicating with the stakeholders regularly, and establishing long-term stakeholder relationships.

Conclusion

Five themes considered important for project success were identified after interviews were conducted with the two project managers from SANRAL. From the project manager's perspective, one theme dealt with project communications management, and indicated that communication was a soft skill that was usually neglected. The remaining four themes dealt with project stakeholder management, pointing out that stakeholders' expectations should be met, stakeholders should be involved in decision making, stakeholders should be involved throughout the project life cycle, and stakeholders should be on board from the beginning and demonstrate commitment towards the e-toll project.

In addition to several issues which may be seen as constraints on the project, such as the cost of the project, the unskilled labor force, the materials and the handling fees, as well as the lack of support of the stakeholders (Matsiliza, 2016), it is evident from the above that the respondents were of the sentiment that there was minimal communication and engagement with the Gauteng motorists, being one of the key stakeholders for the e-toll project.

The research was aimed at assessing the impact of project communications management and project stakeholder management on project success through a case study of the SANRAL Gauteng e-toll project. It was also aimed at answering questions regarding whether there is a relationship between project success and communications management, as well as between project success and project stakeholder management. In conclusion, it can be stated that effective communication is crucial for project success. Stakeholder management also affects project success. This is measured by the level of engagement with stakeholders, who must be engaged at all costs to ensure successful projects in the future.

Preliminary Estimation of Natural Gas Pipeline Construction Costs with Regression Analysis

C. Çakmak and M. Erdal
Gazi University, Department of Civil Engineering, Ankara, Turkey
coskuncakmak@gazi.edu.tr, merdal@gazi.edu.tr

Abstract

Natural gas pipeline construction (NGPC) projects are inherently includes high changefulness like any other construction works. Considering that variability, it can be stated that to make an accurate cost estimation is difficult. The main objective of this paper is to achieve a coherent mathematical equation to be able to make a preliminary cost estimation of NGPC costs. To this end, a number of pipeline cost data, which is in US dollar currency, was obtained for the period 1986-2010. With this data, a simple regression equation was tried to be revealed by working through statsmodels, one of the libraries used for the Python programming language. It was concluded that a significant part of the NGPC cost could be explained with the diameter and length variables. In this respect, this paper has the potential to assist the institutions responsible for the execution of the NGPC processes of the Turkey or the contractors considering investment or at the decision-making stage. Moreover, the paper presents a first attempt at both predicting of NGPC costs in Turkey and executing that operation by using Python programming language.

Keywords: *natural gas pipeline, preliminary cost estimation, python.*

Introduction

An accomplished cost estimation is one of the key factors of project success in construction sector (Kim et al., 2004). It plays a vital role for each part of a construction project. It is crucial for owners to be able to create a systematic investment program in the meantime, while it is lifesaving for contractors for calculation of profitability and forecasting of cash flow. It should be noted that a real-like cost estimation would also set the designer's limits. Especially, preliminary cost estimation (PCE) techniques with limited project information are very helpful for partners of construction works like owners, designers, contractors and so on (Arage & Dharwadkar, 2017). The earlier successful cost estimation before beginning of the project brings early decisions among those partners. Thus, an environment arises in which each partner of construction works can foresee the future and people can make more solid decisions. Just as an accurate PCE may increase the profitability of the contractor, an improper one may affect the profitability of contractors negatively and lead indispensably project failure (Cheng & Hoang, 2014). It is a well-known fact that a high level of detail does not exist at PCE stage. That is why we need an amount of data of similar previous projects to make estimation. When we take the competitive environment of construction sector into consideration, it is very clear to see the necessity of a fast and efficient estimation method for

the people who are employee in cost and planning department of construction companies (Uğur, 2007).

Natural gas pipeline constructions (NGPCs), like other construction works, have pretty much uncertainty in terms of project cost because of its nature. To be able to make an accurate cost estimation is thereby considerable not easy. In the literature, there are a small number of research scrutinizing costs of NGPC projects. Those studies, almost all of which were studied in United States, indicate that there are several cost components in NGPC like labor, material (pipes), miscellaneous and right of way (ROW) (Parker, 2004; Rui et al., 2011a, 2011b, 2012; Thaduri, 2012; Ulvestad & Overland, 2012; Zhao, 2000). In these studies, details of which will be shared in literature part, while some researchers try to obtain an equation that gives total estimated cost with those four cost components, others contributed the descriptive statistics of the total costs of pipeline projects in the past to the literature. In Turkey, unfortunately, there is no a database where the costs of the NGPCs are kept by dividing them into components unlike in the United States. Therefore, it is not possible to study with aforementioned cost components and to obtain an equation, which is result of those. Under these circumstances, this research has focused on constructional independent variables that are inherent for NGPCs instead of general cost components like labor, material, miscellaneous and ROW. Details of constructional independent variables will be presented in later sections. The research suggests an early estimation technique of NGPC costs via an equation created with statsmodels library of Python. Since the maximum possible number of data is reached during the data acquisition phase, it was necessary to comment that the research on a whole count, not a sample, for our study. This is the most important limit of the research and that is why further statistical evaluations were not executed such as normal distribution of residuals.

Literature

There are many studies covering cost estimation techniques in construction sector via various methods (Erdal, 2021; Sueri & Erdal, 2022; Ugur et al., 2019). However, few of them focus on the NGPCs. Lack of the information in detail about NGPCs or arrangement difficulty of existing complex database may be the main reason of that deficiency. In this part, a few studies addressing only cost estimations in NGPCs or other pipeline systems have been explained. In addition to these, although not directly aimed at estimating natural gas pipeline construction costs, a few related studies are also included in this section.

Zhao (2000) reported the distribution and cost variation of natural gas pipelines in Europe, Asia and United States. Researcher stated in her study that material and labor costs cover 80% of the NGPC costs for onshore while it is 84% for offshore (Zhao, 2000). Parker (2004) investigated the cost differences in hydrogen transmission lines based on the costs of natural gas, fuel oil and oil pipelines. Author concluded that NGPC costs consist of 26% material costs, 45% labor, 7% miscellaneous expenses (research, inspection, insurances, permits, etc.) and 22% ROW (Parker, 2004). Rui et al. (2011a) developed five different regression models and tried to estimate the costs of 412 onshore natural gas pipelines built between 1992 and 2008 in different regions in the United States. In the study, the authors determined that large-scale natural gas pipeline projects have more affordable unit costs (Rui et al., 2011a). In another study in same year by Rui et al. (2011b), researchers stated that learning the job by repetition reduces the labor costs over time (Rui et al., 2011b). In his study, Thaduri (2012) collected data on 180 natural gas pipelines and 136 pressure stations completed within the borders of the United States and Canada between 2000 and 2008 and presented descriptive

statistical data. Because of the evaluations, it was stated that the cost items with the highest share in the costs of natural gas pipelines were labor with 40% and material costs with 31% (Thaduri, 2012). Ulvestad and Overland (2012) examined the cost analysis of two different natural gas transmission options, pipeline and liquefied natural gas (LNG). Authors concluded that pipeline transport is a better option for larger natural gas volumes and shorter distances while it is LNG for smaller volumes and longer distances (Ulvestad & Overland, 2012). Bai et al. (2013) estimated the annual cost for the pipelines required for CO_2 supply, with the support of the existing literature in their studies. In the study, where two different routes with similar characteristics were selected in two different regions of China, they estimated the annual costs to be 52.52 RMB/t on average (Bai et al., 2013). Matthews et al. (2015) evaluated infrastructure projects within the scope of the concept of "social cost". Especially in infrastructure construction or rehabilitation projects where excavation is applied, calculation methods are proposed for each social cost category because of the inability to use the road, noise, pollination due to excavation, etc. Researchers determined that the social cost could be calculated between 1% and 9% compared to the project cost (Matthews et al., 2015). Zhang et al. (2016) conducted a research on interregional natural gas supply and infrastructure expansion in China by 2035, using an optimization model. In the study, in which four different scenarios were evaluated, it was stated that natural gas wholesale price and import cost are the most important points for China. In addition, it was evaluated what kind of natural gas supply changes/problems these scenarios will create in the country (Zhang et al., 2016). Kaiser (2021) examined the costs of onshore and offshore oil and gas pipelines in the United States. The author also mentioned pipeline requirements, cost estimation procedures and normalization processes in his study, where he presented the similarities and differences in the construction and demolition processes of onshore and offshore pipelines (Kaiser, 2021).

Preparation of Dataset

Data of available approximately 100 NGPCs in Turkey were reached by a not easy way. The information of all projects made between 1986 and 2010 was examined manually and dataset was finalized. After the examinations, in first stage the independent variable candidates that can be used in our regression model were pipe diameter (inch), length of pipeline (km), excavation amount (m^3), ideal depth (m), line valve (number), take-off valve (number), pigging station (number) and project duration (day). In examined papers, information of some projects were missing. Therefore, number of data decreased to 57 because of lack of information that can be used as a variable like project duration, cost etc. As an example, information of first five projects of 57 natural gas pipeline projects were showed in Table 1 which was created with codding *df.head()* (df is name of the dataset) in *Pandas* library which is one of the most popular modules in Python.

After finalizing the dataset some descriptive statistics of variables and correlation between variables were calculated with codding *df.describe().T* and *df.corr()*. Descriptive statistics including important explanatory statistical information such as mean and standard deviation are presented in Table 2. Table showing correlation values between variables and formatted as a heat map is presented in Figure 1.

Table 1. First five data item of the dataset.

Number	Diameter	Length	Excavation	Depth	Line	Take-off	Pigging	Project	Cost

	(inch)	(km)	(m^3)	(m)	valve (number)	valve (number)	station (number)	duration (day)	($)
0	16	1.57	1992.31	1.41	0	0	0	343	1478615
1	40	110.96	385488.94	2.32	3	0	1	747	47364121
2	12	12.64	12375.07	1.22	0	2	2	14	860314
3	40	102.47	355973.83	2.32	3	0	1	771	44619968
4	16	25.00	31644.00	1.41	0	2	1	46	2640478

Table 2. Descriptive statistics of 57 NGPC costs.

Parameters	**Mean**	**Standard Deviation**	**Min**	**25%**	**50%**	**75%**	**Max**
Diameter (inch)	21.68	13.51	6.00	10.00	16.00	36.00	48.00
Length (km)	77.89	68.97	1.57	32.22	59.62	100.15	320.00

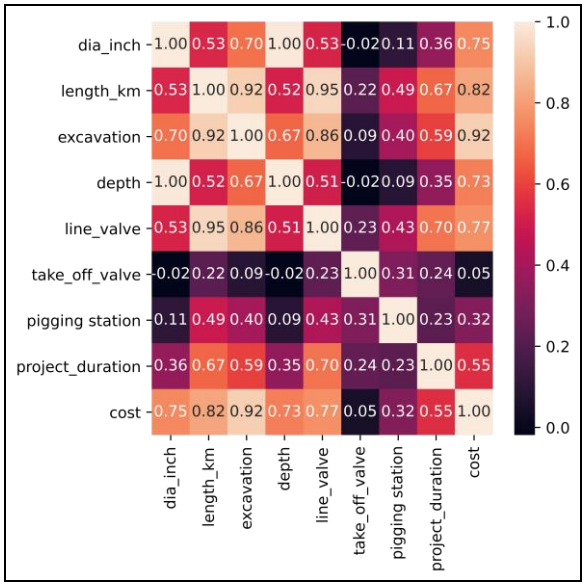

Figure 1: Heat-map of correlation between variables.

Data Preprocessing

To increase the quality of data is the first step of executing of any model because it can lead fallacious results (Pyle et al., 1999). At first blush, it is easy to see that dataset includes cost data taking places in a wide range by looking at Table 2. Even in Table 1, which shows only first five data of all dataset, there is a considerable amount of variability. Data set with an average of about $25M has a standard deviation of about $36M by the way. However, a correlation problem of independent variables was determined. In Figure 1 one can easily say that excavation and depth parameters look like a result of a mathematical equation due to the fact that correlation higher than 0.9 value. Same comment is available for line valve variable

by the way because of its high correlation value. That means we do not need those variables to be able to explain the variability of cost data as the diameter and length parameters are enough. It is most probable that excavation and depth parameters are calculated values by length and depth respectively. Therefore, it is a better way to eliminate these parameters from dataset. On the other hand, we should be awake to differences between 75% quartile cost value and maximum cost value. The gap between those two values makes one think about existing of outlier values. At this stage, it was decided to define and eliminate outlier values by creating a boxplot of cost data. The boxplot created with *seaborn library* in Python in which 25% quartiles can be seen is given in Figure 2.

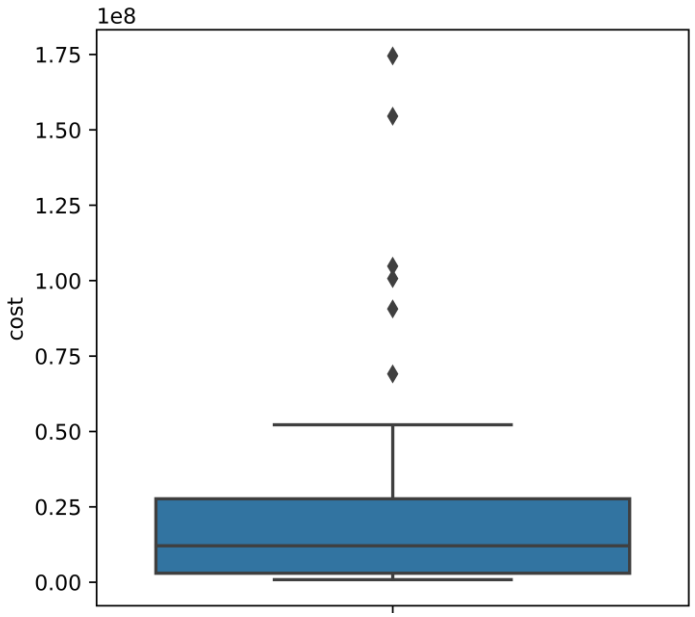

Figure 2: Boxplot of cost data.

According to plot, cost values higher than approximately $60M are outlier values and should be subtracted from dataset because it is thought that those values would affect negatively the final equation. After all these arrangements number of cases decreased to 51 and 3 independent variables were taken out of the dataset. After these processes, descriptive statistics and correlation matrix of variables were created and shown in Table 3 and Figure 3.

Table 3. Descriptive statistics of 51 NGPC costs.

parameter	**mean**	**standard deviation**	**min**	**25%**	**50%**	**75%**	**max**
Diameter (inch)	19.22	11.96	6.00	10.00	14.00	24.00	40.00
Length (km)	59.89	36.06	1.57	30.98	58.28	74.89	164.50
Take-off valve (number)	2.06	4.82	0.00	0.00	1.00	2.50	34.00
Pigging station (number)	1.06	0.54	0.00	1.00	1.00	1.00	2.00
Project duration (day)	399.12	285.81	14.00	174.00	358.00	585.50	1205.00

Regression Analysis by Statsmodels Library

In this part of the research, a regression analysis were executed by using statsmodels library. Statsmodels library is one of the useful modules of Python for statistical models, hypothesis tests and data exploration (Seabold & Perktold, 2010). It is beneficial in terms of information it gives and the time it saves. Actually, exiguousness of data was a supreme challenge for this kind of an analysis. In this research, to have just about 50 data to be able to use in creating regression model is an example of that challenge. The more data actually the more learning and the more deep analysis. We conducted the operations under these conditions with statsmodels library by using least squares methods. After data preprocessing, dataset finalized and regression model was executed by statsmodels library and its functions. Codes showing how to create model with statsmodels are given in Figure 4.

```
import statsmodels.api as sm
import statsmodels.formula.api as smf

df.drop(df[df.cost > 60000000].index, inplace = True)
df1 = pd.DataFrame(df)
df1.drop(columns=["depth", "excavation", "line_valve"], inplace=True)
df2 = pd.DataFrame(df1)

X = df2.drop(columns =["cost"])
y= df2["cost"]
```

```
X = sm.add_constant(X)
lm = sm.OLS(y, X)
model = lm.fit()
model.summary()
```

Figure 4: Codes for creating model by statsmodels.

A regression model using ordinary least squares method was created by means of statsmodels. Results of this code and details of the final model, including important metrics such as R-squared, adjusted R-squared and Prob (F-statistic), are given in Table 4 and Table 5.

Table 4. Ordinary least squares regression results.

Dep. Variable:	cost	R-squared:	**0.777**
Model:	OLS	Adj. R-squared:	**0.752**
Method:	Least Squares	F-statistic:	31.39
No. Observations:	51	Prob (F-statistic):	1.30e-13
Df Residuals:	45	Log-Likelihood:	-876.66
Df Model:	5	AIC:	1765.
Covariance Type:	nonrobust	BIC:	1777.

Table 5. Ordinary least squares regression results.

parameters	coef	std err	t	P>|t|	[0.025	0.975]
const	-1.347e+07	3.43e+06	-3.922	**0.000**	-2.04e+07	-6.55e+06
dia_inch	8.419e+05	9.48e+04	8.884	**0.000**	6.51e+05	1.03e+06
length_km	1.781e+05	3.76e+04	4.741	**0.000**	1.02e+05	2.54e+05
take_off_valve	-3.833e+05	2.46e+05	-1.557	0.126	-8.79e+05	1.12e+05
pigging_station	1.156e+06	2.16e+06	0.536	0.595	-3.19e+06	5.5e+06
project_duration	1266.9667	4433.852	0.286	0.776	-7663.269	1.02e+04

In first trial, independent variables except diameter and length had p-value higher than 0.05. It statistically means that those variables are inadequate to be able to explain the variability of target cost value. At this stage, an equation can be formed with the values in Table 5 and the model can be terminated, or the independent variables with high p-values can be removed from the model and a trial can be made again. On the purpose of presenting some real statistical result, those variables were removed from the dataset. Therefore, only diameter and length variables were left for the regression model. Results of this final trial were presented in Table 6 and Table 7.

Table 6. Ordinary least squares regression results.

Dep. Variable:	cost	R-squared:	**0.765**
Model:	OLS	Adj. R-squared:	**0.755**
Method:	Least Squares	F-statistic:	78.15
No. Observations:	51	Prob (F-statistic):	8.00e-16
Df Residuals:	48	Log-Likelihood:	-878.01
Df Model:	2	AIC:	1762.
Covariance Type:	nonrobust	BIC:	1768.

Table 7. Ordinary least squares regression results.

parameters	coef	std err	t	P>|t|	[0.025	0.975]
const	-1.223e+07	2.41e+06	-5.071	0.000	-1.71e+07	-7.38e+06
dia_inch	8.549e+05	9.17e+04	9.324	0.000	6.71e+05	1.04e+06
length_km	1.689e+05	3.04e+04	5.555	0.000	1.08e+05	2.3e+05

As it can be seen from the Table 6 that created model has a $R^2 = 0.765$ value. It may be accepted as a not bad result specific to engineering problems. In the model, two independent variables have p-value less than 0.05, which means it is an appropriate choice to be able to explain the variability in dependent variable with those parameters. At this stage, as a PCE option that Eq. 1 emerged:

Cost ($) = -12226990.71 + 854865.97 × “Pipe Diameter” + 168936.70 × “Pipeline Length” (1)

where cost is in US dollars, pipe diameter in inch and length in km. To simplify the equation “D” can be used instead of Pipe Diameter and “L” for Pipeline Length. The revised Eq. 2 is given below.

Cost ($) = -12226990.71 + 854865.97 × D + 168936.70 × L (2)

The constant of the model was located in equation unpleasingly. Moreover, it is clear to see that some misestimations may come true because of such a huge constant value. Even if no one can say negative constants are awkward for regression analyses, it is normal to boggle because of having a constant lowering the result about $12M. It will be beneficial to look at the predicted costs and real costs. Some helpful statistics were presented in Table 8 to measure success of the final model. Explanations about details of the table are below the table.

Table 8. Real cost – predicted cost relationship.

Cost ($) = -12226990.71 + 854865.97 × D + 168936.70 × L		
Predictions	**Number of projects**	**Average real project costs of these projects ($)**
Negative cost results	6	1751854.27
Underestimation	25	11455554.97
Overestimation	26	17069053.52
Error range under $1M	12	6388981.00
Error range between $1M and $2M	5	16424855.22
Error range between $2M and $3M	7	9122743.09
Error range between $3M and $4M	8	3383372.35
Error range between $4M and $5M	2	24305072.25

The model made negative cost estimation 6 times as projected after creating the equation. Average real project costs of those six ones was about $1.75M and none of them higher than $2.4M. The model made 25 underestimation while it is 26 for overestimation. For 12 ones of 51 projects, model can be presented as successful because of estimation with an error under $1M. In addition, it estimated the cost with an error range between $1M and $2M for five projects while the average real project cost of which was nearly $16.5M. On the other hand, to have an error range between $3M and $4M while the average of real costs was just $3.83M

looks like a failure for PCE. Nevertheless, the model can be seen as partially successful in view of limitations and challenges about getting and arranging the data besides missing and lack of the useful data.

Conclusion

This research has been conducted to produce an equation for a PCE method of NGPC costs. Much as lack and acquisition of information tended to demotivate, the studies carried out in United States encouraged the authors about workableness of that subject. To prepare the dataset manually and missing of a number of values of cases were the main challenges of the research. After all this process, an equation was obtained that can reveal the NGPC cost estimates while the projects are still in the preparation stage, with a not bad coefficient of determination which is $R^2 = 0.765$. This study covered only a basic regression model. The proposed method can be used in the construction sector considering the statistics presented in last paragraph before conclusion part. In our future research, we intend to concentrate on increasing the number of the data and running analysis by machine learning techniques. In addition, in such large works in terms of cost, it would be desirable to conduct a study that will reveal how much of a mistake would be considered tolerable by the investor in a preliminary estimation that can be made with limited information.

Evaluation of Update Rates of the Contracting Certificates and Work Experience Certificates

alevkaya@ktun.edu.tr

Abstract

While choosing the contractor there have been several criteria. Demanding a work experience certificate of similar working groups with the determined rate of commitment value of the work is the main point. According to the data from TUIK 2022 construction cost index of March has shown an annual increase of 101,57 percent. The 2022 updating indexes in the bulletin, which has been used to classify the contractors and announced by the public authority, has been lower than this rate. The volunteers who want to participate in a tender have updated the total amounts of work experience certificates based on domestic producer price index through electronic public procurement platform. However, the updated numbers have failed to satisfy the increases due to the inflation. In such an atmosphere, construction investment costs have highly increased above the total amounts of work experience certificates. Under these circumstances, contractor companies have less opportunities to bid on new jobs. In this study, the updated amounts of work experience certificates and construction costs in free market have been compared and the difference between them have been searched in terms of the ability of the contractors to bid in the future.

Keywords: *construction costs, construction management, index, work experience certificate.*

Introduction

The market makers in public and private sectors use bidding to carry out their current jobs under best circumstances. Bidding brings the opportunity to a fair competition for the volunteers who have similar conditions in terms of public. On the other hand, it brings a cost advantage for the private sector, too. In a study conducted in 2010, Erdoğan defined "bidding" as contractually leaving the cost responsibility of the production and the presentation of a service whose circumstances are formerly determined to a private person/entity.

The concept of "bidding" expresses the "process" through which the management chooses a volunteer for a certain job under certain procedures (Demircioğlu, 2014). According to Binmora and Klemperer (2001), "bidding" has been advised as the method to value the sources in the best way.

In Turkish Administrative Law, bidding has been defined as “the formation process of contracts to purchase necessary good and services, whose cost would be paid by the administration, in order to carry out the services that fall into the administration’s area of responsibility”. Bidding is also “the formation process of contracts to make a private person, who offers the best among volunteers, conduct a job within a competitive environment which is formed by obeying the codes of practice stated by law” (Yıldırım, 2016).

The market makers in public and private sectors have been sharing and decreasing their risks by bidding construction investments. Construction sector carries various risks depending upon the costs, resource utilization and organization. By giving a job to a volunteer through bidding means risk sharing for the administration.

In their study in 1990, Al-Bahar and Crandall have determined “risk” as the realization probability of being exposed to events that would negatively or positively affect the aim of the project due to an uncertainty. Similarly, Turkish Language Association also defines “risk” as the danger of being exposed to any damage.

By determining the applicant through bidding, it is expected the contractor to take the risks. The owners are generally assumed to be in the group who does not like risks or ignores the risks depending upon the scale and complication of the project. On the other hand, the contractors might have an attitude as taking risks, ignoring risks, or disliking risks according to the scale and complication of the project and market conditions. While owners generally tend to expect the contractors to take all risks that might come from any source, the contractors hope to secure themselves by trying to increase the bid price (Zaghluol & Hartman, 2003).

Each constructional project is specific and unrepeatable, is huge in number and requires to combine various fields of specialization. Besides, each project emerges at the end of a long, complicated and compelling production process from the idea stage to the construction stage. All these specialties have been basic and determinative factors in construction sector. Meanwhile, these specialities make this sector riskier compared to other sectors. When a general classification is done for the risks in the sector, it is seen that there are different categories such as prepare for bidding risks, political risks, market risks, financial risks, natural disasters, cultural risks, company risks, construction risks, design risks, contract risks, legal risks, and environmental risks (Kaplan, 2014).

After the pandemic, there have been a deterioration in expectations and supply demand equilibrium due to the loose monetary policies all over the world. As the central banks in countries have fallen behind with the precautions, an inflationary atmosphere has occurred. When recent conditions have been taken into account, it can be said that the most important risk that the contractors who want to participate into a bidding would take is to determine the bid price depending upon construction costs. The inflationary pressure over the costs reduces the determination of the participants and increases financial risks. And this condition negatively affects the duration of the completion of the projects.

The volunteers who want to participate into the bidding both in public and private sectors have to provide certain conditions. Work experience certificate, in other words the completion of a similar job certificate is one of the most important conditions. According to the public procurement law, it is essential to choose from the participants who are able to bear the cost in

the optimum way, have a same or similar experience and references that show they are capable of doing the job subjecting to tender (Yıldırım, 2018).

There is an idiom in our culture means "give the job to the competent person". This comes out in public affairs too as giving the job competent contractors. Through public procurement law, a condition which includes having a certificate that shows certain capabilities and competences related to the job subjecting to the tender has become a must for the volunteers who want to participate into the bidding. As a result, the concept of "work experience certificate" has occurred (Bozkurt et al., 2015). In a study in 2014, Demircioğlu has interpreted that in a certain area, if there are more professional volunteers who have proven themselves as competent, they will be more preferable than the ones without any experience and this will be on behalf of the public weal.

"Work experience certificate" has a special importance among the certificates required to determine the professional and technical competences in construction works biddings. Because in construction works biddings, it is compulsory for the volunteers to own a work experience certificate in order to encourage to be experienced without taking into consideration the approximate cost (Yıldırım & Gelişen, 2017).

Work experience certificate gives a clue about the contractors about whether they are capable of completing the job or not by evaluating the previous works (İnan, 2015). It is a kind of reference and as it is a legal must, it can be understood that it is a crucial certificate. In order to take part in a public bidding, the participants have to own this certificate. Besides they need to have a work experience certificate that is similar to the work area and will meet the required rate. Therefore, the work certificate determines the scope, quality and size of the work that the contractor might take part in (Yıldırım, 2018).

However, in view of current circumstances, it is great importance for such an important certificate to maintain its value that the market conditions should correspond to the parameters determined in a bulletin by the Ministry of Environment, Urbanization and Climate Change. In this study, these parameters and current market conditions have been compared and the results and suggestions have been presented.

The Concept of Work Experience Certificate and Varieties

In the literature, there have been various definitions for "work experience certificate". However, it is defined in the regulation for implementation of construction works, in article 3, subclause (d) that "work experience certificate expresses the certificate of work conduct, certificate of work inspection and certificate of work management that shows the experience of the participant on the work subjecting to tender or on similar works".

In the same regulation, in article 3, subclause (b), "similar works" is defined as "the works that is similar to the work/parts of work subjecting to tender in respect of quality and quantity and that requires the same or similar construction engineering, facility, machine, equipment, financial capability, specialization, organizational needs. Although the regulation has drawn a line for the definition of "similar works", the main point is that the experiences should be close to the size, construction engineering, machine, equipment, and organizational structure of the work subjecting to tender. It is vital to determine the working groups in order to choose the contractors who have the technical competences and who have the most reasonable tender.

If it is possible to choose volunteers who have similar work experiences in the past, it will prevent the waste of public and private sector funds. Thus, it will be possible to save labour, time and funds.

Under the heading of the conditions for drafting document, in the regulation for implementation of construction works, in article 44, the requirements for this certificate have been determined. Based on this article, for the pledged works depending upon a single contract, the certificates are prepared as;

a) "Contractor's work completion certificate" in works with substantial completion,
b) "Contractor's work conduct certificate" in ongoing works, if the first contract price is completed and if the rate reaches at least 80% of the total contract price, precisely.
c) "Subcontractor's work completion certificate" on condition that the pledged work part is completely finished and subjecting work part is partly accepted by the management, or substantial completion is done related to the initial contract through an agreement which includes a cost for the contractor who has made a commitment to the institutions and organizations which are authorized to prepare a work experience certificate.
d) "Work inspection certificate or Work management certificate" in ongoing works, given to the architects and engineers who have conducted task of inspection and management with the rate of at least 80% of the first contract price, on condition that the first contract price is completed and if the rate reaches at least 80% of the total contract price, precisely.

"Similar work groups list" has been formed to provide fair competition conditions, to define and to classify the works subjecting to tender in accordance with the public procurement law no. 4734. In this list, similar works are classified under five main headings as; "infrastructure works", "superstructure (building) works", "sanitary installations and mechanical installation works", "electric work" and "electronic and communication works". These main headings are divided into sub categories in the details of the list. The management can examine the list and prepare a pre-condition to the bidding for similar works subjecting to tender.

The Evaluation of Parameters of Assessment for Work Experience Certificates According to Current Construction Costs

In Turkey, construction sector, with its greater work load, is a leading sector among others compared to developing countries. Whether the employment rates or investment amounts are evaluated, it can be seen that the sector is huge in terms of numbers. Especially, the majority of investments in a developing country like Turkey are directly related to construction sector. Developing countries have to improve their standards and cope with many different compulsory actions such as completing deficient infrastructures, conducting industrial activities, increasing production, maintaining logistic activities through ports, airports, and highways for ultimate outputs. For this reason, all the items of work mentioned are directly or indirectly related to the construction sector (Kazaz et al., 2019).

As a result, the recession or the mobility in construction sector directly affects the financial situation in the country. Likewise, the developments in macro economy also directly reflects in construction sector. Recently, inflation has been rising up globally which has an important influence in construction costs. In relation to rising costs, individual investors, who want to preserve their savings, tend to housing and institutional investors speed up the work for their industrial constructions by moving their capacity increase plans to an earlier time. These

attempts deteriorate the supply and demand equilibrium in the sector. This can be seen in the data from TUIK March 2022 data, too. While current consumer price index has increased by 73,50% annually, construction cost index has increased by 101,57% and building materials index has increased by 128,11% annually. As its understood from the statistics, construction cost increase is far above the inflation rate.

Considering these data, for the investments whether through public or private sector, the work experience certificates have become crucial for the volunteer companies to bid. It is important to own updated certificates for companies to be classified as competent for similar or upper-level works.

In order to determine the current values of the work experience certificates, a bulletin called "Assessment parameters of contracting certificates used for construction, facility and repairment works and work completion certificates in 2022" by the Ministry of Environment, Urbanization and Climate Change is being used firstly to classify the contractors. Work experience certificates are being updated through EPPP depending upon domestic producer price index if companies want to bid on. In an inflationist atmosphere, it is possible for a company to preserve its required competences to bid on only through updating the rates according to current conditions. However, lately, the updated rates remain under the prices that are occurred in the market conditions. In this study, the current values of investments in Konya Organized Industrial Zone and the work experience certificates that the contractors own have been compared and it is tried to be evaluated whether they are suitable for current market conditions or not.

Investment 1

The project evaluated under the title of Investment 1 includes rain water, drain water and road infrastructure works of Konya Organized Industrial Zone expansion area. Via this investment it has been aimed to remove the waste during the production phase of industrial facilities that is going to be set up in the expansion area, to remove the rain water in order not to have rain water floods and to form an infrastructure for a healthy transportation.

Within the scope of the investment, about 60.000m. reinforced concrete pipes in different sizes and 6.000 m. glassfiber-reinforced pipes in different sizes have been used. Due to the geographical conditions of Konya, as the natural ground in the working area does not have enough slope, digging height has been increased. This has been resulted in a cost increase.

The cost of this investment is approximately 130.000.000 TL and it was contracted out for 124.526.945,41 TL on 10.11.2017. On 18.12.2017 the contract was signed; construction site was delivered and construction works started. The investment was made with the set amount and was put in service.

When work experience certificate is updated through EPPP depending upon the bid date, it is seen that the total amount becomes 629.881.573,53 TL. For this calculation, basic domestic producer price index (ppi) was 306,04, and current index was taken as pre-June 2022 index-1548,01- as it was the date of inquiry. When the same amount is updated with the rate of 3,428 according to the bulletin called "Assessment parameters of contracting certificates used for construction, facility and repairment works and work completion certificates in 2022", the result is 426.878.368,86 TL.

However, if this project was put into practice at the present time, the amount of the investment would be much higher than the one calculated above. It can be seen that, when items of work in the same project, by keeping the sizes same, is re-calculated according to the market conditions, the amount rises up to 785.277.019,38 TL. In order to explain this increase, it will be enough to examine the increases in some basic materials. Contract values and current values of some basic materials are given in Table 1.

Table 1. Contract values and current values.

Material	Unit	Length in metres	Unit price (tl)	Contract sum (tl)	Current unit price (tl)	Current sum (tl)	Increase rate (%)
Ø3800 mm glassfiber-reinforced pipe	Meter	1370	8.750,00	12.075.000,00	52.500,00	71.925.000,00	596
Ø2800 mm glassfiber-reinforced pipe	Meter	1960	6.000,00	11.760.000,00	27.632,05	54.159.170,00	461
(making) 15cm plant mix base layer	Ton	3500	140,00	350.000,00	430,00	1.505.000	430

As it can be seen in Table 1, the prices of different materials used in the work have been increased in different rates. These rates are above the total amounts compared to whether the bulletin or the updated work experience certificate done through EPPP. A summary of information belonging to Investment 1 is given in Table 2.

Table 2. A summary of information belonging to investment.

Job name	Rain water, drain water and road infrastructure works
Bid date	10.11.2017
Bid amount	124.526.945,41 TL
Updated amount according to the bulletin	426.878.368,86 TL
Updated amount according to EPPP	629.881.573,53 TL
Updated amount according to the market conditions	785.277.019,38 TL

Investment 2

The project evaluated under the title of Investment 2 includes the work of the road that is 26 km. long and has different platform width and road top layers in Konya Organized Industrial Zone 4th expansion area. With this project, the last pledged investment of the expansion area has been completed and it is aimed to provide industrial facilities to have modern and permanent transportation.

Within the scope of the investment, totally 210.000 tons of asphalt concrete have been used in bituminous treated base, binder and wearing courses. Moreover, rainwater grates, road strips and pavement regulations in restricted areas have been done.

The approximate cost of road top layer work calculated by the management was 49.000.000,00 TL. It was contracted out for 44.984.350,00 TL on 16.07.2020. The investment was completed on time and was put in service.

When the investment amount is updated through EPPP depending upon the bid date, it is seen that the work experience certificate given to the contractor becomes the value of 143.355.574,68 TL. For this calculation, basic domestic producer price index (ppi) was 485,37 and current index was 1548,01. When this amount is updated with the rate of 2,058 given in 2020 according to the bulletin, the result is 92.536.632,30 TL.

It can be seen that, when items of work in the same project, by keeping the sizes same, is re-calculated according to current market conditions, the approximate cost rises up to 209.627.071 TL. Especially, the high prices of the production including petroleum-derived raw materials such as bitumen can be explained by the increasing prices of global commodity. When this project was contracted out, brent petrol was about 20 dollars and this supports the condition mentioned above. Contract values and current values of some basic materials are given in Table 3.

Table 3. Investment 2, contract values and current values.

Material	Unit	Length in metres	Unit price (tl)	Contract sum (tl)	Current unit price (tl)	Current sum (tl)	Increase rate (%)
Doing bituminous base course work with 11 cm thick pressed asphalt concrete	T	95.000	177,00	16.815.000,00	885,00	84.075.000,00	500

Doing binder layer work with 8 cm thick pressed asphalt concrete	T	70.000	184,50	12.915.000,00	960,00	67.200.000,00	520
Hot mixture wearing course and patch work (with robot)	T	3.000	425,00	1.275.000,00	2.150,00	6.450.000,00	506

As it can be seen in Table 3, with the increase in petrol prices and exchange rates and the increase in prices due to the inflationist atmosphere, road top layers investment has shown a much higher increase than the rates determined in EPPP and the bulletin. A summary of information belonging to Investment 2 is given in Table 4.

Table 4. A summary of information belonging to Investment 2.

Job name	4th part road top layers work
Bid date	16.07.2020
Bid amount	44.984.350,00 TL
Updated amount according to the bulletin	92.536.632,30 TL
Updated amount according to EPPP	143.355.574,68 TL
Updated amount according to the market conditions	209.627.071,00 TL

Investment 3

The project evaluated under the title of Investment 3 includes the work of surrounding walls and parcel walls in order to ensure general security of 160 industrial parcels and the region in Konya Organized Industrial Zone 5th expansion area. Totally, 67.000 metres long walls have been produced in different heights. The approximate cost of the project calculated by the management was 21.000.000,00 TL. It was contracted out for 19.144.451,65 TL on 04.11.2020. The investment was completed on time.

It is seen that, when the work experience certificate that the contractor has deserved updated with current indexes through EPPP, it reached a value of 55.556.018,67 TL. When this amount is re-evaluated with the numbers in the bulletin by the Ministry, it is only 39.399.281,50 TL. However, after the current market researches, it is seen that if the investment was desired to be re-done, the price would become 99.821.682,16 TL.

The increasing costs of energy cost after the COVID 19 pandemic have made the prices of raw materials for concrete much higher compared to the average inflation numbers. The estimated numbers above prove this situation as the work of building walls is a concrete and iron-based production. Contract values and current values of some basic materials are given in Table 5.

Table 5. Investment 3, contract values and current values.

Material	Unit	Length in metres	Unit price (tl)	Contract sum (tl)	Current unit price (tl)	Current sum (tl)	Increase rate (%)
C25 / 30 concrete; pouring with a concrete mixer (sulphate resisting cement product)	M^3	27.000	250,00	6.750.000,00	830,00	22.410.000,00	332
Concrete steel	T	1.200	4.210,00	5.052.000,00	13.600,00	16.320.000,00	323
0-25 mm broken stone filler work	T	112.000	20,00	2.240.000,00	60,00	6.720.000,00	300

Table 6. A summary of information belonging to Investment 3.

Job name	5^{th} part surrounding walls and parcel walls work
Bid date	04.11.2020
Bid amount	19.144.451,65 TL
Updated amount according to the bulletin	29.399.281,50 TL
Updated amount according to EPPP	55.556.018,67 TL
Updated amount according to the market conditions	99.821.682,16 TL

Results

During Covid 19 pandemic, expansionary fiscal policies that are applied by Central Banks in countries not to lower the demand and to sustain their economies has created a demand and supply gap after the pandemic. Taking into consideration of the base effect of energy prices, as they have been rising up in high rates, the world has to come up against the concept of inflation which has been forgotten for a while. As the precautions have been delayed in many developed countries, a price instability has occurred.

Recently, the inflation has been rising up in our country, too. On the date that this study was conducted, the annual consumer price index was 73,50. As it is given in details in the study, the inflation in the construction industry is much higher than this rate.

When the economic conditions in our country is based as an opinion, the construction sector has always been a trigger. As it can be understood from the economic growth performance of Turkey, the construction sector has always become extended relatively more than the average numbers in the country. However, the latest increases in prices affect construction costs negatively and many contractors have difficulty in determining a price for the works they want to bid on. Both in housing and other construction investments, especially within the last year, there has been an uncontrolled increase.

Both public and private investors give their construction investments out by contract and determine certain criteria for their contracts. In this study, one of the most important criteria in these contracts, work experience certificate has been examined and the consistency of the amounts have been questioned. As samples, three different projects with different goods have been chosen. In each project, the amounts of updated work experience certificates have been lower than the current amounts of the investments.

Investment 1 is an infrastructure project. The main entries are reinforced concrete and glassfiber-reinforced pipes. If the contractor of this project wants to use the work experience certificate for other projects in the future, the amount will be 629.881.573,53 TL. However, if the contractor wanted to do the same job again, when the current market conditions are taken into consideration, the amount for that investment would be 785.277.019,38 TL. In this case, it would be impossible for the contractor to bid on a new contract in private sector which requires an exact amount of work experience certificate. The work experience certificates updated through EPPP will be 20% lower than the price determined for a new job, according to the market conditions.

Investment 2 is a road top layer project. However, while examining this investment it should be kept in mind that it was the pandemic year and petrol prices drew back to 20 US dollars. The main entry of the investment is petroleum-derived bitumen and when the work experience certificate has been updated the amount is 143.355.574,68 TL. The same investment can be done for 209.821.682,16 TL with updated prices. Despite the fact that there has been a base effect of the pandemic, the amount of work experience certificate is 32% lower than the current value. In this case, the work on asphalt negatively affects the competence of the contractor.

Investment 3 is the work of surrounding walls and parcel walls. Main entries for the job are furnace materials, mould manufacturing, iron manufacturing, and concrete manufacturing. These headings directly concern the housing industry and are accepted as the main items of

construction works. With the increasing risks due to the Russian-Ukrainian war, the increase in energy prices have made the prices of raw materials in concrete manufacturing rise much higher than the inflation rate. Specific to our country, when the increases in foreign exchange rates have combined with these risks mentioned, the prices of fuel oil have risen up to 300%. This situation has been negatively affecting the manufacture and transportation processes of the materials and the concrete. As a result, the updated amount of the work experience certificate of the contractor has become 55.556.018,67 TL. If the same investment was desired to be re-done, the cost would be 99.821.682,16 TL. As it can be understood from the numbers, the value of work experience certificate is 44% lower than the current amount.

Considering the evaluations above, it is seen that work experience certificates do not reflect the real competences of the contractors. In this case, for the contractors, an offer opportunity for new contracts is negatively affected.

As the amount of work experience certificates vary from the market conditions, building contractors have an obstacle to grow their extend of work. If the global inflationist atmosphere becomes permanent, the approximate costs that are calculated by the managements will increase more compared to the value of work experience certificates, and the number of volunteer contractors will be lower in time.

Several precautions must be taken in order to prevent this. Firstly, it can be suggested that a different platform might be prepared to update work experience certificates not according to domestic producer price index but according to differential index. Indexes should be determined according to similar work groups and the certificates should be updated according to them. As a result, in an atmosphere where the prices of concrete become much higher than the prices of bitumen, a job that includes concrete as a main entry should have a higher updating rate.

Secondly, it can also be suggested that until this inflationist atmosphere becomes an end, the managements might reduce their demand about work experience certificate rates. As a result, the contractors will have the right to bid on more works with their current certificates, and they will have the chance to own new certificates. It is assumed that, the second suggestion is easier, faster and more applicable because to prepare the substructure will be quicker.

Abstract

Subcontracting has become a frequently used position in the construction industry to work on projects in a more organized manner, to create new employment for different groups or individuals, to share risks and to complete work in a limited time frame. Administrative situations and problems related to subcontracting should be well identified in order to establish and manage organizations such as tender, contract and execution between main contractor (MC) and subcontractor (SC). This literature review was carried out with the aim of researching and bringing together the studies related to SC management in recent years and to serve as a guide for researchers. In line with this goal, the studies encountered in the literature related to the SC management side of the managerial issues between the MC and SC were examined. The studies were categorized under six groups as follows; 'subcontracting practices in construction', 'general subcontractor management' 'evaluation and selection processes', 'collaboration with main contractor', 'subcontractor performance appraisal on-site' and 'subcontractor risk management'. 'Evaluation-selection processes' came first among the subjects that the researchers focused more on, it was determined that there are still few studies and the subject that needs more research and study is 'Subcontractor performance appraisal on-site'.

Keywords: *Subcontracting, subcontractor management, selection, evaluation, performance appraisal*

Introduction

Subcontracting in the construction industry has become an increasing need or habit with each passing year. MCs divide the entire work they receive from the employer into parts and have others undertake these parts, both reducing the workload and sharing the risks. The use of SCs has been adopted in the construction sector, which requires special expertise, has large-scale costs and requires advanced equipment. (Yoke-Lian et al, 2012) Selecting SCs, making contracts, managing them, managing their relationships, maintaining their organization can be the summary of a project's success or failure.

Certain responsibilities fall on both MCs and SCs for the common good of the project. The main success factors in a project can be listed as mutual trust of the parties, transparency, well-defined scope of work, clear definition of responsibilities and cooperation. The success of a project in which many SCs will work together will emerge as a product of joint effort. In the construction industry, where cooperation is very important, trust, loyalty and reliability are the factors that ensure cooperation. (Deep et al, 2019) Trust-based relationships allow for better teamwork, which is believed to increase productivity. (Chalker and Loosemore, 2015) Relationships between MCs and SCs are one of the types of relationships that are affected by issues that can create situations of distrust. (Manu et al, 2015) If the relations between MCs and SCs are not managed properly, the performance of construction projects is directly or indirectly affected negatively, and the relations between these parties become more and more important in achieving the desired goals of the construction projects. (Tan et al, 2017)

Although formal commitment is established with the contracts, it is desired that the project be carried out at the desired standards with a more effective cooperation between the SC and the MC. While subcontracting and SC management is so important for the construction industry, there has been a need for continuous research on this subject. The aim of this study is to identify trend SC management studies in recent years and to identify gaps in this subject. With this literature review carried out for this purpose, the study areas were determined and the study densities were shown.

Methodology

An in-depth literature review was conducted to gain a comprehensive insight into the SC management researches in construction industry. This literature review was carried out using Google Scholar and Scopus databases. By examining the studies on the topic of SC management, especially the last 15 years (2006-2021), it is aimed to reduce it to a more understandable level by categorizing the subjects related to SC management, which can be a guide for researchers who want to do research. Studies related to SC management, with the keywords 'subcontracting', 'Subcontractor', 'Subcontractor management', 'Subcontractor performance evaluation', 'Subcontractor selection', 'on-site subcontractor performance', searched and investigated. 322 documents that may be relevant to the subject were examined. Afterwards, the titles and abstracts of the studies were checked and elimination was carried out. A total of 62 documents were examined in depth through this scan. By examining these studies, trend researches in SC management were categorized in six different groups. The number of documents of each group is written and their percentages in the total studies are shown.

The Research Trends on Subcontractor Management

This literature research is based on the concept of subcontracting in the construction sector and was conducted on the question of which dimensions or areas of subcontracting have been carried out. As a result of the studies examined, when we group the subcontracting studies in the construction sector in the literature, the following titles are formed: ’Subcontracting practices in construction’, ’general subcontractor management’, ’subcontractor evaluation and selection processes’, ’collaboration with main contractor’, ’subcontractor performance appraisal on-site’, and ‘subcontractor risk management.’

Subcontracting Practices in Construction

In the construction industry, the subcontracting system is a common practice dating back to ancient times. (Sun et al, 2020). When this is the case, it is necessary to have a good grasp of the definition of subcontracting. According to Abdullahi (2014), a SC is a person or a commercial firm that is contractually agreed with him/her to fulfill some or all of the obligations of the contracts of another person or firm.

After thoroughly adopting the definition of subcontracting, we can talk about its practices in the construction sector. Memili et al. (2011) compare the management preferences of family and non-family companies according to their subcontracting tendencies. Yoke-Lian et al. (2012) conducted a literature review on the types of SCs, the problems posed by SCs, and current methods proposed to improve subcontracting practice, and indicated that the success of a construction project depends on the MCs ability to select the appropriate SC during the bidding process and the proper management of the SC during construction. Lew et al. (2020) conducted a study to investigate the multi-layered subcontracting practice in the Malaysian construction industry, to identify the problems arising from this type of subcontracting system, and to identify methods for improving quality performance.

General Subcontractor Management

By keeping the SC potential wide in the works, the contractors want to complete the projects in the desired time and share their responsibilities. While they share most responsibilities and risks with SCs, managing, administering and monitoring them is an important management or business area. It is obvious that problems may arise in any subject in a construction site or project, as well as problems related to SC management. It has been seen that building information modeling (BIM), which has been used for a long time and its use is increasing rapidly, with the inclusion of developing information technologies in the construction sector, is also used in the field of SC management. Gurevich and Sacks (2014) created a BIM-based information system to be used in the task selection of SCs and worked on a system that shows processes accurately and reliably.

In the researches, it is seen that the SC management policies are examined and there are studies that are of a developmental nature. Biruk et al. (2017) stated that previous researches dealt with SC management and planning separately and aimed to create a decision support mechanism that integrates the steps of SC selection, coordination and determination of the appropriate division of labor with timing. Akinwale and Olusanya (2020) examined the impact of contracting and working processes with SCs in Nigeria on wages and workloads. They have determined that wages and workloads are not suitable, especially by making evaluations on the basis of workers.

Collaboration with Main Contractor

In a construction project, the MC is both a responsibility to the customer/employer and is obliged to manage the SCs. The construction market, which is an environment where relations can deteriorate quickly or very successful projects can be produced with good relations, can easily be affected positively or negatively by MC-SC relations. Manu et al. (2015) by dealing

with the issue of trust in the MC-SC relations in projects, examines the factors affecting this situation, which is of great importance in terms of relations in projects. A healthy cooperation in projects creates power in the project. Therefore, in cases where cooperation weakens, the execution of the project becomes more and more difficult.

According to Mudzvokorwa et al. (2020), with the increasing need for and dependence on SCs in the construction industry, improving the operational relationship between MCs and SCs increases the probability of the project's success and the overall project performance. Korb and Sacks (2020), by developing a simulation, conducted a study based on the relationships between the main and SCs on how to direct the control strategies of the MCs and the labor resources of the SCs. In order for a harmonious relationship to be established, relationship types must be defined and adopted. For this, Tan et al. (2017) in their research examining the relationships between MC-SC based on a survey study, named the types of relationships and divided them into four groups as oppositional, competitive, collaborative and partner.

Subcontractor Evaluation and Selection Processes

Researchers have often emphasized that SC selection is the most important and first step in SC management in a project. Prior performance data is usually taken into account when making this selection. It is desired by everyone to have a fair selection that will provide more objective results for the selection of SCs, and will provide profit in terms of cost, time and quality. Many different decision support systems have been proposed by researchers from past to present that facilitate the decision-making of MCs. Ko et al (2007) conducted a study aimed at improving existing practices to evaluate the performance of SCs. The appropriateness of adopting the Evolutionary Fuzzy Neural Inference Model (EFNIM) to ameliorate the disadvantages was examined.

In the SC selection model that Ulubeyli and Kazaz (2016) developed, it has been seen that it can be used as a consultation system for MCs to reduce the risk in the selection of SCs. In this model, it is aimed to understand the MC's strong and weak points of each bidder, and as a result, to make informed and correct decisions. Abbasianjahromi et al. (2014) in their research, found that previous studies evaluated the selection of SCs on the basis of criteria, but did not consider the number of tasks assigned to SCs. Considering this situation, they proposed a hybrid model applying the continuous ant colony and fuzzy set theory.

In the construction sector, where costs are at the forefront, the price offers they give when choosing a SC often precede their other features. Polat (2016) stated that MCs generally tend to choose SCs that offer the lowest bid price, and that working with unqualified and underfunded SCs can lead to inefficiencies and failures. For this reason, it proposes a decision approach in which AHP and PROMETHEE are used together, which considers the financial capacities and qualifications of the SCs in the SC selection process. Shivam and Khasiyani (2018) developed a conceptual model for SC selection in different construction projects by proposing an integrated decision approach that uses the relative importance index (RII) for the SC selection issue and the preference ranking organization method for enrichment assessments (PROMETHEE). Keshavarz-Ghorabaee et al. (2018) have proposed a new approach by defining the SC evaluation process as a dynamic multi-criteria group decision-making problem. This is designed based on the EDAS method, which is a new and efficient MCDM approach. Koçak et al. (2018) have adopted an approach to create a new alternative to

SC selection with the Additive Ratio Assessment Method, which is one of the multi-criteria decision-making techniques that can be more scientific, instead of traditional practices in the construction industry.

The MCs need to set out with the right strategies in order for the works in the project to go well, and as the first step of this, they should pay attention to the selection of the appropriate SCs. Nov and Peansupap (2020) stated that the MCs have wrong practices in selecting SCs. Thereupon, they developed a new model using artificial neural networks to determine the type of relationship between main and SC. Vo et al. (2021) presented an overview to assist MCs by presenting a study targeting the development of appropriate SC evaluation and selection factors in their projects in the construction industry. Karaman and Sandal (2021) aimed to develop a selection criteria model that could contribute to the pre-qualification conditions for SCs in the future SC selection process and to measure their impact on project success.

Subcontractor Performance Appraisal On-Site

The literature reviewed is mostly on the measurement of performance in the bidding period and the selection of SCs according to this performance. There are deficiencies in measuring and evaluating the performance of SCs during construction execution. NG and Tang (2008) have defined performance evaluation criteria that will form the basis for the development of a new SC performance evaluation system and facilitate the viewing and comparison of performances. NG and Skitmore (2014) then propose an approach to develop a balanced scorecard SC evaluation model through a survey study in which baseline and target performance levels are determined for large-scale skilled SCs. Yang et al. (2015) in their research based on the concept of Total Quality Management, focused on the performance evaluations of employees and SCs. Chamara et al. (2015) by investigating the performance of SCs in the project in terms of time, cost and quality, which are crucial issues in the sector, aimed to bring their current performance to the desired levels. With the right organization, the difficulty level of managing multiple SCs involved in a project can be reduced. In this context, MCs have important duties. MCs should consider how to develop different relationships with different SCs and how to protect cooperating SCs for the success of the project. (Tan et al. 2017) For this, SCs can contribute to the project by developing a dynamic and effective management model with continuous performance evaluations during the construction process.

Subcontractor Risk Management

Risk identification before and during the project lifecycle can significantly determine the success of project risk management. (Wu et al, 2017) The management of the identified risks is also one of the situations that requires an organization or a new management style in itself. While most of the works are transferred to SCs, their performance in the project is very important in terms of achieving the desired quality. Many construction projects either fail to meet deadlines or exceed the budget allocated for the project. (Maria Krechowicz, 2017) MCs have to manage a significant risk in terms of the success of the project, depending on the performance of the SCs in these matters. As it is known, construction projects are complex structures in which many SCs work together or in different time periods. It is risky to predict the future with the previous data of the SC. In this regard, Cheng (2016) has also considered risk assessments to improve the accuracy of the estimates of the possible performances of SCs

before starting the construction phase of a project. While creating products in construction projects, the effects of risks on quality performances are one of the most important issues to be considered. Adinyira et al. (2020) have published their study aiming to examine the impact of the management of risks arising from the use of SCs on the quality performance of building construction projects.

Results

Table 1 provides information about the authors, years and frequency of the documents. Accordingly, it has been observed that the researches carried out by the researchers with the help of different methods on the selection of SCs at the bidding stage are intense. The importance of selecting the appropriate SC has been frequently mentioned by the authors in general. While the studies in other groups were close to each other, it was understood that attention was paid to the studies showing the importance of cooperation between MC and SC. For MCs in construction projects, the success of the SC while the current work is in progress is critical, but this issue has not been mentioned very often in the literature.

Table 1. Summary table of the subcontractor management topics, authors, years and frequency

Subcontractor Management in Constructıon	The Authors' Researches on Subcontractor Management Between 2006-2021	Frequency
Subcontracting practices in construction	Yoke-Lian et al. (2012), Choudhry et al. (2012), Abdullahi A.H. (2014), Lew et al. (2020), Rostiyanti et al. (2020), Memili et al. (2021)	6/62 (%9,70)
General subcontractor management	Flynn C.J. (2008), Thomas and Flyinn (2011), Gurevich and Sacks (2014), Biruk et al. (2017), Jazayeri et al. (2018), Mambwe et al. (2020), Akinwale and Olusanya (2020)	7/62 (%11,30)
Collaboration with main contractor	Wood and Ellis (2005), White and Marasini (2014) Loosemore (2014), Manu et al. (2015), Chalker and Loosemore (2016), Liu et al. (2017), Tan et al. (2017), Adeyekun (2019), Fagbenle et al. (2018) Deep et al. (2019), Mudzvokorwa et al. (2020), Korb and Sacks (2021),	12/62 (%19,40)

Subcontractor evaluation and selection processes	Ko et al. (2007), Hartmann and Caerteling (2010), Fagbenle et al. (2011), Abbasianjahromi et al. (2013), Cheng and Huang (2012), El-Kholy (2019), Ulubeyli and Kazaz (2016), Marzouk et al. (2013), Abbasianjahromi et al. (2014), Shahvand et al. (2016), Polat (2016), Basu et al. (2017), Abbasianjahromi et al. (2018), Shivam and Khasiyani (2018), Keshavarz-Ghorabaee et al. (2018), Kocak et al. (2018), Palha et al. (2019), El-khalek et al. (2019), Nov and Peansupap (2020), Abdullah et al. (2021), Afshar et al. (2020), Vo et al. (2021), Karaman and Sandal (2021)	23/62 (%37,00)
Subcontractor performance appraisal on-site	NG, (2007), NG and Tang (2008), NG (2010), NG and Skitmore (2014), Yang et al. (2015), Chamara et al., (2015), Tesha and Luvara (2017), Poovitha et al. (2018)	8/62 (%12,90)
Subcontractor risk management	Krechowicz (2017), Arrto et al. (2008), Cheng (2016), Wu et al. (2017) Artan İlter and Bakioğlu (2018), Adinyira et al. (2020)	6/62 (%9,70)

Conclusion

This research has been prepared to examine the development of studies on SC management in recent years. The administrative issues of the MCs on the SCs were categorized and the studies were divided into different groups. When this categorization is examined, it is seen that much more attention has been paid to the 'evaluation and selection processes'. Considering the needs of the sector, the evaluation of SCs before they are employed in the project and the selection processes within the framework of the selection criteria will provide an environment where the risks are reduced for the MCs in the following processes. In this context, the subject that the literature focuses on more frequently has taken shape in line with the needs of the sector. On the other hand, establishing a SC performance appraisal process by measuring the performance of the SCs on-site and making the necessary evaluations according to these data during the project implementation phase will again have positive results for the MCs. However, the issue of performance measurement and evaluations in on-site has not attracted much attention in the literature. It is thought that future work will be carried out in this direction.

Organizational and Team Resilience: Construction Industry Survival in the Pandemic Crisis

E. Köseoğlu and S. Ergönül
Mimar Sinan Fine Arts University, Department of Architecture, Istanbul, Turkey
emrekoseoglu33@gmail.com, sema.ergonul@msgsu.edu.tr

Abstract

Organizations have to navigate difficult, uncertain, rapidly changing times of crisis. They need resilience capacities to survive in uncertain environments, bounce back from crises, adapt to change, and foster future success. Organizations have been structured more team-based lately. Therefore, understanding and developing the contribution of team resilience to organizational success is important for the organization to move forward. Organizational and team-level resilience supports organizations' development towards success beyond surviving in challenging times. With the outbreak of the COVID-19 pandemic, many industries faced an unexpected crisis and uncertainty. The construction industry and organizations have also been significantly affected by the challenges posed by the pandemic. Many construction companies have had difficulties in business continuity due to quarantines. In this changing and uncertain adversity, teams had to change the way they do business and faced many difficulties in maintaining their performance. Therefore, building organizational and team resilience is vital for organizations' business continuity and future success in a pandemic such as the COVID-19 pandemic. This paper aims to examine organizational resilience and focus on team resilience to encourage organizations to build resilience in the face of crises such as the pandemic.

Keywords: *construction industry, COVID-19, organizational resilience, pandemic, team resilience.*

Introduction

It is not new for people to work together as a group to increase their odds of survival. Teams consist of individuals who are interconnected and have common goals (Salas et al., 2015). As the complexity of the work increases, utilizing teams in most sectors is becoming widespread. Teams provide more potential in the face of complexity, both by enabling efficiency and creativity for organizations and by dividing responsibility and decision-making among their members (Conti & Kleiner, 1997). Teamwork reduces the need for coordination and simplifies the organizational structure. Moreover, teamwork can improve productivity and lead to lower costs over time. Team members can share experiences and knowledge with each other as a learning opportunity, which can increase the team's overall creativity. However, not every industry may have effective teamwork due to its own obstacles since efficient teamwork depends on management structure, leadership styles, and organizational flexibility (Tarricone & Luca, 2002). Teamwork efficiency in the construction industry is not high as the

productivity in the effort put into the construction industry and the resulting product value is low. The construction industry mainly focuses on technical skills such as the iron triangle of time, cost, and quality to achieve project success. Moreover, the social skills in teamwork and resilience are neglected in the project success because the projects heavily focus on the factors such as low bid prices, which creates fragmented teams and results in poor team performance in the industry. Due to the nature of the industry, construction project teams are usually assembled at the project location, sometimes with local individuals, for a certain amount of time. Teaming up people who may have never met before and putting project responsibilities on the team can be problematic and come with challenges.

Projects are becoming more and more complex and challenging, requiring the ability to deal with challenges at the individual, team, and organizational levels (Varajao et al., 2020). In recent years, a lot of research has been done on resilience in management and business. One of the meanings of resilience is the ability of the system back to its original state (or to adjust itself to the new state according to the new situational demand) from an adverse event (Xue et al., 2018). Although some researchers argue that resilience is a process that ultimately leads to resilient results, it is the process of how organizations react when facing adversities to achieve resilient results (Hillmann & Guenther, 2021). Organizational resilience includes the organization's ability to face adversities, maintain its sustainability, and move forward on track with its future goals (Bui et al., 2019). However, construction projects are open to being affected by external factors, have uncertainties, and the risk is high, which makes them complex. Therefore, construction organizations need to be resilient in order to provide stability and survive in a competitive environment. Since organizations have been structured more team-based lately, resilience has become a team-level concept rather than being an individual-level capacity. Moreover, teams are implemented in organizations with their strengths as well as their weaknesses, thus team resilience can affect organizational resilience. In order to achieve organizational resilience, its teams as units can be investigated by focusing on team resilience and on strategies to develop team resilience.

Organizations operate in a dynamic environment, yet, with the development of technology, the global economy is now inevitably more volatile, uncertain, complex, and competitive. Internal and external factors such as weather, geopolitics, pandemic outbreaks, scientific and technological innovation, and other non-human factors lead to “black swan” and “grey rhino” incidents more frequently and affected global business (Liang & Cao, 2021). Most recently, the sudden outbreak of the Covid-19 pandemic has affected the global economy more than any other crisis in the history of mankind.

Apart from concerning health issues, the Covid-19 pandemic forced lockdown all over the world, which caused economic shutdowns and heavy losses. Since the construction sector was interdependent with many sectors both directly and indirectly, the industry has been one of the sectors most affected by the pandemic. Global restrictions caused supply chain issues, delays in activities, revenue losses, increased cost of construction outputs, contractual issues, and many other issues (Assaad & El-adaway, 2021). Therefore, the industry had to absorb these financial shocks just like every other business. However, while other sectors can develop innovations with modern managerial methods after the crises, the construction sector lags these developments. Remote teams have been used in many sectors for years, but the Covid-19 pandemic has globally required organizations to adopt them for self-isolation purposes. Therefore, the development of remote collaboration has made teamwork in the construction industry more complex.

The construction industry suffers from tight timeframes, task complexities, poor working environments, complex business relationships, poor teamwork, and other factors. This paper aims to explore how the Covid-19 epidemic affects teamwork in the construction industry and emphasize the importance of organizational and team resilience. In this context, it is hoped that this study will increase awareness of the subject by revealing the importance of effective teamwork and developing organizational and team resilience in the industry.

COVID-19 Pandemic and Construction Industry

In December 2019, in Wuhan (China), the epidemic started and has been a major global threat to human health. As of 11 March 2020, The World Health Organization (WHO) announced this outbreak as a pandemic (Sierra, 2021). Since the disease can be transmitted by respiratory droplets in direct contact with the mouth, nose, or eyes and by direct contact with infected people or indirect contact with infected surfaces, containment measures introduced have included recommending people stay at home and quarantining outbreaks regions (Pirzadeh & Lingard, 2021). Therefore, most governments around the world have enforced strict lockdowns, including restricting people's movements and gatherings, to decrease the spreading of the virus (Sierra, 2021). Both human health and the operational health of businesses were affected because of the pandemic. Work health and safety issues have also become a challenge for organizations and industries to carry on business operations during the pandemic (Caligiuri et al., 2020). Governments and employers have encouraged workers to work at home (also can be referred to as teleworking). Moreover, 88% of worldwide organizations implemented home-based work according to the survey that 800 globally leading human resources attended (Pirzadeh & Lingard, 2021). However, dramatically decreased demands and production have impacted most sectors of the economy. Covid-19 has had major effects on the global economy through forced lockdowns and economic shutdowns - beyond easy recovery (Ogunnusi et al., 2021). For instance, the US economic activities by GDP have shrunk by 5% in the first quarter, and 32% in the second quarter of 2020 resulting in one of the most severe economic shocks in modern times (Meyer et al., 2022). The construction industry was not immune to the impacts of the pandemic either and had to absorb these financial shocks just like every other business.

The construction industry is one of the biggest industries in the world and it makes for about 13% of the global gross domestic product (GDP) (Biorck et al., 2020). Moreover, the construction sector has relationships with many sectors both directly and indirectly. Therefore, the construction industry is considered an important operator of economies (Assaad & El-adaway, 2021). Even without Covid-19, the construction sector has always been battling time and cost overruns as one of the major setbacks (Ogunnusi et al., 2020). With the restrictions, as in most industries, many construction projects also stopped. Being behind schedule and the exceeding costs of idling equipment made it an expensive issue for the sector (Alkhalouf, 2020). Due to supply chain issues, delays in planning, operational restrictions, and inspections the construction industry was affected heavily by the coronavirus (Biorck et al., 2020). While the sector was being affected by restrictions, many companies were facing collapse and going out of business and some of them resumed working with disrupted workflow. For instance, construction organizations had to either shut down both domestic and/or international sites or continue their projects at a lower capacity resulting in labor, material, and equipment supply issues (Chih et al., 2022). According to the survey conducted by Build UK on behalf of the Construction Leadership Council, from September 2020, the construction company would most likely face a 7.7% reduction in the workforce

while the industry anticipates a 26.7% decrease in agency workers and self-employed (Ogunnusi et al., 2020). Since all these issues such as unemployment and downsizing in organizations are interconnected and have led to a lack of cash, manpower, and resources in general, it created a chain of delays, loss of labor productivity, and contractual issues (Assaad & El-adaway, 2021). Due to the pandemic, the construction industry was not able to adopt telecommuting as easily as other sectors to lessen the safety issues without disrupting productivity (Al-Mhdawi et al., 2022). Furthermore, the construction sector in developing countries was more vulnerable to the challenges caused by the pandemic. Due to financial issues such as rising exchange rates, inflation, fluctuations in material costs, and escalated interest rates the negative effects of the pandemic were more significant in developing countries (Al-Mhdawi et al., 2022).

With the pandemic, it is important for the construction industry to address the challenges in many ways. According to Assaad and El-adaway (2021), the pandemic has many future research areas and one of them could be the implications of teamwork during the pandemic. Moreover, the significance of the organizational context for psychological factors concerning their connection to teamwork can be identified as a subject for future research (Rasmussen & Jeppesen, 2006).

Teamwork Challenges in Pandemic Era

Construction industry workers face many difficulties in teamwork. They were faced with new teamwork challenges with the pandemic. The challenges experienced by teams during the pandemic process can be grouped under the following headings.

Workplace Loneliness

With the implementation of restrictions, many employees, including project-based construction professionals and managers started working from home for self-isolation purposes - creating virtual teams. Therefore, employees are removed from their colleagues hence, their social life at work. During the Covid-19 pandemic, workers may have been impacted negatively by the lack of social interaction and connections through work. Some level of social interaction with co-workers is necessary for almost all jobs. Although utilizing virtual teams through teleworking has been operating for decades, one of the main disadvantages of virtual teams is the lack of physical interactions since the lack of these interactions may create the feeling of isolation and being left out (Kirkman et al., 2002). Moreover, teleworkers feel lonelier, worried, and guilty compared to their office-working colleagues (Mann & Holdsworth, 2003).

Disturbed Life-Work Balance

The adaption of digital technologies has made it possible to use time more efficiently and productively, yet reduced social engagement has also impacted individuals' work and life balance (Lingard et al., 2021). It is reported that social isolation causes psychological issues and reduces the satisfaction of the job among people who work from home (Bentley et al., 2016). Similarly, it is also reported that increased stress which related to social isolation such as not being able to separate work from family, or ending up working longer hours (Montreuil

& Lippel, 2003). For example, according to a survey of 436 teleworkers in Lithuania during the COVID-19 pandemic, the difficulties of new ways of working remotely impacted some employees negatively in terms of self-organization and separating work from personal life (Raišienė et al., 2020). In addition to the challenges of working from home, some construction professionals also may choose to work even though they should be resting (Ogunnusi et al., 2021).

Reduced Engagement

Conventionally, it can be thought that teams that work face-to-face are more productive and satisfied compared to virtual teams that have feelings of isolation and disengagement towards their job (Ogunnusi et al., 2021). Adopting remote working to utilize remote meetings or enabling remote site inspections are beneficial for many construction organizations (Lingard et al., 2021). However, along with the benefits of home-based teleworking for individuals and organizations, the negative aspects are sometimes overlooked. For instance, it is reported that home-based teleworkers in the US experience less social support and increased uncertainty about their roles at work (Pirzadeh & Lingard, 2021). As a part of the negative impacts of Covid-19 on the construction industry, some people working home-based reported that they did not have enough space at home and due to distractions at home, had challenges focusing on their work (Ogunnusi et al., 2021).

Lack of Communication

Sharing knowledge, coordination and communications are the keys to expecting the effectiveness of the team, therefore, in virtual teams, the coordination decreases as it is harder to communicate (Garro-Abarca et al., 2021). Decreasing social interactions may result in reduced commitment and performance. Lack of direct communication with managers and team members due to virtuality, in general, may cause confusion, miscommunication, and uncertainty among team members (Raišienė et al., 2020).

Lack of Trust

Trust provides stronger leadership, communication, and cohesion to the teams. Therefore, it can be considered that trust has one of the most important roles especially in increasing virtuality because of the Covid-19 pandemic (Garro-Abarca et al., 2021). In the creation of successful virtual teams and organizations, building trust can be the greatest challenge, therefore, barriers such as traditional attitudes are needed to be transformed into thinking cooperatively (Kumaraswamy et al., 2005). The level of trust among teams working remotely is generally lower compared to ones who work face-to-face (Raišienė et al., 2020). With reduced communication with social isolation, some challenges may arise such as concerns and jealousy among employees which may lead to mistrust (Bentley et al., 2016). Moreover, lack of trust becomes an issue in the execution of work effectively for teams. Many organizations require constant social interactions to build trust which virtuality eliminates (Raišienė et al., 2020). However, trust within teams can be built when people deliver what they promised and meet the results.

Overwork

Some studies show that working remotely is more beneficial for employers than for employees because it requires teleworkers to put more hours and effort beyond normal office working hours (Pirzadeh & Lingard, 2021). According to the study of Covid-19 effects on the UK construction, reduced workforce on-site affected schedules, and required employees to manage sites without a margin of error, thus, increasing working stress among employees. Moreover, conditions like these increased the risk of fatigue from overworking and negatively affected well-being (Jones et al. 2020). Even though online interactions may reduce teleworkers' feelings of isolation, overworking remotely and constant communication due to limited other social activities because of Covid-19 may also cause individuals to spend too much time at work (Pirzadeh & Lingard, 2021). In addition, teleworkers may experience being 'out of sight, out of mind' and concerned about opportunities they may miss, which can lead to overworking more to impress managers among other employees (Bentley et al., 2016).

Organizational Resilience

The word “resilience” comes from the Latin word “resilire” which can be characterized as the capacity to recover rapidly from troublesome and possibly hurtful circumstances (Xue et al., 2018). Resilience is based on "bouncing back" from the stressful experiences people gain throughout their lives (APA, 2013). Moreover, the idea of resilience can be applied to any functional system (Turner et al., 2017). When the resilience concept is applied to society, it becomes defined as being able to protect itself from harmful events such as wars, natural disasters, or revolutions (Vale & Campanella, 2005). In an economic concept, resilience means the ability of a business organization to be able to endure risks and seize opportunities even in unfortunate events (Delli Carri, 2019). Therefore, over time, the concept of "organizational resilience" has been studied as a characteristic of the organization to cope with internal or external shocks arising from disturbances and unexpected situations in the organization (Bui et al, 2019).

The main definition of organizational resilience is described as the organization's ability to recover from hardships or challenging events, by responding to endangering situations (Varajao et al., 2021). Moreover, this ability not only includes the organization to endure challenging circumstances but also bounce back from them to continue staying on track for its needed future objectives safely (Fleming, 2012).

From the perspective of human resources, the main objectives for a resilient organization are to be flexible, agile, and dynamic, thus, to have a better chance to survive against external factors mostly arising from the competition (Bui et al, 2019). From another perspective, organizational resilience can be described not only as bouncing back from unexpected challenges but also as an opportunity to absorb adverse situations and enabling organizations to exploit more opportunities for the future (Lengnick-Hall et al., 2011). Bouncing back definitions assume a single desirable outcome for resilient organizations. However, if crisis situations are considered a cascading process, the organization must be able to evolve by constantly responding to challenges (Darkow, 2019).

Organizational resilience is generally thought of as being able to anticipate risks and avoid potential difficulties. However, for practicality, it may be simpler to develop immunity by confronting what has happened before than to avoid risks that are unlikely to happen - perhaps

never happen (Andersson et al., 2019). Additionally, an organization may try to expect possible future risks, however, these anticipations may cause a weakness towards other unpredicted circumstances (Hillmann & Guenther, 2021).

Having resilient systems that are both strong and able to adapt quickly simultaneously brings a paradox to organizational resilience (Zolli & Healy, 2012). This means needing high-quality operations without requiring too many resources as well as balancing between planning long-term development and short-term effectiveness of operations (Andersson et al., 2019). Thus, structural efficiency issues come from rigidness problems that resilient organizations have to deal with (Linnenluecke et al., 2012).

Organizations have been structured more team-based lately (Hollenbeck et al., 2012). Thus, resilience has become a team-level concept, not only by managing the challenges effectively but also by enabling teams to adapt to adversity and manage pressures, rather than being an individual-level capacity (Hartwig et al., 2020). For the success of the organization, it is of great importance to investigate its units - teams, and how they work, process, and learn (Rodríguez-Sánchez & Perea, 2015).

Team Resilience

Team resilience can be defined as the capacity of a team to cope with difficulties, absorb them, and maintain positivity against challenges (Carmeli et al., 2013). From one perspective, when team resilience is defined as being able to cope with difficulties, it is considered an observable ability only in the face of difficulties and can be studied in the post-difficulty phase (Hartwig et al., 2020). However, from another perspective, team resilience can actually be defined as a dynamic process in which adversities are effectively overcome continuously (Morgan et al., 2013).

As projects become more complex day by day and their degree of adversity increases, it becomes necessary to cope with these mostly environmental challenges on an individual, team, and even organizational level (Morcov et al., 2020). Due to these increasing complexities, projects require more teamwork and the roles of teams in organizations are becoming more important (Amaral et al., 2015). Teams are included in organizations with their strengths and weaknesses. Therefore, the decisions of the organization can directly affect the resilience of the team (Rodríguez-Sánchez & Perea, 2015). With the help of resilient thinking, managers can improve performance and reliability through flexible and systematic approaches to challenges. Moreover, they can provide stability by solving problems by creating new conditions (Varajao et al., 2020).

According to researchers, the presence of only resilient individuals in the team is not enough to create a resilient team (Hartwig et al., 2020). Having a resilience capacity does not necessarily mean having a resilience capability (Lengnick-Hall et al., 2011). In other words, a group of individuals with high resilience may not be able to cope with adverse conditions or communicate effectively in an organized manner as they should (McEwen & Boyd, 2018). Therefore, in order to develop team resilience, it is necessary to provide individuals with a team structure that has common rules and values, transformative leadership, and is in constant interaction with each other, even in unexpected times of difficulty (Morgan et al., 2015). Resilience in challenging situations can be achieved with a team with common goals, interdependence, and result-oriented work (Hartwig et al., 2020).

Just like the behavior of individuals, teams have similar behavior and working systems (Stewart, 2010). Teams, like individuals, have knowledge of what they think, skills about what they do, and attitudes about how they feel. Moreover, they can be adversely affected in times of stress even though the negativities are on an individual basis, their effects will be reflected in the team's functioning (Dietz et al., 2017). It is important for teams to develop their resilience, as well as individuals, against adverse situations. For example, employees in a more resourceful work environment (such as supportive co-workers) increase their own resilience. This suggests that the quality of relationships is important for team resilience (Meneghel et al., 2016). In addition, while resilience reduces psychological stress, it has the effect of increasing task performance and job engagement (Hartwig et al., 2020). Strategies are factors that help develop resilience, moreover, it is necessary to understand the skills and support for building resilience required (Holdsworth et al., 2019).

Conclusion

The construction sector, which is one of the largest sectors affecting the economy of countries, is prone to be adversely affected by unexpected events. It is crucial for construction organizations to develop resilience to the unexpected. This paper emphasized the significance of team resilience in improving the resilience of construction organizations against unexpected situations such as Covid-19.

The Covid-19 outbreak has adversely affected construction organizations. It has made it compulsory for the sector to switch to working conditions that it is not accustomed to. This necessity has changed the way teams in construction organizations work and has faced many difficulties. The challenges were grouped as workplace loneliness, disturbed life-work balance, reduced engagement towards work, lack of communication, lack of trust, lack of motivation, and overwork. These challenges highlighted the importance of building resilience at the team level. Team resilience enables individuals in the team to cope with difficulties, absorb them and maintain a positive attitude at the same time. Thus, the difficulties caused by Covid-19 can be overcome and the resilience of the organization can be ensured. Therefore, it becomes important to promote the development of team-level resilience to increase the resilience of organizations.

Abstract

Construction business executives, like any other business executives, make various types of decisions. The concept of decision making has been a popular research topic for decades. There is no evidence that this interest will decrease in years to come. The question of why business executives are making again, and again poor or wrong decisions has been fully resolved. The concept of overconfident behavior is considered one of the most promising approaches to address this challenging question. The concept of overconfident behavior refers to a biased way of acting at a given situation. Overconfident behavior may have positive or negative performance outcomes. It becomes more apparent when construction business executives have to make decisions under the conditions of "low control" and "relative performance". The research presented here proposes a conceptual model to guide construction business executive to address the challenge of decision making. The proposed model builds on concepts of "overconfident behavior", "low control" and "relative performance".

Keywords: *low control, overconfidence, overconfident behavior, relative performance.*

Introduction

Construction business executives, like any other business executives, make different kind of decisions as a part of their routine managerial activities. These decisions can have important consequences not only for their organization but also for the whole construction industry. It is very common to observe unfavorable results of these decisions. Studies of the psychology area have been developing explanations to explain unfavorable behaviors in the decision-making process. Pioneering studies, such as Simon (1955) and Tversky and Kahneman (1973), introduced a number of path breaking concepts such as 'bounded rationality' or 'heuristics' respectively, to study decision making process.

One of the commonly known decision-making heuristics is overconfidence. Overconfidence is a broad term which refer to mention irrational behaviors causing high levels of confidence which is not parallel with reality (Moore & Schatz, 2017). It is a very ordinary to observe

overconfident behaviors in daily life. For instance, many people believe that they are better drivers than other drivers. Likewise, students reason their failures as a result of the subjectivity of lecturers.

Overconfidence as a concept and as a term is widely used in decision making studies to cover a variety of irrational behaviors. However, overconfidence is not a single unitary distortion in decision making processes (Moore & Schatz, 2017). Research studies define the types of overconfident behaviors by adopting varying terminology. A quick internet search with the use of keyword of "overconfidence" yields results such as "better-than-average effect", "illusion of control", or "miscalibration". Moore and Schatz (2017) classify this confusing terminology into three types of overconfident behaviors: (1) overestimation, (2) overplacement and (3) overprecision. Overestimation is the belief of an individual evaluating herself or himself as better than she or he is. Overplacement is related with comparison with rivals and locating yourself in a better position to rivals exaggeratedly. Overprecision is the trust on own knowledge sophistically.

There is a growing body of knowledge about heuristics or similar psychological causes of irrational behavior including overconfidence in decision making processes. Yet research studies in business management area express that managers are failing to eliminate the negative consequences of overconfidence in decision making process. Rosenzweig (2013) argues that the underlying reasons of such failures is not paying attention to the context of decisions making process. Rosenzweig (2013) suggests that the context of decision making process can be conceptualized in two dimensions; namely (1) the level of control and (2) the relativity of and performance. Rosenzweig (2013) develops a four quadrant model using two diemsnions. Each quadrant uncovers differing effects on the consequences of decisions. In parallel, he underlines that to prevent from consequences of irrationality in decision processes, decision makers have to act accordingly with the context of the decision that is being made.

Heuristics are commonly evaluated as the main causes of poor performance and undesirable results in the area of business management. Overconfidence is not an exception. Yet more recent research studies argue that overconfident behavior is needed in some special cases such as entrepreneurship or new product development activities (Moore & Healy, 2008). Similarly, some research studies report the positive outcomes of overconfidently made decisions due to the motivational influence of overconfidence. This study develops a conceptual model explain the effects of overconfident behaviors in varying levels of control and relativity of performance and also discusses its possible benefitable or destructive outcomes.

Types of Overconfident Behaviors

Overconfidence is used as a broad term covering differing behaviors distorted from rational behavior. According to different research streams, different meanings are associated to the overconfidence. For instance, studies in the behavioral finance such as Lovric et al. (2010) mention calibration errors of own data as overconfidence. Other studies concentrate on the ambitious behaviors of top managers as overconfident behavior (Malmendier & Tate, 2005a, 2005b). Some researchers express the necessity to classify overconfident behaviors (Glaser & Weber, 2007; Moore & Schatz, 2017). Accordingly, this section aims to describe this diversity in more detail. In this perspective, definitions and classification in Moore and Schatz (2017) is used as a foundation for the review present herein. Moore and Schatz (2017) classify

overconfident behavior under three sections: (1) overestimation, (2) overplacement, and (3) overprecision.

Overestimation

Overestimation in individuals' judgement processes is linked to self-evaluation of personal capabilities. The key element in overestimation is the belief of an individual that locates herself or himself as a more ambitioned than her or his real situation. Moore and Schatz (2017) explain this behavior by referring to the individuals' distorted judgement that stating she or he has more control over consequences of actions than her or him in reality. Overestimation is an internal process, and it is not linked to the comparison to others' performances. According to the authors, this irrational judgement may trigger over-optimistic behavior that is damaging for the individual. For instance, an athlete evaluating herself or himself in a desirable situation although she or he is not in reality, may reject to practice adequately for a tournament and may perform poorly. Similarly, a student may prefer to study under low performance and receive relatively low grades for her or his capacity.

However, the concept of overestimation is not as smooth as expected in all cases. Decision makers do not tend to expect positive outcomes in all cases. Moore and Schatz (2017) state that task difficulty is a determinant which may reversely effect self-evaluation. According to the authors, easy tasks direct decision makers to feel that their performance will be better than reality. In contrast, decisions related to the tough tasks uncover the concept of 'underestimation'. When the task is relatively difficult, the decision-maker evaluates her or his self-capability as lower than reality.

Overplacement

Overplacement is a distorted view of an individual's self-capability evaluation. The main difference between overestimation and overplacement is the addition of others' performances in the judgement process of decision makers. The term "better-than-average effect" is used for the overplacement effect in some texts (Beer & Hughes, 2010). Very briefly, overplacement is the mental distortion that cause an exaggeration in an individual's performance evaluation relatively to others' performances (Moore & Schatz, 2017).

In contrast to overestimation, task difficulty plays an opposite role in overplacement. The relatively evaluation of own performance by adding others' performances to the judgement processes, leads to underplacement when the task is easy (Moore & Schatz, 2017). Individuals perceive easy tasks as easy for all. According to the decision maker, others are able to carry out the evaluated task easily, so her or his capabilities are not adequate. However, relativity between individual's capabilities and others' capabilities is still the same. As a result, 'underplacement' of own capabilities may occur in easy tasks' decisions.

Overplacement is sensitive to confusion with the concept of 'egocentrism'. In this behavioral attitude, decision makers deny others' capabilities (Moore & Cain, 2007). Egocentric behavior is rejection of others' performances although evaluation of performance is relative. Egocentric decision maker ignores competitors and only focus to own personal evaluation. Camerer and Lovallo (1999) define egocentric behavior as "reference group neglect". In

egocentric behavior, the cause of distortion is not related to self-performance evaluation, so the concept is not evaluated as a point of overconfident behavior.

Overprecision

Some empirical and experimental studies on overconfidence design their research methodology to measure individuals' confidence intervals of own data about a subject and compare its accuracy with the reality (e.g., Lin and Bier (2008), Hoffrage (2016)). Excessive trust to own data is defined as overprecision (Moore & Schatz, 2017). As expected, overprecision is a distortion in the internal judgement processes of individuals. Similar to overestimation and overprecision, alternative terminology is also used for overprecision. Most commonly, term "miscalibration" is used in the area of behavioral finance rather than overprecision (Lovric et al., 2010).

Overprecision is effective when decision makers use past data to make future predictions. An investor's previous stock performance, an organization's previous product introduction performance are examples of past data for decision-makers. A contractor's past bidding results is an example to past data of construction organizations. Past data is a precious information for the decision makers. However, the decision under consideration may show variety to the past cases. Furthermore, attractivity of the possible outcome can trigger the desire to undervalue the possibility of negative consequences. As a result, decision maker may ignore the level of variance in the past data and concentrate to the mean if it supports the ambitioned choice.

Studies researching overprecision are not only based on empirical data but also on experimental data. In virtual simulations, overprecision is represented by manipulating standard deviation of past records (like distortions in confidence intervals in empirical studies) and observing its consequences as results of mathematical models. In addition to revealing effects of overprecision at individual level, these studies enable researchers to observe whole environment such as stock markets.

Contexts of Decisions

The major causes of unfavorable consequences of decisions have been studied for a long time. In a variety of research disciplines such as psychology to business management, there are plenty of studies those are focused on exploring the reasons of undesirable outcomes of decisions. Similarly, many normative studies develop models to assist managers to prevent from adverse decisions. In the domain of construction project management, causes of adverse decisions have been explored from the perspective of technical errors. However, there is a growing body of knowledge about the behavioral aspects of decision-making in particular insights about the explanation of irrationality in decision making processes. Heuristics (biases) and in some cases deliberate political distortions similar to Flyvbjerg (2008)'s "strategic misrepresentation" explain negativity in the consequences of decisions which cannot be expounded by technical errors.

There is a growing body of knowledge about technical and behavioral aspects of bad decision-making process. This body of knowledge can offer more insights to managers to improve the process of decision making and in turn eliminate unfavorable decision outcomes.

However, research studies in business management or similar areas that suggest that failures in decision processes are still effective. Normative studies cannot protect decision-makers from adverse consequences. Rosenzweig (2013) clarifies the causation behind the unimprovement of the decision-making process without criticizing the growing body of knowledge about decisions. Rosenzweig (2013) explains the mechanism of poor decision making by taking attention to context of decisions. In order to clarify this context, author defines two dimensions: (1) control and (2) performance.

Rosenzweig (2013) states that control dimension is the ability of decision-maker to influence the outcomes of decisions. For instance, decision of selecting which model of an automobile is going to be bought is a low control decision as the performance of the decision (satisfaction from the selected choices) cannot be influenced by the decision maker. It is determined by the selected product. In contrast, if the performance of the outcomes of the decision can be shaped by the decision-maker, the decision offers high level of control. A student's decision to apply to a university program is an example to high control decision. According to the decision-makers performance the consequence can be a valuable graduation or failing out.

Performance dimension is determined by the way how the success is measured. If the decision's outcome is compared with other decision-maker's performance, it is a relative decision. In contrast, if the success of the decision is independent from rivals' decisions, it is an absolute decision. At the first scenario, in order to get a satisfying result from a decision, decision-maker has to be in a better position from her or his rivals. In construction, bidding process is a good example to decisions with relative performance. If the contractor submits the most desirable tender to the client organization, it gets the privilege to sign the contract. In contrast, performance of a selection of a finance instrument to invest in is an absolute performance decision. Profit from the instrument is independent from other investment tools' performances.

Two dimensions divide context of decisions into four areas (Figure 1). In first quadrant decisions, decision-maker does not have the ability of improving the outcome once the decision is made (Rosenzweig, 2013). Furthermore, performance of the decision is constant, it is not affected by what rivals do. Rosenzweig (2013) states that this field of decisions are sensitive to systematic biases. For instance, 'gambler's fallacy' can be harmful in this area. This bias is related to unrealistic evaluations of possibilities in consecutive cases. When the decision-maker face frequent negative outcome, the belief to positive outcome in the next step increases without proof. This bias can easily affect first field decisions. In this field of decisions, once the decision is made, any enhancement in consequences of the biased decision is impossible because of the disability of effecting outcomes.

Second quadrant decisions provide opportunity to the decision-maker to influence the outcomes of the decision (Rosenzweig, 2013). The success of decisions is not related to others' performance. For instance, if a student decides to apply to a proficiency exam in a foreign language, she or he can affect the result by studying more or less. Decisions in this field may be affected by biases, but the decision-maker has the ability of lowering negative consequences as she or he can affect outcomes of the decisions. Furthermore, as the decision-maker still has the ability to affect the outcome of the decision after the decision-making, motivating biases such as optimism can force the decision-maker endeavor to improve performance of decisions.

In the third quadrant, performance is relative, but control is low. Relativity in performance evaluation increase the importance of rivals' performances. In order to get successful results from this kind of decisions, decision-maker has to perform better than competitors (Rosenzweig, 2013). This triggers competitiveness. Like first quadrant decisions, a vital issue about third field decisions is the inability of affecting outcomes once the decision is made. This field reveals the need for strategic thinking. Concepts such as game theory explain and prescribe decisions in this field.

In the fourth quadrant, the decision-maker has the ability of improving the results after the decision is made. The performance of the decision is determined relatively to competitors' performances (Rosenzweig, 2013). Rosenzweig (2013) takes attention to strategic management concepts in fourth field decisions. Enlargement of service locations of a contractor organization can be an example of fourth field decisions. The organization can affect the outcome by hard competition and the success is performing better than rivals. Complicated nature of this field makes decisions more sensitive to biases and technical errors. Decision-makers have to act with sufficient measures (such as Kahneman (2017)'s two system thinking) in order to prevent from behavioral and technical errors.

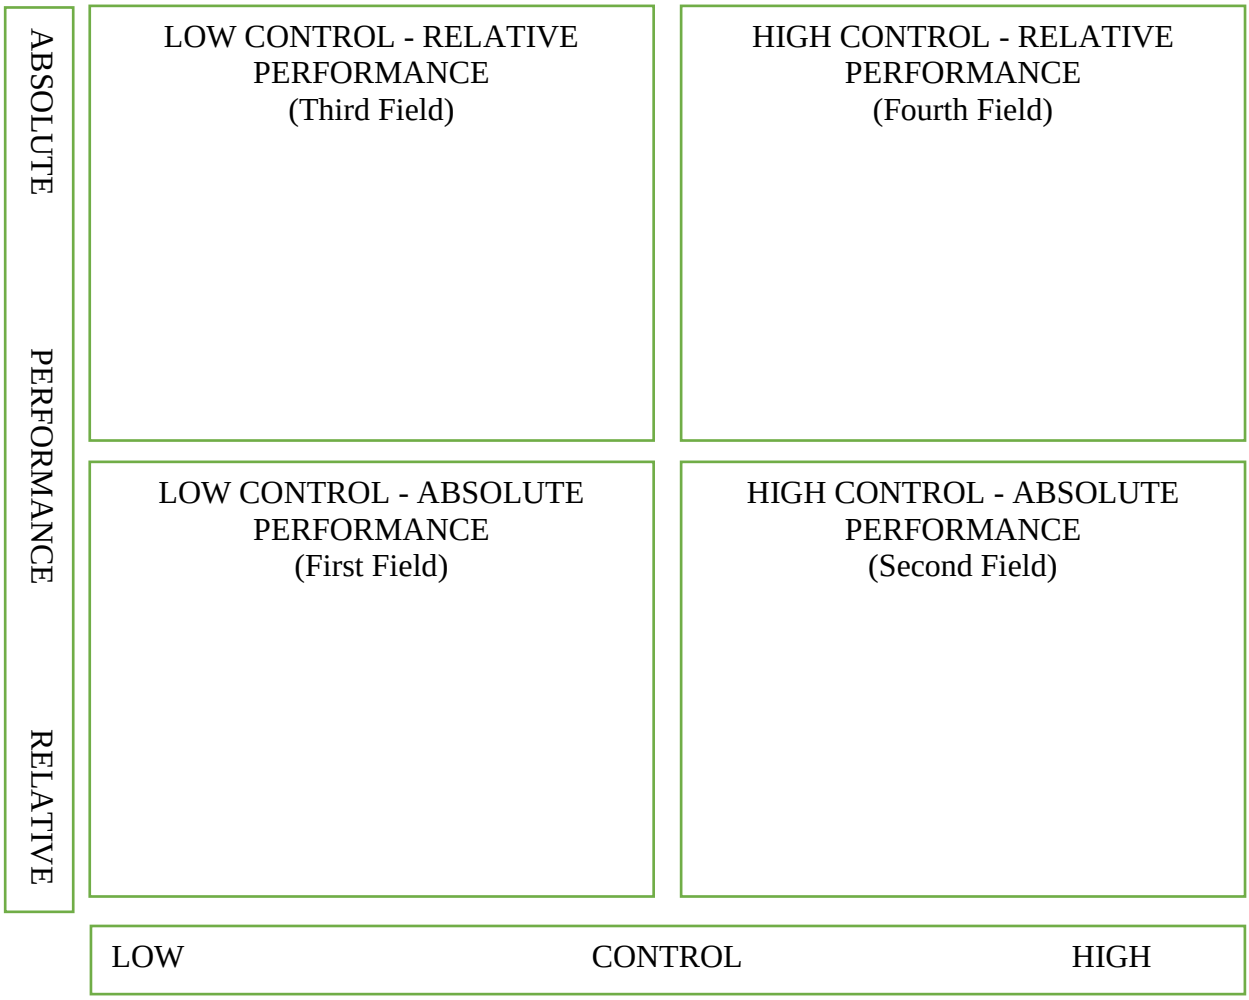

Figure 1: Four fields of decisions (Rosenzweig, 2013, p. 91).

Discussion

In the perspective of behavioral studies, heuristics including the overconfidence effect are evaluated as causes of undesirable negative consequences of decisions. Illusive inferences of overconfident judgements may lead individuals to make unrealistic decisions. Moore and Healy (2008) remark possible negative outcomes of overconfident judgement including even catastrophic events in the history such as World Wars. However, in their evolutionary study Johnson and Fowler (2011) criticize negative opinions on overconfidence by pointing to its existence in evolutionary continuum. Some biases are not eliminated by evolutionary selection. According to authors, unbiased decisions are not the best option in all cases. Similar studies support the possible positivity of overconfidence. For instance, Vitanova (2021) mentions that overconfidence supports leadership of chief executive officers (CEOs) in organizations. As a result, this overconfident behavior in CEOs' actions develops positive outcomes. In a similar vein, Moore and Cain (2007) concluded supportive effects of overconfident behavior on market entries.

Lowering impacts of loss-aversion is an example to benefitable points of overconfidence. Loss-aversion is a quite common behavioral reaction to the risk or uncertainty. Negative behavioral impacts of losses are more influential than positive behavioral impacts of gains (Kahneman & Tversky, 2012). For this reason, individuals feel reluctant to act in risky situations such as market entry or new product introductions. Moore and Schatz (2017) highlight that, overconfident behaviors such as overestimation and overplacement may minimize the effect of loss aversion. Here, it is needed to be reminded that not all the new product introductions or market entries bring success as a result. However, to gain competitive advantage in strategic areas, appropriate entrepreneurial movements are necessary.

Johnson and Fowler (2011) help clearing the idea behind the dilution of effects of loss-aversion by overconfident behavior. In their model, authors define an award (a scarce resource), and two individuals who may decide to compete for gaining it. Capabilities of individuals for achieving the award are not same. As the situation is uncertain, both the more capable and less capable individuals may make decision to struggle for gaining the award. When its rival decides not to attend to the competition, other individual gets the award without the necessity of being more capable. If two of the individuals decide to compete, more capable one gets the award. Individuals with overconfident behavior are more expectable to join the competition. So, they have more possibility to win without being more capable than their rivals.

Furthermore, an effective impact of overconfidence becomes visible when the decision-maker has control over consequences of the decision. Behaving under effect of overestimation or overplacement motivates decision makers to endeavor for improvement of results. Similarly, Flyvbjerg (2021) mentions that overplacement triggers an ungrounded optimism that increases managers' efforts for getting favorable outcomes from a decision. In the same vein, Hilary et al. (2016) state that over-optimistic (can be both overestimated or overplaced) behavior of managers trigger extra effort to meet targets.

Malmendier and Tate (2005b) state that the belief of having control of actions makes decision makers more optimistic. In contrast, when the decision-maker's control on the outcomes of the decision is low, previously mentioned positive effects of overconfidence lose effect. Under low control decisions, decision-maker has to select the best possible alternative as she

or he is not capable of effecting consequences of the decision. As a result, distorting effects of overconfidence will become damaging in low control decisions.

Accordingly with preceding discussion, overconfidence cannot be classified as harmful or unnecessary in all cases. Rosenzweig (2013) states that varying characteristics of decisions necessitates different measures of action. Accordingly, a model for possible effects of overconfident behavior in different fields of decisions is discussed and developed.

Harmfulness of overconfident behavior can be defined as the difference between the cost of the actions to accomplish the objective and the value of the gained award. In cases ensuring more benefit from cost of overconfident actions, overconfidence causes positive outcomes. In contrast, when the overconfident actions cost more than the benefits gained from the actions, overconfidence causes negative outcomes. As mentioned in Johnson and Fowler (2011), motivating effects of overconfidence make individuals struggle more to accomplish to the objectives. As presented in Figure 2, some level of overconfidence rescue individual from loses and enable gaining benefits. However, increase in the effort is not expected to have a linear shape and become disadvantageous after a point as the level of increase in the benefit as a result of increase in the effort decreases.

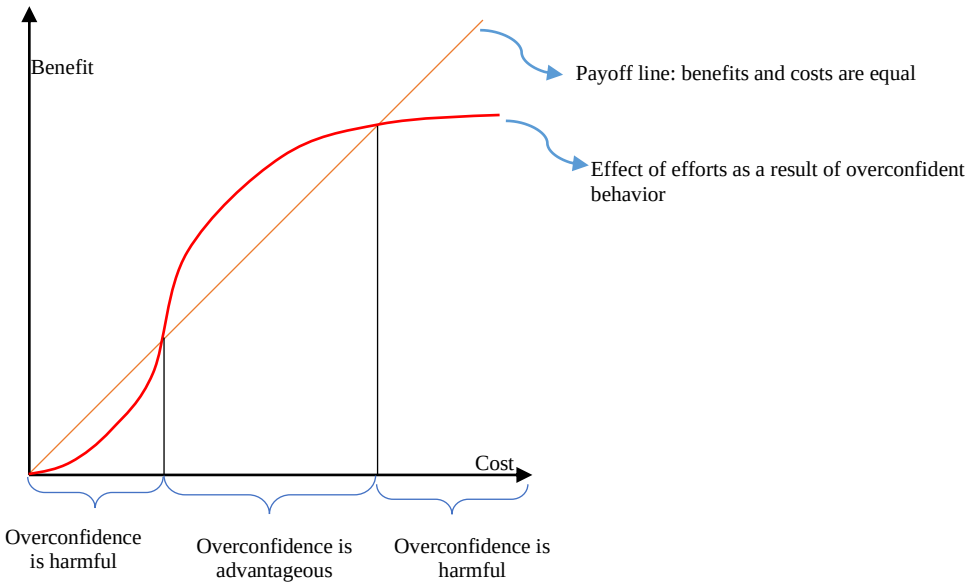

Figure 2: Effect of overconfidence over cost and benefit in decisions (generalized).

The generalized effect of overconfident behavior described in Figure 2 is not valid in all cases. Ability of controlling outcomes or relativity of performance support the positivity of overconfident behavior. However, if the decision does not provide opportunity to the individual to influence the outcome or the performance evaluation is absolute, efforts as a result of motivation of overconfidence becomes ineffective. Figure 3 presents the possible effects of overconfident efforts for the four quadrants of decisions described in Rosenzweig's (2013) model.

Conclusion

Cognitive biases and other causes of failures have been the subjects of research studies for a long time. These studies offer precious insights for decision makers on how to achieve their predefined goals. Yet, general business management studies report that failures caused by poor decision-making process are still plague organizations. Rosenzweig (2013) proposes that the poor decision-making process can be improved by paying special attention to the context of decision-making process.

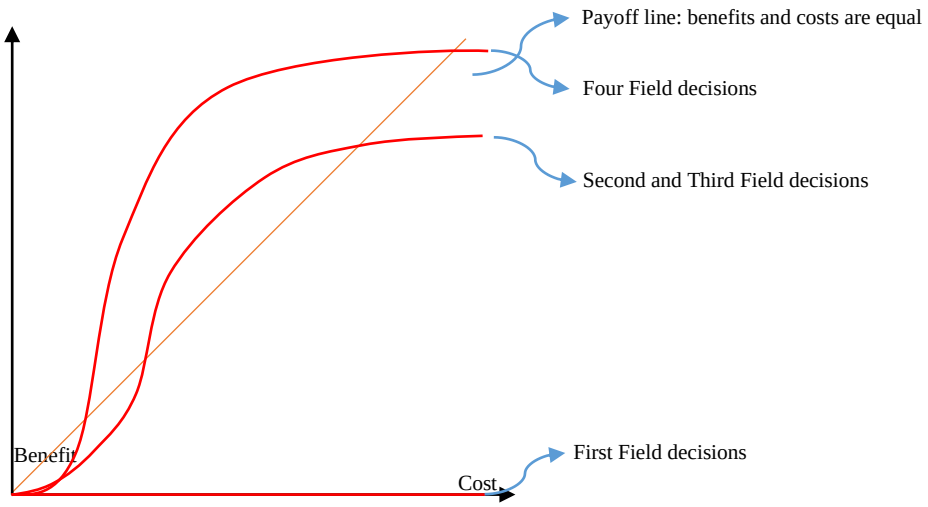

Figure 3:Changing effects of overconfidence in Rosenzweig's (2013) four field of decisions.

Overconfidence, like all kinds of behavioral biases, has negative connotation for decision making process. Yet more recent research studies reject the negative connotation about the overconfidence and argue that the elimination of all types of overconfident behaviors in all contexts of decisions is not a constructive behavior. When the decision maker has ability to influence the outcome or the performance is relatively evaluated, overconfident behavior holds possibility to improve the outcome. In some cases, such as entrepreneurial decisions or competitive decisions are positively affected by overconfidence. In contrast, decisions in the context of absolute performance evaluation and low control are sensitive for negative impacts of overconfidence.

As a further research study, the impacts of overconfident behavior can be explored and validated explored by using empirical and/or experimental studies. Future research studies based on empirical or experimental studies may offer more guiding results to decision makers. Accordingly, this model does not provide a normative model for decision makers. The objective of the research presented herein is to propose the possible overconfident behaviors in differing decision-making contexts and informing decision-makers about its possible negative and positive consequences. Overconfidence is not a curse that the decision-maker has to eliminate in all cases. Further comprehensive research may give opportunities for developing a normative model supporting decision-makers for eliminating negative impacts of overconfident behavior.

The Changing Role of Project Professionals in a Digitally Disrupted Environment

C. Mallet and M. Dulaimi
Leeds Beckett University, School of Built Environment, Engineering and Computing, Leeds, United Kingdom
mmcmallet@gmail.com, M.Dulaimi@leedsbeckett.ac.uk

Abstract

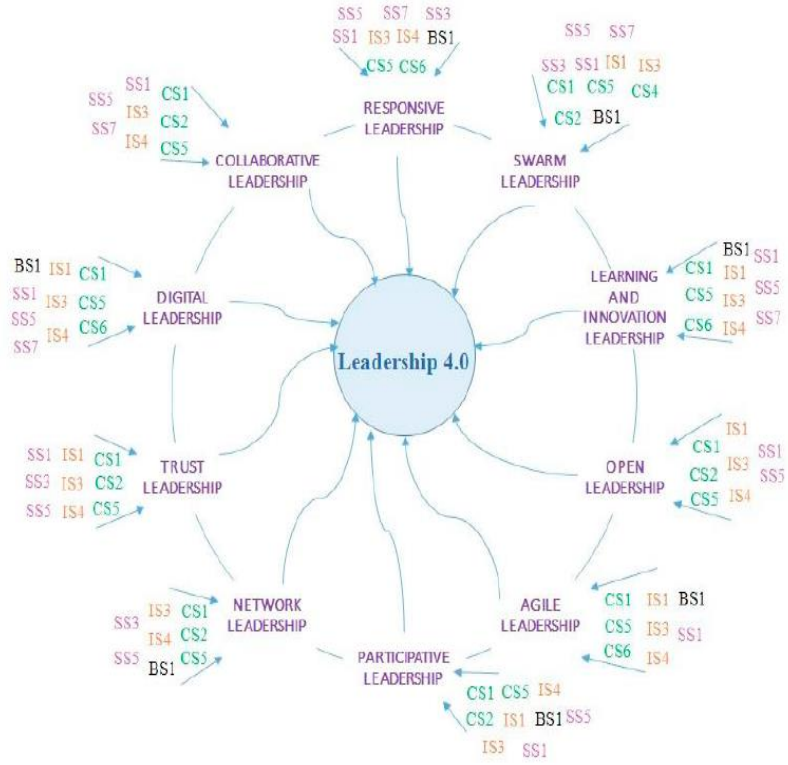
Industrial revolutions (IRs) have brought to the world a massive change in the political, social and economic environment, greatly influenced by technological advancements, altering the way we work and deliver projects. Yet, evidence suggest that digital transformation goes beyond the mere implementation of disruptive technologies. The aim of this paper is to investigate the leadership skills required at project level to lead transformation in an increasingly disrupted digital environment. The paper examines the elements and skills that are required to lead the necessary change. Based on literature reviews, a conceptual model is developed and presented to illustrate the dynamics of project leadership of this industrial revolution 4.0. The major facets of digital transformation demonstrated the crucial role of leadership as well as enabling aspects such as culture and strategy. The primary data analysis collected from professionals involved in projects has examined the degree of awareness and acknowledgement on the enabling aspects that shape the project leader 4.0. The analysis suggests that project professionals put more emphasis on the strategic nature of project leaders' roles. Furthermore, the mixed research method revealed how project leadership is seen to be crucial in delivering transformation.

Keywords: *culture, digital disruption, leadership skills, project management, strategy, transformation.*

Introduction

The backbone of the global economy relies on industrial revolutions. Technologies such as Artificial Intelligence (AI), Internet of Things (IoT), nanotechnology or cloud computing are creating opportunities, foreseen and unforeseen, with an increased competition allowing businesses to thrive in ways never seen before. The increased competition is putting pressure on organisations and inducing them to adopt and adapt to changing technologies in a surviving attempt to remain in business with barriers to entry being virtually none. In fact, technologies are forcing organisations to address the broader strategy, the 'why' of their business, the *'what'* to produce or offer and the *'how'* to do it. This game changing business environment has brought disruption. Christensen (2020) described disruption as a *"process by which a product or service powered by technology enabler takes root in simple applications at the low end of a market, typically by being less expensive and more accessible, and then relentlessly moves upmarket, eventually displacing established competitors".* Digital

transformation therefore is about *"how companies are adapting to the new reality created by digital disruption"* (Kane, 2019). The imperative of digital transformation is an insistent subject matter for many executives, virtually in every industry, even the most unexpected ones. And, as disruption is becoming the new normal, organisations are required to embark on a transformation journey. Forbes Insights (2018), on behalf of the Project Management Institute (PMI), conducted a survey of executives across the globe and found out that nearly 80% of the organisations have undergone a significant transformation using disruptive technologies, yet only 25% of the projects at those organisations generated tangible benefits realised against the original goals and business intent. Accenture (2018) mentioned leadership as one of the factors in embracing a culture that would bring change and drive digital transformation. It seems obvious that while dealing with disruption, it is important for executives and project professionals to understand the disruptive trends affecting their business. On the other hand, in embracing the digital journey, it is also crucial for project leaders to have more than just the technical skills. It implies that new technologies involve new skills set, new mindset requiring a new perspective for project and programme management. Organisations therefore have to rely on project professionals to take advantage of disruption, and not simply be reactive of it. Kane (2017) put forward that the key problem faced by organisations when it comes to digital disruption is not the technology but rather is a people issue. Similarly, amongst the challenges identified by Forbes (2018), it is seen that people related challenges in the form of fear, resistance to change, responsibility or capacity to drive change represent the main constraints to a culture of change towards digital transformation. In fact, the McKinsey Global Institute report (2017) analysing 46 countries estimated that 60% of occupations have at least 30% of constituent work that could be automated and that by 2030, between 400 million and 800 million individuals could be displaced by automation and would need to find new jobs. The economists Brynjolfsson and McAfee (2014) referred to this phenomenon as the *'second age machine'*, that is, technologies spreading to areas that used to be exclusively handled by humans. The Covid-19 pandemic has showed the value and necessity of digital transformation with organisations accelerating this transition. The pandemic has had some immediate negative impacts on organisations as well as some positive impacts with some companies seeing a peak in their activities while it was also observed (Iansiti & Richards, 2020) that *"this need to virtualise work due to Covid-19 is driving digital transformation and deepening differences across people and across firms at an incredible rate".* The research further stated that any process that could be '*rapidly digitised has been virtualised'*, from video conferencing to telemedicine. However, the *'trap'* to avoid as put forward by Carr (2003) is to focus on technology as *'an end in itself'*. A study conducted by *MIT Sloan Review Management* and Deloitte (cited by Kane et al., 2015) to understand the challenges and opportunities associated with the use of social and digital business, identified *'Strategy'* as the key driver in the digital field and further mentioned that the power of digital technologies does not lie in the technologies individually. Kane et al. (2015) stated that *"the ability to reimagine the business is determined in large part by a clear digital strategy supported by leaders who foster a culture able to change and invent the new".* In fact, the research conducted by the authors found out that organisations at an early stage of digital transformation have a decidedly operational focus with improving efficiency and customer experience as digital strategies rather than seeing transforming the business as the digital strategy. The research further concluded by stating that leaders must be able to tackle the following questions in their journey towards transformation. They should ask themselves whether their organisation has a *'digital strategy that goes beyond implementing technologies'*, that is, does it transform how the business works. The authors also raised the question of whether the *'culture fosters digital initiatives'*, changing mindsets to stimulate greater digital progress. And finally, whether the



organisation is confident in its leadership in paving the way for transformation. In fact, while organisations may articulate strategies for disruptive technologies and digital transformation, they may however face challenges to execute against that strategy and the intended results. APM (Association for Project Management, 2019) stated that the *"project profession should play an important role in shaping the future…projects are how successful change happens: they are the way that businesses and governments deliver social, economic, business, and environmental outcomes, so it will be in the form of projects, programmes, and portfolios that change is delivered"*.

Leadership

In this digital age, it is important for organisations to reinvent themselves, moving from the traditional project leadership to leading the transformation, requiring new skills to adapt, guide and navigate into the digital world for effective strategy delivery. Leadership refers to the behaviours of an individual and processes applied while directing and coordinating the activities of group members. There exist different theories on leadership from defining it by traits, contingency approaches, and situational styles or through behavioural or participative theories and more recently popularised, emotional intelligence. Leadership is an important quality in any organisation as it drives organisational effectiveness and competitive edge. Digital leadership therefore requires leaders to adapt and augment some of their core skills to face the challenges and embrace the opportunities of the disruptive business world. The study of Guzmán et al. (2020) resulted in 10 leadership characteristics found for the industry 4.0 and their relationship with 4 leadership skills groups which are *(i) cognitive (ii) interpersonal (iii) business and (iv) strategic skills* which they recommended leaders to consider in their transformation journey. Guzmán et al. (2020) cited Kelly (2018) regarding his analysis of phases to characterise leadership for each industrial revolution (IR). Kelly (2018) referred to the 1st IR as *'charismatic'* leadership relating to how leaders perform through actions and personal characteristics. The 2nd IR was influenced by scientific management with a top-down approach reflected in a *'directive'* leadership. The 3rd IR recognised the achievement of goals and is characterised by *'transactional'* leadership but also as *'transformational'* as autonomy, ideas and collaboration are empowered. Guzmán et al. (2020) suggested that both existing and new leadership characteristics are required for the 4th IR. They further referred to the term *'leadership 4.0'* requiring investment and openness to culture change with leaders not only able to deliver value through technologies and innovations but also having the ability to a create a friendly environment, further stating that a *'swarm (moving crowd)'* leadership is needed and is responsive as leaders act in an agile environment. The model below (Table 1) was developed by Mumford et al. (2007) and acknowledged 4 groups of leadership skills. In addition, Guzmán et al. (2020) cited the work of Ashkenas and Manville (2018) who identified 6 leadership skills based on interviews of successful leaders *(i) 'shaping a vision for focusing and challenging the team' (ii)) 'translating the vision into clear strategy about what action to take and what not' (iii) 'recruiting, developing and rewarding a team of great people' (iv) 'focusing on measurable results' (v) 'promoting innovation and learning to sustain the team or organisation' and (vi) 'leading yourself'.* Guzmán et al. (2020) then created the model (Figure 1) that demonstrates the 10 leadership characteristics with the required skills (Table 1). Each skill group highlights the relationship with the characteristics skills *(in purple).* For instance, the model shows that for strategic skills, visioning and identification of key causes were important skills while for business skills, the relationship with leadership characteristics were lower.

Table 1. 4 Groups of leadership skills by Mumford et al., 2007 (Guzmán et al., 2020).

Cognitive Skill (CS)	Business Skill (BS)	Interpersonal Skill (IS)	Strategic Skill (SS)
CS1: speaking	BS1: operations analysis	IS1: social perceptiveness	SS1: visioning
CS2: active listening	BS2: management of personnel	IS2: coordination	SS2: systems perception
CS3: writing	resources	IS3: negotiation	SS3: system evaluation
CS4: reading	BS3: management of financial	IS4: persuasion	SS4: identification of downstream
comprehension	resources		consequences
CS5: active learning	BS4: management of material		SS5: identification of key causes
CS6: critical thinking	resources		SS6: problem identification
			SS7: solution appraisal

Skill Group	Code	Skill description	Frequency
Cognitive Skills (CS)	CS5	active learning	10
	CS1	speaking	9
	CS2	active listening	6
	CS6	critical thinking	5
	CS3	writing	0
	CS4	reading comprehension	0
Interpersonal Skills (IS)	IS3	negotiation	10
	IS4	persuasion	10
	IS1	social perceptiveness	7
	IS2	coordination	0
Business Skills (BS)	BS1	operations analysis	7
	BS2	management of personnel resources	0
	BS3	management of financial resources	0
	BS4	management of material resources	0
Strategic Skills (SS)	SS1	visioning	9
	SS5	identification of key causes	9
	SS7	solution appraisal	5
	SS3	system evaluation	3
	SS2	systems perception	0
	SS4	identification of downstream consequences	0
	SS6	problem identification	0

Figure 1: The network of characteristics and skill requirements for Leadership 4.0 (Guzmán et al., 2020).

Ready et al. (2020) identified 3 reasons why leaders are not as ready as they think they are in embracing change and these are (i) *'a deficiency in digital savviness coupled with outdated mindsets'* (ii) *'a series of blind spots; cultural, strategic, human and personal that prevent them from seeing a clear path forward'* and (iii) *'multiple embedded tensions that undermine strategic execution'*. Among the findings of Kane et al. (2019), it was observed that it is also important to understand the technology that is the digital literacy of leaders as well as team members. The authors further stated that digital literacy of leaders would help to position themselves as agent of change and support the transformation. Adaptability is another factor that is to be considered in the change process for a more fluid and flexible workplace. These transformations can be achieved via continuous training, formal education, cross-generational reverse-mentoring programmes or online programmes (Kane et al., 2019). The demand for digital leaders is strong with a need for organisations to develop the right talents. Kane (2018) analysed the top 4 trends that digital leaders should have, and these are (i) provide vision and

purpose to drive the digital transformation (ii) create conditions to experiment new ideas, new models (iii) empower people to think differently by adopting inclusive leadership, and (iv) enable collaboration across boundaries. Anthony and Putz (2020) stated that in embracing digital transformation, leaders must first transform themselves in an environment where growing technologies render old technologies obsolete, that is, their inner capacities, awareness and mindset to *"combat basic biases that make it hard to make decisions in uncertainty and toggle between different frames"*. They further argued that there are four flawed assumptions that leaders tell themselves (i) *'We are safe'* - taking comfort in data thinking everything is going fine (ii) *'It is too risky'* - investment in innovations is a bold risky bet (iii) *'My shareholders won't let me'* - managing the short term returns rather than maximising shareholders' value (iv) *'My people are not up for the task'* - people resist change. Kegan Robert (cited by Anthony & Putz, 2020) described a self-transforming mind as the 5th order of consciousness whereby one sees beyond himself, others, and systems and develop an understanding of how all people and systems interconnect, the cognitive flexibility which most leaders lack. Anthony and Putz (2020) put forward that this is so because most leaders grew up either in a *'disciplined or entrepreneurial'* world but *'rarely or never both at the same time'* to cope with the *'emerging needs'*.

Implications on Project Management

"Traditionally, project managers operate at the surface, where they are predominantly concerned with the delivery of a product or an outcome through the completion of tangible actions, tasks and activities" (Madsen, 2015). PMI (2018) reported that *"innovators believe that the role of the project manager will evolve to one that advocates for the technology, motivates teams to implement, supervises course corrections, and becomes an authority on disruptive technologies".* PMBOK (2017) stated that *"leadership skills involve the ability to guide, motivate, and direct a team"* and in addition, the skills include capabilities of project leaders to negotiate, show resilience and critical thinking, communicate, be solution oriented as well as to demonstrate interpersonal skills. Similarly, Svejvig and Andersen (2015) talked about a *'rethought'* version of project management whereby they suggested project management to be viewed as beyond completing a project on time and within the budget. They positioned project management as a more holistic approach managing complexity, uncertainty, and change and value creation. The traditional approaches to project management focus mostly on planning and managing risk. However, the influence of the PM is not to be neglected. PM plays an important role in not only leading the team in delivering the strategic objectives of the organisation, but the PM also has a crucial role in directing and communicating the *'vision of success of the project'* (PMBOK, 2017). PMI (2018) stated that *"just over one in four respondents mentioned the ability to learn, understand, apply, and keep up with technology as the most-needed skill for project managers to respond to the impacts of the digital transformation.* Other skills include communication; leadership and management skills; change management, adaptability, and flexibility (PMI, 2018). The success of projects is no more encapsulated by the traditional *Iron Triangle* and stated that *'if project management is to be tasked with transformation',* the *Iron Triangle* then goes beyond efficient projects (APM, 2019). It also acknowledges the value of relationships as well as the importance of change and recognises that project management has evolved and that in this digital era, it has started to reflect in the profession.

Conceptual Framework

An extensive review of the relevant literature has revealed a number of prevalent themes as summarised below.

- Leadership: Project managers require a certain level of digital savviness (Ready et al., 2020; Kane et al., 2019).
- Strategy: Shaping a clear digital strategy and vision endorsed by leaders who encourage and translate a culture of change and inventing the new (Kane et al., 2015; Guzmán et al., 2020).
- Culture: Creating an innovative and learning culture and mindset that engage all levels in the organisation with a more holistic and strategic approach to transforming and delivering value (Accenture, 2018; Forbes, 2017; Kane et al., 2015).
- Project Team: Project professionals must broaden their skills, superseding the basic project management skill (PMI, 2018; APM, 2019; Kane, 2018).
- Project: Project is a vehicle for change and practitioners must reflect on the profession by adopting a continuous learning culture, a more holistic and strategic approach to transforming and delivering value (APM, 2019; Svejvig & Andersen, 2015).
- Skills: Reskilling programmes are required with investment in training, formal processes, and transfer of knowledge (Anthony & Putz, 2020; PMI, 2018; Kelly, 2018).

Based on the above, the following conceptual framework was developed (Figure 2).

Enablers refer to the backbone within the organisation that facilitates the transformation of the leader. The two enablers that are identified in this framework are (a) Business Strategy and (b) Culture. Elements of the **enablers** have also been identified as actions or input that could be considered at organisational level to create this environment for the leadership 4.0. As reviewed in the literature, reimagining the business depends greatly on a clear strategy that supports and invests in leaders' transformation. Hence, the importance of an organisational culture that embraces change and innovation and encourages people to lead the transformation. Some of the enablers identified include the business model of an organisation, how the organisation may be structured to create an environment that allows for innovation or approaches to managing and leading talents towards an empowering and learning culture that would help to navigate the VUCA (Volatile, Uncertain, Complex, Ambiguous) environment. The challenge today, is the increasing pace at which economies are being disrupted. Transformation is therefore required through sets of new skills, initiatives and actions that would transform businesses and people.

Skills Group represents the skill categories identified in the literature reviews as predominating and/or emerging in the digital industry. Four categories of skills are suggested in the conceptual framework and is as follows:

a) Strategic / Transactional Skills Group refers to the project leader 4.0 to demonstrate the ability to build in strategies and make strategic choices in addressing digital disruption and transforming business and people. The leader is transactional in that it requires a structure and a directed environment to achieve goals, reshape and lead the organisation in a way of thinking and doing.

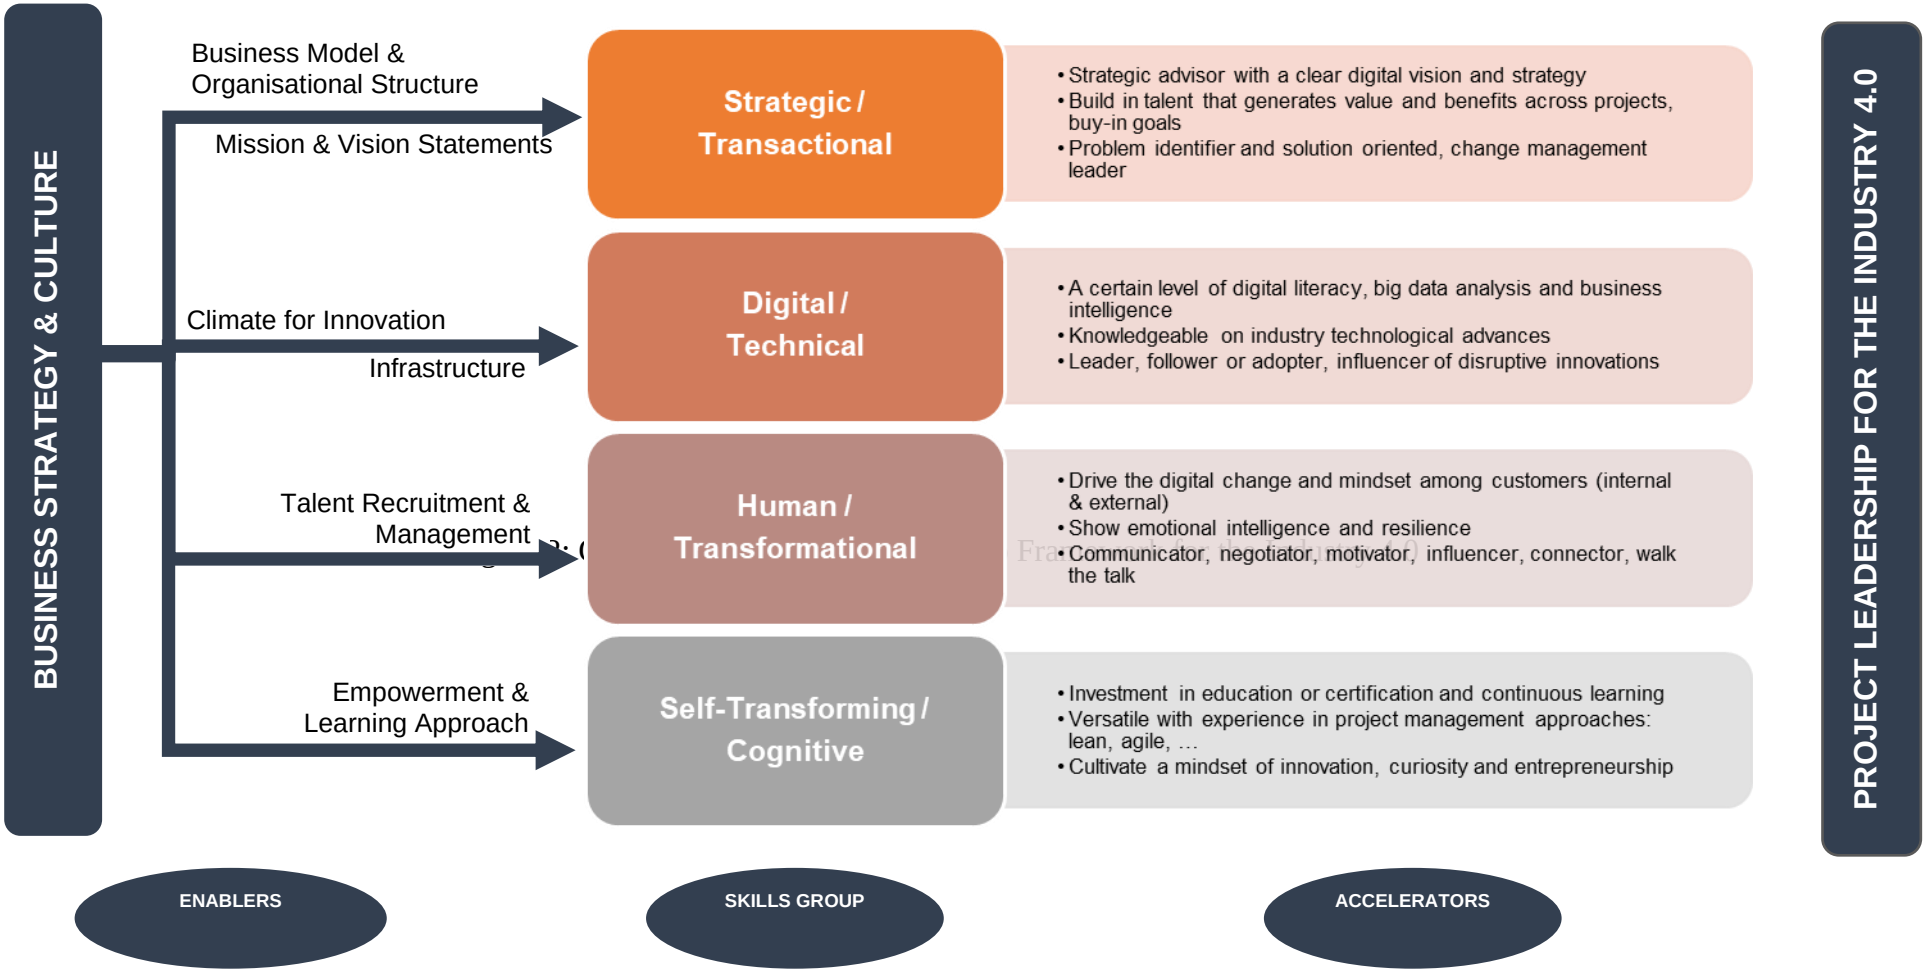


Figure 2: Conceptual framework.

b) Digital / Technical Skills Group suggests that the leader has to be up to date with the latest trends or technologies of the industry. As put forward by Kane (2019), *"it is a lot easier to teach executives the technology knowledge they need than to teach technologists the leadership skills they need."* This group skill involves the leader to develop an understanding or working knowledge of technologies and how to capitalise or apply to the organisation or areas of business in delivering value.

c) Human / Transformational Skills Group implies that digital transformation is led by people and the need to understand and embrace the purpose behind the transformation. The skill group requires leaders to develop and articulate the right mindsets and behaviours that influence, engage and connect with people.

d) Self-Transforming / Cognitive Skills Group indicates that the leader has to be a reflective practitioner and build on skills that bridge the knowledge gap. It suggests that leaders must become aware and invest in their own learning and development and demonstrate agility and entrepreneurship in navigating through digital disruption.

Accelerators shows the drivers or characteristics that contribute to each **Skill Group** that are to be developed and nurtured by leaders. For instance, the conceptual framework suggests that project leaders developing versatility regarding different project management approaches and methods contribute to the Self-Transforming / Cognitive Skills. It further shows the ability and capability of the leader to adapt through VUCA situations.

Research Methodology

Mixed methods research was undertaken through self-administered questionnaire and interview survey with individuals working on projects. Saunders et al. (2016) stated that survey strategies using questionnaire are *"popular as they allow the collection of standardised data from a sizeable population in a highly economical way, allowing easy comparison"*. It also allows for a multitude of information from participants and enable the researcher to analyse quantitatively using descriptive and inferential statistics. The targeted population for this study concerned individuals working on projects in the UK regardless of the sector. A simple random sampling was used, and individuals were contacted via their companies randomly and through professional networks to gather data. Another approach that was used to collecting data for this study includes online interviews with individuals working on projects. A list of questions based on the conceptual framework were sent to the participants prior to the interview. Upon their consent to participate to this survey, an online interview was then carried out. However, it was decided that the conceptual framework developed is shown to the participants only at the end of the interview to collect further feedback. This was done to avoid any bias or influences in responses or feedback. We must also acknowledge some limitations to this study. It is to be noted that the survey was conducted in a time of global pandemic disrupting work environment and jobs, and due to time constraint, the targeted population being quite large, only 58 questionnaires were collected. Another limitation also concerns the qualitative feedback whereby only one professional consented to be interviewed, therefore suggesting further research on the developed conceptual framework. The skills were searched to support the leadership characteristics and, subject to an abductive analysis, the relation and construct were made. However, Maxwell (2012) explained that a conceptual framework changes, both because the

information gathered lead to new ideas and understandings, and because the process of doing this may lead to more awareness of, or question parts of the previous conceptual framework.

Findings

The data analysis showed that overall, respondents are aware of the impact of digitisation and new technologies. Some responses may suggest that depending on companies, the importance of some skills or the implementation of those skills might differ. This, however, requires further analysis in terms of maturity of companies (which was not covered in this survey).

Organisation Culture and Strategy

The *'enablers'* developed in Figure 2 identified elements or inputs that define the business strategy and culture of an organisation for a leadership 4.0 in this disruptive environment. This part of the survey assesses the perception of the participants regarding the importance to which their organisation has embraced digitisation. The data obtained demonstrate that from the perspective of the respondents, their organisations acknowledge the importance of adopting new technologies, embracing a culture of change, creating a climate for innovation, developing the appropriate skills, and reinventing the business model, that is, the *'enablers'* that help in defining and positioning an organisation in its digital transformation journey. In fact, the mean results for the statements *'Investing in technologies to better enable project success', 'Creating a culture receptive to change', 'Instilling a climate for innovation'* and *'Empowering and developing talents with the necessary technical skills'* are all above 4 which implies that most respondents consider that their organisation has embraced digitisation and acknowledged those statements in their transformation process as *'important'*. However, the mean result of the statement *'Creating a business model responsive to new technologies, digitalisation and market conditions'* is 3.97 which is slightly below 4 but nevertheless close to *'Important'*. The standard deviation results from the participants seem to be consistent, implying that the results converge towards the average.

Strategic and Transactional Skills

This section examines the data collected regarding the *'skills group: strategic / transactional skills'* as described in the conceptual framework. As suggested, this skills group involves the leader's ability to act strategically in decision making, directs and leads to achieve goals, shape, or reshape the project's organisation and environment. The statements set for this section analyses the perception of the respondents as to how they assess the importance of the mentioned skills for a PM role in a disruptive environment. From the data obtained, it is observed that the statement *'The PM is a strategic advisor to the company'* has a mean result of 3.43 which is closer to 3, that is, the respondents assessed this skill requirement as '*moderately important*' for a PM. The next statement *'The PM has a clear digital vision and strategy and is capable of inspiring such vision and strategy to the team'* has a mean of 3.76, nearing 4 *(Important)*. On the other hand, the statements *'The PM is forward looking and solution oriented'* and *'The PM is capable of developing talents that generate value and benefits across projects'*, indicated mean results above 4 *(Important)* but however, the mean result for the former statement is higher, which implies that more respondents tend to agree that this required skill is important to the PM role. Similarly, we observed a lower standard

deviation for the statement *'The PM is forward looking and solution oriented'* compared to the other statements, which means that the lower the standard deviation, the values tend to be closer to the mean. The 3 other statements have a standard deviation result above 0.9 which is explained by greater disparity in the responses. Further analysis show that 52% of *'Project Manager'* responses deemed that the PM being a strategic advisor to the company is of low or moderate importance with only 7% considering this statement as *'very important'* in the transformation process while 29% of *'Project Team Member'* respondents checked this as *'very important'*. Similarly, 34% of the *'Project Manager'* responses believed that having a clear vision of the digital strategy and being capable of inspiring such vision and strategy to the project team is of low or moderate importance. It is to be noted that 31% of the participants who answered *'low importance'* or '*moderate importance'* for this statement are from the Construction sector, 36% from Financial Services and Banking Results and 38% from Technology. The data collected showed that there is a certain degree of awareness amongst the PMs and project team members in recognising the strategic and transactional importance of the role of the PM. Hence, it can be said that the role of the PM in delivering change and transformation is expected to be of strategic nature.

Digital and Technical Skills

This section evaluates the responses of the participants regarding how they would rate the importance of digital and technical skills to the role of the PM. It is seen from secondary sources that some level of digital literacy is required but however, it also includes subject matter expertise and ability for professionals to demonstrate agility in the transformation process. It is observed that the statement *'The PM is versatile with experience in different approaches: lean, agile, hybrid… and methods that give flexibility and better results in delivering projects'* has a mean result of 4.22 and a standard deviation of 0.727 which implies that there is a convergence towards the mean result. Respondents tend to agree that this is an *'important'* requirement to the role of PM. The 2 other statements *(i) 'The PM has business analytics expertise, is able to analyse big data and apply business'* and *(ii) 'The PM is knowledgeable on industry technological advances'* have mean results below 4 *(important)* which may suggest greater disparity in responses as seen by the standard deviation of 1.110 for the statement *'The PM has business analytics expertise, is able to analyse big data and apply business'*. This may be interpreted as the profession does not yet fully integrate such dimension into the role of project management. Crosstabulation statistics between the sector of operation and this statement show that 38% from the Construction sector considered this statement of no, low or moderate importance while in the Financial and Banking sector, 54% thought so and 77% in the Technology sector.

Human and Transformational Skills

Industry insights showed the importance of engaging individuals and stakeholders to address the gaps and challenges such as skills, resistance to change and foster an innovation mindset and culture. This section examines the feedback from respondents concerning the importance of transformational skills required for the PM role. 3 statements were rated by the respondents and the statement *'The PM demonstrates emotional intelligence and interpersonal skills that contribute to projects*' performance' has the highest mean with a result of 4.64 and a standard deviation of 0.583, the lowest amongst the 3 statements. This implies that responses for this statement converge towards the mean and therefore, the respondents considered this as an

'important' aspect required for PMs in contributing to project performance. Similarly, the respondents also deemed *'important'* (mean result of 4.38) the necessity for PMs to be able to create the culture for change and lead accordingly. However, the other statement *'The PM is capable of instilling a digital and innovative mindset across stakeholders, both internal and external'* has mean result of 3.86 which is slightly below *'important'*. Furthermore, it is to be highlighted that only 18% of the 'Project Manager' respondents ticked as *'very important'* the statement *'The PM is capable of instilling a digital and innovative mindset across stakeholders, both internal and external'* as opposed to 29% among the *'Project Team Member'* respondents. Project Management is strongly influenced by hard paradigms (Pollack, 2007) associated with factors that focus on *'efficient, expert-led delivery, control against predetermined goals and an interest in underlying structure'*. These roots, however, require a shift to more *'softer'* aspects with emphasis on the people side of project management, emotional intelligence, roles that would encourage innovative mindsets, influence, and engage stakeholders.

Self-Transformation and Cognitive Skills

This section examines the *'accelerators'* elements of the skills group *'Self-transformation / Cognitive'* and gathered the opinions of the respondents on the importance of learning and development for the PM role. It is observed that for all the 4 statements *(i)* '*The PM should have ongoing project management training' (ii) 'There is a need for PM to acquire more knowledge and subject matter expertise beyond the standard certification' (iii) 'The PM should cultivate a mindset of innovation, curiosity, and entrepreneurship' and (iv) 'The PM should demonstrate the ability to learn, understand, apply and keep up with technology'*, the mean results are above 4 *(important).* In terms of standard deviation analysis, it is seen that the last statement *'The PM should demonstrate the ability to learn, understand, apply and keep up with technology'* is the one with the lowest result which implies that respondents tend to agree more on its importance, the result in fact, converges towards the average. Overall, the findings for this section show that there is an acknowledgement amongst the respondents that learning, training, development, and investing in self are important elements that also form the leadership skills of PMs.

Qualitative Findings

For this part of the primary data collection, only 1 individual *(*Participant *P1)* provided his consent to participate to the online interview. *P1* has a civil engineering background with 7 years of experience in the construction industry. He holds the position of Project Co-ordinator in one of the major construction players in the UK. The feedback from *P1* revealed that there is an understanding and awareness of the impact of digitisation, new technological advancement on the workplace and professional activities. The addressed questions provided an insight in the interviewee's industry and the main themes and interpretations were around culture, leadership, learning skills, knowledge, and adaptability. However, the dominant factor during this conversation concerned the organisational culture. *P1* stressed on the culture developed within the organisation that sets the guidelines and structures the approach and behaviour of the PM and decision makers. It is also interesting to note that the interviewee emphasised on external elements such as legislations, and professional institutions in defining and structuring the construction industry. *P1* mentioned the voice of leaders are powerful in communicating and influencing players in the industry. Therefore, if construction players are

looking for a strategic and competitive advantage they might as well adopt, follow, and keep up to date with the industry advances. Another focus of this interview was around learning skills, that is, the importance according to *P1* to invest in people. On one side, *P1* suggested that it must be part of the company's culture to offer training to its people but on the other side, it is important for professionals to invest in self, through certification, and other courses. Regarding the framework, the interviewee described it as the *'ideal'* required skills, which might suggest that this is not the case in real world. In addition to that, *P1* mentioned that often, new technologies and developments are owned by other departments or stakeholders which may not necessarily urge project professionals to acquire those skills but rather adopt a more *'execution'* role.

Conclusions and Recommendations

This study tackles a contemporary challenge in practice. Firstly, project professionals have to take advantage of disruptions to re-skill, up-skill and lead the transformation. It has been seen that it is crucial for project leaders to have more than just the technical skills. The study revealed that there is an acknowledgement on the importance the role of the project leader to expand to other aspects such as forward thinker and the human side in response to rapid evolutions. However, this study also suggests the importance to define and view the role of the PM as of strategic nature. The ability to reimagine project management and project delivery in a digitally disrupted environment is largely determined by a clear digital strategy, supported by project leaders who foster a culture enabling change. In fact, we have seen in the literature review chapter that academics as well industry insights suggest that transformation requires a clear strategy. Secondly, technology is only as valuable as the new business strategies and practices it enables. Culture hence is essential in leading transformation. Leveraging on disruptive technologies requires companies to embrace a culture of change that encourages transformation that is, engaging in a process of change management and therefore presenting opportunities to evolve to the next best practices. As seen in the framework developed, culture can be identified through the approaches implemented such as empowerment, learning, talent management or the climate for innovation. This study also showed that having strong leadership figures influence the strategy and the culture of the company, providing for direction and identity to its people and fostering (digital) initiatives. Finally, the conceptual model was developed to identify the themes and patterns and was further tested and explored through data collection. The purpose was to examine characteristics and skills required by leaders to interact and operate in a digitally disruptive environment. The findings of this study contribute to understanding the linkages in the construct of the project leader 4.0. Indeed, the findings revealed that overall, this study is consistent with research that indicate that digital transformation is not only about technologies, but that leadership is also a major facet in the transformation. The *skills groups* identified and tested demonstrated that there is a degree of awareness among people involved in projects on the importance of the 4 *skills groups* categories (a) Strategic / Transactional (b) Digital / Technical (c) Human / Transformational and (d) Self-Transforming / Cognitive. Some recommendations can be made for academics and project management practitioners:

a) Further tests on the developed framework (Figure 2) may benefit academics in developing the set of leadership skills required for PMs. The tests may explore more variables such as mature organisations, small or medium enterprises, countries or more project positions/different experience on projects.

b) The project management discipline should emphasise more on the strategic nature of the profession rather than portraying a '*hard'* version, an 'execution' role.

c) Self-awareness amongst practitioners is essential in order to leverage on disruptive technologies to reinvent their role, learn and acquire more subject matter expertise.
d) PM should recognise that they have the power to lead change and transform processes not only through technical knowledge but through their capability to exploit their human skills, for instance, through emotional intelligence, communication and negotiation skills with stakeholders.
e) Organisations should not view disruptive technologies as an operational challenge but rather define a clear strategy, strong culture and leadership to navigate through.

Implementation of Geert Hofstede's Cultural Dimensions to Multinational Construction Management

E. Şenkaya
Middle East Technical University, Department of Civil Engineering, Ankara, Turkey
esenkaya@metu.edu.tr

Abstract

Since the dawn of enlightenment era in seventeenth century, understanding human behavior has become the major concern of social sciences. Particularly philosophers and later scientists devoted their efforts to comprehension of patterns, shaping human actions and reactions in and across societies. This approach yielded in another field of study namely Behavioral Science, differentiating from social sciences in respect of implementing empirical data to decision making processes as well as business strategies, taking into account impacts of society on the individuals or groups which can be named broadly as "culture". Geert Hofstede, during 1970s, managed to collect an immense data set from IBM employees in worldwide offices, to compile into meaningful figures, which reflect cultural deviations of societies; later referred to as Hofstede's Cultural Dimensions. This model found a large implementation area in multinational business practice in last decades. Current study will cover, to what extend a cultural model can be implemented in various areas of multinational construction management.

Keywords: *behavioral science, culture, multinational project management, strategy.*

Introduction

Influential thinkers and philosophers -even being followers of empiricist school- were well aware that there is space beyond human experience forming basis of human understanding, which would be named as innate powers of human mind, are actually the main factors that varies our interpretations of the external world and essentially how we react to it. This subconscious space is the factor behind deviations of human behavior; actions, non-actions, reactions, responses, decisions etc. from individuals to individuals or groups to groups. Inquiries on cultural parameters affecting individual and social behaviors go back to ancient times; sixth century BC Kleistenes and Solon in Greece and Servius Tullius in Rome (Oskay, 2015), who tried to re-organize social structuring of their societies noticing deep inter-relation between societal institutions and process of civilizations. Since then, efforts for understanding the cultural patterns of societies and intervention to the natural route of the evolution of the society never ceased.

Culture, is a main gate to the understanding of multi-national business environment, especially when there is close interaction of entities. One way to categorize groups of people behavioral-

wise is using nations as samples, though it may not essentially reflect the real case about particular individuals. Geert Hofstede was among the first few to systematically categorize the deviations of behavioral patterns of different cultures relative to each other and in his initial study (Hofstede, 1980) based on IBM's employee data, relieved four major cultural aspects, which he called "*dimensions"*. These dimensions identified by Hofstede were; Power Distance (PDI), Uncertainty Avoidance (UAI), Individualism-Collectivism (IDV) and Masculinity (MAS). Hofstede later developed his model adding a fifth dimension, of *Long versus Short Term Orientation* (LTO) in 1991 taking into account surveys in China and a sixth dimension in 2010, Indulgence versus Restraint (IVR) generated from World Value Survey (Hofstede, 2010).

Modern studies regrading interactivity of sociology and business practices started with Abraham Maslow's culture-independent work about "hierarchy of needs" (Maslow, 1943). Anthropologist George Murdock (1957), first time introduced a worldwide cultural varieties classification. Anthropologist Mary Douglas was the first to utilize a two-dimensional Cartesian framework to illustrate cultural variations incorporating *individualism/public* classification and *social boundaries* (Douglas, 1970) setting a methodological ground for Hofstede's 1980 work. Following Faucheux et al. (1982) who pointed out the importance of cultural variations in organizations, the subject initiated more concern. Aaron Wildavsky's (1989) prescription of four varieties of cultures (*hierarchy/collectivism; apathy/fatalism, competition/individualism and equity/egalitarianism*) followed them. Another alternative to Hofstede's dimensional categorization came from Fons Trompenaars, who proposed a seven dimensional cultural diversity model applicable in business practice (Trompenaars, 1993), which included *universalism vs particularism, individualism vs communitarism, neutral vs emotional, specific vs diffuse* and *achievement vs ascription* dimensions together with *orientation of time* and *attitudes to the environment*. This new model proposed was criticized by Hofstede (1996) for not positioning countries distinctively in dimensions; not validating country scores with respect to independent parameters and confusion of using deductive conceptual categories based on approaches of *sociologists and anthropologists of 1950s and 1960s.* Debate continued with the answer (Hampden-Turner & Trompenaars, 1997) criticizing Hofstede to categorize cultures linearly in "True-False" type of logic with a universalist approach, neglecting shades of gray; presenting his findings in not very meaningful cross-axis diagrams and his reductionist approach to include as minimum as possible dimensions of factors to model wide varieties among cultures. In 1994, Shalom H. Schwartz –to facilitate cross-cultural research- introduced a new set of dimensions working on 41 cultural groups in 38 countries (later 72 countries), taking into account individual values *of the sample on psychological and social variables* (Schwartz, 1994). Schwartz Value Survey (SVS) was conducted among limited samples, composed of students and teachers while further analysis (Fischer et al., 2010) found similarity between individual level values of SVS and Hofstede's country scores. However, this similarity was far from a *near-perfect* match except scores of IDV. As Hofstede in a joint study with US psychologist Robert R. McCrae, rightfully concluded, personalities are not independent from cultural factors (McCrae, 2010). By 2000, Hofstede's 1983 work had become already *more than a classic* (Baskerville, 2003). Baskerville's literature survey illustrated that, in 18 years, "Culture's Consequences" was cited by journal articles in business, psychology, and anthropology/sociology topics 712, 540 and 48 times respectively with an overall citations reaching to 1706; but noted the relatively low citations in anthropology and sociology fields. Baskerville argued this relatively low citations' reasons as: Hofstede's work was based on only one company's data far from being representative and its insufficiency against George Murdock's wider work "Ethnographic Atlas". In his Atlas, Murdock (1957) had examined 565

different cultures referring to variety of cultures within the same countries, which was deemed to be neglected by Hofstede while reducing them all into nation states.

Regarding the structures of organizations in multi-cultural environments, there is a vast amount of literature accumulated after the second half of the twentieth century; but until 1980s, scholar works on organizational development like Bennis (1969), Friedlander and Brown (1974), Alderfer (1977) were based on American practice and did not take into account cultural diversity as criticized by Adler (1983). The global awareness on the failure of Western styles of management approaches in different cultures, started simultaneously with the Chinese economic reforms in 1980s, when Western style project management was tried to be implemented in China in a broad sense especially in construction sector (Chen & Partington, 2004). Wang and Liu (2007) provided empirical evidence from china indicating the cultural barriers to the use of Western project management values in China; their analysis relieved major deviations in Western and Chinese values over *Horizontal – Vertical* management, *Team-Family* consciousness together with *Task-Boss* orientation. A research study (Özorhon, 2007), demonstrated the specific importance of cultural varieties in International Construction Joint Ventures. Prado et al. (2017) illustrated the detrimental effects of cultural varieties on organizational strategies.

Regarding the relation of project management and effects of cultural differences, the contributions followed organizational development issues. Upon, Laurent's (1983) work, which pointed out process of management was in significant correlation with biases of managers and revealing significant diversities among managers in ten different European countries, Hofstede (1984) published another work to implement his cultural dimensions in management and planning denoting the fact that "*no management activity can be culture free"*. Archibald (1991) pointed out the significance of adjustments in attitudes and understanding to overcome cultural barriers in project management function. Archibald's "barriers" were closely related to PDI and UAI. Kendra and Taplin (2004) pointed out the significance of cultural framework's importance in a collaborative work about project success within an organization. Prabhakar et al. (2008) in a study regarding culture and conflict management topic carried out on 150 telecom sector project managers from France, Great Britain and India found significant correlation between Hofstede's IDV and MAS dimensions and some with UAI dimension for project managers adopting an approach to avoid conflicts. Bredilet et al. (2010) found direct correlation between Hofstede's IDV dimension and project deployment while PDI and UAI dimensions were reported to be supportive cultural factors.

This limited scope study intends to cover coherence or divergence of Hofstede's cultural dimensions with respect to multinational construction management applications based on the observations of the author. For those who are alien to the subject, a brief introduction to the cultural dimensions is also provided.

Term "Culture"

Prior to moving further with Hofstede Dimensions, a common understanding of the term "culture" should be discussed. For centuries, interpretation of culture varied drastically with respect to time and incorporated disciplines, but a consensus has not been reached among scholars. The etymological background of the term goes back to Latin, as Cicero, in first century

BC, referred to it as "*Cultura animi philosophia est* -Philosophy is the cultivation of soul-". This definition of culture relating it to "progress via cultivation and settlement" later evolved into a parallel understanding of *culture* with *civilization*. Cicero's analogy essentially bonded culture to human activities, thus *civil life in the city*. This self-generation of the **self** was explained later by French historian Jules Michelet; as "***the decisive shaping of self by self"*** or as Karl Marx put it*; **"the production of people by people"*** (Braudel, 1995). This parallelism between culture and civilization has become a common understanding and Encyclopedia Britannica describes anthropological definition of culture as "*a concept, called attention to the non-biological, nonracial, non-instinctual dimension of human life, the basis of what is called civilization: its values, techniques, and ideas in all spheres*."

Combining all above definitions, we can simply compile the common characteristics of the term "culture" into the following benchmarks; *implies a society sharing the same environment, acquires knowledge via morals, custom, habits, beliefs, behavior patterns, routine practices, and it is an evolving institution reproducing itself, essentially parallel to civilization and its economic activities.*

Hofstede's Interpretation of "Culture"

Without understanding particular definition of Hofstede for "culture", an effective understanding of his dimensional model would not be comprehended. In his 1991 work (Hofstede, 2010) Hofstede, evaluated definition of "culture" as "civilization" or "refinement of mind" as a narrow approach. For him, culture is a "*mental software*" which has a broader use that is common to sociologists and especially anthropologists. In this respect, he discriminates human nature from culture, using a computer world analogy; while human nature is an operating system (which all human beings inherited via their genes;), culture is not something innate, and implies that culture is an application which, main inputs collected from the environmental factors of the society one borne into. In that respect, human beings use their innate nature to interpret the external world but express or reflect their feelings thru the software called "culture". Figure 1 is a visual representation of "practices" (rituals, heroes, symbols) as the software of the mind running on the operating system of "values", altogether shaping the society's behavioral patterns.

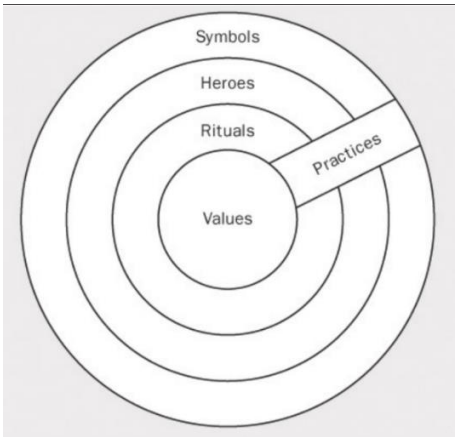

Figure 0: Hofstede's (2010) "onion" manifestations of culture.

Hofstede, tries to provide significant factors how human beings response to external world, and why there are deviations in these responses from nation to nation. Therefore, Hofstede's cultural model is based on nation-states where such measurements of deviations can be handled more easily. This approach is essential (though Universalist) in multinational business practice where entities cannot run particular psychological and sociological surveys for each case. Shortly, as Hofstede (2011) expressed in his YouTube interview; "*what makes us different is, the forest we were born in*." That is the reason why nationwide characteristics merge, as the public is the byproduct of that typical "*forest"* they live in. From the viewpoint of business economy; nation-wise cultural factors have a broad influence, as they constitute "*a stable set of values, perceptions, preferences, and behaviors*" that have been learned by the individual in a particular environment.

Hofstede's Interpretation of "Dimension"

Hofstede (2010) defines dimension as "*an aspect of culture that can be measured relative to other cultures*". Using a dimensional model, made it easier to group together "*a number of phenomena in a society that were empirically found to occur in combination, regardless of whether there seems to be logical necessity for their going together*." Therefore, the heart of the dimensional study rests in this inductive argument; the dimensions produced themselves based on the survey used, instead of a logical and biased pre-determination. In this respect, one can –at the first sight- might have difficulties in interpreting these **self-relieving** cultural dimensions of the study, as it might deviate from classical classifications.

A Review of Hofstede's Cultural Dimensions

Hofstede, upon encountering with a similar survey –Chinese Value Survey (CVS)- in 1971 by a Canadian researcher, Michael Bond, a new dimension which was not correlating with Hofstede's initial dimensions was relieved and Hofstede added that dimension to his model as "LTO-Long-Term versus Short-Term Orientation" being the fifth dimension in 1984. And finally, Michael Minkov's drilling into World Values survey data relieved the final (sixth) dimension of "IVR- Indulgence versus Restraint" in 1991.

Sample Data

In post-World War II economic booming years; IBM was among the few multi-national companies, which employed thousands of employees worldwide. During 1970s *IBM employee survey data comprised the largest cross-national collection of comparative value statements anywhere in the world* (Hofstede, 2010). The work, which started with 40 countries extended to 72 in a short. Although the surveys conducted initially were generally misinterpreted to be pertaining to managers only, Hofstede (2011) points out that they covered all levels of employees' dataset. The sampling and its outcome indices should be interpreted as relative weights of nations (countries) with respect to each other, rather than being absolute figures. While computation, mix of occupations surveyed were kept constant for all countries, as Hofstede (2010) pointed out, *Spanish engineers were not compared to Swedish secretaries*.

Validation of Dimension Indices with Other Measurable Parameters

When the question is about deviations of cultures, the major difficulty will be about commensurability. One has to find ways to make abstract and relative measurements, put them into one coordinate system where values of the axis which is also subjectively defined by the researcher. So, interpretation of the relative values designated to the factors should be checked for coherence using measurable country specific parameters like, GNI (Gross National Income), violence rates, income inequality, religion, savings etc. Some of Hofstede's correlation factors are given Table 1. Referring to his initial study (1980), Hofstede points out that these cultural dimensions were validated using four hundred significant correlations with other independent country-specific parameters and additionally points out that the indices scores are not time dependent, i.e. the relative rankings of countries in 2010 were close to the rankings of 1970.

Table 1. Correlation of cultural dimensions with country parameters.

Dimension	Corr. Type	Independent Correlated Country Parameter
PDI	(+)	Use of Violence, Income Inequality
IDV	(+)	Level of GNI
MAS	(-)	Share of GNI for government aids to poor countries
UAI	(+)	Roman Catholicism
LTO	(+)	National savings rates

In his interviews (Hofstede, 2011), he also points out the fact that, *"though the indices figures might change in time, relative positions (rankings) of countries with respect to each other remain stable"*.

Understanding Hofstede's Dimensions

The remarks hereon, are based on Hofstede's latest work of 2010. However, for the scope of this study in multinational construction management, specific intention will be given on PDI, IDV, UAI and LTO dimensions, which supposedly provide more significant distinction factors. The data interpretations are made on the summary data obtained from Geert Hofstede web site, made publicly available for researchers. However, for the sake of homogeneity, the countries where some dimensions not measured, were excluded from this study; so the data used comprises of 61 countries plus the Arabic, East Africa and West Africa regions.

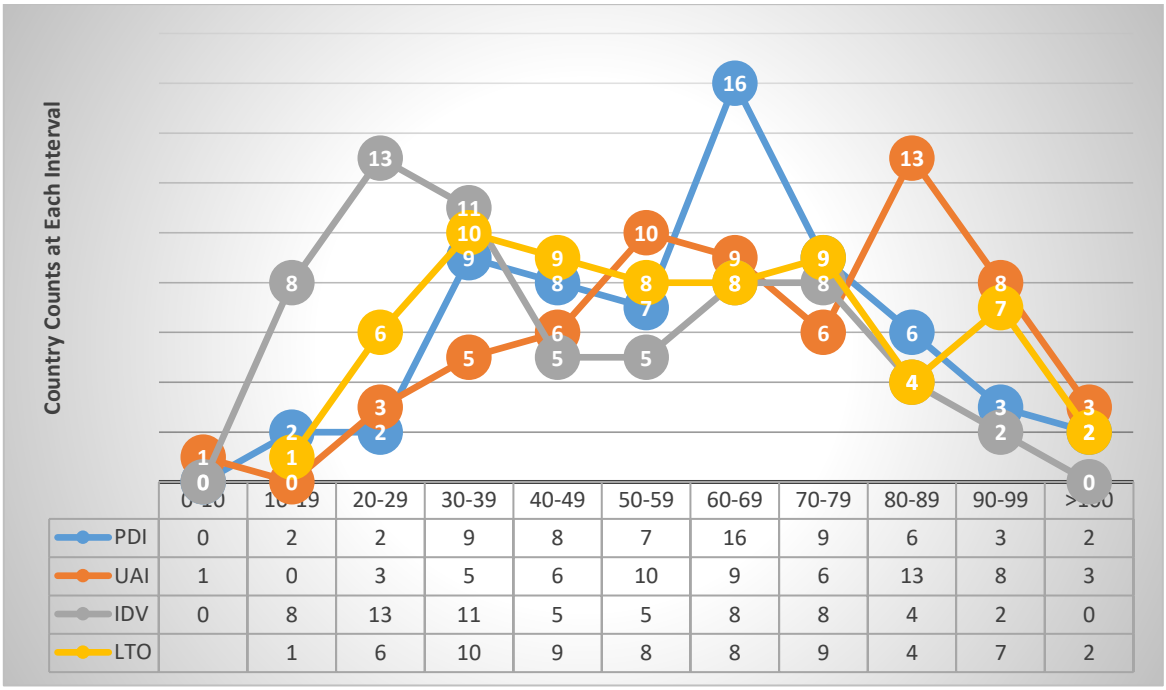

Figure 0: Distribution intervals of country scores by dimensions.

In some of the below interpreted data, several country scores are exceeding 100, which indicates that, the country data is added later, upon finalization of the normalization process. Figure 2 represents distribution intervals of country scores with respect to four dimensions chosen for this study.

Power Distance Index (PDI)

The dimension referring to PDI aims to measure the degree of inequality between members of a society. IBM's employee survey included questions regarding how subordinates were feeling free to express their ideas or counter-arguments in front of their superiors. As the index value increases, the power-distance between subordinates and superiors are increasing. i.e. 0 for small power distance and 100 for large. Figure 2 demonstrates the variation of PDI scores (in blue) worldwide corresponding to the lowest standard deviation (20.44) among all other dimensions. The mode of the distribution is 60-69 interval, and a slight tendency to a lower PDI score can be observed. Highest and lowest five PDI scoring countries and respective behavioral differences specifically related to business practices are listed in Table 2. More "democratic" oriented business practices were observed in Scandinavian countries, whereas authoritarian approach increases in East Europe and Far East.

Table 0. Highest and lowest PDI scores.

	Country	PDI	Some behavioral differences noted by Hofstede
Top	Malaysia	104	Children more obedient to parents, both parents worked fulltime, educational process is teacher centered, budgets spent for higher
	Slovakia	104	

	Philippines	94	education, at work superiors and subordinates are existentially unequal, state authority tends to be traditional and symbolic elements used to show power, have tendency of using centralized power, subordinates expect to be told what to do, power and wealth coincide, weak check and balance mechanisms
	Russia	93	
	Romania	90	
Bottom Five	Norway	31	Children learn to say "no" and to contradict, one parent works fulltime, educational process is student centered, budgets spent for secondary wide-spread education, at work flat hierarchy exists, tendency for power use is decentralized, subordinates expect to be consulted, power and wealth need not to coincide, strong check and balance mechanisms
	Sweden	31	
	Ireland	28	
	N. Zealand	22	
	Denmark	18	

Hofstede's striking finding on PDI is about geographic correlation of the scores; approaching to the equatorial zones, power distance increases and for him this fact is caused by prehistoric migrations of people; equatorial zones require hard work to grow crops necessary for survival. British Historian Ian Morris (2010) had described a similar geography effect on civilizations as "Lucky Latitudes", which provided more suitable environmental conditions for agriculture / horticulture and yielded to development of division of labor together with vertical hierarchy.

Individuality versus Collectivity Index (IDV)

The dimension referring to IDV aims to measure the degree whether the interests of the group prevails over interest of the individual in a society. The separation is initially generated from family structures; in collectivist nations, families are in extended forms to include grandparents to grandchildren, whereas in individualist nations families are nuclear (core). Hofstede (2010) found a strong relationship between a country's national wealth and degree of individualism in that nation; higher the individualism higher the wealth of that nation. This finding is not surprising as long as wealth is measured in terms of commodities; so, in the countries where private ownership is praised, wealth in that respect will be naturally higher. Private ownership by definition, entails individuality following the assumption of Adam smith that; *each individual is motivated by self-interest and self-interests of individuals are for the benefit of the whole society*. Anglo-American governance of high IDV scores confirms this assumption.

Figure 2 demonstrates the variation of IDV scores (in grey). The left side shifted IDV distribution in Figure 2 demonstrates a general tendency towards collectivism against individualism in world scale (σ=23.14). This is denoted by Hofstede as "*collectivism is the rule in our world, and individualism the exception*" (2010, p. 97). To have closer look, Highest and lowest IDV scoring countries and respective behavioral differences are listed in Table 3.

Table 2. Highest and lowest IDV scores.

	Country	**IDV**	**Some behavioral differences noted by Hofstede**
Top	U.S.A.	91	Higher national wealth, children encouraged to develop own opinions, longer and explicit contextual approach (contracts),
	Australia	90	

	Great Britain	89	encourage independent self, prefer to live in detached houses, more life insurance policies sold, weaker labor unions, management is understood as management of individuals, trust is to be established with organizations rather than individuals, confronting views welcome, preference of freedom over equality, employer-employee relationship is calculative
	Canada	80	
	Hungary	80	
Bottom Five	Peru	16	Lower national wealth, children forced to obey, shorter contextual relations (contracts), encourage interdependent self, prefer to live in communal apartments, hiring family members in businesses, stronger labor unions and labor conflicts, management is understood as management of groups, trust is to be established among individuals, confronting views not expressed, preference of equality over freedom, employer-employee relationship is moral
	Trinidad and Tobago	16	
	Indonesia	14	
	Colombia	13	
	Venezuela	12	

Uncertainty Avoidance Index (UAI)

The dimension referring to UAI aims to measure the degree of anxiety levels of a society under contingent or ambiguous situations. The relative values of nations were measured via survey questions reflecting one's stress level at work, ideas about breaking company rules and whether they intend to work for the company (IBM in this case) for a long time or not. High stress levels, fear of breaking company rules (as they endanger one's future expectations) and plan for keeping the work for a long time are indicators of anxiety levels. Higher the anxiety, higher the UAI. Figure 2 shows the distribution of UAI scores shifting to right (with σ=22.71), which is a clear indication that, nations worldwide have a general tendency of avoiding uncertainties. Hofstede (2010), in his interpretation of uncertainty avoidance, gives particular attention to the fact that, this dimension should not be confused with risk avoidance. As he points out; "*uncertainty is to risk as anxiety is to fear. Fear and risk are both focused on something specific: an object in the case of fear, and an event in the case of risk. … Uncertainty has no probability attached to it.*" Uncertainty avoidance is avoidance of one from a *complete unknown*. Table 4 summarizes behavior characteristics of high and low UAI scores of countries selected for business-oriented events.

Table 3. Highest and lowest UAI scores.

	Country	UAI	Some behavioral differences noted by Hofstede
Top Five	Greece	112	High stress and high anxiety, personalities are more neurotic, strong superegos, what is different is dangerous, more worries about health and money, in shopping search is for purity and cleanliness, new cars expert repairs, conservative investments, time is money and urgency prevails, top managers concerned with daily operations, need for precision and formalization, more corruption, conservatism governs, principles governs over practice
	Portugal	104	
	Uruguay	100	
	Malta	96	
	Russia	95	
Botto	China	30	Uncertainty is a normal feature of life, low stress and low anxiety, personalities are more agreeable in nature, weak superegos, what is
	Vietnam	30	

Hong Kong	29	different is approached curiously and tolerantly, fewer worries about health, money and time, in shopping search is for convenience, prefer used cars DIY repairs, risky investments, time is framework for orientation, top managers concerned with strategy, tolerance for ambiguity, less corruption, liberalism governs, practice governs over principles
Sweden	29	
Denmark	23	

Very high UAI scores of Greece, Portugal and Russia in Table 4 is not surprising. As they have scored even more than 100, evidently the data for these countries were collected later most probably after 2008 economic crisis, which affected these countries most. On the other hand Scandinavian and Far Eastern countries differentiate from the rest of the world with lowest scores most probably due to trust in future and particular philosophical teachings respectively. This finding is strongly correlated to the LTO dimension below.

Long Term versus Short Term Orientation (LTO)

Hofstede explains the appearance of this dimension which appeared from CVS, with the influence of Confucian teaching in the high LTO countries. Major Confucian ideas reflected are; stability of the society to be based on un-equal status relationships, a person is primarily a member of society (relating to IDV), not treating others as one would not like to be treated oneself, main work virtues to be acquiring skills, hard work, patience and preservation. So almost four out of eight values of the CVS was directly related to Confucius' teachings as Hofstede (2010) denotes; "*culture rises from its ashes like a phoenix*." A new dimension's discovery in a survey pertaining to Far Eastern countries relieved another fact regarding methodology; surveys directed by Western "minds" would not be reflecting the truth in the Eastern societies or vice versa; in Hofstede's (2010) words: "*a questionnaire invented by Western minds produced a fourth dimension dealing with Truth (refers to UAI); a questionnaire invented by Eastern minds found a fourth dimension dealing with Virtue.(refers to LTO)"*. Hofstede's conclusion is; scientific research very well copes with analytical thinking ***but organizational capacities like management or government requires synthetic thinking***.

Figure 2 shows the uniform distribution of LTO scores (in yellow) with several modes ending up in the highest standard deviation (σ=23.22) among other dimensions. Table 5 illustrates highest and lowest LTO countries together with selected behavioral differences regarding business operations.

Table 4. Highest and lowest LTO scores.

	Country	LTO	Some behavioral differences noted by Hofstede
Top Five	Korea South	100	Support entrepreneurial activity via persistence or tenacity, sustained efforts for slow results, subordination of oneself for a purpose, respect for circumstances, main work values of hard work, learning, honesty, adaptation, accountability, and self-discipline; importance of profits ten years from now, investment on lifelong personal networks, matter and spirit are separated, synthetic thinking, investment in long term real estate, disagreement does not hurt
	Taiwan	93	
	Japan	88	
	China	87	
	Germany	83	

Bottom Five	Morocco	14	Quick results expected, concern with social status and obligations, respect for traditions, main work values of freedom of expression, individual rights, achievement and thinking of oneself; importance on this year's profits, meritocracy –reward by abilities-, matter and spirit are integrated, analytical thinking, investment in short term mutual funds, need for cognitive consistency
	Iran	14	
	Colombia	13	
	Trinidad and Tobago	13	
	Africa West	9	

LTO champions of South Korea, Taiwan, Japan and China are also the world industrial growth leaders in the final quarter of twentieth century; named among Five Dragons. Although major scientific inventions of twentieth century took place in the "analytical" western world, Far Eastern countries managed to adapt themselves with their hard work, perseverance and tenacity to cope with those inventions and even to take them to further level as observed in automotive and electronics sectors. Germany shines being the highest LTO country among Europe and not surprisingly, it was the European Union's growth leader by 2010 scoring twice the average of EU countries (World Bank, 2022). It is evident that, LTO index provides coherent data for reflecting a country's sustainable growth rate.

Incorporation of Hofstede's Cultural Dimensions in Multinational Construction Management

Multinational construction has become a major field of business activity starting from the post-World War II period, significantly after 1960s. Upon reconstruction of Europe, the workforce and related resources accumulated there had to be shifted to third world countries to ensure to sustainability of growth in the West. Establishment of United Nations (UN), World Bank and International Monetary Fund paved the routes of that growth. By the end of 1950s international forms of British Construction contracts (JCT -originated from RIBA-, FIDIC -originated from ICE- etc.) were made available to be used all around the world, based on their local forms prepared under Common Law and using British legal jargon; and naturally conflicts were inevitable. 1958 New York Convention by UN, prepared the infrastructure for resolution of international conflicts by allowing the recognition of international arbitral awards by local governments making international contracting business more feasible for Western companies. Upon saturation of Western construction giants' appetite, other countries started taking their part in worldwide game making use of their competitive advantages of factor conditions (human and physical resources), developing firm strategies (Porter, 1990).

As per Deloitte's Global Construction Powers Report 2019, with respect to Top 100 Global Construction Companies sales (GPoC ranking) China has become by far the world leader holding almost 44% of worldwide construction revenues, Japan follows with 13% and South Korea is the fifth one with a share of 5%. From the Western world US keeps the highest position with a market share of 9% followed by France and Spain with shares 8% and 5% respectively. Turkish companies in GPoC 100 shares 0.3 % of construction revenues by 2019 (Deloitte, 2019).

Expected Cultural Conflicts

This new global environment turned the world into one large "forest". Slowly but surely, understanding the needs of the environment, the international construction giants started to transform themselves into multinational giants, making more use of local human resources to take the advantage of their skills in the particular regions. Business entities were not struggling anymore only with the suppliers and employers of other nations but also with wide range of nationalities within their own organizations; therefore reshaping organizational strategies was essential. In this context, Hofstede's cultural dimensions model would be a rather convenient tool for avoiding conflicts within and interacting entities.

Hofstede's country scores are grouped in ten major regions in this study, presumably reflecting similar characteristics originating from historical facts in Figure 3, which illustrates the worldwide cultural deviations, compiled from averages of country scores involved. The much lower standard deviations of dimensions (10-12) among countries within regional groups defined, than the overall standard deviations (20-23), indicating a coherent grouping. Putting aside Scandinavian countries, there is a convergence of scores in MAS dimension, i.e. almost all the world is equally masculine; that dimension is inherent to nature of human beings; thus might have little differential effect in multinational business.

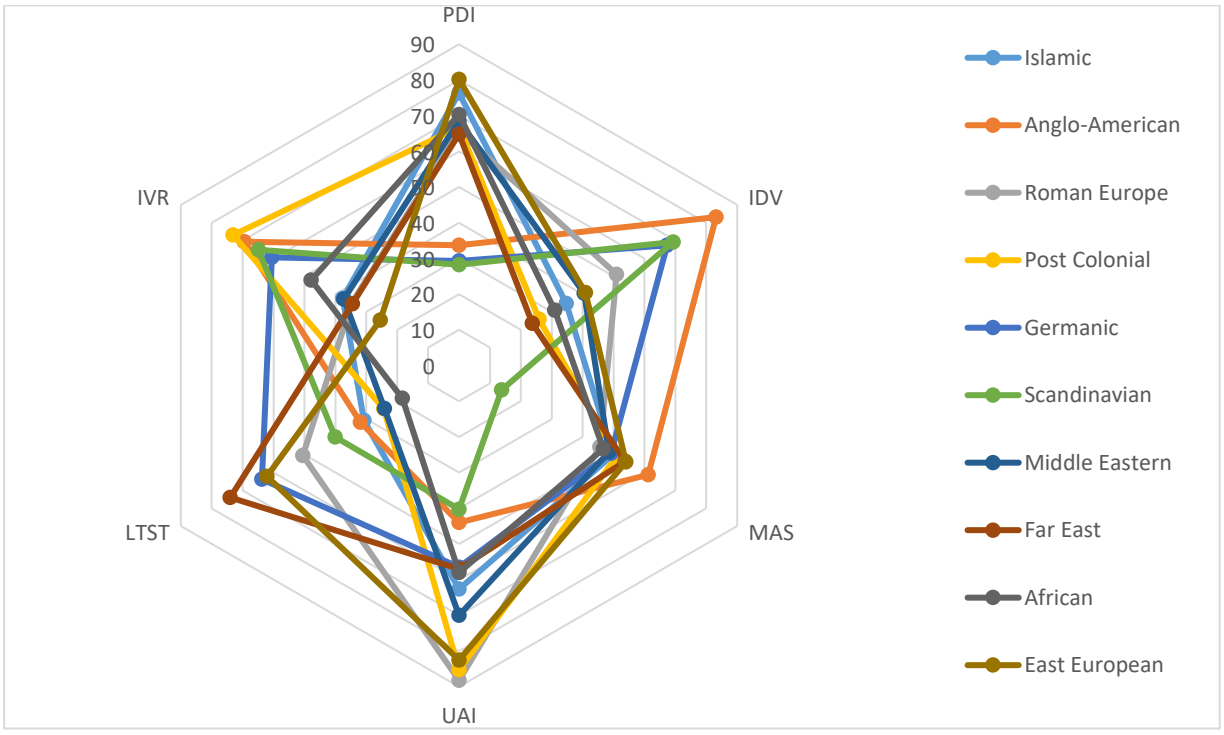

Figure 1: Worldwide cultural dimension deviations in representative regions.

Expected Effects of Power Distance (PDI)

As seen from Figure 3, low and high PDI countries concentrate in two poles; generally indicating the wealth level. It is interesting to note that, lower PDI cultures (wealthier ones) are those, who made advantage of trade concessions they gained historically from the higher PDI

cultures. Both sides of these countries have very long-term historical business relations with each other. Closure of borders to foreigners did not contribute to wealth of neither Japan nor China historically; besides they had lost their positons in front of the Western countries.

Power Distance is an important factor especially in multinational companies where managers and subordinates are from diverse cultures. A manager from a high PDI culture might find the expressions and attitudes of lower PDI culture subordinates offensive and conversely for a low PDI culture manager, non-confronting behavior of high PDI culture subordinates might risk business. Lower PDI culture employees prefer to be listened and their advice taken for important issues; this should not be taken as an offense by their managers of a high PD culture. High PDI cultures are more dependent on centralized power. In this respect, implementation of Western management recipes like Management by Objectives (MBO) (Drucker, 1955), might not be effective in high PDI countries (Hofstede, 1984). While conducting business, this factor will make quite difference; especially when negotiating with members of a high PDI culture, highest rank officials are required, as subordinates will not be provided with authority to give away any item during bargaining, and this is a tricky situation when the other side is represented with full authority.

Expected Effects of Individualism versus Collectivism (IDV)

Figure 3 demonstrates an important the separation of wealth between Anglo American, Scandinavian and Germanic countries with higher IDV scores compared to the rest of the world. 1960's had become the turning point for a paradigm shift from collectivism to individuality. Effects of cold-war between socialist and capitalist countries should not be underestimated in this paradigm shift. Propaganda tools to show especially socialist countries as "evil empires" played a great role in changing consumer behaviors as well; individualism came with an explosion of consumption; smaller houses, more appliances, more automobiles and growth of related industries. A significant negative correlation between IDV and PDI scores can be seen in Figure 3.

As Hofstede (1984) pointed out; "*in individualist cultures, the relationship between the employee and employer is a business relationship based on the assumption of mutual advantage: it can be called a calculative relationship.*" A lower IDV score culture making business with a higher score IDV culture should be prepared for clearly defined long contractual agreements and a more organizational behavior. In high IDV cultures, trust is expected to be achieved only at organizational levels instead of establishing good relations with individuals. High IDV culture entities while making business with lower IDV cultures should be prepared for willingness of their local managers to work with extended family members and first circle friends; thus the risk of nepotism will be higher. Strong labor unions in lower IDV countries may be the sources of conflicts with local workforces in multinational projects. Therefore, contingency factors regarding local workforce and contractual risk mitigation should be carefully distributed especially under Force Major, Suspension and Termination clauses of contracts.

Expected Effects of Uncertainty Avoidance (UAI)

Figure 3 represents a clear negative correlation between UAI and IDV dimensions; higher the IDV lower the UAI. Generally, discussions made above for IDV holds right considering the negative side in UAI scores. However, some specific care should be given to the delivery methods incorporated in construction contracts. A high UAI culture's representatives should avoid making contracts -when they are employers- under Cost Plus or Unit Price terms with open ends. Best selection of contracts in that respect will be lump sum turnkey basis and if there is sufficient time and funds, EPC type delivery will work better. High UAI culture contractors will face tension under Design-Build contracts as the party responsible for design will be struggling with higher contingencies. In this respect, it has to be kept in mind that high UAI culture representatives are *not good negotiators when outcome of the negotiation is very ambiguous* (Hofstede, 1984). Once the risks are defined and followed together with consequential effects, stress and anxiety level of high UAI culture representatives might be taken under control. So following a Risk Register (like in NEC) during works might help.

When multinational lower UAI entities or corporations are working with higher UAI culture managers, they have to give specific importance to follow corporate long-term strategies, as their managers will be busier in dealing with daily matters more. A striking finding of Hofstede was the increasing level of corruption together with increasing UAI score and representatives or corporations of lower UAI cultures should be prepared for consequential effects of corruption especially in contingency factors in high UAI countries.

Expected Effects of Long Term vs Short Term Orientation (LTO)

As can be seen from Figure 3, LTO is not correlated with the other dimensions relieved from IBM survey, however, it generates quite a useful tool in understanding *eastern* minds while conducting business relations with the rest of the world. When getting into business relations with Far East cultures, others should be aware that inner harmony and slow but sure steps forward would prevail. Business strategies should be established considering long-term arrangements and profit expectations in short periods might not realize. Patience will be the key factor for a successful business partnership. Corporations with lower LTO scores when engaged with subordinates of high LTO cultures, can trust their hard work, adaptation, honesty and accountability as long as required respect is shown for their cultural values. Acceptance of other options than a single unilateral truth is another key factor. However, a high level of consultation or confrontation even for the benefit of the business relation might not be expected from high LTO cultures. Far Eastern cultures are very good business partners especially on PPP or BOT type long-term engagements, where results would be obtained slowly but surely. That is the reason; Chinese and Japanese giant construction companies are widely involved in BOT type contracts with long-term engagements with governments.

Sample Cases

In the following cases, observations of the author who was involved in Turkish, Polish, American, Russian and German construction companies in various positions among Middle Eastern, European, post-Soviet Union, American and African cultures, will be illustrated in

reference to Hofstede's cultural dimensions. It should be noted that the arguments below reflect the subjective opinions of the author. There exist a wide opportunity for future empirical work.

Case I- Russia and Turkey

Since the resolution of Soviet Union in1990, Russia and Turkey have become important business partners. CIS countries opened numerous opportunities to Turkish contractors especially in modernization of infrastructure and building advanced trading centers and industrial facilities.

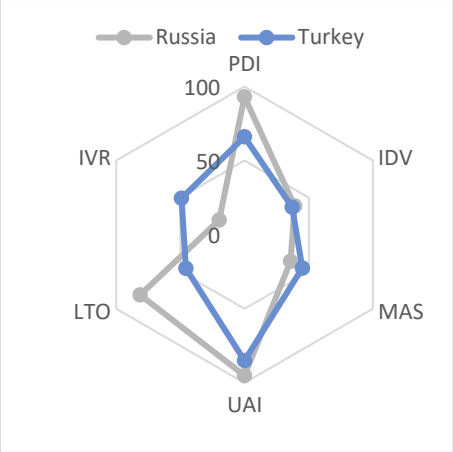

Figure 4: Major deviation factors.

As illustrated in Figure 4, major deviation factors between two countries lay in PDI and LTO scores. Autocratic management character (high PDI) of Russian entities did not constitute a serious problem, as Turkish companies were acting as contractors in service of the prior. Typically Russian sides in contractual negotiations were represented by lower level non-authorized representatives as a higher PDI culture, and this situation created an unbalanced bargaining power to compensate lower negotiation skills arising from higher UAI scores of the Russian side. As both nationalities have similarly low IDV, they were expecting more personal trust rather than organizational level trust. Whenever stronger/individualistic personalities have started to represent Turkish contractors, conflicts started to escalate and almost all the big scale contractors of early 90's had already disappeared from Russian market by early 2000s. This was the consequential effect of higher LTO scores of the Russian side. Turkish companies with short term expectations did not meet the longer term oriented Russian minds; only contracting companies, who adapted themselves to the environment survived.

Case II- Turkey and USA

Especially upon resolution of Soviet Union, US government and companies found lots business opportunities in former CIS countries, like construction of embassy and consulate facilities in the new states employing Turkish contractors. This co-operation progressed strongly in military facilities construction business after Iraq's and Afghanistan's occupation by US forces by early

2000s. Turkish contractors used their competitive advantages of logistics and cultural similarities in the subject countries to take part in the niche market.

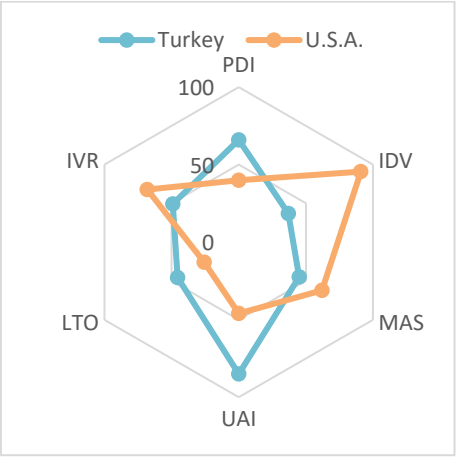

Figure 5. PDI scores.

As illustrated in Figure 5, significant deviations at PDI scores created tension especially in Turkish contractors to adopt themselves to the check and balance mechanisms required by the Americans like QA/QC and document control systems. The second cultural conflict area appeared in very high deviation in IDV scores. While American side preferred to work with well-defined contractual terms and scopes, Turkish side tried to compensate the gap by personal relations, which did not work out well. American side was always looking for systematic organizational relations as a matter of trust. UAI scores can be misleadingly interpreted from Figure 3-3 that US entities were ready to take major part of the risks in conflict zones, however, it was the Turkish entities taking the majority of risks while collaborating with occupation forces in a hostile environment. Uncertainty avoidance is different from risk avoidance as discussed before and in general, these assessed risks were well managed by Turkish construction industry, who were capable of developing interpersonal relations with third parties in those regions, where they had historical strong cultural ties.

Conclusive Remarks

Above two cases based on construction management experience of the author illustrates significant coherence of Hofstede's dimensional varieties when applied to construction management practice. Expectations and experience well match however, needs further survey among construction managers and their everyday faced difficulties while working in multinational environment. Of course, time to time, individual characters might highly deviate from the expected national culture values. However, as it is not possible and practical to carry out personal socio-psychological tests on business counterparts, a broader cultural understanding on the national scale might guide business efficiently.

For centuries, historians to sociologist and anthropologists to psychologists developed numerous theories to describe the origins and parameters, which are making cultures and civilizations so different from each other. Significant number of those studies concentrated or focused on the deviation axis between East and the West; most famous being the Clash of

Civilizations by Samuel P. Huntington in 1996. However, it was not primarily civilizations, but cultures clashing. In this respect Geert Hofstede's cultural dimensions study constitutes an important landmark on understanding human nature, thus understanding international or multinational conflict areas. Its methodology of using only IBM employees might be questioned in regards to reflective sampling, however, the results obtained generally match with worldwide observations and validated by works of others. Increasing the awareness on possible conflict areas is a key factor for a more harmonious world.

Another remarkable issue regarding conducting social survey studies worldwide is the identity and personality of the surveyor. As Hofstede admits, it is hard to relieve facts about *eastern* cultures with surveys prepared by *western* minds; similar to quantum physics, where presence of observers might change the results of observation. However, until a completely new methodology is invented, this is the only valid option in our hands. Lastly, Hofstede's idea that *cultural dimension rankings are isolated from time-wise effects as the change is global*, may not be reflecting the regional radical deviations of the last decades. Still -to some extent- revolutions and counter-revolutions continue; 1979 Iran, 1989 Soviet Union, dissolution of Yugoslavia in 1992, are a few samples of which, cultural differences were the motivating forces of disintegration and for the newly formed states, national behavior patterns are radically changing.

Hofstede's contribution will be continued to be questioned for its deterministic and sometimes reductionist approach for modelling of a very complex subject, but it will definitely keep its benchmark position for further surveys.

Abstract

The quality offered by the suppliers is a very important factor in total quality management practices in the construction sector, and it is necessary to establish standards regarding product quality, to determine the quality expected from suppliers with specifications, standards etc. and to inform suppliers, to identify problems and to support suppliers in improvement studies in order to provide the product at the desired standards, in good quality, economically and at the best time. It is possible to improve communication, establish trust-based, harmonious, and long-term relationships with suppliers, and ensure their participation in quality practices, by applying the partnering approach, which is a collaborative approach that involves customers, contractors and suppliers dedicating themselves to closer working relationships to increase performance and improve production. It is necessary to ensure the participation of all employees for continuous improvement of the process and to establish a corporate culture for total quality management practices to be successful.

In this study, the partnering approach in total quality management practices in the construction sector, quality culture, the importance of it in terms of the success of the practices will be mentioned.

Keywords: *Corporate culture, partnering, quality culture, total quality management.*

Introduction

Total quality management is an integrated management concept for the continuous improvement of product and service quality with the participation of everyone involved in the organization. It is the continuous improvement of all activities in a company and achieving profitability by satisfying employees, customers and all other project stakeholders with the participation of all employees in the organization. Since various research studies have shown that quality-focused companies achieved success, the expectations from total quality management are generally expressed as better employee participation and relations, improved product and service quality, higher productivity, greater customer satisfaction, increased market share, and improved profitability (Evans & Lindsay, 2019).

The facts that the product has different features than the other sectors, the function, location, size of the project, the scope of the service to be provided, the construction technique, architectural features, the qualifications of the project team, etc. with the uniqueness of

project, the participation of many disciplines in the process, the differentiation of the organization in each project make the implementation of total quality management in the construction sector difficult. It is seen that the implementations are unsuccessful due to reasons such as lack of questioning what to achieve from total quality management, failure of employee participation, lack of motivation, failure of suppliers to be included in quality practices, lack of infrastructure required for change (technical tools etc.), training applied only at the top management level (Güner & Karaçar, 2016).

Ensuring the effective employee participation for continuous improvement of the process in practices is one of the most important factors affecting the success of total quality management. Since the construction sector has sub-systems, it is possible for many different units to work with each other, and everyone in the organization is each other's customer. However, the establishment of temporary organizations at the project level and the constant change of participants in the process due to the uniqueness of the project causes communication and motivation problems and hinders the employee participation. In order to ensure employees participation, in addition to applications such as authorization and teamwork, employees'opinions should be sought regarding applications such as examinations, quality inspections, quality control circles, self-managing teams, etc. and other issues such as communication, top management leadership, education and training, motivation, workplace quality, salary satisfaction, recognitions and rewards, corporate culture, etc. and appropriate motivation tools should be used. It is necessary to ensure the cultural change required for continuous improvement and to create the corporate culture (Güner & Karaçar, 2016).

Corporate culture is a set of habits, behaviors, rules and principles in a company. In order to create a corporate culture in a company, it is necessary to provide cultural change within the framework of a holistic structure (Sommerville & Sulaiman, 1997). Cultural change is a change in personal and organizational behavior. This change requires communication between all employees and top management as well as communication with customers and suppliers. Change must start from top management, and everyone must be involved. Since it is not easy for people to give up the values and habits they have adopted, cultural change takes time and is very difficult. Top management should support and lead this change (Güner & Karaçar, 2016).

The quality offered by the suppliers is a very important factor in total quality management practices in the construction sector, and it is necessary to establish standards regarding product quality, to determine the quality expected from suppliers with specifications, standards etc. and to inform suppliers, to identify problems and to support suppliers in improvement studies in order to provide the product at the desired standards, in good quality, economically and at the best time (Berry, 1991). It is possible to improve communication, establish trust-based, harmonious, and long-term relationships with suppliers, and ensure their participation in quality practices, by applying the partnering approach, which is a collaborative approach that involves customers, contractors and suppliers dedicating themselves to closer working relationships to increase performance and improve production (Barlow, 1996).

Project partnering is a means to apply total quality management to the construction industry through teamswork with various parties (Kanji & Wong, 1998). Partnering is more than a set of goals and procedures; it is a state of mind, a philosophy and it represents a commitment of respect, trust, cooperation, and excellence for all stakeholders. Partnering is a system of conducting business that maximizes the potential for achieving project intent, attaining

specified quality, improving communication and resolving conflicts (Bayramoğlu, 2000). However project partnering, managing the supply chain as a whole and adopting total quality systems and procedures cannot yield best results without the creation of a quality culture for the parties to operate in (Kanji & Wong, 1998). In this respect, the organizations need to shift from their current culture to a total quality management culture that focuses on quality as a key strategy. Changing corporate culture or organizational culture is increasingly recognized as one of the primary conditions for successful implementation of total quality management (Mahmood et al., 2006).

In this study, the partnering approach in total quality management practices in the construction sector, quality culture and the importance of it in terms of the success of the practices will be mentioned.

Partnering in Total Quality Management Practices and Quality Culture

In the construction sector, the client, consultants, contractor, subcontractors, suppliers involved in the project, play a role in delivering a quality project. Here someone's failure affects the success of the project. The quality offered by the suppliers in total quality management practices, is a very important factor. Accordingly, it is necessary to include suppliers in the quality organization established at project or company level and to determine the quality expected from suppliers with specifications and standards, to identify problems, to support suppliers for improvement studies, to establish trust-based, harmonious, and long-term relationships with them and to guide them in total quality management process (Berry, 1991; Güner & Karaçar, 2016). In this respect, applying the partnering approach, which is a collaborative approach that involves customers, contractors and suppliers dedicating themselves to closer working relationships to increase performance and improve production, is required in terms of ensuring the participation of suppliers in quality practices (Barlow, 1996).

The partnering approach is the key that will unlock the techniques and principles of total quality management to provide customer satisfaction in the construction projects. Partnering and total quality management work within a continuous improvement approach by sharing common goals, and are placed in close proximity in this respect (Bayramoğlu, 2000). Partnering is a management approach used to achieve business value and increase the efficiency of the construction industry. Partnering aims to accomplish a positive environment for the project focused on achieving success for all participants by establishing a good relationship and a "*pain and gain sharing*" mentality (Hosseini et al., 2018). By applying project partnering, results such as improved efficiency, cost-effectiveness, reduced cost overruns and delays, lower administration costs, better time control, increased productivity, less conflict and improved conflict resolution strategies, dispute reduction, the opportunity for innovation, sharing risk between parties and financial success because of win-win attitudes are obtained. Moreover, partnering leads to improved work environment and continuous improvement of quality in product and services and earlier completion of the project (Hosseini et al., 2018; Bayramoğlu, 2000).

Successful partnering requires a plan in which partnering approach can be applied in an organization that focuses on quality, an effective project team, a set of tools by which the partnership approach can be structured and applied, implementation of determined standarts and specifications about product and service quality, management's commitment and

leadership, identification of problems and establishment of long-term and trust-based relationships between different parties for continues improvement. Project partnering is an approach used to enable the different parties involved in a project to work cooperatively. Project partnering is a collaborative management effort among contracting and related parties to compete a project in the most efficient, cost-effective method possible, by setting common goals, keeping lines of communication open and solving problems together as they arise (Kanji & Wong, 1998). It requires for cultural changes among the different parties to cooperative relatonships. Much of the literature tends to presume that cultural alignment where organizations share some basic values, attitudes and beliefs, is a prerequisite for partnering (Bresnen & Marshall, 2000). Effective partnership requires a high level of trust and sharing, and achieving it calls for a cultural and behavioral change in values, organizational structure, the way people work together.

Cultural change is a change in personal and organizational behavior (Sommerville & Sulaiman, 1997). Cultural change requires communication between all employees and top management as well as communication with customers and suppliers. Change must start from top management, and everyone must be involved. It is necessary to analyze the main influence factors determining the culture of the organization in order to ensure cultural change in a company and to create a corporate culture. The factors determining the culture of the organizations consist of internal influence factors (routine, ritual and procedures, control and reward system, organization structure, stories, myths and heroes, symbols, power structure) called as the cultural web and external influence factors (societal values and business environment). In order to change these values in the long-term, planning, patience and determination are required together with top management leadership (Figure 1) (Sommerville & Sulaiman, 1997).

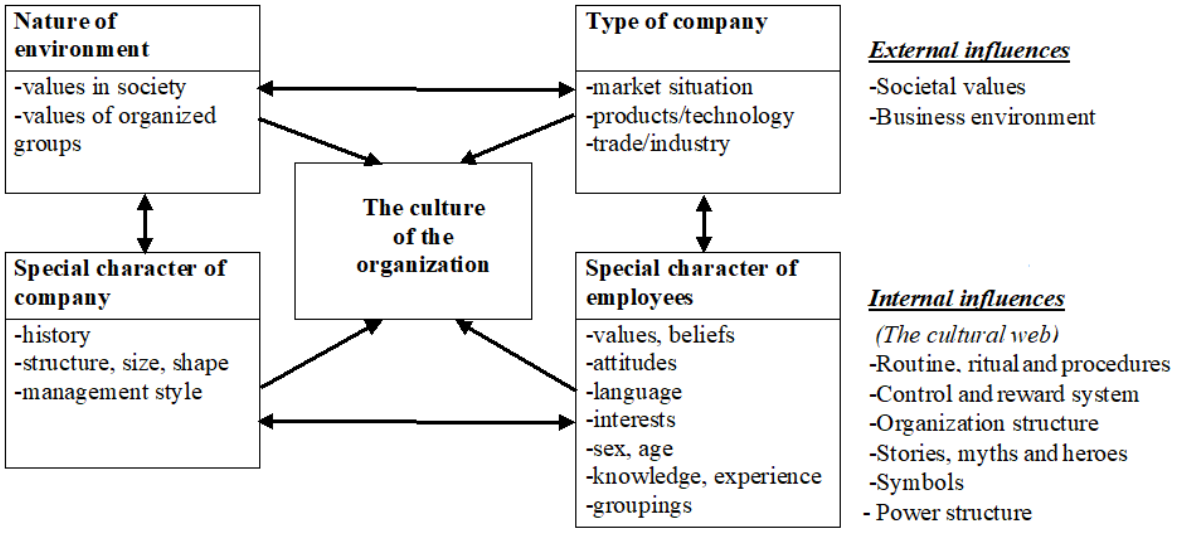

Figure 1: Factors determining the culture of the organization in the construction sector.

Here, it is easy to change the organization structure, control and reward system, routines and procedures which are expressed as hard part of the cultural web but stories, myths and heroes, symbols, power structure (politics that influence decision) which are expressed as soft part of the cultural web are difficult to change. Figure 1 shows the main influence factors affecting

the culture of the organization and the change in any of these elements will affect the culture of the organization (Sommerville & Sulaiman 1997).

In an organization where cultural change is achieved, there is a belief that everyone feels responsible for continuous improvement of work processes and customer satisfaction (Güner & Giritli, 2004). Systems that enable participation such as quality circles, recognition and rewards etc. should be used in changing the corporate culture. Education and training should be widespread in the organization in order to change the attitudes of employees and increase the productivity (Güner & Karaçar, 2016). If the corporate culture obtained after cultural change meets the needs of all stakeholders, including suppliers, in the continuous improvement of the process, this adaptable nature is called quality culture. Quality culture is referred to as an environment reflecting positive commitment to quality outcomes, products, systems, and processes; it stresses upon continuous improvement (Alotaibi, 2014). An organization with quality culture is also defined as an organization with clear values and beliefs that promote total quality behavior (Linkow, 1989).

Partnership approach, which is a tool for applying total quality management to the construction industry through teamwork, is a business execution system that maximizes the potential of improving communication, resolving conflicts, achieving quality determined by the application of total quality systems and procedures in managing the supply chain as a whole. Barriers to partnering are expressed as old style management, top management's failure to understand partnering, lack of commitment, poor planning, communication problems, having different values and failure to achieve culturel change (Bayramoğlu, 2000). In research studies it is seen that these factors also affect total quality management practices. In a study while the factors such as top management's commitment and leadership, communication, corporate culture, training, teamwork, employees' satisfaction and participation, establishment of long-term relationships with subcontractors and suppliers are identified as critical success factors in total quality management practices in the construction sector, factors such as lack of top management's commitment, perception of costly and time-consuming practices, lack of training and communication, lack of employees' participation, challenges in cultural change, and selection of subcontractors with low bids are also identified as barriers to total quality management practices (Shoshan & Çelik, 2018).

Conclusion and Recommendations

In total quality management practices, a plan in which partnering approach can be applied in an organization that focuses on quality, an effective project team, a set of tools by which the partnership approach can be structured and applied, implementation of determined standarts and specifications about product and service quality, management's commitment and leadership, identification of problems and establishment of long-term and trust-based relationships between different parties for continues improvements are required for successful partnering, which is a teamwork approach that involves customer, contractor and suppliers dedicating themselves to closer relationship to increase performance and improve production.
Establishing such trust and cooperative relations requires a cultural change; cultural and behavioral change in the way people work together and participate in quality practices. In total quality management practices, the organization at both project and company level should be established by including suppliers and ensuring that all employees communicate with each other and with top management. Systems that enable participation such as quality circles, recognitions and rewards, etc. should be used in ensuring cultural change. Training should be

widespread in the organization and appropriate motivation tools should be used. Top management should demonstrate commitment and leadership in applying project partnering and support cultural change with clear and visible actions.

Abstract

Reinforced concrete industrial chimney is a special type of building in construction sector with using slip form system and continuous concrete casting technic. One of the hardest operations in reinforced concrete industrial chimney is to save the center point on vertical direction. There are limited standards and source about reinforced concrete chimney construction. In this study, the issues have to be paid attention at construction process are approached by following the method which is using in chimney construction site application works in order to ensure available criteria in standards.

Keywords: *reinforced concrete industrial chimney, continuous concrete casting, slip form, project management.*

Introduction

Reinforced concrete industrial chimney is a special type of construction with using sliding form system and continuous concrete casting technic. It is needed to be well planned.

Concrete design, installation of reinforcement, sliding form system setup, handling of construction material while sliding form was rising, continuous concrete casting, saving the center point of chimney on vertical direction are the important subjects for the management of reinforced concrete industrial chimney construction and should be well planned.

There are very limited number of research papers on site practice. In one of these studies, Selmanpakoglu (2011) studied on site application of sliding form system. According to this study; the setup of the sliding form system was done by laser pointers installed on the basement of chimney to check the vertical direction.

Most of the previous studies on reinforced concrete industrial chimneys are about theoretical calculations. Nuhoglu and Sahin (2005) investigated the dynamic behavior of industrial chimneys. Kahyaoglu and Koyluoglu (1972) studied on the calculation method of chimney. Sengun (2010) worked on computer aided design of chimney. Ramesh and Helen (2013) evaluated the feasibility of sliding form system with using building information modelling. Solomin (2016) investigated the tension on the shell of reinforced concrete industrial chimneys.

At this study, the construction method and followed steps of 95 meters height reinforced concrete industrial chimney, which has been constructed in Mersin province, are investigated from beginning to the end.

Material and Method

Reinforced concrete industrial chimney construction; due to the sliding form system and continuous concrete casting technic, it is necessary to decide on concrete design decision, continuous concrete casting, reinforcement installation, sliding form system installation, material handling during the operation, sliding form system setup to save the chimney center point on the vertical direction, and good planning and work follow-up for the management of all these works. Construction management points which are related with these steps shown above are investigated as below:

Concrete Design

Concrete grade, which will be used in reinforced concrete industrial chimney, will be determined by static calculation. Concrete design should be determined according to Turkish Standard TS 802 and there should be specific work bearing in mind that the casting conditions. In order to reduce the workability-setting time of concrete due to the continuous concrete casting and the surface adherence due to the use of sliding form, the design of the concrete should not include sulfate resistant cement, slag or fly ash added cement. The retarder additive to be used in concrete should be decided according to the tests which are performed at site conditions. Crushed sand ratio in the aggregate should be less than general ratio. Washed and separated river sand should be chosen. Concrete mixtures should be prepared according to these general criteria that are given above and cube samples should be prepared, and it should be seen that the 7 days old samples' compressive strength provides the static project value.

Reinforcement

All the rebar to be used for reinforcement must be obtained from the producer who certify that they produced in accordance with Turkish Standard TS 708, and it should be seen that the rebar of all nominal diameters provides tensile strength tests and provide the static project value.

Sliding Form System

After the site application and construction of the basement are completed, sliding form system, which is appropriate to the type and dimensions of chimney, should be installed on the basement. It should be ensured that the deviation distances occurring in the vertical axis from the center of the concrete chimney must be within acceptable limits according to ACI 307-98 standard. In order to track the smoothness in the vertical direction during the upward movement of the sliding form, four fixed points must be prepared on the sliding form system carrier frame. Four target boards should be placed on the chimney basement in the projection of these four points.

Rising Up the Chimney

Moving the sliding form upwards by about 2.5 cm at a time, after each movement of 25cm in total, the deviation of the optical chassis on the target boards should be read and recorded. According to each reading, the sliding form system settings should be intervened, and the sliding form should be moved upwards in the direction closest to the vertical axis of the chimney in accordance with ACI 307-98 standard.

Findings and Discussion

Project Calculation Criteria

As a result of the project work carried out in the reinforced concrete industry chimney, the concrete class to be used is determined as C30/37 and the reinforcement steel rebar class is S420.

Concrete Design

The preliminary design prepared for the concrete in accordance with the requirements of concrete chimney hauling with sliding form, is given in Table 1 following the instruction of experience of project management and the recommendation of the ready-mixed concrete company. In the laboratory environment, concrete was prepared according to Table 1 and it was observed that the concrete prepared by 7 days and 28 days concrete pressure tests fulfilled the calculation criteria (Table 2).

Table 1. The preliminary design of concrete.

Order No	Material	Explanation
1	Concrete Class	C30/37
2	Environmental Impact Class	XC3
3	Consistency Class	S4
4	Chloride Content (Cl) (By weight of cement maximum Cl %0.1)	0.1
5	Density Class	Normal
6	Water/Cement	0.55
7	Water (TS EN 1008)	186 kg/ m^3
8	Mineral Additive Type	No
9	Dmax	22mm
10	0-5mm Crushed Sand (TS 706 EN 12620+A1)	827 kg/ m^3
11	7-15mm Crushed Aggregate	252 kg/ m^3
12	15-22mm crushed Aggregate	741 kg/ m^3
13	Portland Cement CEM I 52.5R / TS EN 197-1:2012	360 kg/ m^3
14	Super Plasticizer (TS EN 934-2:2011+A1:C3.1/C3.2) (By weight of cement %0.8)	2.88 kg/ m^3

Table 2. Concrete compressive strength test results (C30/37).

Sample Age	1.Set (MPa)	2.Set(MPa)	3.Set(MPa)	Average(MPa)
7 days	40.1	39.5	38.8	39.5
28 days	46.6	46.2	43.4	45.4

After achieving the aimed concrete strength in the laboratory, it is necessary to be determine the retarder additive ratio in order to have the desired workability time of the concrete. Since the tests carried out in the laboratory environment can be misleading, this test was performed with the concrete produced directly in the ready mixed concrete plant. By weight of the cement weight 0.2 - 0.3 - 0.4 - 0.5 – 0.6 – 0.7% ratios of the retardant additive (TS EN 934-2 O: 10) (ASTM Type D) prepared with 1 each 100cm * 100cm * 100cm sizes and 6 pieces of 15cm*15cm*15cm sizes cube samples for each ratio were prepared.

After pouring $1m^3$ samples, every two hours after casting and the setting of concrete was observed rodding with rebar (Table 3). Samples with 15cm*15cm*15cm dimensions whose setting conditions are applicable were subjected to 7 days old and 28 days old pressure tests and the observation and test results are given in Table 4. According to the results, the most suitable ratio for the setting retardant additive was evaluated as 0.6% by weight of the cement. Accordingly, the amount of set retardant additive to be used in $1m^3$ concrete (360kg*0.006) was calculated as 2.16 kg.

Table 3. Determination of retarder amount.

Workability	Retarder ratio by weight of cement					
	0.2%	0.3%	0.4%	0.5%	0.6%	0.7%
Slump (cm)	22	21	20	21	21	21
2 hours (cm)	0	0	0	0	0	0
4 hours (cm)	0	0	0	0	0	0
6 hours (cm)	100	100	50	10	0	0
8 hours (cm)	100	100	100	60	75	30
10 hours (cm)	100	100	100	100	100	70
12 hours (cm)	100	100	100	100	100	100

Table 4. Compressive strength of concrete with retarder.

Workability	Retarder ratio by weight of cement					
	0.2%	0.3%	0.4%	0.5%	0.6%	0.7%
7 days old (MPa)	35.5	39.5	39.6	40.3	35.8	36.8
28 days old (MPa)	44.7	45.9	44.9	42.9	44.5	45.7

Reinforcement Steel

It is seen that the rebar of all nominal diameters which come to the construction site provide the project value by performing tensile tests (Table 5).

In the reinforcement installation, all rebar inserts, including the vertical distribution bars left before raft foundation concrete casting, should be installed due to the work area is narrow and the spreading of the workmanship over time due to the continuity of the casting. At the same

time no resistance point is formed in the reinforced concrete structure. In order to make labor possible and to keep the rebar loss at the lowest rate, rebar lengths are taken maximum 6 meters.

Table 5. Rebar tensile test results (S420).

Order No	Nominal diameter (mm)	Yield Strength (N/ mm^2) (min420)	Tensile Strength (N/ mm^2) (min 500)	Tensile Yield Ratio (min 1.15)	Re,act/ Re,nor (max1.3)	Rupture Elongation (%) (min10)	Nominal Weight (kg/m)
1	10	481	588	1.22	1.14	17.90	0.621

Setup of Sliding Form System

After the site application and construction of basement are completed, sliding form system which is appropriate to the type and dimensions of chimney should be installed on the basement. After the sliding form system has been commissioned and the concrete pouring has started, the upward movement of the sliding form, the installation of the reinforcement into its place and the concrete casting works continue uninterruptedly up to the top level where the reinforced concrete construction will be completed. For this reason, continuity of the production and construction of the concrete chimney on the central axis, requires shift work, strict control and coordination.

Lifting system parts of the sliding form are; hydraulic power center, hoses, jacks and climbing rods. After the chimney basement concrete is poured, application and installation of sliding form carrier frames on concrete floor is made. The number of sliding form carrier frames is

selected according to the chimney diameter. On the frames that are bearing the sliding form; depending on the number of frames used, and in at least four of the optical plumbing stands, they are prepared at the same equal distance as possible. Target boards placed at the base upper level are adjusted to show the values to be read in the optical condition depending on the chimney slope and height.

Rising Up the Chimney

From the beginning of the concrete pouring, one immobile concrete pump and one mobile crane are continuously installed in the site and kept ready for service. During the upward movement; after the first 15 meters, the concrete and the reinforcement are transported to the working platform at the upper level by means of the elevator installed in the center hole of the chimney. The concrete, which is carried to the platform by buckets, is casted into the form by hand carts and placed into the form with vibrator. The setting of the concrete is measured by rodding before the 2.5 cm movement of the form again. The chimney reinforced concrete work lasted a total of 27 days and the equivalent cube compressive strength test results of the poured concrete during this period are given below. (Table 6)

Table 6. Chimney concrete compressive test results.

Concrete Casting Day	Compressive Strength of Concrete (MPa)		Concrete Casting Day	Compressive Strength of Concrete (MPa)		Concrete Casting Day	Compressive Strength of Concrete (MPa)	
	7 days	28 days		7 days	28 days		7 days	28 days
1st day	37.8	41.6	10th day	37.8	40.4	19th day	40.1	43.2
2nd day	38.6	43.8	11th day	37.6	39.9	20th day	38.8	44.2

Adjustment of Sliding Form System

The management of the construction team, timely supply of materials, vertical transport of materials as the chimney rises, the form surface adheres to the concrete during the upward movement of the sliding form are all difficulties in the construction of reinforced concrete chimney, but the most important issue is the adjustment of the sliding form to keep it vertical. As the concrete chimney rises, sliding form adjustments should be made depending on the diameter changes according to the project and the deviation distances occurring in the vertical axis of the chimney center should be maintained within acceptable limits.

The vertical movement of the sliding form is adjusted with a part placed inside the jacks and moves about 2.5cm upward at each step. During the upward movement of the sliding form, the smoothness in the vertical direction is ensured by following the projections of the four points fixed on the form and the four target boards fixed on the floor.

The sliding form is moved upwards approximately 2.5cm at each time, and after each movement of 25cm in total, the deflection of the optical plumb on the target boards is read and recorded and the sliding form settings are interrupted according to the reading at each level and the sliding form goes in the direction closest to the vertical axis of the chimney is provided. Considering that the concrete construction speed of the reinforced concrete industrial chimney is approximately 3.5 meters per day, the sliding form moves upwards on average 350cm / 2.5cm = 140 times per day. After every 25cm advance of the chimney, the target board is read. This means that the sliding plate can be adjusted on average 14 times per day depending on the readings on the target board.

The layout of the optical plumb and target board of the 95 m high reinforced concrete industrial chimney constructed in Mersin is given in Figure 1. Due to the installation height of the 1.5m sliding form, along with scaffold and other parts, optical reading started from the 3rd meter. Optical reading was made up to 93.25m height, which is the bottom level of the 25cm thick floor of the 1.5m parapet at the top of the chimney. The deviation from the vertical axis calculated according to the optical plumb-target board readings made during the construction of the reinforced concrete industrial chimney is given in Table 7.

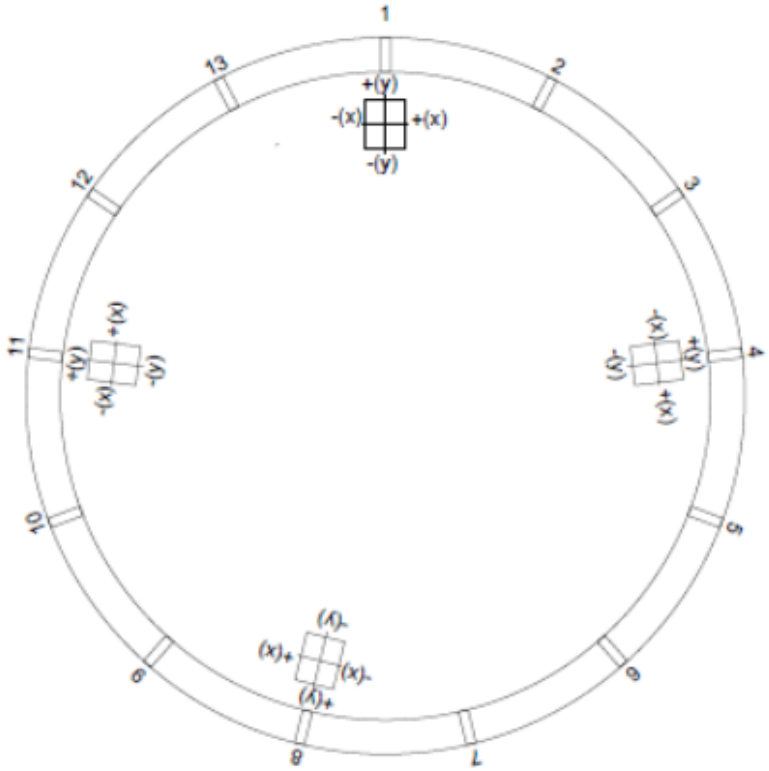

Figure 1: Sliding form feet and placement of target boards.

Table 7. Deviation distance from vertical axis of chimney center.

Optical Readings (mm)									
Order No	h (m)	Optic No:1		Optic No:2		Optic No:3		Optic No:4	
		X	Y	X	Y	X	Y	X	Y
1	3.00	6	-7	-9	2	-10	-8	-2	-5
2	3.25	12	-6	-10	0	-13	-7	2	-17
3	3.50	14	-6	-12	2	-3	-13	2	-17
…	…	…	…	…	…	…	…	…	…
323	83.50	10	-3	-19	5	-17	-19	19	-10
324	83.75	8	0	-15	0	-19	-20	16	-8
325	84.00	8	4	-18	0	-15	-15	19	-10
…	…	…	…	…	…	…	…	…	…
348	89.75	2	-10	5	12	-11	10	3	10
349	90.00	0	0	13	13	-13	10	13	-10
350	90.25	-9	17	-6	15	-13	10	13	8

When the values given in Table 7 are examined, the highest deviation distance from the vertical axis of the chimney center of the industrial chimney; h = 83.75 meters at the optical reading 3, -19mm / -20mm was determined and the deviation distance was calculated as 27.59mm. According to the ACI 307-98 standard, the center point of the shell shall not vary from its vertical axis by more than 0.001 times the height of the shell at the time of measurement, or 25mm, whichever is greater. According to this:

$$95m \times 0.001 = 0.095m = 95mm \quad (1)$$

$$95mm > 25mm \quad (2)$$

The upper limit of the deviation from the vertical axis is calculated as 95mm. The deviation distance from the axis in the highest vertical direction determined according to the optical readings given in Table 1; It is 27.59mm <95mm and conforms to the ACI 307-98 criteria.

Conclusions and Suggestions

The construction of the reinforced concrete industrial chimney is one of the special construction type within the civil engineering sector. Due to the limited number of technical personnel specialized in the site applications of reinforced concrete industrial chimney construction and the theoretical studies addressing issues other than the construction technique of the chimney, there are not enough scientific studies related to the site application of the concrete chimney construction.

In this study, it is expected to contribute to the development of new methods by explaining the main issues to be taken into consideration for the project management of reinforced concrete industrial chimney construction together with their reasons and by giving information about how a site application is performed. In addition, in the construction of reinforced concrete industrial chimneys; management of site teams, determination of concrete class to be used, preparation of concrete design, curing of concrete, working platforms,

vertical transportations and occupational safety is expected to provide benefits in dealing with many issues.

Roadmap For Integrated Usage of BIM And Lean Methods Throughout the Lifecycle of Modular Construction Projects

S. Khodabocus and S. Seyis
Özyeğin University, Department of Civil Engineering, Istanbul, Turkey
sabah.khodabocus@ozu.edu.tr, senem.seyis@ozyegin.edu.tr

Abstract

The emerging modular construction sector has attained ample interest given the plethora of benefits compared to conventional construction. However, with incorrect execution and lack of early planning, exorbitant costs are witnessed. This study focuses on portraying the integrated usage of Building Information Modelling (BIM) and lean construction methods throughout the lifecycle of modular construction projects to aid early planning. In this scope, a systematic literature review was executed and validated with experts' interactions for developing a roadmap. The outputs consist of illustrations shedding light on the topic currently. Previous studies depicted projects integrating these concepts at design stage, supply chain, or during module construction. However, this research considers the whole lifecycle, and the methodology integrates hands-on experiences from qualified industry experts. With the roadmap, project teams can get access to early-on guidance to efficiently handle a modular construction project. Hence, mitigating cost overrun and optimizing quality alongside clear communication with all organizational levels.

Keywords: *Building Information Modelling, design stage, guideline, lean construction, off-site construction, prefabrication, prefabricated construction, productivity.*

Introduction

Modular construction has gained much attention throughout the years due to its applaudable benefits when executed correctly. In brief contexts, modules produced in the factory for various project types are transported to the site ready to be installed and used. The time aspect is a remarkable element in this method of construction whereby site preparation is performed simultaneously to the module construction off-site. Similarly, modular construction positively adds on to sustainable built environment while reducing construction and demolition waste production and enhancing recycling possibilities of module at the end of the project's lifecycle (Ji et al., 2020).

With the fruitful outcomes that are derived from this modern method of construction, offsite construction does witness real-time challenges which are being investigated by researchers till date (Barkokebas et al., 2021). The design, transportation, and installation phases of an offsite project come along with constraints not only structurally but also the movement feasibility to the site (Wei al., 2021). Zhang et al. (2020) emphasizes on the need to consider production line and on-site installation of a modular project for process improvement. Current modular

construction projects lack a lean integrated approach, and it is of utmost importance to showcase effectiveness of lean tools and techniques to be used in different production stages (Innella et al., 2019). Hence, this study generates a structured roadmap showcasing the usage of Building Information Modelling (BIM) and lean construction methods throughout the lifecycle of modular construction projects which will aid in mitigating cost overruns and avoiding redundant waste production.

Research Background

Lean Construction Methods

Initially used in the manufacturing industry, lean production methods determine work cultures which aim at waste elimination. With a single waste source, the expected forecast is like a ripple effect and as production is more than required, cost overruns are witnessed with an overall non-value adding situation (Innella et al., 2019). Most commonly compatible lean construction methods for the modular construction sector include but are not limited to the Last Planner System (LPS), Just in Time (JIT), Value Stream Mapping (VSM), and Kanban system. Xing et al. (2021) investigated the implementation of multiple lean construction techniques and deduced that the most adopted one is the LPS with a percentage usage of 77.3%. Another commonly used lean construction method is the Just in Time technique. The arrival of modules as per and when needed to the site enables eradicating inventory waste (Si et al., 2021). Design for Manufacture and Assembly (DfMA) has seen overwhelming application in the prefabrication sector whereby cost is minimized and overall value adding activities are witnessed (Gao et al., 2020). With the urge for continuous improvement, including all organizational levels from the start of a project and having set goals, enables value adding activities throughout the project's lifecycle.

BIM in Modular Construction

BIM deems as a suitable platform to be embedded in a project aiming for clarity and cooperability from start to finish. Till date, a significant awareness rise was witnessed regarding BIM adoption for boosting efficiency of projects. However, managers are reluctant when it comes to making the investment in the platforms for information sharing and collaborating teams due to the short duration of projects being worked on (Barkokebas et al., 2021). BIM has also seen integrations with other platforms for achieving environmental analysis of prefabricated elements (Ji et al., 2020). For sustainability prospects, material passports are being digitalized into BIM to support an environmentally friendly project (Atta et al., 2021) Internet of Things (IoT) and BIM have also witnessed major attention in current research due to the real time database which exactly pictures the demands for logistics purposes (Lee & Lee., 2021). Smart BIM entered the industry with an aim to facilitate the on-site assembly services (Zhou et al., 2021). As for the possible BIM authoring software, Yin et al. (2019) suggests Revit, Bentley, and ArchiCAD. Quality-wise BIM platforms is a rich and reliable option when opted as from the design phase (Li et al., 2020).

Research Methodology

The methodology consisted of a thorough literature review and precise analysis was performed with the case studies from the publications. To further cover all aspects of the research topic, experts in the field were contacted and their valuable judgement were recorded as well as validations to the derived outputs. This addition ensured that hands-on perspectives were also considered which strengthened the findings from the literature review. Figure 1 summarizes the flow of the methodology and depicts how the outputs were derived.

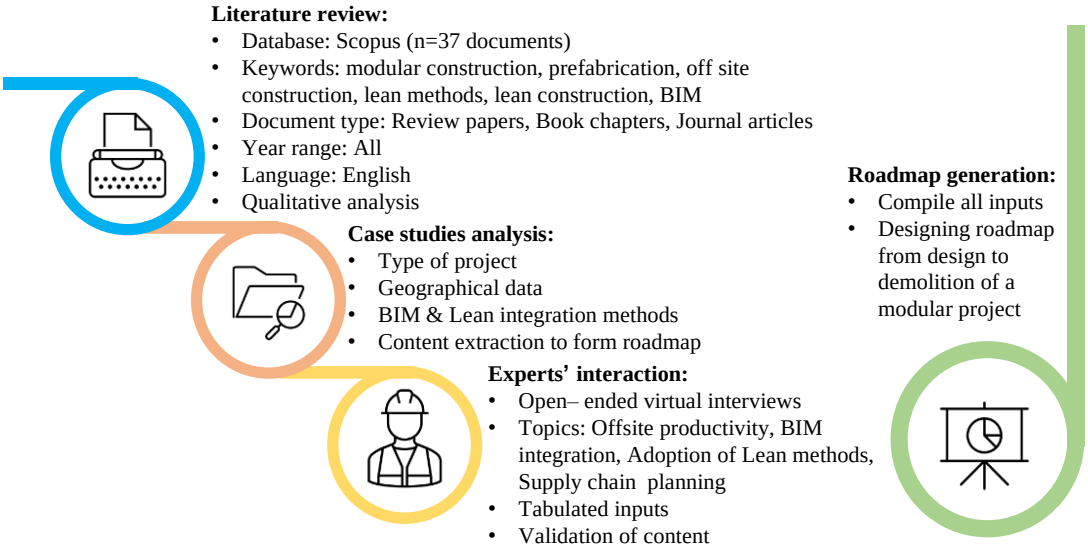

Figure 1: Research methodology.

Database Navigation and Literature Review Process

Throughout the literature search, it was deduced that Scopus deemed as the most reliable and broad database which covered publications holistically. Hence, with some set criteria such as keywords, document type, language, and technical field, the systematic literature review turned out precisely. An example of the database search is as follows: (TITLE-ABS-KEY (modular AND construction)) AND (BIM AND lean) AND (LIMIT-TO (DOCTYPE ,"ar") OR LIMIT-TO (DOCTYPE, "re") OR LIMIT-TO (DOCTYPE , "ch")) AND (LIMIT-TO (SUBJAREA, "ENGI")) AND (LIMIT-TO (LANGUAGE, "English")). An average of 87 documents were found during the database search. With analysis of titles and abstracts, the duplicates were removed, and the most related document were downloaded. Mendeley was used for navigating through and saving the documents. The finalized set of qualitative content was 37 documents. Full texts were checked, and publications that already performed case studies were then classified for data extraction.

Experts' Interaction

Data acquired from literature review were processed with Microsoft Excel in the form of graphs and tables. In the quest to form a roadmap of BIM and lean construction methods inclusion throughout the lifecycle of a modular project, 3 industry experts were contacted. The interaction

was semi-structured open-ended virtual interviews. Topics such as offsite productivity, BIM integration in construction, supply chain management, and overall current modular construction trends were discussed. This proved to be very enriching while experts incorporated their experiences to provide significant feedback on the subject. Hereafter, the experts were asked to validate the outputs derived in the investigation. Table 1 shows the profile of the experts that were considered for contributing to this study.

Table 1. Experts' profile.

Expert no.	Profession	Qualification	Years of experience in modular construction	Country	Interview duration (Minutes)
1	BIM consultant & founder	Bachelor's in Architecture	5	Ireland	40
2	Project coordinator	Bachelor's Applied technology (Architecture, project & facility management)	2	Canada	30
3	Project manager	Bachelor's Civil Engineering (lean 6 sigma black belt, Project Management Professional)	8	United Arab Emirates	25

Findings

Case Studies Adopting BIM and Lean in Modular Construction

Throughout the literature review, case studies were encountered, and the authors have portrayed productivity increase upon applying frameworks which suggest usage of BIM and lean concepts in modular construction. Table 2 below shows the relevant case studies analysed and the according methods applied with the productivity rise percentage.

Table 2. Case studies analysed in the literature review.

Project ID	Type of project	Geographical location	BIM-based methods	Lean concepts	% rise in productivity	Reference
1	Residential	Canada	-	Value Stream Mapping (VSM), Continuous flow, Balanced line	20	Zhang et al. (2020)
2	Commercial	Brazil	3D model-Revit & Dynamo	VSM	23.3	Barkokebas et al. (2021)
3	Residential	China	Luban BIM	-	-	Ji et al. (2020)
4	Residential	USA	BIM & GIS	Just in Time (JIT)	90 (In terms of decreased idle time of module)	Lee and Lee. (2021)
5	Commercial	Hong Kong	3D model-Solidworks	Kanban	50	Jiang et al. (2022)
6	Industrial	China	BIM & laser scanning	-	-	Li et al. (2020)
7	Residential	Hong Kong	BIM with IoT & Blockchain		50+	Li et al. (2022)
8	Commercial	Egypt	3D model-Revit & Navisworks	-	50	Eldeep et al. (2022)
9	Residential	Iran	-	VSM, JIT,Total Productive Maintenance (TPM)	43	Heravi et al. (2019)

Zhang et al. (2020) formed an elaborate framework which demonstrates usage of Value Stream Mapping at each stage of a production line which was segmented to tackle each stage such as floor framing, panel fabrication, among others. By using BIM and Value Stream Mapping at the premanufacturing phases of offsite construction, Barkokebas et al., 2021 achieved a 23.3 % increase in productivity. In China, Luban BIM collaboration platform is commonly adopted for developing the 3D model, quantity take off, and simulation while adding on to the environmental assessment of modular construction projects (Ji et al., 2020). The crucial start, which is the supply chain and logistics handling, can be efficiently tackled if BIM and Geographic Information System (GIS) integration is performed. With real time information by subscribing to the Internet of Things (IoT) databases, the digital twin can indicate exact demands at the logistics stage (Lee & Lee., 2021). In the highly digitalized sector, robot

involvement for assembling of modules proved to enable 50% productivity rise alongside Kanban principles (Jiang et al., 2022). When it comes to a collaborative platform, Li et al., 2022 applied a blockchain enabled IoT BIM platform that included all stakeholders alongside the project team members. A rarely applied lean construction method known as Total Productive Maintenance (TPM) was depicted by Heravi et al. (2019) in a residential building with improvements seen in the timeline and cost-wise.

Experts' Interaction Outputs

The 3 experts contacted in this study all agree that good project management with BIM and lean construction methods form the stable foundation required to achieve efficiency in a modular project. Furthermore, based on their valuable hands-on experiences, a major point that was outlined is that the new technologies would require further investment, and this is linked to the major pillar which is the client. For example, knowing that investing in sensors to monitor health of the structure, would guarantee a better future for the building and the facilities management, the client has the final verdict in this. Similarly, based on location of the project, while being situated in an urban area, the thought should be given to commute and accommodation of workers at the installation phase. This is also another reason where latest technologies are not being opted for by clients if the latter can be done the traditional way and cheaper. In terms of the demolition stage, since modules can be recycled and reused most of the time, a similar approach to the supply chain management performed with BIM and lean construction tools can be integrated again to relocate or organize the demolition process. This shows how modular construction contributes to the circular economy in the sustainable built environment and adds value to the architecture, engineering, and construction industry.

Roadmap for Integrating BIM and Lean Construction Methods Involvement in a Modular Project Lifecycle

Like a hierarchical representation, the roadmap developed proceeds in a systematic order that accompanies the team members of a project from supply chain to the occupancy phase. The holistic consideration promises mitigation of risks early on and prepares a project to achieve full efficiency with integration of all organizational levels. At the occupancy phase, remarkable efforts have been witnessed whereby integrating sensors to BIM platforms have shown how structural health of components can be monitored in real-time (Olawumi et al., 2021). Overall management of a project efficiently can be achieved via a cloud-based BIM platform (e.g., BIM 360 Field), storing all databases made accessible to project teams (Zhao et al., 2019). Taking into consideration case studies' performances and suggestions from industry experts, the roadmap in Figure 2 paves a clear way for the project team to uplift the work culture and make the utmost of the highly digitalized industry.

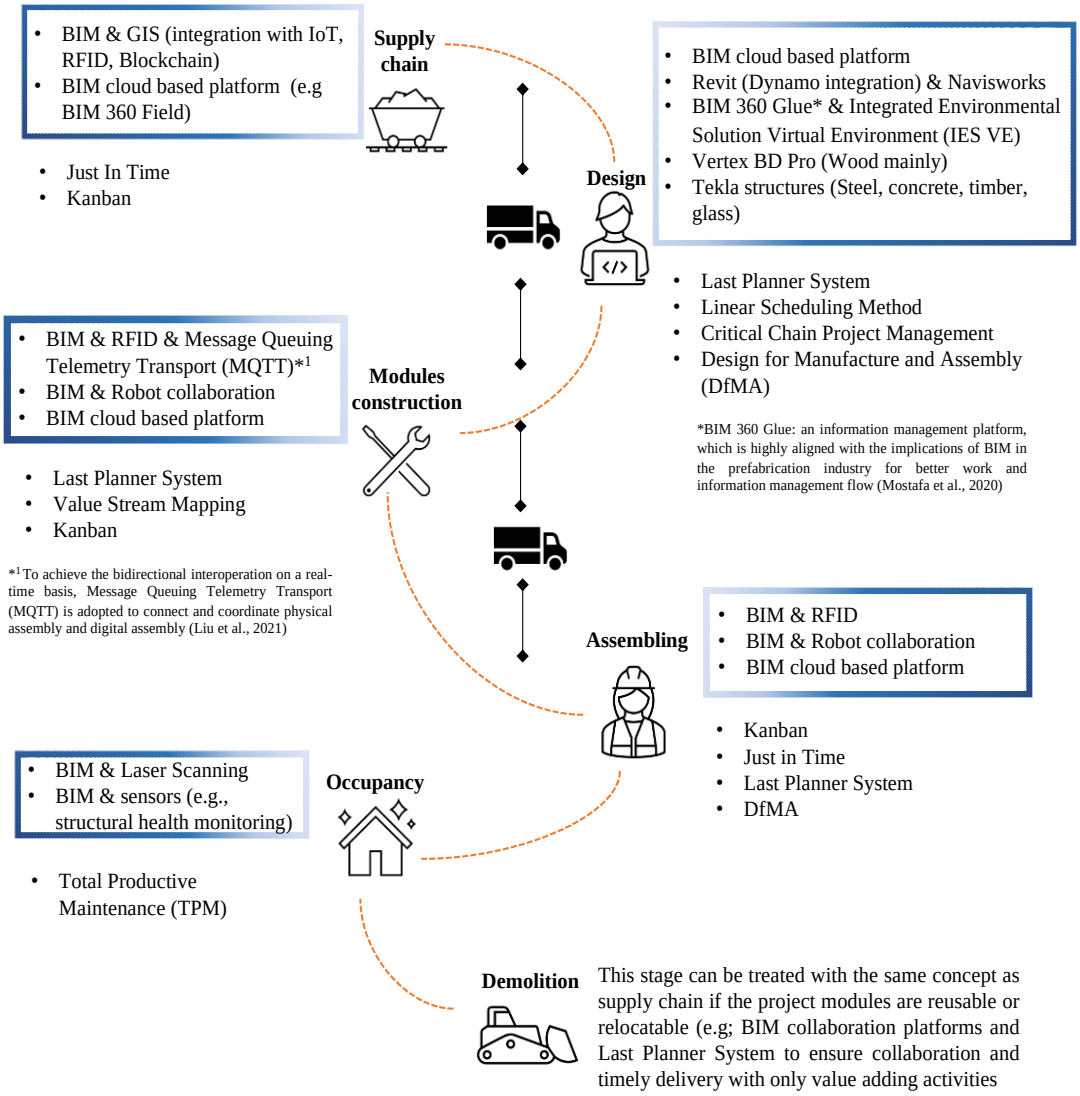

Figure 2: Roadmap for usage of BIM and lean construction methods in the lifecycle of a modular project.

Discussions

With a thorough exploration on BIM platforms and lean concepts used in the prefabrication sector, the most common and major issue withholding projects from making the change is the investment factor. Given the projects' short timeline, project managers are reluctant to invest and are not fully confident in the efficacy range to witness. While investigating the lean construction concepts, Just in Time principles are among the most needed throughout the modular construction lifecycle. However, with the waiting period for supply chain to fully implement the latter, the other parties such as contractor, client, and designers are left with no choice than to witness some barrier between their respective involvement stages (Mossman and Sarhan., 2021). Due to the working style of manufacturing industries, modular projects deem suitable for applying most of the lean concepts and when combined with BIM platforms, the exponentially rising costs could be tackled soon. Moreover, applaudable interest was denoted

in terms of blockchain, laser scanning, RFID, IoT, and Genetic Algorithms usage with BIM platforms. These had as aim to handle the large databases and provide real time updates to all organizational levels; hence, decreasing the cost overruns and scheduling risks of modular construction projects. A remarkable investigation by Li et al. (2018) introduces a concept namely RBL-PHP (RFID/BIM/Lean – Prefabricated House Production) and the latter displays how to decrease uncertainties from the logistics phase with evidence shown in workshops done with academicians and practitioner. Figure 3 shows the identified frequency of the mentioned methods which are applied to modular projects. The frequency appearance was acknowledged from literature review documents and the demolition phase was the sole item depending on experts' statement since there was an absence of literature relating to the latter.

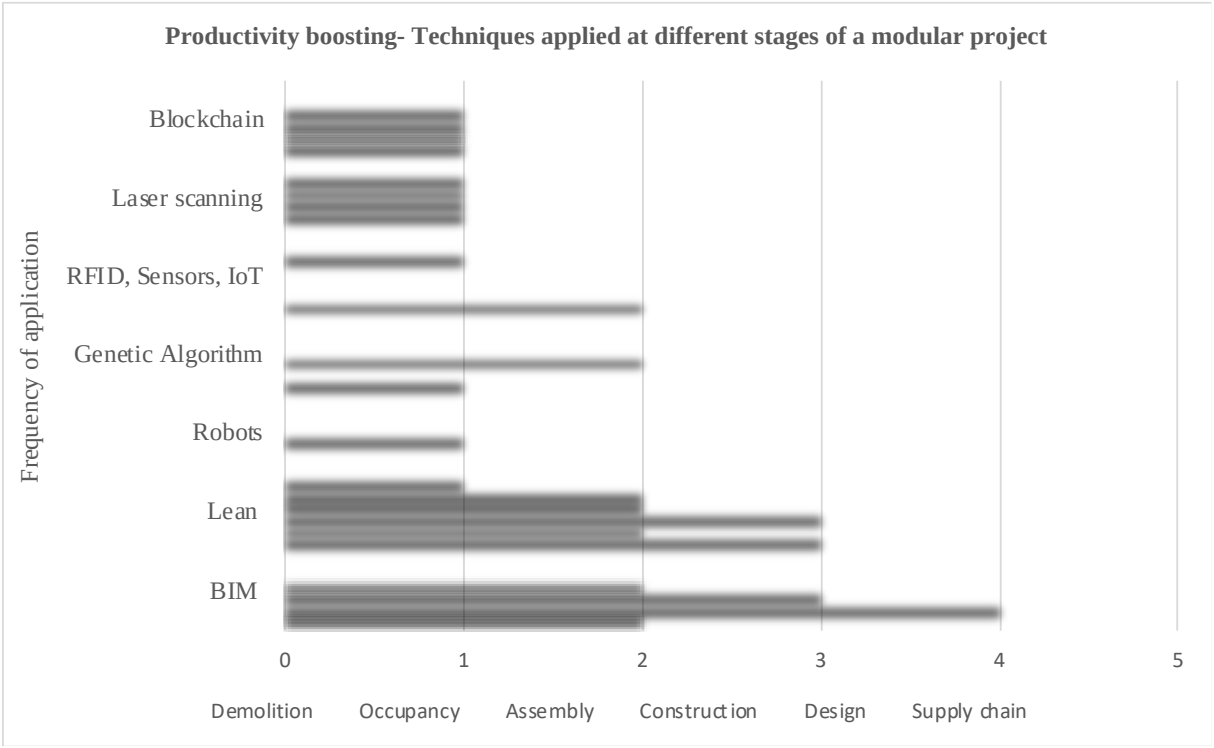

Figure 3: Application frequency of methods for efficient modular construction.

Conclusion

This study specifically indicates how efficiency can be achieved with BIM and lean construction methods usage throughout the lifecycle of a modular project. With the holistic consideration from supply chain to demolition, the roadmap did not leave any loopholes. Referring to the latter can direct team members towards early planning and all-inclusive collaboration, hence mitigating cost overruns and witnessing value adding activities at every phase. BIM platforms have justified their performance in multiple cases as analysed in this study. From the logistics handling to the occupancy stages, with commitment for collaboration and accessibility, the productivity of a modular project is guaranteed. Lean construction methods have depicted the positive integration of all organizational levels while promoting value-adding tasks in the projects. One limitation of this study included the lack of projects or expert's awareness of how the demolition phase could take place efficiently with BIM and lean construction methods. This is mainly due to the lack of BIM and lean adoption in the demolition phase of modular construction projects in the current industry. Future studies could focus on

how to handle the early integration of technologies such as IoT, blockchain, RFID, sensors, and Genetic Algorithms, will lead modular projects towards on budget achievements alongside quality optimization. A precise attention can also be given to the demolition stage of a modular project while bearing in mind the plethora of potential in terms of sustainability achievements.

Exploring The Critical Success Factors of Offsite Construction Method in Turkey

B. Yücel, A. Zafer and S. Çomu
Boğaziçi University, Department of Civil Engineering, İstanbul, Turkey
busra.yucel@boun.edu.tr, alper.zafer81@gmail.com, semra.comu@boun.edu.tr

Abstract

The offsite construction method consists of well-established techniques, which can enhance the productivity of the construction industry by transferring some portion of onsite work to fabrication shops. Even though it has many advantages, the implementation of offsite construction is still limited in the Turkish construction industry, and several challenges affect the success of its applications. This paper aims to examine the Critical Success Factors (CSFs) for successfully implementing the offsite construction method in Turkey. In this respect, a total of 14 CSFs evaluated under five categories by utilizing Analytical Hierarchy Process (AHP). The results showed that the three most critical factor groups are i) leadership, ii) technical, and iii) resources. The first five most significant CSFs were determined as i) project managers' problem-solving ability, ii) contractors' leadership & experience, iii) effective information sharing, iv) skilled labor availability, and v) the maturity of techniques & technologies used. This research provides insight into the Turkish construction industry for further deployment of offsite construction methods in the market.

Keywords: *Analytical Hierarchy Process, critical success factors, offsite construction.*

Introduction

Offsite construction is one of the oldest construction methods. It refers to the planning, design, fabrication, and assembly of building elements at a location other than their final installed location to support a permanent structure's rapid and efficient construction (Schoenborn, 2012). Previous studies have shown that offsite construction has many advantages over traditional construction methods. Improved quality, lower costs, and lower labor requirements on-site (Goulding et al., 2017) are some advantages of the offsite construction method. Moreover, preproduction in a controlled environment minimizes the risk of delays due to weather conditions (Lu & Liska, 2008). Modular construction, which can be defined as a subcategory of offsite construction, can save around 40% of construction time compared with traditional construction methods. Offsite construction offers possible cost reductions with on-site overhead reduction, design standardization, a high energy efficiency level, and higher installation efficiency. Automated machinery usage in offsite construction facilities can result in higher product quality. (Kamali & Hewage, 2016).

On the other hand, although the offsite construction method is deep-rooted, it is not commonly used as the traditional method of construction. The UK's market share of offsite

construction is around 6-7% (Taylor, 2010). The share of offsite construction methods in the USA is 7% (HAC, 2011). Moreover, Polat and Damcı (2007) point out that while the market share of precast concrete is only 6% in Turkey, it rises to 40% in northern Europe. Even though offsite construction is crucial for developing countries like Turkey, not much research has been conducted on determining critical success factors for offsite construction in Turkey. Thus, this study aims to contribute to the literature by determining essential success factors from the perspective of the Turkish construction market.

Literature Review

Offsite Construction

Most applications of the Architecture, Engineering, and Construction (AEC) industry are not appropriate for mass production, and it causes the sector to be inefficient and unproductive. On the other hand, off-site construction has a great potential to increase productivity by providing automation in the production of building elements (precast or compound materials) in a factory environment (Laubier et al., 2019). As Martinez et al. (2021) state, off-site construction has competitive advantages in the industry because of the adoption of automation and innovative approaches. Therefore, the sector has benefited from manufactured construction for years. Modern Method of Construction (MMC) originated in the United Kingdom by referring to both offsite-based construction technologies and innovative onsite technologies (Goodier & Gibb, 2006). As its definitions suggest, MMC is an innovation-based term rather than consisting only of industrialized or off-site techniques (Burwood & Jess, 2005). Especially after World War II, there has been an increasing demand for new housing in the US and Europe. Trials of applying off-site construction techniques in high-rise buildings led to the emergence of twenty and more story pre-constructed buildings. In addition, modern techniques increased the possible complexity level of using off-site construction. Therefore, the construction industry may benefit from off-site construction to achieve its potential, considering the positive effects of emerging approaches.

Factors, Enablers, and Barriers of Offsite Construction

Critical success factors of off-site construction have been a research topic to understand the concept and determine ways to increase its application. Findings from numerous studies vary due to the market conditions of the countries where the study occurs. Several studies have investigated different subsections of off-site construction, such as modularization, prefabrication, preassembly, and industrial building systems (e.g., Kamar et al., 2010; Li et al., 2018; Yunus & Yang, 2012; Gibb & Isack, 2003). In addition, there is much research on off-site construction and its subsections to determine benefits, weaknesses, and barriers. In this research, to evaluate the factors from a broader perspective, literature with different countries' different subsections of off-site construction is used as a source.

James et al. (2014) conducted a study in the US and investigated critical success factors and enablers for industrial modularization. This study determined 21 critical success factors through a literature review. The research findings showed that 57% of CSFs were related to the owner of the project, 33% were related to the contractor, 7% of critical success factors were related to vendors & technology licensors, while 3% were related to other stakeholders.

In this study, CSFs were also examined according to the project phases to which they were related. It was found that 31% of CSFs were related to the assessment phase, while 23% were associated with the basic design, and 20% were related to the selection. Three other phases of the project, execution, opportunity framing, and startup, were related to 27% of CSFs. According to this research, the three most essential CSFs are module envelope limitations, alignment on drivers, and owner's planning resources & processes.

Similarly, Elnass et al. (2014) searched for the factors and drivers affecting the decision to use off-site manufacturing systems in the house building industry. Thirty interviews were conducted with clients, contractors, consultants, project managers, design managers, and contract/construction managers to understand the OSM from the perspectives of construction professionals. The outcomes of the interviews were cross-checked with 15 case studies. According to the result of this research, time, quality, and cost were selected as critical factors affecting the decision to implement off-site construction. Predictability, productivity, interface issues, environment issues, performance, labor, and lack of space were considered moderately essential factors. Safety, project complexity, and logistics issues were determined to be usually crucial with very low importance impact with 10 to 14 out of 100.

Moreover, Xiahou et al. (2018) researched the driving factors of China's construction industrialization (CI). The authors conducted a systematic literature review, and 14 CIDFs were determined using the grounded theory method (GTM). Furthermore, a questionnaire was conducted with 123 professionals involved, and the identified factors were listed according to their relative importance. Findings of this research showed that; lack of labor, shortage of resources, productivity improvement, serious environmental problems, and quality improvement were forming the most significant five driving factors of CI. On the other hand, in Turkish literature, critical success factor determination for off-site construction was partly done by some studies focusing on specific techniques (Polat & Damcı, 2007). Thus, this study aimed to fill this gap in the literature and present the CSFs in Turkish off-site construction.

Methodology

This study aims to find the critical success factors of off-site construction in Turkey and determine a consistent ranking among them. For this purpose, factors were defined through a detailed literature review then an AHP model was developed to prioritize the selected success factors.

Identification of Critical Success Factors

We conducted a literature review to understand the concept of off-site construction and determine its benefits and use areas. In total, over fifty papers were reviewed related to off-site construction. The literature review considered similar terms such as OSM, OSP, OSF, IBS, Pre-assembly, Prefabrication, and Prefab. A systematic selection of the papers was processed to determine CSFs from the literature. As a result of the literature review, a total of 74 factors were selected. Then, the final list of 14 factors was listed under five categories (regulatory, technical, process, resources, and leadership) after combining similar CSFs. Table 1 shows the factor list with references.

Table 1. Factor list.

Group	No	Factor Name	Reference
Regulatory	1	Government Promotion	(Li, et. al., 2018)
	2	Supporting Policies & Legislations	(Xiahou, et. al., 2018), (Yunus, et. al., 2012)
	3	Revisions to Building Regulations	(Pan, et. al., 2007), (Elnass, et. al., 2014)
Technical	4	Timely Design Completion	(O'Connor, et. al., 2014), (Li, et. al., 2018)
	5	Assembly Planning Method	(Li, et. al., 2018)
	6	Preliminary Module Definition	(O'Connor, et. al., 2014)
	7	Designers' Experience	(Li, et. al., 2018), (Kamar, et. al., 2010)
Process	8	Effective Information Sharing	(Li, et. al., 2018), (Kamar, et. al., 2010)
	9	The Maturity of Techniques & Technologies Used	(Li, et. al., 2018), (Kamar, et. al., 2010)
Resources	10	Integration of the Supply Chain	(Xiahou, et. al., 2018), (Ismail, et. al., 2012)
	11	Sufficiency of Manufacturers and Suppliers of Prefabricated Components	(Li, et. al., 2018)
	12	Skilled Labor Availability	(Li, et. al., 2018), (Blismas, et. al., 2008), (Pan, et. al., 2007), (Gibb, et. al., 2003), (Elnass, et. al., 2014), (Kamar, et. al., 2010), (Xiahou, et. al., 2018), (Yunus, et. al., 2012)
Leadership	13	Contractor Leadership & Experience	(O'Connor, et. al., 2014), (Kamar, et. al., 2010)
	14	Project Managers Ability to Solve Problems	(Li, et. al., 2018), (Kamar, et. al., 2010)

Analytic Hierarchy Process (AHP)

AHP was introduced to literature by Thomas Saaty in 1980. It was designed to compare interchangeable elements efficiently and determine their importance by pairwise comparison. The following attributes of AHP make it suitable for this study (Saaty, 1988): measuring priorities and choosing among alternatives, calculating the consistency of the acquired answers. Sipahi and Timor (2010) showed that AHP is used more frequently than Fuzzy AHP, ANP, and Fuzzy ANP alternatives. Since the dependency between the determined CSFs is absent or negligible, AHP is also applied in this study.

We implemented the AHP method in three steps in this study:

1. We defined the goal and established a hierarchical structure.
2. The priorities of the factors were evaluated through pairwise comparison matrices using the Likert scale.

3. The comparison matrix was formed and normalized.

Data Collection

A focus group was formed to evaluate factors determined from the literature review. Collected factors from the literature investigated the offsite construction from every different point of view, so they were not necessarily meant to be critical success factors for the Turkish construction industry. The focus group consists of four experts in various areas of the construction industry to have a broader perspective (Table 2).

Table 2. Focus group information.

No	Profession	Experience
1	Academician	11 years
2	Business Development	18 years
3	Project Management	10 years
4	Manufacturer	13 years

Table 3 shows the details of the participants for AHP analysis. The questionnaire was distributed by e-mail to 138 professionals from the construction market. Forty-two experts responded to the questionnaire with a response rate of 30,4%. Experts with less than five years of experience formed only 22,5% of the total responders. The majority of experts had experienced between 15 – 20 years.

Table 3. Expert information.

Experience	Number of Experts	Percentage (%)
Technical Office	12	30,0
Company Owner	10	25,0
Field - Operation	9	22,5
Business Development	3	7,5
Procurement	3	7,5
Design	1	2,5
Management	1	2,5
Academic	1	2,5

Findings

Factor groups' weights are presented in Table 4. According to the results, leadership (0.232) was selected to be the most critical CSF group. At the same time, the technical category (0.231) was ranked as the second most important factor group. These categories were followed by the resources (0.199), the regulatory (0.171), and the process categories (0.167),

respectively. Finally, in terms of CSFs, project managers' problem-solving ability (0.125), contractor leadership & experience (0.107), and effective information sharing (0.094) were found as the most important critical success factors for offsite construction.

Table 4. Importance weights of CSFs.

Group	Group Weight (w_g)	Critical Success Factor	Factor Weight Among Group (w_f)	Factor Weight Global (W)
Leadership	0.232	Contractor Leadership & Experience	0.461	0.107
		Project Managers Problem Solving Ability	0.539	0.125
Process	0.167	Effective Information Sharing	0.563	0.094
		The Maturity of Techniques & Technologies	0.437	0.073
Regulatory	0.171	Government Promotion	0.322	0.055
		Supporting Policies & Legislations	0.368	0.063
		Revisions to Building Regulations	0.310	0.053
Resources	0.206	Integration of the Supply Chain	0.321	0.066
		Sufficiency of Manufacturers and Suppliers	0.324	0.067
		Skilled Labor Availability	0.355	0.073
Technical	0.231	Timely Design Completion	0.269	0.062
		Assembly Planning Method	0.230	0.053
		Preliminary Module Definition	0.193	0.045
		Designers' Experience	0.309	0.071

Discussion and Conclusion

Offsite construction has many advantages over the traditional method of construction. However, the offsite construction method obtains a meager market share relative to the traditional method of construction. Thus, this study aimed to define CSFs of offsite construction in Turkey. After determining critical success factors through the literature review, a questionnaire survey was conducted, and the AHP model was developed. The results showed that project managers' problem-solving ability (0.127) and contractor leadership & experience (0.107) were the most important critical success factors for offsite construction. These two factors showed that experience and leadership play the most crucial roles in the success of the offsite construction method. A study conducted in Australia resulted that industry knowledge was the most critical barrier to offsite construction methods (Blismas & Wakefield, 2008). The findings of Blismas and Wakefield (2008) match the

conclusions of this study by looking from another point of view. Project managers' problem-solving ability was rated as the second most important critical success factor in a study conducted in China (Li et al., 2018), similar to the results obtained in this study. Another study conducted in the UK also determined the leadership and management level as the second most crucial CSF, which also validates this study (Kamar et al., 2009).

Moreover, Effective information sharing (0.094) was the third most critical success factor according to the findings of this study. Another study in Malaysia shows that good working collaboration and effective communication channels were considered the four most significant critical factors (Ismail et al., 2012). These factors were subcomponents of the factor of effective information sharing that took place in this study. In another study conducted in Malaysia, effective information sharing was found to be the second most crucial CSF for industrialized building systems (Kamar et al., 2010).

This study contributes to the literature by determining critical success factors from the perspective of the Turkish construction market. Moreover, similar developing countries may benefit from the findings when evaluating offsite construction's success factors for their markets. However, this study has some limitations as well. The data used in the analysis are obtained from experts, and the experts' answers are subjective. Future studies might develop this study by applying different analysis methods.

A Review on Implementation of Lean Construction Principles into Off-Site Construction Methods

C. Coskun and A. M. Tanyer
Middle East Technical University, Department of Architecture, Ankara, Turkey
coskun.cansu@metu.edu.tr, tanyer@metu.edu.tr

Abstract

Number of construction projects have increased in the recent decades due to rapid urbanization, globalization, population growth especially at the metropolis cities. Traditional on-site construction methods are not sufficient enough to satisfy demands like performing faster construction, less workmanship on site as well as minimized occupational accidents. On the other hand, off-site construction methods enable to manufacture components of the buildings in a more controlled environment while achieving more efficient construction planning, minimized accidents at site, less workmanship and less disruption to the local people. Project performance of the off-site construction projects can be enhanced by eliminating all unprofitable activities and generating value through the construction project life cycle. The main purpose of this paper is to present possible benefits of implementation of lean construction principles into off-site construction methods. In this regard, a brief information about off-site construction methods and lean construction will be mentioned. Then, a systematic literature review will be carried out regarding the implementation of lean construction principles into off-site construction methods. Finally, possible benefits by implementation of lean principles will be listed based on the results obtained from the systematic literature review.

Keywords: *construction project performance, lean construction, off-site construction, systematic literature review.*

Introduction

Construction projects are unique and non-standardized products (Murphy et al., 2018). The management of the construction projects has become more challenging as the complexity of construction projects increases (Bataglin et al., 2017). As a result, performance of the construction projects ends up with undesirable outcomes such as longer construction time, waste generation and lower efficiency in production (Sutrisna et al., 2022). Off-site construction is a method to manufacture building components in a more controlled environments and it contributes to reduce construction time, defects and unforeseen events (Barkokebas et al., 2021). There are studies demonstrate that off-site construction can be enhanced by integration of lean construction principles. As an illustration, Du et al. (2022) demonstrate to improve production scheduling of prefabricated components by integration of Just-in-time (JIT) and value-based management (VBM). Ahmad et al. (2019) focus on the elimination of non-value added (NVA) activities to enhance production processes in precast

concrete components by JIT, Kanban and layout improvements. In this sense, the main aim of this study to present a systematic literature review to identify possible benefits of implementation of lean construction principles into off-site construction. The structure of the paper is as follows. First, research methodology utilized in this paper will be mentioned. Then, a brief introduction to lean construction and off-site construction will be given. Thereafter, lean construction principles implemented in the off-site construction will be analyzed. Finally, results regarding the previous step will be discussed in detail.

Research Methodology

As a research methodology, systematic literature review has been conducted in order to determine the potential contribution of the lean construction principles though off-site construction. For the selection of the relevant papers regarding the research question, Scopus database has been utilized. Research articles and conference papers that have the key words including both "Lean Construction" and "Off-Site Construction/Prefabricated Construction" in abstract or key word sections are selected. According to initial search results, total number of 75 papers have been listed in the subject area of engineering. Among 75 papers, there are 33 papers encountered explicitly mention "Lean Construction" and "Off-Site Construction" between the years 2002 and 2022, and merely 16 of the papers demonstrated the potential contribution of lean principles via quantitative analysis. As a result, the response for the research question is tried to be drawn among 16 papers.

Lean Construction

Lean production is a management approach that combines principles, tools and techniques in the manufacturing environment which was firstly emerged in the manufacturing sector (Pedo et al., 2021). Lean construction is evolved through the adaptation of lean production systems firstly introduced in car manufacturing sector in 1990s (Koskela et al., 2019). Lean construction aims to reduce waste by eliminating all unprofitable activities and generate value all phases for the construction project (Lalmi et al., 2022). Lean construction principles can be applied to optimize construction management process (Brissi et al., 2022). As an illustration, Sacks et al. (2010) developed a framework in order to analyze the interaction of lean principles on BIM functionality, and they ended up 52 positive and 4 negative synergies between LC and BIM principles based on the previous literature. In that study, contribution of lean principles has been categorized regarding flow process, value generation process, problem solving and developing partners; and contribution of BIM has been categorized regarding design, design and fabrication detailing, preconstruction and construction. Babalola et al. (2019) identified 32 lean practices and associated the benefits with the implementation of lean practices in terms of economic, social and environmental aspects through a systematic literature review. Erol et al. (2017) focused on the positive impacts of implementation of lean construction principles on project duration of the residential buildings. Nowotarski et al. (2016) studied cost saving in the construction projects and revealed that lean management enables ease of cost saving. Fitchett and Rambuwani (2022) proposed lean principles as a strategy to reduce wastes in construction projects.

Off-Site Construction

Off-site construction enables to plan, design, fabricate and assembly of the building components in a more controlled environment rather than the final location of the building components (Marinelli et al., 2022). Off-site fabrication (OSF), off-site manufacturing (OSM), pre-assembly and prefabrication are the alternative terms that commonly used in the literature to mention off-site construction (Sutrisna et al., 2022). Marinelli et al. (2022) underline the biggest advantages of off-site construction as decrease in construction time on site, increase in the quality and elimination of defects. According to Tzourmakliotou (2021), the roots of off-site construction methods can be traced to the Roman time in AD-43 where Romans built same and repeating components of the forts. Britishers also utilized off-site construction method to be able to transport simple modular houses to construct new settlements. In 19th century, United States get benefit of the off-site methods to address the housing needs during the California Gold Rush. In recent decades, usage of off-site construction methods has increased to address problems regarding low efficiency and productivity issues in on-site construction approaches (Ahn et al., 2022). Nowadays, the implementation of off-site construction can be encountered especially in buildings from low-rise to high-rise (Thai et al., 2020). Shibani et al. (2021) mention the predominant building materials used in prefabricated form as wood, concrete and steel. In addition, Ginigaddara et al. (2021) categorize types of off-site construction under non-volumetric (components, panels, foldable structures) and volumetric (pods, modules, complete buildings). Further definitions, examples and features for the off-site construction categorization is presented in Table 1.

Table 1. Types of off-site construction (Adapted from Ginigaddara et al., 2021).

Types of Off-Site Construction					
Non-Volumetric			*Volumetric*		
Components	*Panels*	*Foldable Structure*	*Pods*	*Modules*	*Complete Buildings*
Definition: Non-volumetric elements of any shape or size, excluding flat panels	*Definition:* Flat elements that do not create usable space	*Definition:* A stack of panels interconnected with hinges	*Definition* Enclosed spaces repeatedly made with high level of finishing	*Definition:* Volumetric parts of a whole building	*Definition:* Single unit or single module building
Features: Mass manufacture, high level of pre-design, structural and nonstructural elements	*Features:* Usually rectangular, different subcategories are available	Features: Not common, economically unviable	*Features:* Repetitive, limited mix, high level of finishing	*Features:* Light-weight structures, have potential to become a complete building	*Features:* Large and complex, serves special needs
Examples: Trusses, staircase, columns, beams	*Examples:* Floor, wall, ceiling, roof panels	*Examples:* Residential buildings	*Examples:* Kitchen, bathroom, prison pods	*Examples:* Residential, school, apartment building	*Examples:* Construction site shed, disaster recovery building

Implementation of Lean Construction Principles into Off-Site Construction

Ahmad et al. (2019) highlight that application of the lean approach in off-site construction has several evidence in the improvement of the construction project objectives. In this regard, Meiling et al. (2012) conduct a survey to obtain the most suitable lean management principles applied in timber-framed module prefabrication manufacturing company for ensuring continuous improvement. Fourteen lean principles are divided into 4 categories in terms of long-term philosophy, the right process will produce the right results, add value to the organization by developing your people and partners and continuously solving root problems drives organizational learning. Creation of a continuous process flow to bring the problems, utilization of pull systems to avoid overproduction, stopping the work flow to fix problems in the first time, standardizing tasks for employee empowerment, growing leaders to teach lean philosophy to others, making decisions slowly and implementing decisions quickly, "go and see" to understand work at the exact condition, utilization of reliable technology, respect to other people are listed as the top lean principles used in the lean management based on the survey results. Hermes (2015) argues integration of construction processes with industrial mass production as an innovative approach and points out that continuous improvement can be achieved by utilization of modularization and prefabrication methods. In this sense, two lean approaches namely as Last Planner System (LPS) and Lean Project Delivery System (LPDS) are proposed to structure the manufacturing processes in terms of flow of the information and reduction of wastes. LPS is a scheduling method that requires partnership among project stakeholders. LPS enables to reduce errors and costs as well as catch the project deadlines. In LDPS, different phases of construction project like design, construction and operation are considered simultaneously rather than separately among project participants. LPDS is an efficient method to determine and manufacture standardized prefabricated components by communicating each party in advance. Trevisan et al. (2016) discuss the pull production system in the context of customized prefabricated building elements. The study of Trevisan et al. (2016) reveals that lead times and inventory levels can be decreased by implementation of pull production through customized prefabricated components. Bataglin et al. (2017) mainly focus on the process of planning and controlling the logistics of the Engineer-to-order (ETO) prefabricated buildings. In that study, 4D simulation model was tested for controlling the assembly process of ETO prefabricated buildings. The results demonstrate that visualization ease exchange and update the information among stakeholders and increase the reliability and transparency of the process among different disciplines. Heravi and Firoozi (2017) examine production line of prefabricated steel frames via Value Stream Mapping (VSM). VSM is lean technique that enables to determine non-value activities in the process. Heravi and Firoozi (2017) utilize VSM for identifying wastes and their root causes in the current production line for that purpose. According to remodeling of the production line, lead time of production is reduced by 34% and cost is reduced by 16%. Ahmad et al. (2019) focus on the integration of lean approach into to the reinforcement work process in the component production of industrialized building system precast concrete construction to identify and eliminate non-value added (NVA) activities. NVA activities in the production line are identified as unnecessary inventory, excessive movement and coordination issues; and JIT, Kanban, layout improvement have become the lean principles addressed for the elimination of NVA activities. Murphy et al. (2018) state the problem in prefabricated elements as waste due to waiting and defects during construction. In their study, utilization of Virtual Design and Construction (VDC) methods enable to increase productivity up to 30% during production. In addition, VDC methods address the predictably problem considering the coordination among different trades and provide feedbacks in design phase for the further stages of the production. Xu et al. (2018) propose an integrated cloud-based Internet of Things (IoT) platform to facilitate operation process (production, logistics, on-site assembly) of lean prefabricated

construction. Utilization of IoT technologies enable to enhance automation, real-time data collection, remote control, visibility and traceability of lean prefabricated construction processes. Their study demonstrates that overall paper works have been lessened by 40%; the time for locating a prefab, waiting time for delivery, and order picking time have been reduced by over 20% through real-time information sharing. In addition, on-time delivery rates have been enhanced by 7.3%. Goh and Goh (2019) develop a detailed simulation model to present Prefabricated Prefinished Volumetric Construction (PPVC) operation by Discrete Event Simulation (DES) and VSM. Total Quality Management (TOQ), internet-based Kanban system and construction robotics are the lean principles implemented where those principles enabled to reduce cycle and process times by 81.27%, increase resource utilization rates by 17.91%, decrease work-in-progress levels by 74.30%, enhance process efficiency by 4.58 and labor productivity by 398%. Bataglin et al. (2020) propose a model based on pull production and reduce variability principles for planning and controlling of ETO prefabricated building system in the context of the site installation and logistics. Implementation of the model contributes improvement of the reliability of overall planning process by 95% and productivity up to 39 components per day. Darwish et al. (2020) integrate DES into lean philosophy to analyze various scenarios in multiwall panel production line. In the first scenario, process flow and floor layout modifications were done and according to initial results, idle time was reduced by 40% and total duration is reduced by 30%. In the second scenario, the previous nailing system was replaced, and total duration is reduced by 4% while the idle time increased by 30%. In the final scenario, the approaches used in first and second scenario were combined, and the cycle time and idle time were reduced by 42% and 35% respectively, and the production rate of panels were increase as 8 panels per day. Kanai and Fontanini (2020) study on a method to improve process flow planning of prefabricated concrete panels based on VSM and Visilean® though four scenarios. In the current scenario, real system was taken account to collect factory data. In the future scenario 1, pushed system was used and a little improvement was observed in comparison to the current scenario. In the future scenario 2, time of the current scenario was reduced by 25% with integration of pull system. Finally, process flow time of the current scenario was optimized up to 50% in the ideal scenario by implementing JIT system. Barbokebas et al. (2021) draw on digitalization by BIM-lean approach for enhancement premanufacturing processes during design, procurement, and bidding in off-site construction and a framework was developed in this sense. Lean philosophy was used to measure, identify and implement opportunities for improvements. Data collection and analysis were carried out considering “go and see” and VSM lean principles, planning and improvement for the future processes were done with Kaizen and waste minimization principles. The developed framework via lean-BIM integration ensures 22%-47% of task durations were reduced in pre-award and post-award phases of the project. Ayinla et al. (2022) analyze the wastes in off-site production of wall panel through two case studies. Wastes are identified considering Value Stream Analysis (VSA) and root cause analysis. Their analysis show that 47% NVA time is spent in the production line and overall lead time can be reduced up to 70% in a more organized flow. Du et al. (2022) address the scheduling problem during production of the prefabricated components by applying biogeography-based optimization (BBO) in planning and production stage where JIT and value-based management (VBM) are two core lean principles benefitted for the scheduling optimization in a limited time. Laika et al. (2022) suggest determining wastes in precast concrete production process via root cause analysis and eliminate wastes by 5S (sort, set in order, shine, standardize, sustain) and JIT techniques. According to their analysis results, total production time is reduced by 39%, total production cost is reduced by 33% and total idle time in production is reduced by 90%.

All in all, potential benefits of lean construction principles applied in off-site construction are summarized in Table 2 with their reference studies.

Table 2. Potential benefits of lean construction principles in off-site construction (References: A: Meiling et al. (2012), B: Hermes (2015), C: Trevisan et al. (2016), D: Bataglin et al. ID	*Lean Construction Principle*	*Potential Contribution in Off-Site Construction*	*Reference Study*
1	5S (sort, set in order, shine, standardize, sustain)	elimination of waste	P
2	Continuous improvement	employee and customer satisfaction, improved product quality	A, B, M
3	Decide slowly, implement fast	consideration of all options and risks in advance	A
4	Go and See	observation of the actual work in progress	A, M
5	Just-in-Time (JIT)	elimination of unnecessary inventory, addressing coordination issues	F, L, O, P
6	Kanban	increasing visualization, enhancement of communication among parties	F, I
7	Last Planner System (LPS)	decreasing errors and cost, following up the project deadlines	B
8	Layout improvement	reduction of idle time	F, K
9	Lean Project Delivery System (LPDS)	investigating which components can be standardized in advance	B
10	Pull production	avoiding over production, optimization of lead times and inventory levels, increasing project schedule reliability, increasing productivity	A, C, J, L
11	Root cause analysis	identifying wastes	A, E, N, P
12	Standardization	employee empowerment, decreasing customized work	A, B
13	Stop the line	obtaining a better quality end product	A
14	Value Based Management (VBA)	creation of value for all parties	O
15	Value Stream Mapping (VSM)	identifying wastes and root causes of the wastes	E, I, L, M, N
16	Visualization	ease of exchanging and updating information among parties, increasing reliability and transparency of the process	D, G, H, L
17	Technology (BIM, IoT etc.)	optimization of task duration, increasing automation of the work, enabling real time data collection, better visualization and traceability	H, I, M
18	Total Quality Management (TOQ)	higher productivity, increasing profitability	I

Discussion and Conclusion

In this study, a systematic literature review has been carried out in order to identify potential contribution of lean construction principles in off-site construction. According to literature review analysis, implementation of lean construction principles mainly addresses to optimize construction project time, reduce errors and waste, increase end-product quality, produce more reliable project schedules, enhance project coordination and communication among different disciplines. Optimization of project duration and enhancement of the communication are the top two construction project objectives analyzed in the previous literature. As an illustration, construction project schedule optimization for off-site construction has been performed through lean techniques including JIT, LPS, layout improvement, pull production, standardization and VSM. Besides, Kanban, LPDS, visualization, technology are utilized in order to enhance communication among several trades in off-site construction process. Even though the lean principles have several benefits in off-site construction sector, the shortcomings of the implementation of lean principles can be listed as follows. First of all, lean philosophy is not common in the construction sector, so adopting it might take some time considering the traditional management approaches in the construction sector. As lean construction is a state-of-art method, integration of it may require high initial investment cost at the beginning.

bugan@itu.edu.tr, irlayici@itu.edu.tr

Abstract

The success of a construction project highly depends on delivering it on time, within budget, and at the required quality. To achieve project goals, the assessment of the constructability of the design gains prominence, as well as the well-management of the design process. Failure of design professionals to consider how a builder will implement the design can lead to disruptions and conflicts during the construction process. Consequently, many design-construction interface problems may arise and affect the overall project performance. This study focuses on the causes of design-construction interface problems and how to define them clearly. To achieve research objectives, a comprehensive literature review will be conducted, the most common design-construction interface problems will be identified and their root causes will be determined.

Keywords: *construction management, design conflicts, design-construction interface problems, design management.*

Introduction

With the breakthroughs of the public and private sectors, the process of managing large and complex projects has emerged. Recent years have seen a considerable increase in the push to improve design performance or to create high-quality design solutions in shorter timeframes. This is due to the increasing complexity of projects and the fiercer market rivalry (Tzortzopoulos & Cooper, 2011).

A project is an organization of a wide range of members of the project team. Throughout the project life cycle, each member of the project team is essential. According to Sugumaran (2013), the effectiveness of the decision-making and execution process throughout the entire project team is directly related to the information's availability, dependability, and accessibility as well as one's capacity to visualize what other parties convey. The quality of a construction facility is frequently a reflection of the data produced throughout the planning and design phases, and particularly of the level of construction input to the design process, therefore the design-construction interface is particularly crucial (Sugumaran, 2013).

First of all, it is important to define the concept of "interface". "Interface" is defined by Healy (1997) as; "a boundary where an interdependency exists across that boundary and where responsibility for the interdependency changes across that boundary" (Quoted by Yeganeh, 2019). Interfaces are the contact points for every work package and it's related to stakeholders

or stage/phase. Poorly managed interface management leads to poor productivity, poor quality, and increased cost which affects overall project performance negatively. Alarcon (1998) asserts that to successfully complete this step and improve the design-construction interface, it is crucial to distinguish between tasks that contribute "value" and those that generate "waste" throughout the design and building processes.

It is crucial to identify the major causes of errors and discrepancies and either eradicate them or lessen their negative effects to pinpoint problematic areas in the design-construction interface and create proposals for workable solutions. Accordingly, this study concentrates on;

1. analyzing the management of the design phase, errors, and failing points;
2. identifying causes of problems that occur during the design and construction phases;
3. sorting out relationship networks between stakeholders and assessing the potential causes of inconsistencies;
4. and analyzing the impacts of the above on project performance.

Therefore, this paper aims to focus on the causes of design-construction interface problems, search how to define them clearly. With this aim, the most common design-construction interface problems will be identified and their root causes will be determined. To reach these objectives, a comprehensive literature review has been conducted.

Design-Interface Problems

Many problems occurred in the construction projects, especially in interfaces. But there are no universally accepted definitions of Interface Management and its constituent parts. However, often, interfaces are seen as the divisions between autonomous, yet interdependent systems, project phases and scope packs, building materials, and stakeholders (Shokri, 2016). Problems with the design-construction interface vary in how they are categorized. The main attitude should be to trace and control them. For this reason, it is important to be aware of these problems at every phase and to foresee what causes these problems and what consequences these problems will have.

Bogus et al. (2003) stated that any attempts to reduce the overall project delivery time can be thwarted if design and construction are viewed as independent entities, often with little to no cooperation between them. Such a reduction is possible by moving toward an integrated design-construction interface (Quoted by Yeganeh, 2019). However, sometimes the stakeholders, which have their own goals, face different challenges during any phase of the project. Therefore, understanding the causes and their causation, which are connected to all project phases, can aid practitioners in taking them into account and avoiding their unfavorable effects in future projects, improving the interface integration, and making better judgements that may improve project performance (Yeganeh, 2019).

When the literature is examined, it has been seen that these problems are categorized differently according to the reasons for their emergence and the interfaces they occur. For this reason, what this "interface" is and what it consists of has been tried to be explained. Questions such as what is design-oriented interface management (1), what are the problems in the design management process (2), how is the contract management in particular (3), what are the problems for the project stakeholders (4), and the problems in the constructability axis (5) were examined under the headings.

Interface Management

The idea behind project management is interface management, which provides a "bird's eye perspective" and assists in avoiding time overruns, lowering cost overruns, minimizing reworks in construction, and also gaining quantifiable advantages like increased customer satisfaction (Manoj, 2010). To minimize their potential to have a detrimental influence on the project, interface issues inside the project's organization must be properly addressed. Wideman (2002) made two definitions of Interface Management: (1) *"The management of communication, coordination, and responsibility across a common boundary between two organizations, phases, or physical entities which are interdependent"*; and (2) *"managing the problems that often occur among people, departments, and disciplines rather than within the project team itself."* (Quoted by Chen, 2008) As explained here, Interface Management involves every part of the project in the built environment such as the project life cycle process, different phases of the life cycle, resources, schedules, systems, contracts, etc. Therefore, Interface Management cannot be considered separately from project management activities.

In this study, the authors focused on the problems which affected the design and construction phases especially. These two main processes are closely interconnected and the shortcomings in the design directly affect the construction process. Therefore, the problems in the design phase should be identified firstly, then their potential impacts on constructability will be discussed.

Problems Related to Design Management

The gap between design and management has grown as a result of changes in the construction industry, the continued specialization of professions, and the increasing use of alternative procurement methods. The requirement for a design expert with managerial and technological skills has also been emphasized by the researchers. To maintain the concerns with cost management and design development across the many phases, the role of the design manager as an information manager has evolved and gained relevance (Smith, 2004). Sinclair (2011) stated: 'Design management is the discipline of planning, organizing and managing the design process to bring about the successful completion of specific project goals and objectives.' (Quoted by Knotten, 2017)

To reach the project goals on time and within budget, especially the tendering process should go smoothly. There should be a good management plan for successful tendering. Through the involvement of more assured architects and designers in the planning process, the planning was growing better. It demonstrated the value of management assistance for process implementation (Fundli, 2014). If construction professionals cannot make decisions based on assumptions correctly, design changes can appear at later phases. Undurraga (1996) stated that, in Latin American countries, according to estimates, design errors cost between 20 and 25 percent of the overall building time (Quoted by Alarcon, 1998). According to Sun (2006), changes always necessitate rework, which drives up the cost of the project. In addition to rework, editing project documents, changes in schedules, and procedures can be seen as other effects. Also, "poor constructability of design option", "coordination efficiency between design, procurement and construction is low", "communication with consulting engineers is inefficient", "poor management of design variation processes" and "information management of design is not standardized" are identified as design-related interface management problems

(Zhang, 2018). In the study by Picas (2020), *poor coordination, inherent uncertainty in information flows,* and *the lack of timely responses from clients* are found as the main design problems. According to Zhang (2018), insufficient design data causes; *high construction cost of design option* and *uncertainty of projects' specific scope, and unclear parameters of equipment cause deviation in project cost.*

Knotten (2017) studied success factors in building design management. He finds the design phase important to pass the project process successfully. According to the results of the survey, *communication* and *decision-making* are the most important ones. When analyzed by phases, Alarcon (1998) detected some problems during the execution phase of the projects. They are *poor design quality, lack of design standards,* and *lack of constructability*. After the survey, during design phases, the most important problems are *defects of individual specialists and the lack of coordination among specialties, changes introduced by the owner and the designers, inconsistencies among drawings and specifications, designers with little construction knowledge,* and *non technical specifications* (Alarcon,1998). In another study, Tzortzopoulos (2007) revealed a case study and reached that since design and construction are typically developed concurrently, there is a perception that the detailed design process should be separated from the construction planning phase. However, this does not always occur due to ineffective information sharing with external designers. As a result, a lot of design choices are made on the construction site. Because of that statement, the primary concerns include clear roles and responsibilities, the availability of design managers with the necessary skills, and a clear understanding of what the organization wants to accomplish through design management (Tzortzopoulos, 2007). As Mendelson (1997) stated that the design phase is to blame for 75% of the issues that arise on the job site (Quoted by Choudhry, 2017). In the design phase, *data provided to designer are incomplete* and became the most ranked cause. In the construction phase, *owner proposes changes due to financial problems* got the first position. According to Al Mousli (2016), contractor involvement in the design phase of the project enhance constructability and lower the likelihood of design modifications. The problems at this phase are *lack of contractor involvement during the design phase, delay in preparing construction documents, time limitation in the design phase, lack of coordination inside the design firm* and *undefined owner scope.* After the study, *lack of coordination inside the design firm* became the most ranked design-construction related interface problems.

Design-related Contract Management

A key factor in controlling the design deliverables at various phases is design-related contract management (Zhang, 2018). Every construction project starts with the details set in the contract and the form of agreement. Project duration, management type, quality standards, construction method, and responsibilities of every stakeholder are the topics that the contract should include. There are some requirements to ensure that the contracts are not changed in the other phases of the project. The more details there are, the more accurate the project's start can be. Customer requirements, constructive elements, and quality standards are established during the design phase of construction projects. Drawings, technical specifications, and other design documents are the bases for those requirements. During the design phase, the client's requirements are determined, and methods, drawings, and technical specifications are used to specify the constructive elements and quality standards (Sugumaran, 2013). Contracts that were created based on conceptual designs and clients may have ambiguous project definitions. These deficiencies become design changes when the contractor(s) start work because, while project design is evaluated by the architect, the project is also improving and changing. Especially the change orders are the main reason that affects every possible issue on the

project performance. A change order is a request made in writing to the contractor that is provided after the contract has been signed and authorized by the owner to alter the scope of the work, the contract price, or the scheduled completion date. Changes to the designs and contract paperwork typically result in changes to the contract's timeline or price. Contractual conflicts are also more likely to arise as a result of changes (Yeganeh, 2019). Before the contract execution, the bidding process is a challenging and important step. According to Yeganeh (2019), giving the contract to the lowest bidder despite the quality of the services is in the top 10 significant causes of design-construction interface problems. The other problems about contractual problems are *delays in preparing designs by the design team, delays in design approval by the employer, unclear scope of work,* and *change orders*.

Problems from Construction Parties' View

According to Sugumaran (2013), it is quite typical for the construction team to not participate at all in the planning phase but still take on the duty of effectively completing a project once the design is ready for execution. This lack of an integrated strategy frequently results in antagonistic interactions between project participants, raises the risk of mistakes, and frequently overlooks crucial opportunities for improved project performance. As Arain (2016) cited; building project completion success is largely dependent on effective coordination, cooperation, and communication between construction parties. Owners, designers, construction companies, subcontractors, and maintenance companies are included in these construction parties (Wang, 2000). Construction projects frequently involve numerous temporary groups working in unregulated circumstances (Daniels, 2014). Therefore, relationship networks of multiple stakeholders and their roles in the project phases and the design-construction interface have started to be discussed. Because interface issues arise whenever two or more stakeholders interact to fulfill the objectives of a construction project in this fragmented environment (Marzuki, 2019). One problem can be the most important item for a stakeholder but less important for another. For example, as mentioned in Sugumaran's study (2013), the *effect of incomplete plans* is the most important cause of design-construction interface issues according to contractors, while it is the least important origin for design consultants. Al-Hammad (2000) discussed interface problems among the various construction parties. He grouped problems under these categories: financial, inadequate contract and specification, environmental problems, and other common interface problems. *The owner's low budget for construction relative to requirement, delay in progress payment by the owner, insufficient working drawing details, and poor quality of work* are selected through the survey as the most rated problems respectively. Furthermore, Arain (2016) studied potential causes of inconsistencies from contractors' views. He investigated these problems according to project phases and *involvement of designer as a consultant, communication gap between constructor and designer, insufficient working drawing details, lack of human resources in the design firm, lack of designer's knowledge of available materials and equipment* are listed as the most important causes.

According to Chen (2008), finding solutions for Interface Management that are generally applicable and enhancing the project's overall Interface Management performance becomes quite challenging. This study offers a multi-perspective analysis of the built environment related to interfaces to bridge the gap and explore all the root causes of interface difficulties. He made categories and one is about *people/participants*. From his perspective, four major causes are identified, supported by minor factors and sub-factors: *poor communication among parties, poor decision-making, poor coordination among parties, and financial problems.*

Interface problems between stakeholders that affected project performance are studied very often. In the study conducted by Daniels (2014), he focused on describing the project complexity to the project participants and improving project planning. The project management plan model is suggested for effective interface management among project participants. This plan's early formulation allowed for its effective implementation and had a beneficial impact on the creation of scheduling and budgeting activities. Other key benefits included having a dynamic online version available to all stakeholders and providing training for new stakeholders. Also, Huang (2008) discussed the effects of interface problems among construction parties upon project performance. He categorized them into seven groups: *financial problems, inadequate contract and specification, environmental problems, other common interface problems, technological improvement, track characteristics,* and *cultural difference.* The results of the analyses show that coordination and experience factors directly influence the project's performance. Project partnering and configuration management are two solutions he proposed to improve the performance.

Constructability

There is widespread agreement that constructability reviews must happen throughout the design process (Arditi, 2002). It is often late for this issue, which needs to be considered and planned during the concept design phase of the project. This issue, which is generally limited to the experience and knowledge of the designer, becomes a difficult situation to prevent and when the contractor is selected and the construction activities are about to begin, the problems begin to increase. This naturally results in extra time and extra cost and thus negatively affecting the project performance. According to Arditi (2002), constructability input has been hampered by the designer's incomplete comprehension of construction necessities, divergent objectives between design and construction specialists, and the owners' opposition to formal constructability approaches due to the projects' very visible additional costs. Also stated by Arditi (2002), incorporating construction expertise into design procedures significantly increases the likelihood of completing a project with higher quality standards, safely, on schedule, and for the lowest possible cost. In the study conducted by Arditi (2002), the factors that enhance and constrain constructability are studied. Project complexity, design practices and philosophy by designer, and project delivery system are rated as the most significant factors that enhance constructability. Faulty working drawings, incomplete specs, and lack of communication are estimated as constraints on this issue. As concluded in the study, the application of proven constructability studies to projects, particularly those that are vast and complicated, as early as the conceptual planning phase to save both cost and time (Arditi, 2002).

To summarize, these findings showed that the great majority of the design-construction interface problems are related to the viewpoint of project management. With the inclusion of interface management at project phases, project management will become more comprehensive and open to management. It will make the interface problems easier to control and lessen them. As shown in Table 1, problems are categorized through interface points related to management areas from the literature review findings. Considering that most of the problems affecting the construction activities are caused by the design process and design professionals, with a communication gap in those phases. Insufficient design data causes incorrect assumptions and it brings failure in tendering stage. Subsequently, the contractor who receives the job will have undertaken a job for which the scope is inaccurate, as s/he has received the job as a result of the bidding process with missing documents as a base. As a result, design changes begin to occur, and factors affecting project performance emerge.

Table 1. Design-construction interface problem categories and causes.

Problem Categories	Causes
Problems Related to Design Management **(**Zhang, 2018; Picas, 2020)	▪ Design professional with no management and technological skills ▪ Design changes (rework, editing in project documents, changes in schedules and procedures) ▪ Incorrect assumptions during the tendering stage ▪ Inherent uncertainty in information flows ▪ Insufficient design data (high construction cost of design option, uncertainty of projects' specific scope)
Problems Related to Construction Parties **(**Chen, 2008; Al-Hammad, 2000; Daniels, 2014; Arain, 2016)	▪ Temporary groups ▪ Owner's low budget ▪ Delay in progress payment by the owner ▪ Poor quality of work ▪ Involvement of designer as a consultant ▪ Communication gap between constructor and designer ▪ Lack of human resources in the design firm ▪ Poor decision-making ▪ Poor coordination among parties
Problems Related to Design Contracts **(**Huang, 2008; Yeganeh, 2019)	▪ Change orders (contractual conflicts) ▪ Delays in preparing designs by the design team ▪ Delays in design approval by the employer ▪ Unclear scope of work ▪ Inadequate contract and specification
Problems Related to Constructability **(**Arditi, 2002)	▪ Designer's incomplete comprehension of construction necessities ▪ Divergent objectives between design and construction specialists ▪ Faulty working drawings, incomplete specs

Conclusion

The most important criteria to call a project successful is that it is completed on time, within the planned budget, and with the right quality. The way to a successful project goes through a healthy project management process. Proper communication, effective leadership, timely and accurate schedules, a design-oriented budget and process planning are some of the items in this process. The integration of all components and their smooth operation in the project process can be achieved with interface management. As the use of efficient interface management methodologies spreads, project teams become more collaborative, which boosts profitability, lowers costs, improves time management and strengthens customer/client relationships (Manoj, 2010).

Problems may arise during long project processes. Design, procurement, and construction activities can be intersected coincidently in some project delivery systems that cannot be

tolerated. These “interfaces” are the real break points for the projects and should be solved properly with the right tools. The important thing is to identify these design-construction interface problems at the right time, define and address them to the appropriate location. This research aims to investigate, define and determine the root causes of interface problems in the construction industry with an expanded literature review. The literature has been grouped based on different sub-headings related to the design process especially and it has been tried to go down to the root causes.

In the upcoming thesis project, this study will be extended with real data from the construction industry to successfully combine practice and theory through the effort the of authors.

Abstract

Having a critical importance for the retail sector in Turkey and increasing in number every day, shopping malls have a dynamic structure due to their character. In order to ensure the sustainability of their functionality, those who manage these buildings, which are constantly updated / renewed and exposed to tenant / user circulation, need to regulate the spatial organization processes in order to keep the said dynamism under control. In this sense, the most effective and valid instrument is the decoration specifications.

There is a need for a well-structured specification for the rentable areas within the structure of shopping malls, each of which has a different corporate identity, to carry the design line of the shopping malls and to reflect the brand concept of the tenants. The specification covers not only architectural but also electrical and mechanical projects where all stores are fed from a common infrastructure. In this study, a comparative evaluation of the specifications regulating the decoration processes of the shopping malls, which have become the locomotive of retail merchandising in big cities, is presented in the context of architectural, electrical, and mechanical headings. Within the scope of the study, different scaled shopping malls, which are in Istanbul, which has the highest number of shopping malls in Turkey, and which were determined to operate the decoration processes systematically with expert opinions were handled.

Keywords: *shopping malls, design specifications, design management, retail areas.*

Introduction

Hornbeck (1962) defined the concept of shopping as “the combination of the place where actions such as looking at a commercial product, learning the price, examining and purchasing are done through the exchange method” (Parlakdağ, 2019). Based this traditional definition today it is a bit different because of shopping malls are thought as an important public area. Shopping malls, where the one of the most visited public areas in the world, makes the product, customer and seller come together for not only purchasing, selling the goods and services but also socialization. Today, shopping mall users prefer to spend most of their times in the

shopping malls for shopping, entertainment, food and beverage, socialization, education activities etc. (Dikmen & Bozdemir, 2021). As a result of this, it is needed to design and organize the spaces in an effective way to ensure the needs of shopping mall users (Dikmen & Bozdemir, 2021).

As of Q1 2022, the existing shopping mall supply in Turkey was recorded as 14 million m² in 453 shopping malls. There are approximately 895 thousand m² of leasable area in 30 shopping malls under construction and the total supply in Turkey is expected to reach 14.9 million m² by the end of 2024 (GYODER, 2022).

Because of being many shopping malls, leasable area in these malls and many different sizes and features of shops in the shopping malls, it is important to regulate and manage the design and implementation process in the quickest way for the proper operation process of the shopping malls.

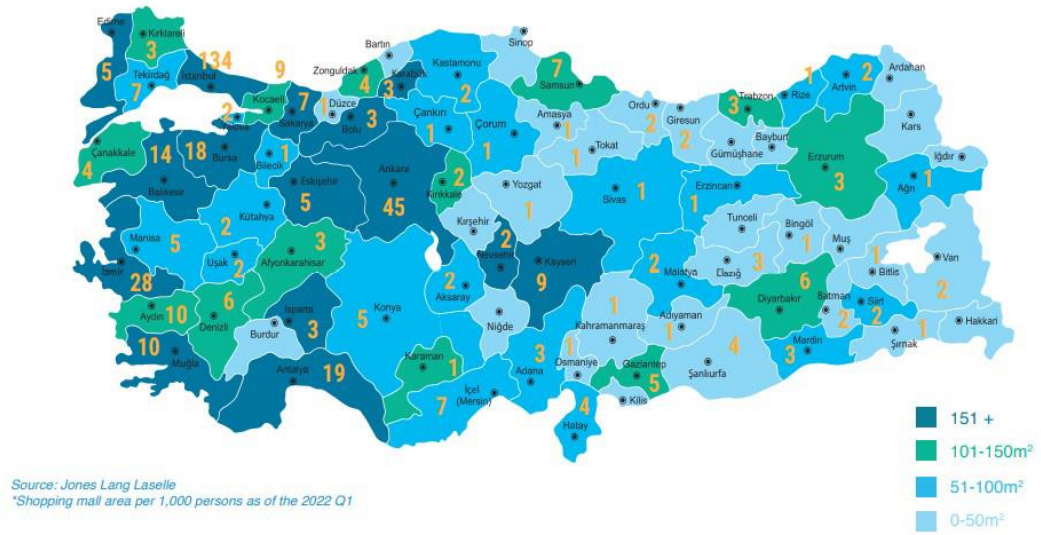

Figure 1: GLA* Volume and number of shopping malls according to cities.

In Türkiye, İstanbul has the most shopping malls as it is seen in Figure 1. So, this study aims to compare the evaluation of the specifications regulating the decoration processes of the three important shopping malls, in Istanbul, considering the highest share of shopping volume and number of shopping malls in Türkiye, to explore the need of detailed specifications to manage the shopping mall shop design and implementation process. So, in this study in the the current technical specifications of these three shopping malls has been evaluated in the context of architectural, electrical, and mechanical headings.

Decoration Specifications of Shopping Malls

In general, there are three aspects of the design for shopping malls. The first of these is the design approach of the shopping mall. This approach also dates a standard for the stores it contains. The second of the three aspects mentioned comes into play here: Leasable areas. It is of great importance that the leasable areas have their own design approach and that they could meet the standardization of the shopping mall. The third aspect could be shown as the corporate identities of the brands in the leasable areas. Each brand has a design approach that defines

itself. In fact, to put it with a metaphor; The corporate identity of brands and the design approach of shopping malls are two different clusters and there are leasable areas at the intersection of these two clusters.

In particular, brands with chain stores have to carry out architectural works in which they could reflect their corporate identities in shopping malls designed with different concepts. The most important tool to capture this intersection is the decoration specifications. For the solution of this problem, each shopping mall has its own decoration specification. Every shopping mall has to define certain limits to the design freedom of its tenants with a specification that could protect its design approach at the maximum level. Brands can also know their own limits thanks to these specifications.

Although the responsibility of the stores may seem like signage and display standards at first glance, it is actually much more than that. Both directly related and independent works such as the level of the floor in the store, the cables to be used in the electrical installation, the capacities of the ventilation grilles must meet the expectations of the shopping mall. Because the units in the mall could be rented. In other words, the continuity of the brands settled in these units is not certain. Therefore, variable users must meet these standards.

The level of detail of a decoration specification should be fine-tuned. Decoration specifications that are not too detailed may create gaps in the design and this may cause conflicts between the owner and the user. Specifications that contain too many details may overwhelm the user and may be the reason why they do not prefer that mall. Therefore, the level of detail needs to be adjusted very well.

In this study, which aims to understand this process with many delicate balances and to determine its open points, if any, the project sets that are included in the decoration specifications of three important shopping malls located on Büyükdere Street, which can be defined as the important commercial axis of Istanbul, and expected from the users, have been evaluated comparatively. Malls whose names are hidden due to data privacy are defined as SM01, SM02 and SM03 (Table 2, Table 3, & Table 4). In the selection of shopping malls, the views of the managers of the architectural offices, who are especially involved in the design and implementation processes of the chain stores, were utilized. Ten different architectural offices, whose opinions were taken, were asked about the shopping malls that they found the decoration specifications to be successful in the projects they carried out, and by evaluating the quantity of the answers, the first three shopping malls at the top of the list were progressed.

Data Collection & Findings

The study consists of two parts: Comparison of the project sets in the decoration specifications and evaluation of expert opinions. The comparative evaluation of the project sets was shared in the paper.

The study was started by taking the opinions of the managers of the companies that mainly make store decorations in shopping malls. First of all, the managers were asked about the content of architectural, electrical and mechanical project sets that are generally required in each project in the interior application works they carry out in shopping malls. The responses received are compiled in Figure 1.

Table 1. Expert value summary of project sets of decoration specifications of shopping malls.

Architectural Project Set	**Electricial Project Set**	**Mechanical Project Set**
Furnished floor plan	Lighting layout	Fire extinguishing installation plan (upright, sprinkler, fire cabinet, etc.)
Suspended ceiling plan (superposition of architectural, electrical and mechanical projects)	Lighting installation plan	Plumbing plan
Wall plan	Socket and switch installation plan	Heating and cooling system plan
Floor plan	Cable tray plan	Ventilation installation plan
Sections	Single line scheme	Natural gas installation plan
Facade views (two and three dimensional)	Clipboard details (dimension, image, etc.)	Account reports
Three-dimensional images of the store	Clipboard loading ruler	Details of the equipment to be used (brand, certificate, warranty certificate, etc.)
Signage design (Plan – section – view)	Total power calculation	
Details of the materials to be used (brand, certificate, color, etc.)	Heat control calculation	
	Details of the material to be used (brand, certificate, warranty certificate, etc.)	

Then, the architectural, electrical, and mechanical project sets included in the decoration specifications of three different shopping malls evaluated within the scope of the study are listed in Table 2, Table 3, and Table 4 in comparison.

Table 2. Architectural project set outline of shopping malls (SM01, SM02. SM03).

SM01	**SM02**	**SM03**
Construction drawings (furnished plan) s:1/100 ~1/50	Floor Plan S: 1/50	Demolition plan for stores that have already been designed and implemented S:1/50
Wall plan s:1/100~1/50	Floor Plan S: 1/50	Architectural construction plan / walls, columns, etc. S:1/50
Floor covering plan S:1/100~1/50	Longitudinal and Transverse Sections S: 1/50	Furnished layout showing movable and fixed furniture S:1/50
Suspended ceiling plan (with ceiling elevation and sections) S:1/100~1/50	Inside Views S: 1/50	Material definitions are specified and dimensioned construction plan S:1/50

Table 2. Architectural project set outline of shopping malls (SM01, SM02. SM03) (continuation of table).

SM01	SM02	SM03
Architectural / mechanical / electrical ceiling coordination plan s:1/100~ partial 1/50 if necessary (lighting, sprinkler heads, hatches, vents, voice alarm loudspeakers, emergency exit fixtures, detectors, music speakers in one plan should be displayed)	Material lists and (if requested) technical specifications of all finishing materials to be used	Material definitions, color separations are specified and dimensioned; Floor plan containing the manufacturer's name and product code numbers of the material S:1/50
Sections S:1/100~1/50 (min. 2 pieces) (may increase according to the size of the area)	Plans, sections and views including the design of the sign,	Ceiling plan and sections containing all ceiling materials, codes, maintenance covers, cat ladder (maintenance platform), locations of all lighting and installation elements, manufacturer's name and product code numbers of the material, technical application details S:1/20
Front View As 2d And 3d Renders S:1/100~1/50	Suspended Ceiling Plan S: 1/50 (Plans showing the superposed state of lighting fixtures, equipment on the ceiling of all disciplines, intervention hatches, fire detection and sprinkler system)	Preliminary electrical plan / lighting, socket locations, switches, thermostat, telephone etc. S:1/50
Sign design (plan section and details) :1/50~1/20~1/5	Fire and Emergency Escape Sign Information	Minimum 2 cross-sections and views specified and dimensioned with material colors and definitions S:1/50
Static project and calculation (required in stairs and mezzanine floor plan)	After the construction is completed, the delivery of the “as-built” projects	Colored store front and signage plan, view and sections S:1/50~1/20
Elevator (if necessary)	3D Modeled showcase image	Colored perspective drawings or pictures and photographs of similar store decorations
Facade static calculation for lifestle park tenants (open space)		Samples of used coating materials

Table 2. Architectural project set outline of shopping malls (SM01, SM02. SM03) (continuation of table).

SM01	SM02	SM03
Drawing of the screen and the visual to be covered with the screen		Site list, details and work schedule
Bill of materials and fire certificates (samples on request)		Projects of facade/showcase design should be presented with 3D visuals and 3D drawings showing their relations with neighboring stores. (in 3ds or skp format)
		Lighting project for lighting design (ceiling, floor, wall plans + luminaire specs)

Table 3. Electrical project set outline of shopping malls (SM01, SM02. SM03).

SM01	SM02	SM03
Electrical projects delivery list	Lighting installation plan S: 1/50	Galvanized cable tray plan
Galvanized cable tray plan	Socket and switch installation plan s: 1/50	Socket and power plan
Socket and Power Plan	Weak current installation plans (fire detection, telephone, data, music broadcast, announcement, securit etc.) S:1/50	Lighting Plan
Lighting plan	Cable tray installation plan S: 1/50	Weak current plan (fire detection, telephone, voice alarm and voice over, security (panic) button and cctv, data, tv)
Lighting installation plan, (S: 1/50) (Lighting on Duty, Kit luminaire and Emergency direction (EXIT) line plans should be on a separate sheet.)	Board loading ruler	Single Line and Control Diagrams (in the form of terminal numbers and cable sections)
Weak Current Plan (Fire Detection, Telephone, Voice Alarm and Voice Over, Security and cctv, data, tv)	Panel single line diagram	Board view, manufacturing details (inside and outside)
Single Line and Control Diagrams (indicating terminal numbers and cable sections)	Panel dimensions and appearances	Voltage Drop Calculation
Board view, manufacturing details (inside and outside)	Voltage drop and heating calculations in cables	Heat Control Calculation

Table 3. Electrical project set outline of shopping malls (SM01, SM02. SM03) (continuation of table).

SM01	SM02	SM03
Voltage drop calculation	Material brands and certificates, warranty documents, material presentation forms to be used during the application	Lighting calculation (sqm / watt calculation should be made to indicate that the lighting power specified in the specification is not exceeded)
Temperature control account	After the implementation is completed, “delivery of as-built projects”	Total Power Calculation (sqm / Watt calculation should be made to indicate that the total power specified in the Specification is not exceeded)
Total Power Calculation (indicating that the total power specified in the Specification is not exceeded) Watt / sqm calculation should be made and its suitability should be stated)		
Board loading ruler		
Panel dimensions and images and panel 3 line diagram (After Project and Single line approval, during Project delivery)		
Legend		
Material presentation files of the materials to be used		

Table 4. Mechanical project set outline of shopping malls (SM01, SM02. SM03).

SM01	SM02	SM03
Fire extinguishing system plans(with upright&pendent sprinklers, if any fire cabinet projects)	Electrical - Mechanical data sheet	Mechanical - Electrical data sheet
WSHP (water source heat pump) Heating-cooling piping system plans	Implementation projects including changes to be made in existing air conditioning-ventilation ducts and vents (Channel elevations must be submitted as written on the plans and together with the sections.) S: 1/50	Plumbing plan (includes grease trap connection for Food-Court, hypermarket, restaurant and cafe Tenants)

Table 4. Mechanical project set outline of shopping malls (SM01, SM02. SM03) (continuation of table).

SM01	SM02	SM03
HVAC (heating, ventilation and air-conditioning) Duct system plans	Clean water installation application projects including the changes to be made in the existing water installation, (Should be submitted with the lower levels written.) (Scale :1/50)	Air conditioning and ventilation plan (with pressure loss calculations in shops allowed by the Management Plan)
Plumbing (clean water and waste water, drainage) system plans	Implementation projects including the changes to be made in the existing sewage and utility water installations S :1/50	Fire installation (sprinkler and fire cabinet) plan
Natural gas installation plans (if any)	Implementation projects including the changes to be made in the existing heating-cooling installation S :1/50	Hood Fire Extinguishing System project for stores with hoods
Section, view plans for critical suspended ceiling areas	Implementation projects including the changes to be made in the existing automation installation S :1/50	Heating-cooling installation project
Wet area 1/20 plan, details and views	Fire detection and warning system projects, water fire extinguishing projects (with installation sub-codes written), emergency lighting and guidance projects, smoke evacuation projects will be submitted for approval. S :1/50	Natural gas project approved by IGDAS (local authority for mechanical issues)
Equipment list (indicates equipment specifications) and Equipment installation procedures	After the implementation is completed, the delivery of the “as-built” projects related to the changes mentioned above S :1/50	Suspended ceiling plan (shows suspended ceiling elevation, sprinkler plans)
Catalogs and certificates indicating the model-brand and technical features of the Equipment to be used,	A list of brands and models of all materials and equipment (battery, etc.) To be used should be given and processed on the projects.	Descriptions
Equipment Election outputs		
Account reports of all projects		
Seismic System projects		

Results

When the project sets obtained from the expert validations are compared with the project sets included in the decoration specifications of the shopping malls covered in the study, it is seen that there is a great similarity in fact. All the projects set details included in the expert opinions are requested in every shopping mall. Expert opinions on the subject are given below:

- Looking at the tables, it can be mentioned that the detail expectation level of each shopping mall is different. For example, it could be said that the electrical project set of SM01, the mechanical project set of SM02, and the architectural project set of SM03 are more detailed than other projects. Experts' interpretation of this situation is in the form of the approach of the architect / engineer who writes the relevant sections in each decoration specification. The experts, whose opinions were taken, stated that they made more than one store application in three different shopping malls selected as samples.

- The experts stated that the project sets included in the decoration specification do not differ significantly in terms of themselves, and that the expectations of each shopping mall are basically the same.

- Experts stated that even though the design concept of shopping malls is different from each other, it is important for brands with tenants to display their corporate identities everywhere, so they must achieve a standard that suits different identities. They especially underlined that the standards regarding leasable areas must be largely similar, since shopping malls are commercial enterprises and brands play an important role in the value they will create.

- The standards in the decoration specifications are considered as the usual project items for professional architectural offices. Thanks to the accumulated know-how developed by working in different shopping malls, he gains confidence in every completed project and is ready for the next project. However, for an architectural office that has just entered the sector, the decoration specifications in question can be considered as a factor that requires long hours. They stated that the level of difficulty decreases inversely with experience.

- In the interviews, it was stated that the determining factor of an interior project carried out in any shopping mall is directly related to the approach of the management of that shopping mall. The experts, who said that besides the decoration specifications being the determining factor, bilateral communication is at least as important as it, said that the negativities encountered during the process are mostly resolved through communication. Experts shared that the difficulty they experience while working on a project is directly related to the character of the technical personnel in the shopping mall management, rather than the complexity of the decoration specification.

Conclusion

In the light of the data obtained in this study, it could be said that the decoration specifications of the shopping malls are basically prepared to reflect the same expectation. It is seen that a systematic approach and setup are needed to accurately reflect the design approach of different brands in different shopping malls for the quick and well design and implementation process. This study is a prelude to the preparation of the said infrastructure.

Analysis of Parameters Affecting Decision Making to Retrofit of Existing School Buildings Using Ensemble Machine Learning Methods

Ü. Bahadır, F. Mostofi and V. Toğan
Karadeniz Technical University, Department of Civil Engineering, Trabzon, Turkey
umitbahadir@ktu.edu.tr, fatemee.mostofi@gmail.com, togan@ktu.edu.tr

Abstract

To protect the occupants' lives, it is important to ensure the structural safety of the existing building stocks. For this reason, the issue of retrofitting existing buildings is a frequently encountered situation today. However, decision-making about building retrofitting or complete demolishment is a cost- and time-consuming challenge. Therefore, this study aims to identify and measure parameters that influence the decision-making process about retrofitting a building. To address this issue, first Pearson correlation was used for establishing the relationship amongst the retrofitting feature, then three ensemble machine learning models (MLs), named Random Forest (RF), Gradient Boosting (GB), and Adaboosting (AB), employed for determining the building health condition. To establish the model's effectiveness, this research collected health monitoring reports obtained from 111 school buildings within eight cities in Turkey. The important building features were used to classify the health condition of the building. Based on the results the AB outperformed both RF and GB considering accuracy, F1 score, precision, and recall metrics (79%, 79%, 80%, and 79%). Also, feature selection using Pearson correlation could improve the performance of RF and GB by up to 3%.

Keywords: *building retrofitting, classification, correlation, retrofitting parameters.*

Introduction

Building structures are designed to safely withstand various loads such as dead, live, wind, earthquakes, and dynamic vibration throughout their lifecycle. Under these loads, building components can be damaged at varying rates and degrees depending on the design, materials, construction methods, quality of workmanship, environmental conditions, and the use of the building. Ensuring the structural safety of the existing building stocks is essential for protecting the life and property of the occupants. In this respect, the decision to retrofit or demolish aged buildings is a frequently encountered task for construction professionals. The decision about the health status of the aged building is a complex, cost- and time-consuming

challenge due to its dependency on several influential parameters. In addition, it is important to determine and evaluate the performance of the building in terms of mitigating financial losses (Perez et al., 2019).

Two ways are followed to increase the declining building performance to acceptable levels as a result of the evaluation. The first of these is the applications aimed at increasing the structural performance of the structure such as retrofitting, renovation, maintenance, and repair. The second is the complete demolition of the structure and the construction of a new structure that can provide the desired performance (Kusar et al., 2013). However, in general, it is seen that applications such as retrofitting or renovation are preferable compared to demolishing and rebuilding the building due to reasons such as causing less environmental pollution (Dong et al., 2005), mostly more economical (Egbelakin et al., 2014) and demolition is not possible in the especially historical buildings (Bruce et al., 2015). On the other hand, it may be preferred to demolish and reconstruct the building for reasons such as life cycle costs of the building, cheaper energy use and meeting the expectations of the building owner (Yılmaz et al., 2018).

Retrofitting has been defined by The Federal Emergency Management Agency (FEMA) as a tool to modify existing structures and reduce disaster risk to mitigate the effects of natural hazards (Witucki et al, 2021). In the Turkish Building Earthquake Code (TBEC), on the other hand, retrofitting applications are defined as increasing the strength and deformation capacity of the building's structural system, adding new elements to the building, strengthening the junction areas and reducing the mass of the building to reduce the effects of earthquakes (TBEC, 2018). With retrofitting applications, the loss of life and property that will occur due to the collapse of the structure under the loads can be prevented. In addition, the durability of the structure can be increased with structural additions. Retrofits require less time and cost than demolishing and rebuilding the structure (Perez et al., 2019; Ghosh Mondal et al.; 2019). Furthermore, retrofitting the structure is a more ecological option when the damage to the environment is compared (Yılmaz et al., 2018).

The building cost ratio (retrofitting cost/ (demolition + rebuild cost)) is usually considered when deciding whether to demolish and rebuild or retrofit a structure. It is generally recommended that the retrofit cost not exceed 40% of the rebuild cost. While calculating the building cost ratio to decide on retrofit or demolition and reconstruction, parameters such as existing concrete strength, existing reinforcement strength and class, number of floors, the age of the building, earthquake zone, foundation type, ground class, and whether there is a shear wall or not are also important along with the retrofit method (Uluöz, 2010). Therefore, the determination of these parameters and relations between the parameters are effective in taking the retrofit or demolish decision.

Although there are many studies on retrofitting methods and varying costs according to these methods in the literature, there are few studies on retrofitting parameters. Jafarzadeh et al. (2014) analyzed the retrofitting projects of 158 schools in Iran and used multiple regression analysis to calculate the cost of retrofitting. It was found that the total area of the building was the variable most associated with the retrofit cost. In another study, a survey was conducted with 385 civil engineers in Turkey and when the answers obtained were examined, it was seen that the earthquake damage level, building statics, and earthquake class were the most effective parameters for the retrofitting cost (Yılmaz et al., 2018).

Recently machine learning (ML) approaches are widely adopted due to their ability to utilize the record for aiding human decision-making within different fields (Bodendorf et al., 2021; Meharie et al., 2021). The successful implementation of ML in different fields encouraged the research on different ML approaches within the construction management field. Consequently, Artificial Neural Networks (ANNs) (Jiang, 2019), Support Vector Machines (SVMs) (Peško et al., 2017), K-nearest Neighbors (KNN) (Farid et al., 2018), Naive Bayes (NB) (Zhu et al., 2021) and Decision Trees (DTs) (Kwon et al., 2015; Mistikoglu et al., 2015) are widely used for classification tasks within construction management literature. To aggregate the benefit from these single ML approaches, ensemble ML predictors are introduced. The ensemble models achieved enhanced robustness and stability (Saqlain et al., 2019) by training single ML approaches to benefit from the best prediction of each contributing ML predictor. To this end, tree-based ensemble predictors, such as Random Forest (RF) (Farid et al., 2019; Zhu et al., 2018), AdaBoosting (AB) (Neloy et al. 2019), and Gradient Boosting (GB) (Ding et al., 2016; Farid et al. 2019) have proven to be successful within different construction management studies. These tree-based methods are using different approaches to combine single DTs for improving the prediction performance of a single DT.

In the light of the above observations, this study aims to develop a machine learning model to identify the parameters affecting the decision-making process regarding the retrofitting of a building, measure the relationships between these parameters, and predict the retrofit or demolition decision. For this purpose, structural health monitoring reports were obtained from schools in different provinces of Turkey. Pearson correlation was used to establish the relationship between retrofitting parameters extracted from the reports, and then three ensemble ML models called RF, GB, and AB were used to evaluate the health of the building. Finally, the results of the three predictor models were evaluated using accuracy, precision, recall and F1 score metrics.

Methodology

The outline of the present study is depicted in Figure 1. This study was conducted in three stages: Data acquisition and pre-processing, feature engineering, and modeling of the ensemble retrofitting predictors. The briefed procedure in this study is coded using Python programming language and associated libraries.

Data Acquisition and Pre-Processing

For this study, 111 structural health monitoring reports were collected from eight cities within Turkey. The health monitoring reports were obtained from school buildings. The parameters associated with the retrofitting decision were extracted from the report using expert judgment. Besides, the decision about the retrofitting or complete demolition was used as labels for every single record. Accordingly, the extracted dataset contained 111 records with 20 feature columns.

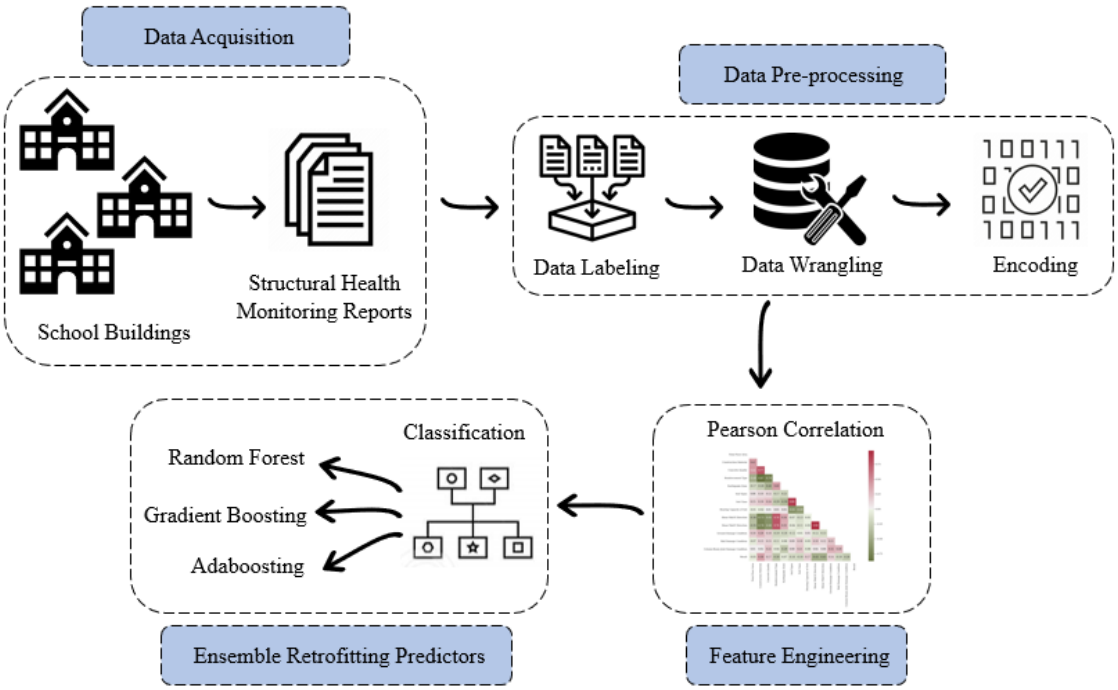

Figure 1: Flowchart of the study.

Following, during the pre-processing stage, the parameters with missing values (retrofitting cost and building cost ratio) were removed. In addition, the redundant retrofitting parameter (floor area) was also erased. Besides, a record with more than half missing values was also removed. This resulted in a dataset of 110 records that were explained through 17 feature columns. To increase the prediction accuracy of the adopted ensemble models, the numerical variables were divided into intervals. Therefore, the 83 collected building age attributes (SP2), ranging between nine to 78 years old, were divided into four intervals, as shown in Table 1. The construction material feature (SP5) comprised reinforced concrete and brick materials. Here, the brick attributes represent the clay brick, hollow brick, and masonry wall materials. The quality of the reinforcement concrete is influential in the structural health status of the building and thus the quality of concrete and reinforcement types are also extracted in separate feature columns. So, the 63 records of concrete quality (SP6), ranging between 0.79 and 23.45, are also divided into four classes. The missing values in the concrete quality feature (SP6) that are associated with the brick materials are replaced with the brick category (Table 1). Likewise, the missing values of the reinforcement type feature (SP7) are also replaced with the brick. Moreover, missing values of the soil type (SP9) and soil class (SP10) features that are described within four classes, are replaced with the mode soil type and soil class of that city. The missing values associated with soil bearing capacity (SP11) are replaced with the average bearing capacity of soil within each of the eight cities. Furthermore, the missing values of the shear wall-X direction (SP12) and shear wall-Y direction (SP13) features are replaced with 0, suggesting the possibility of no shear wall existence in the collected school records. However, for the column-beam joint damage condition feature (SP16) the missing values are flagged with “not defined”.

The displayed variables in Table 1 were evaluated for selecting the influential features and then encoded using label encoding.

* Since they contain a large number of different attribute data, it is stated how many different data were obtained from 110 records together with the minimum and maximum values in attribute and frequency columns.

Feature Engineering

In this study, the Pearson correlation was used for establishing the relationship among the retrofitting features (Figure 2). Based on Figure 2, four feature columns were displaying high correlations with the other retrofitting features. To improve the prediction accuracy, the features with intercorrelation higher than 0.20 are removed. Therefore, shear wall-X direction (0.45), shear wall-Y direction (0.45), construction material (0.38) reinforcement type (0.30) are removed.

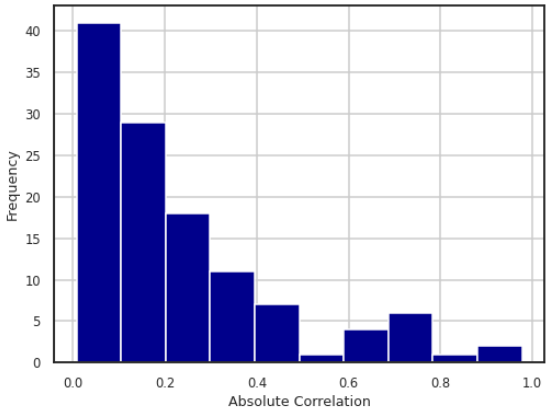

Figure 2: Pearson correlation amongst retrofitting features.

The Pearson correlation of the retrofitting features with the decision column was also evaluated (Fig. 3). The observations from the feature correlations with the output decision variables determine the influential parameters for predicting the demolishing or retrofitting decisions. In this respect, the retrofitting feature with no correlation with the output decision variable was removed. So, the total floor area feature with 0 correlation is removed.

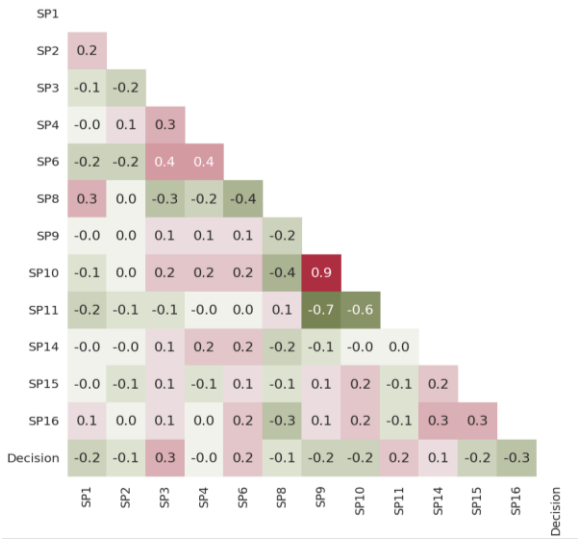

Figure 3: Correlation of feature columns with retrofit/demolish decision output.

The general statistical description is given in Table 2. The processed dataset (Table 2) was used for training the ensemble predictors in this study.

Ensemble Retrofitting Predictors

In this research, three tree-based ensemble approaches were used for decision-making about the retrofitting or demolishing of the studied school buildings. A DT is an ML approach that uses a tree-like structure comprising nodes and branches for predicting different class outputs. Though a single DT often results in a good prediction output, it is prone to overfitting: a predictor that works over a specific dataset only and cannot results in an equally good prediction over a different dataset. To address the overfitting issue of DT and increase its generalization ability, different tree-based ensemble predictors were introduced. These tree-based ensemble predictors are using different methods to train a predefined number of DTs to predict the classes with higher accuracy than the contributing single DTs. In this study, three tree-based ensemble approaches such as RF, AB, and GB have been utilized to predict the retrofitting requirement of the school buildings. The tree-based ensemble approaches (RF, AB, and GB) were fine-tuned by iterating through a different number of trees to find the one that results in the most accurate prediction. The iterations are performed using a grid search procedure obtained from Scikit-Learn (Buitinck et al., 2013; Pedregosa et al., 2012) library. Accordingly, RF is trained with 20 to 200 DTs at 10 intervals (Figure 4).

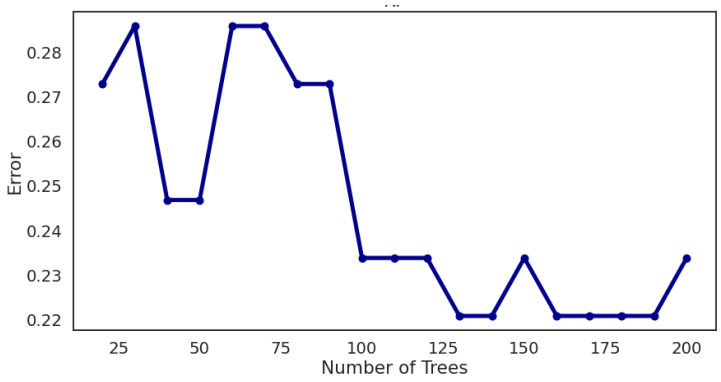

Figure 4: RF iterations for different numbers of DTs.

As is displayed in Figure 4, the RF with 130 DTs resulted in the least error and therefore the RF predictor is trained with 130 DTs. Likewise, the accuracy of AB was iterated with 100, 150, and 200 DTs estimators while using 0.01 and 0.001 learning rates. Finally, the performance of GB is investigated with 5, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, and 100 DTs, while experimenting with each case with learning rates of 0.1, 0.01, and 0.001, as well as 1 and 0.5 subsamples (Figure 5). As suggested in Fig. 5, the GB obtained the best prediction accuracy with 10 DTs. Besides, 0.1 was found to be the optimum learning rate.

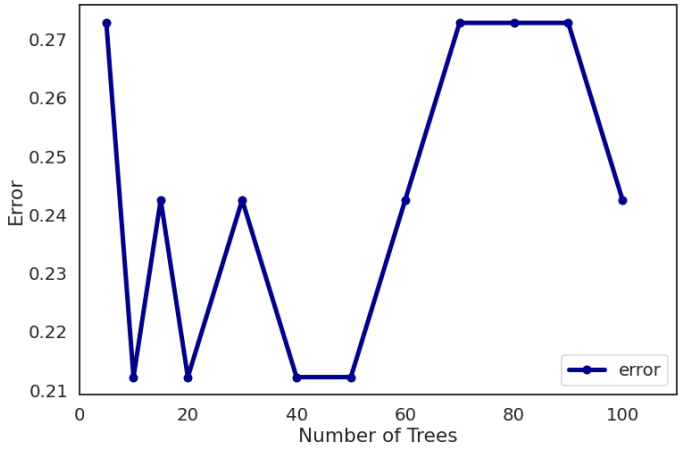

Figure 5: GB iterations for different numbers of DTs.

Evaluation Metrics

To evaluate the model performance, four widely used classification evaluation metrics as accuracy, F1 scores, precision, and recall (Zhou & El-Gohary, 2016) are used. The prediction accuracy of the ensemble retrofitting predictors (RF, AB, and GB) is to be evaluated using the accuracy metric as presented in Eq. 1.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

The accurate prediction of the retrofit and demolish classes are called True Positive (TP) and True Negative (TN), respectively. Thus, the wrong prediction of each decision class is

regarded as False Positive (FP) and False Negative (FN). So, the accuracy of each ensemble predictor was evaluated by adding the number of TP and TN predictions as displayed in Eq. 1. While, accuracy provides insight into the overall performance of all classes, to evaluate the accuracy of each class, the F1 score is used (Eq. 2), using precision (Eq. 3) and recall metrics (Eq. 4).

$$F1\ score = \frac{2\ \times (Precision\ \times Recall)}{Precision + Recall} \tag{2}$$

$$Precision = \frac{TP}{TP + FP} \tag{3}$$

$$Recall = \frac{TP}{TP + FN} \tag{4}$$

The three described ensemble predictors are to be trained using 70% of the school building records for classification between retrofit and demolish decisions. Also, 30% of the school dataset is to be used for evaluating the RF, AB, and GB prediction performances.

Results and Discussions

This section represents the performance evaluation of the ensemble retrofitting predictors using the described methodology. In this respect, Figure 6 presents the accuracy of the three adopted ensemble predictors.

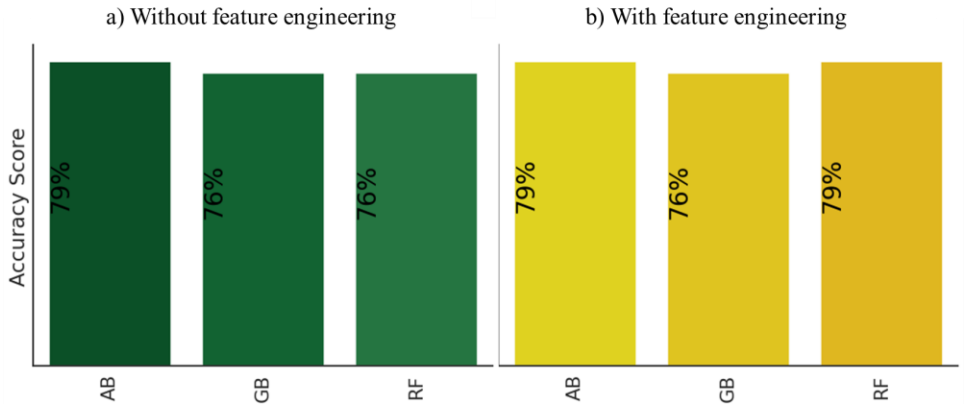

Figure 6: Accuracy performance of ensemble retrofitting predictors.

As shown in Figure 6a, AB outperformed RF and GB in terms of accuracy. Also, Figure 6b indicates that feature engineering using Pearson correlation could improve RF performance by up to 3%. In addition, the precision, recall, and F1 score metrics are also evaluated (Figure 7).

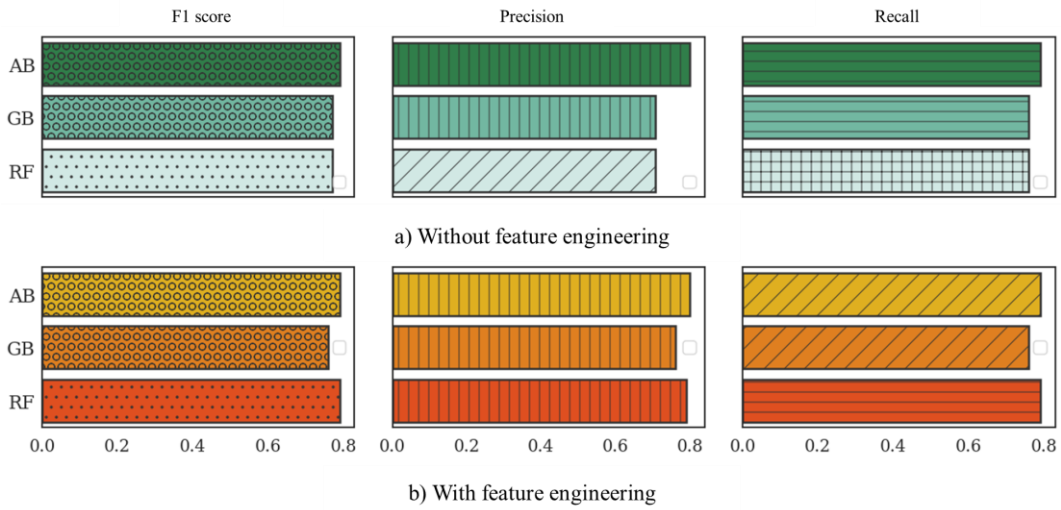

Figure 7: Precision, recall, and F1 score metrics of ensemble predictors.

As it is observed from Figure 7a, both AB and RF show high prediction performance considering the F1 score and recall metrics. However, for precision, the AB displayed superior performance compared with RF and GB. Also, selecting the influential features using Pearson correlation could improve the precision of RF and GB predictors and also enhance the recall metric in the RF model. The observations from Figure 6 and Figure 7 show the effect the feature engineering using Pearson correlation in improving the prediction accuracy of the RF and GB ensemble approaches. However, AB has not shown any improvement in selecting the input feature variables.

In addition, to evaluate the prediction performance within each demolish and retrofit class, the confusion matrix of each ensemble predictor is assessed (Figure 8). Even though, both RF and GB could outperform the prediction associated with the demolish decision, their prediction accuracy for the retrofit decision is less accurate than that of AB. In contrast, AB could achieve equally good prediction accuracy for both retrofit and demolish classes.

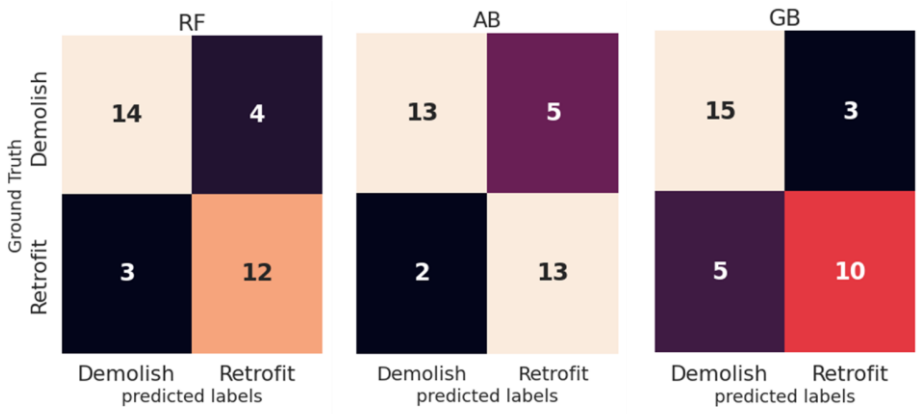

Figure 8: Ensemble retrofitting predictor accuracy for retrofit and demolish classes.

Furthermore, the computational cost of three ensemble retrofitting predictors is compared, considering the training time. In this regard, RF, AB, and GB consumed 0.16s, 04.69s, and 2.05s, respectively. AB was observed to be the most expensive predictor consuming 4.69s of

GPU time to train 100 records. Hence, for decision-making with high accuracy and low computational cost, the RF showed to be a better predictor compared with AB and GB.

Conclusion

The retrofitting or demolition decision regarding the health status of the building is an important decision that has a huge impact on the safety of the existing building and occupants' lives. Though ML approaches proved to be successful for data-oriented decision-making, their prediction accuracy is largely dependent on the abundance of data and choice of ML. As a result, this study proposes an ML-based methodology that allows predicting the retrofit status of the school buildings using very limited records while achieving high prediction accuracy.

This study evaluated the structural health status of the school buildings with a framework consisting of data collection and pre-processing, feature engineering, and modeling of three ensemble predictors. Here, the Pearson correlation was used for selecting the retrofitting features that have low intercorrelation along with a high correlation with decision output. The selected features are used to train and test RF, AB, and GB ensemble predictors. The results demonstrated improved prediction by combining the Pearson correlation and ensemble predictors. Besides, the AB and RF displayed superior prediction considering both accuracy (79%) and F1 score (79%) metrics. Considering precision metric, AB (80%) outperformed both RF (79%) and GB (76%). The observations suggested that utilizing AB over selected influential features can achieve high retrofitting prediction. However, AB is considerably more computationally expensive than RF. Therefore, for decision-making based on both accuracy and computational efficiency criterion, RF results in a better performance.

Even though this research was conducted using a small dataset of 110 records, combining feature engineering with ensemble predictors allows for achieving high prediction accuracy. The data collection is an expensive and lengthy procedure; therefore, the outcome of this study allows professionals to benefit from ML-based prediction using limited available records. This, in turn, facilitates integrating expert judgment with machines to enhance the decision-making quality while reducing human error. Moreover, this study is performed over the balanced dataset and thus the proposed methodology remains to be experimented with over the imbalanced structural health monitoring dataset. This can extend the practicality of the proposed approach for construction professionals.

Abstract

Water scarcity is seen as one of the most serious disasters that humanity have started to face. As construction is one of the leading sectors contributing to the water footprint, effective actions are needed to be taken to reduce embodied water of buildings. Water-related matters in the construction industry are generally addressed to reduce consumption at the operational stage. Green building assessment and certification systems which aim to improve water, energy efficiency and indoor air quality are mainly focused on water consumption at building operation stage. Construction materials have a significant impact on embodied water of buildings. For this reason, at the early stages of design (conceptual design and/or initial phases) definition and application of alternative materials, techniques and/or systems can help to reduce embodied water of buildings significantly. Based on literature review, this study aims to examine and develop design strategies for reducing embodied water of buildings at the design stage which can be used both at the regional and global scales.

Keywords: *design, design management, embodied water, green buildings, water footprint.*

Introduction

Water is one of the primary and non-replaceable sources for all living beings. There is a substantial strain on the availability of freshwater supplies (Arosio et al., 2019) due to rapid growth in world population, industrialization, waste generation, contamination of water resources and rapid depletion of resources without commensurate increases. The water shortage which is one of the most challenging problems humanities face nowadays is anticipated to result in much greater problems in the future (Ercin & Hoekstra, 2013). These problems are projected will not to be only economic but also social (Chai et al., 2021). According to the World Economic Forum, due to its effects on health and livelihoods, water scarcity is a primary factor of migration (The Global Risks Report, 2022).

The construction industry has a substantial environmental impact with its production process and outputs (Sertyeşilışık & Sertyeşilışık, 2017). In addition, it consumes lots of supplies including materials, land, energy and water (Bardhan, 2011). In order to produce building

materials, more than 3 billion tons of raw materials which corresponds 40-50% of global resource use are consumed every year around the world (Abd El-Hameed et al., 2017). Even the water demand of the construction sector is very high (Rivero-Camacho & Marrero, 2022; Tian et al., 2019; Mannan & Al-Ghamdi, 2020), the impact of buildings on freshwater is still unclear (Pomponi & Stephan, 2021; Stephan & Crawford, 2014).

Based on the literature review, most of the studies regarding the water use in buildings focus only on the operational phase (Stephan & Crawford, 2014). Green building assessment and certification systems which are the driving forces for energy and water efficiency of buildings and indoor air quality improvement in buildings and current building regulations focus solely on the operational phase too (Al-Qawasmi et al., 2019). In Leadership in Energy and Environmental Design (LEED), only water consumption of indoor water fixtures, irrigation and mechanical processes are assessed (USGBC, 2021). Building Research Establishment Environmental Assessment Methodology (BREEAM) mainly focuses on water use in indoor water fixtures; but it also has a criterion about monitoring water consumption of construction plant, equipment, and site accommodation (BRE, 2021). Water and energy nexus is generally neglected in green building systems and current regulations (Pinto et al., 2017).

In spite of rising of environmental concerns, current methods only include adapting environmental criteria to existing projects and procedures to meet legal and business objectives (Morini et al., 2019). All these drives humanity to understand and take an action regarding the water crisis. Life cycle practices is becoming more prominent in construction sector (Chan et al., 2022). As a matter of fact, comprehensive evaluation methodologies that can be employed globally are needed (British Standard, 2016). To serve this purpose, the concept of water footprint (WF) and embodied water emerged (British Standard, 2016).

Design process influences 80% of the products' environmental effect (Thackara, 2016, as cited in Morini et al., 2019). Therefore, it is crucial to specify construction materials with low embodied water at early design stage (Sertyeşilışık & Sertyeşilışık, 2017). In order to solve sustainable challenges with respect to the environmental or social implications of the materials used, current approaches, which are created for the financial advantage of the corporations utilizing them, are insufficient (Kruzner, 2012). In green building systems, using the Environmental Product Declarations (EPD) certified products is encouraged in terms of life cycle of materials, there is no requirement regarding embodied water (USGBC, 2021; BRE, 2021).

This study aims to evaluate the current design strategies and methods as support for the low embodied water buildings. Through evaluation of literature, it is intended to support building designers and stakeholders on how to reduce the overall WF of buildings during the early design stages by material selection.

Embodied Water of Buildings

While water is needed to produce raw materials and finished goods, it is also required for main energy sources like electricity (Mousavi et al., 2015). Therefore, in order to analysis total water consumption, these invisible variables should also be accounted for in the calculations. WF is index of freshwater consumption covering direct as well as indirect water use, and it is comprised of blue, green and grey components (Hoekstra et al., 2011). Blue WF means surface and groundwater which is a measure of freshwater consumption to produce

something or service; green WF refers the rainwater meaning the rainwater retained in the soil, and grey WF refers pollution, and it means measure of freshwater consumption to remove contaminants (Čuček et al., 2015).

Embodied water, also referred as virtual water, is the total water volume consumed in manufacture and transport a product during all production process and it consisted of both direct and indirect water demands (Abd El-Hameed et al., 2017). Hoekstra et al. (2011) indicated that while the embodied water is referred to as volume of the water embedded in the product, WF is assessing type of water and as time and location of the water use. Since these two terms (embodied water and WF) are accepted to mean the same in the literature, they are assumed to be interchangeable in this paper.

Both direct and indirect water usage are taken into consideration while calculating the embodied water (Hoekstra et al., 2011; Abd El-Hameed et al., 2017). Although it depends on the scope of the studies carried out, direct water consumption covers water demand of production process (Abd El-Hameed et al., 2017), and indirect water consumption include required volume of water for the amount of energy used during the production process and mining of raw materials (Mousavi et al., 2015). In some studies (e.g., Ding et al., 2021) water consumptions of facilities are also included in direct water consumption while meals served to staff are included to indirect water consumption.

Even while the current emphasis is on water usage in construction operations, looking from the life cycle perspective is becoming more popular (Chan et al., 2022). Studies show that embodied water of materials is much higher than the consumption of water in operational phase. Stephan and Crawford (2014) calculated water used by residential building during its entire lifespan (the study includes pre-construction, construction, use, maintenance, and repair phases; excludes demolition phase) as 35,881 kL. Embodied water presents the most significant contribution with 13,673 kL which corresponds the 38.20% of the whole building water consumption while the water consumption of operational phase is 11,856 kL (Stephan & Crawford, 2014). Another study analyses the WF of the residential building covers the urbanization, construction (includes embodied water of materials), renovation (for 20, 40, 70 years) and demolition phases shows that construction phase has the biggest rate in terms of water consumption (Rivero-Camacho & Marrero, 2022). According to Gimeno-Frontera et al. (2018), water demand of production, construction, use, and end of life stages of food retails store is 1.73E+02 l/m^2 year, 7.21E+00 l/m^2 year, 1.61E+04 l/m^2 year, and 1.29E+01 l/m^2 year, respectively. Therefore, it is crucial to select low embodied water materials during the design stage (Sertyeşilışık & Sertyeşilışık, 2017) and adding the requirements to construction specification to guide the other decision makers and contractor.

Research Method

This paper investigates design strategies based on material selection for reducing embodied water of buildings. A comprehensive literature review which consisted of the peer- reviewed articles published in academic journals till the end of 2021 have been conducted. Articles were retrieved from the following databases: Science Direct, Scopus and Web of Science. Following an in-depth literature review, relevant articles that focus only the construction materials are analyzed, and design strategies have been gathered.

Findings

Most of the studies (e.g., Bardhan & Choudhuri, 2016; Gerbens-Leenes, 2018; Nezamoleslami & Hosseinian, 2020) are conducted on embodied water of agricultural or animal products since these are the most contributing materials. Majority of literature and references in Table 1 and 2 calculates the embodied water of building materials includes materials and/or manufacturing processes of these materials that are used in structural system (Figure 1). Structural materials are the bulkiest and heaviest components of a building, these materials consume high amount of water (Tian et al., 2019). Furthermore, manufacturing process has a determining impact on water pollution (Mousavi et al., 2015). Selection of building materials with low embodied water has a major impact to reduce embodied water of buildings (e.g., Stephan & Crawford, 2014). As all references in Table 1 and 2 have different results even the same product is assessed the embodied water indicators (location, type of water and time), calculation methodologies and databases are different. The purpose of this current study is not comparing the results of the examined literature and references in Table 1 and 2, the focus of this study is evaluating different outcomes and factors that affect the embodied water within the same study.

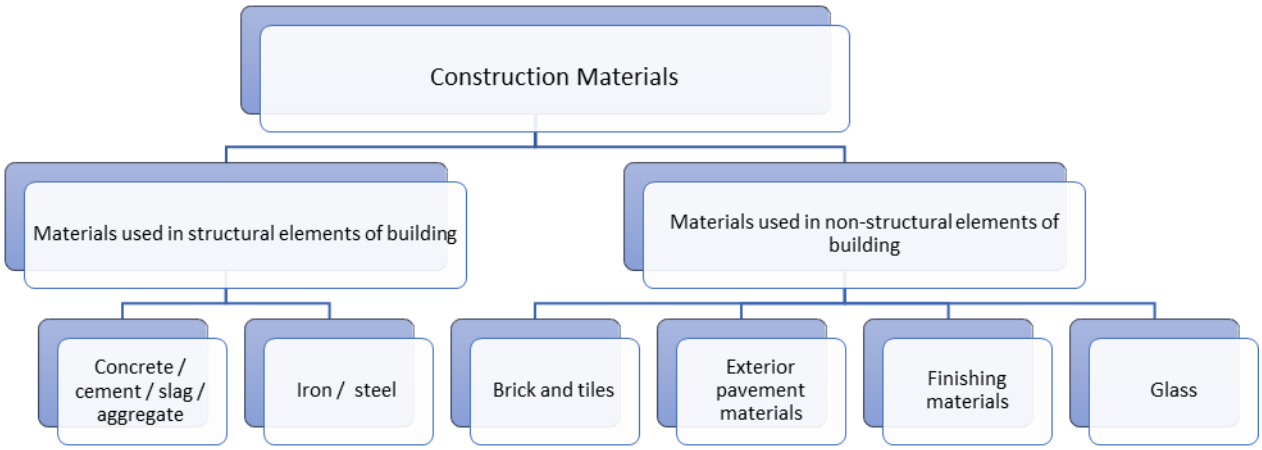

Figure 1: Types of building materials studied in literature.

In recent years, studies on embodied water of concrete and/or its raw materials (cement and slag) have been increased. This is mostly due to the fact that a substantial quantity of water is used in manufacturing process of concrete (Meyer, 2009; Ding et al., 2021). Ding et al. (2021) indicated that the most contributing items to embodied water of concrete are coarse aggregate. Using aggregates gathered from marine instead of land aggregates and using seawater in locations which suffer from the water-stress instead of freshwater will help to decrease the embodied water, but travel distance should be taken into consideration (Arosio et al., 2019). Portland cement has a huge impact on embodied water of the product (Wang and Chang, 2021). According to Gerbens-Leenes et al. (2018) and Batuecas et al. (2021), embodied water of the cement can be decreased with using alternative raw materials mentioned in Table 1 to Portland cement. Based on the WF of concrete analyses conducted in different locations, Ding et al. (2021) stated that the reason of higher embodied water could be result of undeveloped economy, and inadequate transportation systems in that region.

Table 1. Examples for studies on embodied water of concrete/cement/slag.

Study	Material	Blue WF	Grey WF
Gerbens-Leenes et al. (2018)	Portland cement (CEM I)	2.2 l/kg	210 l/kg
	Portland and composite cement (CEM II/B)	1.8 l/kg	210 l/kg
Hosseinian and Nezamoleslami (2018)	Cement plant	3,614,035 m^3/year	
Arosio et al. (2019)	Concrete with land aggregates (freshwater used in process) - Baseline	1.65-5.48 m^3/m^3	
	Concrete with land aggregates (seawater is used in process)	2%-9% reduction from baseline	
	Concrete with marine aggregates (seawater is used in process)	36%-80% reduction from baseline	
Vergara and John (2019)	Concrete (30 MPa, d: 2362.5 kg/m^3)	0.547-2.634 m^3/m^3	
Batuecas et al. (2021)	Ordinary Portland cement	116.96 m^3/m^3	
	Alkaline activated slag	114.56 m^3/m^3	
	Hybrid from slag	97.46 m^3/m^3	
	Hybrid from fly ash	96.85 m^3/m^3	
Ding et al. (2021)	Concrete	2,115.79 L/m^3 - 2,407.48 L/m^3	

According to study conducted by Gerbens-Leenes et al. (2018), grey WF of the steel and iron production is much higher than the blue WF. The reason is that significant risks relating to water are raised by steel and iron industry (Gu et al., 2015). It is important to improve sewage treatment efficiency and monitor the leakage through the water network so that grey WF can be reduced (Nezamoleslami & Hosseinian, 2020). According to Octavia et al. (2017), wastewater treatment system should be integrated to decrease water pollution and reduce gray water footprint. The ingredient of the material has also a determining impact as the production process and generated waste are different (Gerbens-Leenes et al., 2018; Wang & Chang, 2021). Since the equipment used for the manufacturing consume considerable quantity of both direct and indirect water, installing and/or replacing energy efficient equipment and fittings help to reduce WF (Nezamoleslami & Hosseinian, 2020). Using renewable energy systems which can produce the required energy for the production process helps not only reducing the water footprint but also carbon footprint (e.g., Ding et al., 2021).

Table 2. Examples for studies on embodied water of steel and iron.

Study	Material	Blue WF	Grey WF
Gu et al. (2015)	Iron and steel enterprise	2.44×10^7 (m^3/year)	6.5×10^8 (m^3/year)

Gerbens-Leenes et al. (2018)	chromium-nickel unalloyed steel	76.9 l/kg	1500 l/kg
	unalloyed steel	11.8 l/kg	2270 l/kg
Ma et al. (2018)	Crude steel	7.19 m^3/ton	12.04 m^3/ ton
Nezamoleslami and Hosseinian (2020)	Steel plant	56.868 million m^3/year	

In addition to structural materials, finishing materials also have considerable impact on embodied water (Abd El-Hameed et al., 2017). Ingredients and different processes during manufacturing alter the WF of the material and marble tiles and natural stones for flooring; silicate paints for internal coating and silicone acrylic paint for external coating can be selected to reduce embodied water based on study conducted by Abd El-Hameed et al. (2017). While the Solvay process has determining impact on blue and grey water of the glass (Gerbens-Leenes et al., 2018); additional processes such as laminating and strengthening also increase the embodied water of the glass (Abd El-Hameed et al., 2017).

Discussion

This study provides a framework for understanding the significance of material selection in reducing the embodied water of buildings. From the water efficiency point of view, important spots to be considered during the material selection and preparing specifications are summarized in this study. Designers and other decision makers can use the outputs of this study in the design stage.

It is crucial to lower the WF of construction materials to reduce the embodied water of the buildings (Stephan & Crawford, 2014; Rivero-Camacho & Marrero, 2022; Gimeno-Frontera et al., 2018). Type of the raw materials affects overall WF of the construction materials as shown in literature and references Table 1 and Table 2. Selecting raw material that meets the performance requirements, lower embodied water of the whole product (Gerbens-Leenes et al., 2018; Arosio et al., 2019; Batuecas et al.,2021). Alternative raw materials for concrete, cement and aggregate listed in Table 1 can be suggested to designers while selecting building materials. Ordinary Portland cement has a large carbon footprint owing to the quantity of cement clinker it contains (Qu et al., 2021) which also has a greater WF related to carbon footprint. Using composite cement with Portland cement, alkali-activated and hybrid cement mortars may reduce embodied water by about 20%, 4%, and 17% respectively as shown on Table 1. Different materials and/or processes might have opposing effects on blue and gray water footprints; as shown in Table 2, Gerbens-Leenes et al. (2018) found that although the blue WF of chromium-nickel unalloyed steel is greater than that of unalloyed steel, its grey WF is lower. Furthermore, while examining alternative raw materials with low embodied water, it is critical to assess their long-term performance (Arosio et al., 2019). Using seawater and marine aggregates in concrete as alternative to fresh water and land aggregates which is suggested by Arosio et al. (2019), may raise additional concerns regarding the long-term performance of the structural system. Marine aggregates, which are available in the sea naturally or dredged from the seabed, are widely utilized in the United Kingdom, several European nations, Japan, and China due to the worldwide scarcity of land aggregates (Liu et al., 2018). Due to chloride and sulphate content, marine aggregates have detrimental effect on concrete such as sulphate attack and steel corrosion (Liu et al., 2018) which are the same durability implications of utilizing seawater in concrete (Qu et al., 2021 and Tang et al., 2015). While protection measures against steel corrosion can be listed as coating reinforcing

steel with epoxy, using stainless steel and/or galvanized steel, application of fibrous composites as an alternative to steel, and using corrosion inhibitors; strategies against the sulphate attack could be using mineral admixtures for instance ground granulated blast furnace slag, increasing the depth of burial coating, blending mortar with ground glass powder, addition of magnesium oxide, superplasticizer and barium carbonate (Tang et al., 2015). All these strategies can be evaluated according to economic and durability concerns during the design stage (Sertyeşilışık & Sertyeşilışık, 2017) and any clauses may be added to construction specifications. Since the extraction of marine aggregates has negative impact on sea topography and sea ecosystem (Desprez, 2000), further investigation is needed before encouraging the use of marine aggregates (Arosio et al., 2019). Construction materials are exposed to different processes during the manufacturing stage to meet different performance needs (Gerbens-Leenes et al., 2018; Abd El-Hameed et al., 2017).

Water and energy nexus is often neglected (Pinto et al., 2017). Indirect water consumption as a consequence of the energy consumption is higher than the direct water consumption (Hosseinian & Nezamoleslami, 2018). Therefore, efficiency of equipment used in the production line is critical (Nezamoleslami & Hosseinian, 2020). It may be advised to repair and maintain the process equipment on a regular basis and to replace it with more efficient models after it reaches the end of its useful life (Nezamoleslami & Hosseinian, 2020). Based on these explanations it might be recommended to designers to add these requirements to construction specifications and identify the manufacturers that meet these criteria.

Water consumption of meal of personnel working in final assembly also has a significant effect on embodied water of construction material (e.g., Ding et al., 2021). Hosseinian and Nezamoleslami (2018) calculated the WF of a cement plant which is located in Iran. Ding et al. (2021)'s study revealed that average WF of concrete production of Northwest China is 2,159 L/m^3 and WF of personnel meal accounts for 35.20% of the overall WF. Nezamoleslami and Hosseinian (2020) determined the WF of steel plant in Iran to be $56.868*10^6$ m^3 whereas staff meal is 36.14% of the total WF. For this reason, it is crucial the management of human resources (Nezamoleslami & Hosseinian, 2020) and automatization of manufacturing processes (Ding et al., 2021) are.

As indicated by Mousavi et al. (2015), manufacturing process generates large amount of waste that releases to water. It can be suggested to consider manufacturers who provide waste treatment systems and leakage monitoring systems (Nezamoleslami & Hosseinian, 2020). For this reason, these requirements can be added to construction specifications.

The findings presented in this study are limited to literature review consisted of the peer-reviewed articles published in academic journals till the end of 2021. Blue WF is calculated in most of the studies (e.g., Vergara & John, 2019). Although the grey WF of manufacturing process is higher than blue WF as indicated in all references in Table 1 and Table 2, there are relatively few research (e.g., Ma et al., 2018) that include grey WF into the calculations. Further studies need to be conducted for different types of construction materials in different locations. Moreover, since embodied water depends on the type of water used and time, these parameters should be taken into account in future studies.

Conclusion

This research aims to examine existing literature on embodied water of buildings and gather the design techniques and approaches to reduce whole water demand of the buildings. It is important to giving the right decisions that reduce the environmental effects of the building at the design stage (Sertyeşilışık & Sertyeşilışık, 2017). Therefore, it is crucial to select low embodied water materials during the design stage and adding the requirements to construction specifications to guide the contractor, other decision makers and manufacturers. Even the embodied water depends on the location, time (for example rainy season or drought season) and type of water used (Hoekstra et al., 2011); based on the literature and references in Table and 2, there are several measures that can be used both regionally and globally to reduce embodied water of the construction materials. If the alternative raw material which requires less water (e.g., Gerbens-Leenes et al., 2018) meets the performance requirements, it could be substituted with traditional material. Until recently, virtual water was neglected while assessing the water consumption of building and/or building material (Al-Qawasmi et al., 2019; Stephan & Crawford, 2014). Studies (e.g., Ding et al., 2021) show that virtual water which is an indicator of water consumption of energy usage, raw material extraction, and staff meals have a greater impact than direct water consumption. Energy demand of the equipment can be reduced with replacing them with the efficient ones (Nezamoleslami & Hosseinian, 2020). Furthermore, using renewable energy systems will help to reduce fossil fuel consumption, carbon footprint as well as water footprint (Ding et al., 2021; Hosseinian & Nezamoleslami, 2018; Nezamoleslami & Hosseinian, 2020). Since the manufacturing process releases large amount of waste to water (Mousavi et al., 2015), to reduce grey water footprint sewage and waste treatment systems should be installed or improved and leakage monitoring system to intervene when there is a leak should be installed (Nezamoleslami & Hosseinian, 2020). Water consumption due to personnel meals also has a determining effect on total WF which highlights the industrial processes' reliance on people and the importance of human resourcing (Ding et al., 2021; Hosseinian & Nezamoleslami, 2018; Nezamoleslami & Hosseinian, 2020). Moreover, based on literature review it can be recommended that in material selection phase designers may ask embodied water calculations from the manufacturers or check this information from the EPD or other relevant documents if available.

Construction in Uncertain Economic Conditions

Y. Arıcı Üstüner and B. Balaban Ökten
Fatih Sultan Mehmet Vakıf University, Department of Architecture, İstanbul, Turkey
yarici@fsm.edu.tr, burcuokten@fsm.edu.tr

Abstract

According to the reports of the Central Bank of Turkey for 2020, construction companies constitute 14.76% and the number of employees working in sector constitutes 9.91% of Turkey in general. The construction sector has an active role in the Turkish economy. The Turkish construction sector has been adversely affected by epidemics, the wars in the region, the migrant crisis, inflation, and exchange rate increases. Turkish Contractors Association reported, grew in the first half of 2021, albeit quite limitedly; contracted again and sharply in the third quarter. Uncertain economic conditions leave investors undecided between build or not to build. This research aims to find data in construction sector in uncertain economic conditions. Google Academic is used as the search engine in this research. "Foreign exchange rate", "risk", "building", "inflation", "construction industry", "construction sector" are selected as keywords to conduct research for this study. The search was carried out between March and April 2022, and 168 results were listed. According to their relevance to the topic, nineteen articles are selected. From the selected articles, it is observed that there are researches in the literature about affordable housing, cost estimation, late payment, challenges, international construction markets and risk factors and the critical success factors of construction companies. These articles show that there is a significant connection between the construction sector and economic situation of the countries and there are some precautions to prevent economic loss for the companies. As a result of this study, it has been thought that the production of solutions for these uncertain conditions of the Turkish construction sector will be supported by examining the studies conducted in the literature.

Keywords: *construction, economic conditions, exchange rate, inflation, risk.*

Introduction

Construction sector effects both domestic and global economy of the world. This powerful sector also influenced by the change in the economies of the countries and world. Bid or no bid decision (Li et al., 2020), and to build or not to build decisions (Adabre et al., 2022) identify by the uncertain economic conditions.

Along with the pandemic, a serious economic crisis has emerged in the whole world and in Turkey. With the material and labor prices changing and increasing day by day, and increasing, serious cost differences have emerged between the start and end of the project in the construction sector, and it has become difficult for the sector to cope with such conditions Considering that there have been uncertainties in the economy in the past, this study aims to

reach studies that examine the attitudes and solutions of the construction sector in such crises and uncertain economies. For this reason, in this study, literature sources were examined using the "Google Academic" database and the problems encountered in economic uncertainties in terms of the construction sector and the approaches taken against them were summarized. Thus, it is thought that this study will be a roadmap for the current economic situation.

Methodology

Construction under uncertain economic conditions is a problem with broad implications. In this study a literature review is conducted to address effects of the uncertain economic conditions to construction sector. Systematic literature review technique is a method for reaching knowledge with a systematic way. A traceable and repeatable research method is important for future research (Jesson et al., 2011). Jesson et al. (2011) defined six methodology stages to define systematic literature review. These are, define the research question, design the plan, search for literature, apply exclusion and inclusion criteria, apply quality assessment and synthesis. In this study, the literature review was shaped around with two simple research questions. These questions can be summarized as below;

- What are the effects of uncertain economic conditions to the construction sector?
- Are there any studies that offer solutions to the problems of the construction sector in uncertain economic conditions?

Google Academic search engine was used to reach relevant studies to the research questions. Keywords were selected to identify economic condition and construction sector. Selected keywords were “foreign exchange rate", “risk,” “building”, “inflation”, "construction industry" and "construction sector". The search was carried out between March and April 2022, and 168 results were listed. Nineteen studies were selected by reading abstracts of the studies and determination of their relevance to the questions.

Findings

As a result of the literature review, it has been shown that researchers have started to be made on the effect of uncertain economic conditions on the construction sector in recent years. Selected studies for this research are summarized in Table 1. When the nineteen selected studies were examined, it was seen that the studies could be classified within the framework of five main topics. These topics can be summarized as affordable housing, cost estimation, late payment and nonpayment, challenges associated with international construction markets and risk factors and critical success factors. Selected studies will be summarized under these topics in the following sections of this study.

Affordable Housing

It has been seen that one of the nineteen selected studies can be examined under the title of affordable housing. This study can be summarized as below;

Adabre et al. (2022) emphasized in their study that the gap between income groups in developing countries has increased. Housing needs of people from middle- and low-income groups is a problem.

The residential buildings with high-rise buildings, which the government has brought as a solution for low- and middle-income groups, are not preferred by people, they turn into uncontrolled areas and as a result, ghost housing areas are formed. For this reason, states are torn between whether to build housing for low- and middle-income groups. The increase in the construction costs and the increase in the land prices increase the housing prices. In the solution proposals for people to produce their own houses, this time the demand for the land increases and speculative prices emerge. Housing structures for high-income groups are being built. A hybrid model is required here. Housing structures built by the private sector under the coordination of the state. It is expected that the decisions to be taken will be economically, socially and environmentally sustainable. Housing prices and rental prices should be accessible (affordable), environmentally friendly designs should be made, access to clean water, energy and sewerage systems, work, shopping areas, education and health services should be accessible. Housing production is in direct relation with the political and economic situation of the country. In their study, delays in payments by/clients are at the forefront of the risks that prevent the development of sustainable housing needs in the country. In the second place is fluctuation in exchange rate. Third place is fluctuating cost of finance (interest rates). In the fourth place, inflation rate volatility was determined. The fact that the first four risks are related to financing shows that the construction sector and accordingly the housing need are directly

affected by the economy. Together with the studies summarized above, it is seen that the issue of affordable housing is especially important for the construction sector.

Cost Estimation

It has been seen that three of the nineteen selected studies can be examined under the title of cost estimation. These studies can be summarized as below;

Oteng-Abayie and Dramani, (2019), emphasized in their study that investors are curious about the current costs associated with construction, as well as how costs will rise during construction. Firms use consumer price index and exchange rate in order to make cost estimations of construction projects in an inflationary environment. In this study, they aimed to test the accuracy of this method. The study was conducted in Ghana. They found that the prime building cost index and the non-food consumer price index go together. To make short-term project investments for investors in regions with high inflation. They emphasized that domestic materials should be preferred due to the increase in exchange rates in materials supplied from abroad.

In the other study, Ujene and Idoro, (2015), developed cost estimation models of the structural elements of low and medium height structures. In three of the models they developed, they also added inflation data to the model. It is thought that the participation of inflation data in direct cost calculation models is important for economies where inflation is effective.

Another research is conducted by Olatunji (2010) that investigated the effect of oil price regimes on construction costs in Nigeria. As a result of the study, a significant relationship was found between oil prices and inflation, between cement prices and oil and inflation, and between these and construction costs. This research is important as it is a study that proves the effect between oil prices and construction costs.

Together with the studies summarized above, it is seen that the issue of cost estimation is especially important for the construction sector. Suggested solutions and models can help project stakeholders in cost estimation, enabling them to finish the project process with less damage in uncertain economic conditions.

Late Payment and Nonpayment

It has been seen that two of the nineteen selected studies can be examined under the title of late and nonpayment. These studies can be summarized as below;

Abdul-Rahman et al. (2013) emphasized in their study about late payment and nonpayment situation in the construction sector. In the construction sector, which is a labor-based sector, late payments to contractors make workers' payments difficult. Although the approach of the employers to make the payments as late as possible seems to be advantageous for the employer but the late payments of the subcontractors cause a series of late payments and cause the non-financially strong contractors to increase their borrowing-by-borrowing. Timely payment is an important factor for companies to make a profit. Among the reasons for late payment, it is stated that the employer's deficiencies in management, insufficient financing for the project, and the contractor's use of late payment for his own advantage. Uncertainties in the market also cause

late payments. In the other study, Odediran and Windapo (2018) conducted research about delays in payment and shortage in payment are among the financial risks for companies that will do business in the international construction sector. It is seen that the problems related to payment are frequently mentioned in the literature and are a general problem.

Together with the studies summarized above, it is seen that the issue of late payment and nonpayment especially important for the construction sector.

Challenges Associated with International Construction Markets and Risk Factors

It has been seen that eleven of the nineteen selected studies can be examined under the title of challenges associated with international construction markets and risk factors. These studies can be summarized as below;

Gunduz et al. (2022) investigaed in their study, the short-run impact of relatively wealthy foreigners on the residential property prices in Istanbul investing to buy a Turkish passport. It was found that the Turkish CBI (Citizen by Investment) program positively impacts house prices by 2% in the districts, which are likely to be favored most by immigrant investors.

In other studies, Bovkun et al. (2021) proposed a methodological approach to minimizing risks in road construction in their study. In this study, the researchers identified the risk factors of the road construction and according to those data, key risk indicators were developed. At the end of the study, the researchers predicted and assessed the likelihood of risk materialization during road construction. Chattapadhyay et al. (2021), developed a risk prediction system based on a cross analytical-machine learning model for construction megaprojects. With this model, the researchers aimed to help stakeholders in achieving project success.

Another study that can be evaluated under this topic is done by Tam et al. (2021) and the researchers aimed in their study to express the correlation between stakeholder motivation and profitability in relation to the inflation in these macro-economic conditions and come up with a human motivation theory. On the other hand, Li et al. (2020) proposed a model for Chinese international contractors to make a bid or no bid decision. Researchers have identified some factors for the decision to participate in the tenders of international construction projects. In the proposed model, foreign exchange rate fluctuation of currency and inflation rate fluctuation risk in host country factors are included under the country risks category.

Yap and Cheah (2020) emphasized in their study that exchange rate fluctuations in developing countries pose a financial risk for international contractors. Inflation is an important risk that affects material, labor and transportation costs. In the research, it was seen that exchange rate and inflation are among the main problems of Chinese contractor companies doing business in Malaysia. In the other study, Odediran and Windapo (2018) have identified the risks of the international construction market and make recommendations on how they can reduce the risks so that South African companies can enter the international construction sector. In this study, volatility in foreign exchange rates, fluctuation in inflation rate/rising inflation and volatility in interest rate were found among economic and financial risks.

Moraghen et al. (2020) analyzed the structure of foreign direct investment inflow in different sectors of the Mauritian economy. In that study, the researchers emphasized that the construction sector has shown continuous growth during the past decade, even in the last years,

the trend of the growth of the construction sector is began to go downtrend. In other study, Nguyen and le Hoang Thuy To Nguyen (2020) searched for a decision-making approach for calculating critical factors that affect the construction price index in their study in Vietnam. The research results showed that the top five critical factors affecting the construction price index in Vietnam are consumer price index, gross domestic product, basic interest rate, foreign exchange rate, and total export and import.

Gonzalez et al. (2006) investigated the effect of interest rates on sectors in Spain. In the study examining the data between 1993 and 2001, it was determined that the increase in interest rates affected the construction sector the most. The reason for this finding was defined as the construction sector is being a capital-intensive sector and the construction sector is being the active sector in the growth of the Spanish economy. Chua et al. (2003) examined the factors of cost growth in East Asian countries, China and Singapore in their study. It has been determined that the construction costs in China are higher than in Singapore. Among the reasons why costs are generally higher are losses due to fluctuation of foreign exchange rate, and losses due to fluctuation of labor and material prices.

Together with the studies summarized above, it is seen that the issue of challenges associated with international construction markets and risk factors is especially important for the construction sector. Suggested solutions and models can help project stakeholders enabling them to finish the project process with less damage in uncertain economic conditions.

Critical Success Factors

It has been seen that three of the nineteen selected studies can be examined under the title of critical success factors. These studies can be summarized as below;

Omotayo et al. (2018, 2020) suggested the Kaizen method to improve the processes of Nigerian construction companies. Financial risk management is among the critical success factors so that they could apply the kaizen method to their companies. It has been mentioned that inflation and late payments create financial risks and affect the improvement of processes. It is thought that the construction sector is necessary for growth in developing countries, and therefore, it is thought that it will be beneficial for both companies and the country's economy if construction companies review and improve their processes. In the other study, Moreno Cabezali and Fernandez-Crehuet (2020), studied risks associated with Additive Manufacturing (AM) Research and Development (R&D) Project Management. The results of this study showed that the risks “Defects occurring during the manufacturing process”, “Defective design”, “Poor communication in the project team” and “Insufficient financing” are determined as the most critical success factors in AM R&D Project Management.

Together with the studies summarized above, it is seen that the issue of critical success factors is especially important for the construction sector. Suggested solutions and models can help project stakeholders enabling them to finish the project process with less damage in uncertain economic conditions.

Conclusion

In this research study, answers to two questions were sought from the literature. These questions were (i) What are the effects of uncertain economic conditions to the construction sector? and (ii) Are there any studies that offer solutions to the problems of the construction sector in uncertain economic conditions? When the studies in the literature are examined, it is seen that the studies are shaped around the topics of affordable housing, cost estimation, late payment and nonpayment, challenges associated with international construction markets and risk factors and the critical success factors. In the examined nineteen studies, some models were developed, and some solutions were presented in order to cope with the uncertain economic conditions in the construction sector. When the studies' common view is summarized, it is clearly seen that the construction sector is directly affected by the uncertain economic conditions. Because, it has been seen in some of the examined studies that even though growth in many sectors stops and the growth rate in the construction sector decreases during economic crises, the sector must continue working and progress in order to fulfill the needs such as housing and infrastructure etc.

In this study, it is seen that there is a strategic relationship between the construction sector and the economy in terms of countries. Therefore, it should be investigated how the construction sector can function and how the production in the sector can continue with minimum damage during economic fluctuations and solutions should be produced in this direction. It is thought that such preventions can be taken together with the academical studies, and the solutions produced in the sector.

The Effect of Economic Factors on the Bidding Decision of Contractor Construction Firms: The Case of Antalya Province

A. Kazaz and E. Erkovan
Akdeniz University, Department of Civil Engineering, Antalya, Turkey
akazaz@akdeniz.edu.tr, ersan_erkovan@ yahoo.com

Abstract

Public construction projects are mostly awarded to contractors by tender method. The survival of contractor construction companies in a competitive environment depends on taking on new projects that will offer them the highest return and market share. The decision to bid or not to bid on new projects has always been an important issue for contractor construction companies. It is very difficult to make a decision to bid, because it is affected by many factors and because of the complexity and uncertainty it contains. For this reason, many academic studies have been conducted on the determination of the factors affecting the decision to bid and on decision support methods for bidding. When the literature is examined, it is seen that the biggest factor in bidding is economic factors. In this study, the effect of current economic factors in Turkey on the decision of the contractor construction companies to bid was investigated. In the case study, public construction tenders held in the province of Antalya were examined.

Keywords: *construction, decision to bid, factor, project management, tenders.*

Introduction

The construction industry is one of the most important industries in any economy because the annual value of construction put in place is very large, the industry employs a very large number of workers as it is very labor-intensive, and it affects the activities of many side industries such as materials, manufacturing, chemicals, etc. All private and public investments are directly or indirectly related to the construction industry (Sümer et al., 2020). Globally, the construction industry has continued to play a critical role in economies of both developed and developing nations (Zhao et al., 2014). The developing countries' construction contracting firms are on the rise and are becoming important global players (Low et al., 2020). Developing countries' construction contracting firms are playing an important role in the worldwide economy, and are nowadays open to different challenges as they need to operate in risky political conditions and markets (Korkmaz & Messner, 2008).

Finding a project to bid on is essential for construction engineering contractors to survive market competition (Yan et al., 2018). To survive in a competitive construction industry, it is extremely imperative for a firm to secure tenders and produce a profit (Egemen & Mohamed, 2007). While the construction market offers contractors considerable opportunities to bid, it requires contractors to carefully select construction projects that are most suitable to them

(Wang et al., 2020). Any invitation to tender is potentially a business opportunity. A decision is needed to either explore it (so use time and resources to prepare a bid) or decline it in search for better options. This implies that a variety of decisions are taken at different management levels to minimize cost and increase revenue (Biruk et al., 2017). The decision is not only related to win or lose the chance of the tender, but it is also about the ability to finish the project as planned with expected profit (Egemen & Mohamed, 2007).

The bidding process involves the bid/no-bid decision which is crucial and associated with risks and uncertainties due to various factors that influence it (Enshassi et al., 2010). The influencing factors might relate to the contractor himself, to the client, or to the project conditions and the general environment. Bidding decision problems are highly unstructured. Typically, contractors make their decisions based on their common sense or the rule of thumb which may lead to suboptimal decisions. This is why many researchers have been involved in the development of bidding strategy models (Mahamid, 2022). The aim of this study is to investigate the effect of current economic factors on the bidding decisions of contractor construction companies in Antalya. For this purpose, a literature review will provide a summary of the previous studies conducted to identify the related factors, then the effect of the current economic situation on the bidding decision will be revealed.

Literature Review

Over the years, the bid/no bid decision has attracted the attention of many researchers. A relatively large number of studies have focused on identifying the factors affecting the decision, but few studies have investigated and developed relevant bidding strategy models (Enshassi et al., 2010). Some of the studies conducted for this purpose are presented below under two main headings which are “Studies Focused on Factors” and “Studies Focused on Bidding Strategy Models”.

Studies Focused on Factors

One main problem of bidding strategy models is the inability to illustrate how a bidding decision was made. Ahmad and Minkarah (1988) argued that one way to minimize such an issue is only through uncovering potential underlying factors affecting the decision. Based on a questionnaire survey conducted among the top construction contractors in the United States (USA), Ahmad and Minkarah (1988) identified 31 factors affecting bid/no bid and markup decisions. Since then, their opinion is echoed by many kinds of researches focusing on the determination of factors affecting bid/no bid decision (Li et al., 2021). Bageis and Fortune (2009) concluded that the critical factors affecting the bidding decision in Saudi Arabia to be client financial capacity, prompt payments, project payment system, clarity of the work and specifications, and project cash flow. Alsaedi et al. (2019) conducted a study to identify the factors affecting the contractors’ bidding decisions in Saudi Arabia-based construction projects, and found 6 critical factors. the top six critical factors were “size of the job”, “type of the job”, “company’s strength in the industry”, “designer/design quality”, “rate of return”, and “project cash flow”. In Nigeria, Oyeyipo et al. (2016) conducted a study to identify the main factors influencing contractors’ bidding decisions in construction projects. Based on the findings of the study, the most significant factors affecting the bid/no-bid decision were “financial capability of clients”, “availability of capital”, and “availability of material”.

Shokri-Ghasabeh and Chileshe (2016) conducted a study to investigate and rank the critical factors influencing the bid/no-bid decision criteria and their importance in the Australian construction industry. They identified the 26 most common decision-making criteria and they accordingly grouped them into 5 categories, namely project, market, contractor, client, and contract. Li et al. (2019) investigated the factors affecting bid/no-bid decisions of international projects in Chinese construction projects. A total of 41 factors were identified through a literature review as having an impact on the bid decision. Ultimately, 9 main factors were identified as influencing the bidding decision, with contractor's capability and country risk of the host country, being the most important. Chileshe et al. (2020) investigated and ranked the critical factors influencing the bid or no-bid decision and their importance for the indigenous small building contractors within the Tanzanian construction industry. The 7 most highly ranked factors (among the 30 considered) are: availability of capital, financial condition of the client, project size, expected profit, project type, need of work, and current workload. Oke et al. (2020) indicated that the decision to bid is a complex activity that requires the consideration of several factors. These factors can be related to capability, time requirement, and cost implication. They performed a study to evaluate the factors related to time and cost performance to test their effect on the bidding decision. Structured questionnaires were used to gather data from construction professionals in both consulting and contracting firms. The study reported the reputation of the client as the most critical factor related to time performance that influences bidding decisions, while location and condition of the site were identified as the key factors related to cost performance. Thus, the reputation of the client, the location, and the condition of the site should be given the most priority by a contractor at the time of bidding.

Studies Focused on Bidding Strategy Models

A great number of research studies have been done to develop bid/no-bid models; and thereby aid the contractors to make the best decision during the bidding process (Biruk et al., 2017; Chisala, 2017; Egemen & Mohamed, 2007, 2008; El-Mashaleh, 2010, 2013; Lesniak & Plebankiewicz, 2015; Lin & Chen, 2004; Lowe & Parvar, 2004; Ratekar et al., 2016; Shi et al., 2016; Wanous et al., 2000, 2003). Lesniak and Plebankiewicz (2015) designed a bid/no-bid decision model based on fuzzy theory, the authors distributed surveys to operating contractors in Southern Poland in order to make a list of the most influential factors in a bidding decision. The fuzzy set theory was incorporated into the evaluation of overall factors to find a convenient solution to the problem. Shi et al. (2016) introduced a novel model by using a rough set (RS), and general regression neural network (GRNN), based on niche particle swarm optimization (NPSO) algorithm for bid/no-bid decision-making. Biruk et al. (2017) developed a parametric approach, which was a combination of the Analytic Hierarchy Process (AHP) and linear programming model for the purpose of making a decision about whether to bid or not based on a calculation of the total price of the bid. The authors drew a relationship between the bid price and project attractiveness. Chisala (2017) developed a quantitative model to support the decision-makers during the bidding stage. the proposed model was based on a simple additive weighted scoring (SAWS) to produce importance weights of the critical bidding factors and to generate importance scores based on external and internal factors. The decision tree algorithms are used in several real-world applications. It is used in businesses in the visualization of probabilistic business models; in intrusion detection for generating algorithms to design rules for an automatic intrusion detection system; in energy modelling for building; in medicine for diagnosis of various diseases; in the industry for production quality control (Patel & Rana, 2014). The decision tree algorithm has been

effectively used in modelling systems for capturing and extracting the knowledge from datasets. The primary task implemented in these systems is using algorithms to determine the best classification of data according to the decision tree rules (Magesh et al., 2013). Gündüz and Al-Ajji (2021) developed bid/no-bid models for design-bid-build projects for contractors by using Chi-square Automatic Interaction Detector (CHAID) and Classification and Regression (CRT) decision tree algorithms.

In conclusion, as seen from previous literature studies, the most important factors affecting bidding are economic factors.

Current Economic Factors in Turkey

In a year passed after the whole world faced an epidemic of a prevalence that has not been experienced for a long time; the human burden has increased, millions of people have been unemployed, and the social and economic difficulties have become more acute. However, despite the ongoing uncertainties regarding the epidemic, the way out of this eco-health crisis has become more visible as a result of the rapid progress in vaccination efforts. After a turbulent 2020, the global economy is finally starting to emerge from the worst phases of the Covid-19 pandemic. Rapid worldwide policy responses to the post-pandemic economic and health crisis have prevented potential worsening consequences. In addition, consumer behavior that changed with the epidemic led to an increase in demand in some sectors, while disruptions in supply chains led to an increase in the costs of imported intermediate goods. Inflation risks arising from high input costs, shortage of supply and relatively high demand on a sectoral basis maintain their importance in the global economy. In the last quarter of 2021, global economic activity increased more slowly than expected due to concerns about the Omicron variant in the Covid-19 outbreak, the chip crisis, problems in global supply chains, rising inflation on a global scale, and related interest rate hikes (SBB, 2021).

The Russia-Ukraine war increases global risks at a time when the impact of the Covid-19 epidemic is decreasing. The global effects of the war were felt through many channels. Rising commodity and food prices, supply cuts and food security problems stood out as the most obvious consequences of the war. War causes global financial fluctuations and political uncertainties. In addition, the planned and planned sanctions against Russia and the reactions to these sanctions cause uncertainties in terms of global economic activity. On the other hand, the global recovery tends to slow down as the extraordinary government incentives implemented during the epidemic period are reduced to a minimum (SBB, 2022).

Due to the global economic crisis, problems such as high inflation and slowdown in growth rates have emerged in all countries of the world. On the other hand, Turkey is one of the countries experiencing the problem of high inflation at the highest level in the world. According to the latest issue of the World Bank's Turkey Economy Monitor report published on February 25, 2022, the Turkish economy, which recorded a strong growth beyond expectations in 2021, is expected to grow at a much slower pace in 2022, with increasing domestic macroeconomic and financial difficulties slowing growth. Frequent changes in monetary policy settings and a series of interest rate cuts since last September caused the Turkish Lira to fall to historical lows and inflation to record highs (World Bank, 2022).

As a result of the above mentioned economic difficulties; the construction industry in Turkey has also faced serious cost increases. According to the data of the Turkish Statistical Institute

(TUİK) which is shown in Table 1, the Domestic Producer Price Index reached its highest level in the last 20 years (TUİK, 2022a). Similarly; annual construction cost change rate which is shown in Figure 1 have reached 106.87% (TUİK, 2022b). As can be seen in Figure 2, the market prices of rebar and concrete, which are among the basic cost items in the construction sector, have increased significantly in the last year. The main reason behind all these price increases is the depreciation of the Turkish Lira against the US Dollar. Average exchange rates are shown below in Table 2.

Table 1. Domestic producer price index (D-PPI).

Year	D-PPI (%)
2001	88.6
2002	30.8
2003	13.9
2004	13.8
2005	4.54
2006	11.58

Bidding Decision of Contractor Construction Firms: The Case of Antalya Province

Within the scope of this study, the proposals of the contractor construction companies that bid for the tenders of the public institutions in the province of Antalya were examined. Considering the date of September 15, 2021, when the dollar exchange rate started to rise in Turkey, the effect of firms on their decision to bid or not have been examined. For this purpose, the necessary data has been obtained from the Electronic Public Procurement Platform (EKAP), where the tender statistics are published by the Public Procurement Authority (KİK). The tenders for which the results of the tenders have been published since 2018 have been taken into account, and it has been examined whether the ratio of the tenders for which no bids have been given among the canceled tenders has increased in the period when the economic situation deteriorated. Demolition tenders, which were among the canceled tenders, were not taken into account.

As can be seen in Table 3 below, a total of 454 construction tenders were made in 2018, with the result announcement published. 96 of these tenders were canceled for various reasons. Among the canceled tenders, the number of those for whom no bids were made is 14. Its ratio to the total number of tenders is 14.58%.

A total of 230 construction tenders were made in 2019, with the result announcement published. 38 of these tenders were canceled for various reasons. Among the canceled tenders, the number of those for whom no bids were made is 6. Its ratio to the total number of tenders is 15.79%.

A total of 305 construction tenders were made in 2020, with the result announcement published. 53 of these tenders were canceled for various reasons. Among the canceled tenders, the number of those for whom no bids were made is 2. Its ratio to the total number of tenders is 0.04%.

Between 01 January 2021 and 15 September 2021, a total of 292 construction tenders were made. 54 of these tenders were canceled for various reasons. Among the canceled tenders, the number of those for whom no bids were made is 10. Its ratio to the total number of tenders is 18.51%.

Between 15 September 2021 and 31 December 2021, a total of 133 construction tenders were made. 62 of these tenders were canceled for various reasons. Among the canceled tenders, the number of those for whom no bids were made is 25. Its ratio to the total number of tenders is 40.32%.

Between 01 January 2022 and 01 June 2022, a total of 203 construction tenders were made. 89 of these tenders were canceled for various reasons. Among the canceled tenders, the number of those for whom no bids were made is 27. Its ratio to the total number of tenders is 30.33%.

Table 3. Total rate of no-bids.

Period	Total Tenders	Total Canceled Bids	Total No-bids	Ratio
01 January 2018-31 December 2018	454	96	14	14.58%
01 January 2019-31 December 2019	230	38	6	15.79%
01 January 2020-31 December 2020	305	53	2	0.04%
01 January 2021-15 September 2021	292	54	10	18.51%
15 September 2021-31 December 2021	133	62	25	40.32%
01 January 2022-01 June 2022	203	89	27	30.33%

Conclusion

This study contributes to the body of knowledge in bid/no-bid decision-making in construction projects. The economic factors seen in the literature review are among the most important factors affecting the bidding decisions of construction contractor companies.

In this study, it has been tried to determine whether the economic environment in our country has an effect on the decision of the contractors to bid. According to the results of the tenders held in Antalya, obtained from the Public Procurement Authority, it has been observed that there has been a decrease in the bid submission decisions of the contractor construction companies since mid-September, when the exchange rate increased rapidly in Turkey. This allowed the strong influence of the economic factors mentioned in previous studies on the decision to bid in a real economic uncertainty situation to be observed.

The limitation of this study is that it was carried out only in a narrow scope, such as the tenders of public institutions in the province of Antalya. In future studies, it is thought that expanding the scope of the study across the country will be more beneficial in academic terms.

Causal Relationships between Construction Cost Index and Macroeconomics in Turkey

S. Aydınlı
Cukurova University, Department of Civil Engineering, Adana, Turkey
saydinli@cu.edu.tr

Abstract

Construction cost fluctuations are crucial for project performance and it is very difficult to predict future cost fluctuations in developing and volatile economies. The construction cost index (CCI) is a statistical indicator that is an aggregate of material and labor costs produced and published by the Turkish Statistical Institute every month. CCI is widely used for future cost prediction by practitioners. This study aims to determine causal relationships between construction costs and major macroeconomic indicators such as; the consumer price index, producer price index, exchange rate, construction turnover index, etc. Autoregressive Distributed Lag (ARDL) Model and Granger Causality Test are employed to determine the cointegration and causality between the construction cost index and other macroeconomic indicators. This study provides important findings for improving future construction cost estimates. It also provides important candidate variables that can be used in cost estimation algorithms in the future.

Keywords: *construction cost index, cost estimation, Granger causality test, time-series analysis, Turkish construction industry.*

Introduction

Construction projects are complex due to long-term activities and several inputs such as material, equipment, labor and management. Such projects should be managed properly to ensure project success. Cost fluctuations caused by economic developments are one of the major problems affecting construction project performance (Enshassi et al., 2009, 2010). Fluctuations in both material and labor prices should be predicted accurately for proper budget allocation. For this purpose, practitioners should determine leading indicators and predict future construction costs using several forecasting models, especially in developing countries.

In recent years, forecasting models, developed using time-series data, have been implemented by many researchers. The determination of the independent variables used in these models is also of key importance for the success of the model. Many factors from supply-demand indicators to general economic conditions may affect future construction costs. Thus, determining potential leading indicators of construction costs is very crucial to forecast accurate future costs. Considering the macro-level, it can be claimed that macro cost indices such as consumer price index (CPI) (Shane et al., 2009) and producer price index (PPI) may

help to determine construction costs. Besides, there may be mutual effects between industrial indicators such as construction turnover, housing starts, etc… and construction costs. Finally, the exchange rate ($/TL) can be seen as potential factors affecting construction cost movements.

In this context, this paper aims to investigate potential leading indicators to forecast construction costs in Turkey. For this purpose, major potential indicators were determined using literature studies and causal relationships between these indicators and construction cost index (CCI) were investigated using Autoregressive Distributed Lag (ARDL) Model and Granger Causality Test.

Literature Review

Many studies have investigated leading indicators and their effects on CCI. While some studies have focused on accurate CCI forecasting, some have focused on determining leading indicators.

Shane et al. (2009) studied internal and external factors affecting construction cost escalations. The authors emphasized that market conditions and inflation are significant factors causing project cost escalations and they should be taken into account in cost forecasting. With the determination of the effects of economic indicators on construction costs, there has recently been an increase in the use of time series methods. From the earliest studies, Hwang (2011) developed a forecasting model to predict CCI using CPI as the independent variable. The author compared the vector autoregression (VAR) model as a multivariate time series model and the autoregressive integrated moving average (ARIMA) model as a univariate model. As a result, it has been observed that the VAR model with CPI made more accurate long-term predictions. Ashuri et al. (2012) have identified leading macroeconomic indicators affecting CCI movements. To that end, the authors employed Johansen cointegration and granger causality tests. The results showed that CPI, PPI, GDP and money supply are the major leading indicators affecting CCI. Xu and Moon (2013) constructed a VAR model using CPI to forecast CCI and the results showed that multivariate models can provide more accurate predictions. Yorucu (2013) used two time-series methods, ARDL and granger causality test, to investigate the relationships between construction industry indicators and macroeconomics in North Cyprus. The author has determined the causal effects of macroeconomics on gross domestic product and construction value-added. Shahandashti and Ashuri (2016) forecasted Highway CCI using the vector error correction model (VECM). Independent variables used in the model are determined using granger causality and Johansen cointegration tests. The authors determined crude oil prices and average hourly earnings as major indicators for the prediction model. Moon and Shin (2018) which is the latest literature study, predicted CCI using the google search query. A VECM model has been constructed and the query of ‘project management salary’ has been determined as the independent variable. The results show that the VECM model produces more accurate predictions than univariate models.

Literature studies mostly focused on United States of America data and there is no evidence on model applicability in developing countries. This study investigates causal relationships between CCI and certain macroeconomic indicators in Turkey which is one of the developing countries.

Methodology

This paper employed ARDL model and granger causality test to determine the relationships between major price indexes and CCI. Potential price indexes are determined as CPI, PPI, exchange rate (ER) and construction turnover index (CTI) between 2015-2020 using literature findings and data were collected using several institutes provide official data such as Turkish Statistical Institute (TURKSTAT), The Organization for Economic Co-operation and Development (OECD), and The Central Bank of the Republic of Turkey (CBT) (Table 1). Owing to structural breaks in economies during the COVID-19 epidemic, collected data is limited to 2020.

Table 1. Time-series variables and data sources.

Variable	Source
Building Construction Cost Index (CCI)	TURKSTAT
Consumer Price Index (CPI)	OECD
Producer Price Index (PPI)	OECD
Exchange Rate ($/TL) (ER)	CBT
Construction Turnover Index (CTI)	TURKSTAT

Augmented Dickey-Fuller Unit Root Test

The nature of the time-series data is an important factor to employ an appropriate model. Most time-series models are required stationary data. Augmented Dickey-Fuller Test (ADF) (Dickey & Fuller, 1979) is a widely used technique which determines lag lengths using Akaike Information Criterion (AIC) (Akaike, 1974) and whether the data is stationary or not. ADF test is a kind of hypothesis test that tests the null hypothesis is that time-series data is not stationary. If the test results indicate that data is not stationary, data should be differenced using Eq. 1. Differencing should be repeated till ADF test results show that data is stationary.

$$\nabla X_t = X_t - X_{t-1} \tag{1}$$

where: ∇X_t : Differenced X_t

X_t : X value at t time

X_{t-1} : X value at t-1 time

Autoregressive Distributed Lag (ARDL) Model

Autoregressive Distributed Lag (ARDL) Model proposed by Pesaran et al. (2001) is a type of cointegration test implemented to time-series data. If two time-series are cointegrated, it means that one influences the other's direction. ARDL model can determine both short-run and long-run cointegration and main advantage of model is that it can be implemented both stationary and non-stationary time-series. The most important assumption in the model is that the dependent variable should be stationary in the first difference (I(1)). The ARDL model representation is given in Eq. 2 and 3;

$$\Delta CCI_t = \alpha_0 + \sum_{i=1}^{n} \alpha_{1i} \Delta CCI_{t-i} + \sum_{i=0}^{n} \alpha_{2i} \Delta CPI_{t-i} + \sum_{i=0}^{n} \alpha_{3i} \Delta PPI_{t-i} + \sum_{i=0}^{n} \alpha_{4i} \Delta ER_{t-i} + e_t \quad (2)$$

$$\Delta CTI_t = \alpha_0 + \sum_{i=1}^{n} \alpha_{1i} \Delta CTI_{t-i} + \sum_{i=0}^{n} \alpha_{2i} \Delta CCI_{t-i} + e_t \quad (3)$$

which represents dependent variables CCI and CTI in t time and independent variables, their lagged values and error term. Long-run and short-run cointegration between variables is tested using Eq. 2 and 3. ARDL model is fitted using Bayesian information criterion (BIC) which is an indicator denotes model fit introduced by Schwarz (1978). ARDL model uses the bounds testing procedure which is based on F statistics. If the computed F statistics is higher than reference values, this indicates a significant cointegration between variables.

Granger Causality Test

Granger causality test proposed by Granger (1969) is a hypothesis test that determines whether a time-series data is useful for short-term forecasting of another. Granger causality test depends on Wald statistics and if the significance value of the Wald statistic is lower than 0.05, it means that X independent variable and its lagged values Granger cause Y dependent variable. In other words, the null hypothesis of the Granger causality test is that X does not cause Y. In this study, the Granger causality test was used to determine the causality direction of the variables that integrated each other.

Results and Discussion

ADF Test Results

As mentioned before, it is crucial to determine whether the time-series data are stationary or non-stationary. ADF test results of the time-series included to analysis are presented in Table 2. The null hypothesis of tests is that data has a unit root and it is non-stationary. As is seen, all time-series are stationary at their first differenced data.

Table 2. ADF test results.

Variable	Original data		1st differenced data	
	ADF Test Stat.	p-value	ADF Test Stat.	p-value
CCI	0.4614	0.9839	-6.1125	0.0000
CPI	1.9407	0.9998	-3.7181	0.0064
PPI	0.31122	0.9769	-3.6718	0.0072
ER	-0.4296	0.8964	-4.2670	0.0013
CTI	-1.4451	0.5536	-6.7591	0.0000

The ARDL model and Granger causality test, two main methods employed, require different types of data in terms of stationary. ARDL model requires data stationary at most first difference (I(0) or I(1)) (Nkoro & Uko, 2016). Contrary to ARDL model, Granger causality

test requires stationary data (I(0)) (Granger, 1980). Therefore, raw data were used for the ARDL model and first differenced data were used for the Granger causality test.

ARDL Model Results

This paper examined two different cointegration models. First model (Model 1) employed CCI as dependent variable and CPI, PPI and ER were decided to be independent variables. Second model (Model 2) employed only two variables that are CCI and CPI. The bounds test model diagnosis results of the models are presented in Table 3. As a result of the preliminary analysis, it was observed that the CPI did not cause a significant change and was excluded from Model 1. The bounds test is a hypothesis test in which the null hypothesis is that there is no cointegration relationship.

Table 3. Bounds test results and model diagnostic of ARDL models.

Model	Calculated F-statistic	Significance level	Critical bound		Model Diagnostic (Prob.)		
			I(0)	I(1)	Breusch-Godfrey LM Test	Heter. Test (ARCH)	Ramsey RESET Test
Model 1	5.51	10%	3.28	4.27	0.4849	0.8287	0.1141
		5%	3.98	5.09			
	BIC	Adj. R^2	Specification				
	40.4022	0.9973	ARDL(1,4,1)				
Model 2	3.72	10%	4.15	4.92	-	-	-
		5%	5.12	6.04			
	BIC	Adj. R^2	Specification				
	-	-	-				

As shown in Table 3, F-statistic of Model 1 is higher than all critical bounds (I(0) & I(1)) which means that a significant long-term cointegration between variables was detected in Model 1. On the other hand, F-statistic of Model 2 is lower than all reference bounds which means that there is no level relationship in Model 2. Analysis results confirm that PPI and ER are cointegrated with CCI.

After a statistically significant model has been established, model diagnosis should be examined. Model diagnosis consists of a set of tests; lack of serial correlation and lack of heteroscedasticity of residuals, specification errors, and stability of the model. For a fit model, the null hypothesis of model diagnosis tests should be accepted. Besides, CUSUM and CUSUM of squares should remain within the reference range (Figure 1). It is seen in model diagnosis results, Model 1 is fitted and statistically significant (Table 3 and Figure 1).

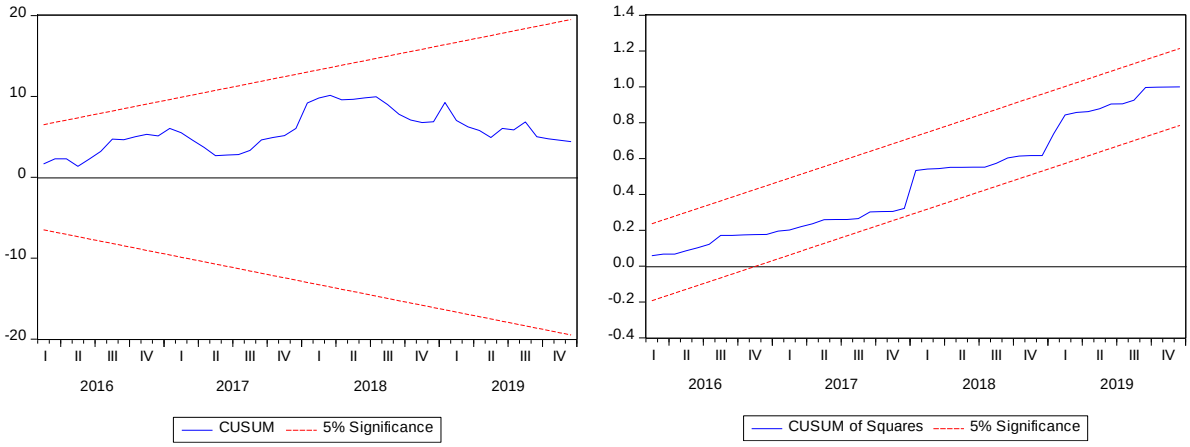

Figure 1: CUSUM and CUSUM of squares.

Following testing model diagnostics, long- and short-run regression coefficients can be discussed. Regression coefficients of Model 1 are given in Table 4 and 5.

Table 4. Long-run coefficients of ARDL model.

Variable	Coefficient	Std. Error	t-Statistic	Prob.
ER	4.5667	7.4435	0.6135	0.5425
PPI	0.8711	0.2623	3.3205	0.0017

Table 5. Short-run coefficients of ARDL model.

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	1.8372	0.4043	4.5437	0.0000
ER	-4.5466	2.7958	-1.6262	0.1106
ER^{-1}	-6.5143	2.2421	-2.9053	0.0056
ER^{-2}	-1.0569	1.4826	-0.7128	0.4795
ER^{-3}	-5.4179	1.4158	-3.82674	0.0004
PPI	1.3742	0.2615	5.2544	0.0000
CointEq	-0.3049	0.0734	-4.1529	0.0001

As seen in Table 4, while PPI long-run regression coefficient is statistically significant, ER has no statistically significant long-run effects on CCI. The short-term regression coefficients given in Table 5 reveal a different situation. First and third lagged values of ER have statistically significant effects on short-run cointegration relationship. Literature studies mostly pointed to a cointegration relationship between CPI and CCI and shaped the prediction models using this variable (Hwang, 2011; Xu & Moon, 2013). These studies were conducted on the USA, which is a developed country and has a reserve currency. This study shows that PPI also should be considered as a leading indicator of CCI. Besides, it is clearly seen that ER is another leading indicator of CCI in developing countries.

Granger Causality Test Results

ARDL model reveals long-run relationships between variables and cointegration results are not directional. Thus, in order to identify unidirectional causality, the Granger causality test

was applied. As mentioned in the methodology section, the Granger causality test determines causal relationships and its null hypothesis is that "lagged X values do not explain the variation in Y". Granger causality test results for CCI, PPI and ER are given in Table 6.

Table 6. Granger causality test results.

Causal Relationship	Chi-Sq	df	Prob.	LM Test	Heter. Test
ΔER Granger Cause ΔCCI*	18.6295	4	0.0009	0.4071	0.5140
ΔCCI Granger Cause ΔER	5.5393	4	0.2363	-	-
ΔPPI Granger Cause ΔCCI*	19.6932	4	0.0006	0.5429	0.7002
ΔCCI Granger Cause ΔPPI	2.9248	4	0.5705	-	-

Granger causality test results show that ER and PPI granger cause CCI. Thus, both variables in the cointegration model also cause the variation in CCI. Considering that the literature findings mostly on country with reserve currency, it is understood that ER should be considered as an important leading indicator of CCI in developing country economies. Especially in countries with high import rate, this effect may increase. On the other hand, another variable a causal relationship determined is PPI which is the major indicator of costs in the manufacturing industry. The manufacturing industry is the major industry that supplies materials for the construction industry. Cost increases in the manufacturing industry are directly reflected on the product, therefore the input costs of the construction industry also increase.

Conclusion

This study determined the leading indicators affecting CCI using time-series analysis techniques ARDL Model and Granger causality test. The variables included in the analysis were determined as CPI, PPI, ER and CTI based on the literature. The cointegration test between the variables was performed using the ARDL model, and cointegration was detected between the PPI, ER and CCI. However, it is observed that CPI and CTI have not any cointegration with CCI. After the cointegration analysis, the direction of the causality relationship between the variables and CCI was determined using Granger causality analysis. As a result of the analysis, it was seen that both variables had effects on CCI. This study revealed that price index of manufacturing industry is the one of the major factors affecting construction costs. In addition, ER is crucial for costs especially due to its effects on imported materials and energy costs. The study is considered to be one of the pioneering studies, especially in developing economies. In the future, it will be possible to produce more successful cost estimations with forecasting models developed using these variables.

Abstract

Finance-based scheduling (FBS) has been a focus of debate over the last two decades and is of considerable interest to professionals and researchers. In the early studies, researchers have developed models that deal with cash flow constraints and scheduling problems. On the other hand, recent studies consider resource and finance constraints simultaneously. Some of these recent studies have also considered different financial alternatives and project valuation methods. Even though researchers have generated quite a volume of academic work on FBS, there has been no attempt to offer a comprehensive review to summarize and critique the existing literature on FBS and to provide ideas for future work. A comprehensive and thorough review of previous studies in the area of FBS would be of great value to researchers who want to explore future research opportunities in FBS. The objective of this study is to provide enough insight to the state of the research in the existing literature, hence drawing the attention of researchers to new directions in FBS. This systematic review of FBS-related studies identifies the research gaps and highlights virgin areas for further research. The new directions presented in this study can motivate researchers to undertake FBS-related research, which in turn may help schedulers to develop and implement reliable financially sound work schedules in their construction projects.

Keywords: *cash flow, finance-based scheduling, scheduling.*

Introduction

One of the most important factors in the success of construction projects is the efficient use of resources. Procuring required resources when needed is essential to accomplish the project goals. Failing to provide the necessary resources on time may lead to another failure in completing the project on time and within the allocated budget. Besides, having the required

cash readily available to supply these resources is another critical factor in accomplishing the project goals. Hence, financing the required cash is considered to be one of the challenging tasks of contractors in the construction industry (Elazouni, 2009). For example, cash deductions in progress payments for collateral purposes and delay in progress payments by employers are claimed to be the main reasons for financing problems of contractors (Alavipour & Arditi, 2018a). These factors may destabilize contractors' cash flows, which brings the need of additional cash to prevent imbalances in the cash flows. This additional cash can be obtained from financial institutions in return of a fee paid by the contractors (Ali & Elazouni, 2009). It should be noted that this fee is a cost for the contractor which is also known as the finance cost. It directly affects a contractor's cash flow. Therefore, it is crucial to consider the need of additional cash to prevent imbalances in the cash flows and its finance cost while establishing schedules. However, it is commonly claimed that the financing cost has been ignored in establishing schedules by schedulers. Elazouni (2009)'s contention is that schedulers usually consider scheduling and project financing as two different and independent processes. The need for an approach considering these two processes simultaneously has led researchers to develop the Finance-Based Scheduling (FBS) approach. The FBS approach includes financial constraints in the scheduling process. In this study, a systematic and detailed literature review was conducted to investigate and clarify the research gap in the existing FBS literature. Within the scope of this study, it was aimed to determine which factors, methods, constraints, and objective functions are concerned in the existing studies. In addition, methodologies and techniques used to solve FBS problems in existing studies are identified in this study. Finally, the research gap in the existing FBS literature is discussed.

Methodology of Systematic Literature Review

In this study, the existing FBS literature has been reviewed to highlight the future research trends. A systematic literature review is conducted by following the steps defined in Amer et al. (2021)'s study. The steps of the systematic literature review can be seen in Figure 1. In this study, Scopus has been selected as the database to review the literature. The following search query is used in this study: {"finance-based" AND "scheduling"} OR {"financing cost" AND "scheduling"} OR {"finance cost" AND "optimization"}. The research with these keywords returned a total of 367 publications. They were screened by looking at the titles, and those that were not relevant were excluded. This step led to selection of 60 publications for abstract-based screening. When their abstracts are examined, 6 publications were excluded due not being able to access to full text of them. In addition, 8 publications were excluded due to their irrelevance to FBS. Then, the full textes of the selected publications were screened. After the full text screening step, 39 publications were considered to be relevant. Then, the references of each publication were examined which led to addition of extra 15 publications to the existing list. Next, author knowledge-based screening was performed. It was observed that 4 more publications can be added to the existing group. All previous steps were repeated until there were no other relevant publications that could be added to the existing group. Finally, the findings of the systematic literature review were presented and discussed.

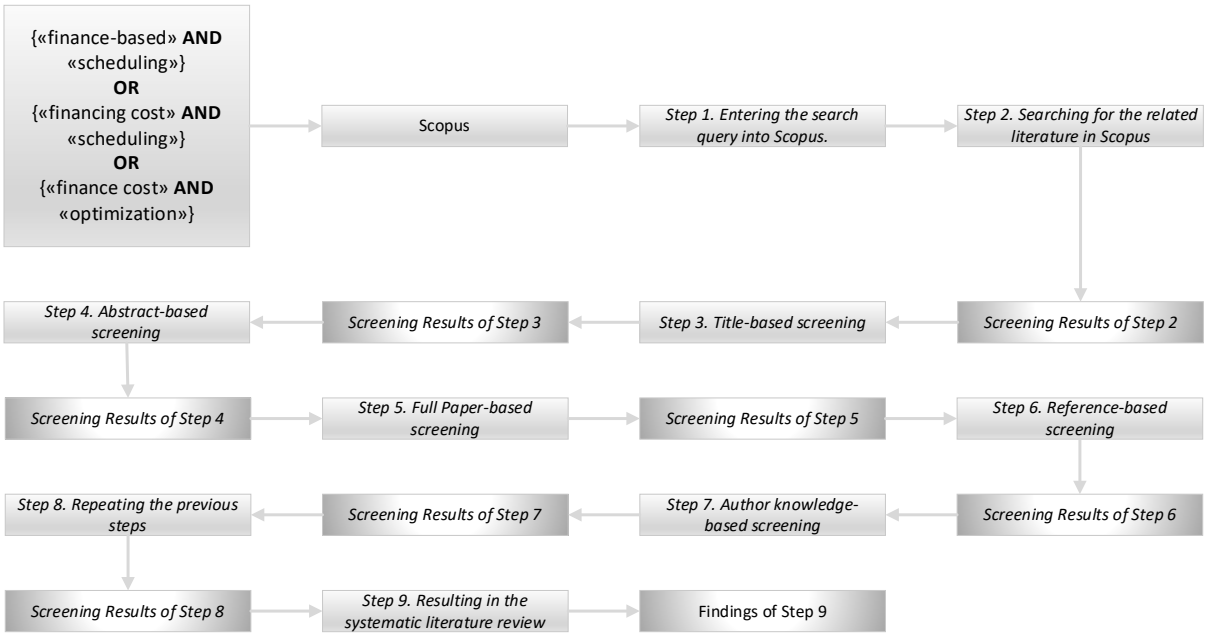

Figure 1: Flow diagram of the systematic literature review.

Findings of the Systematic Literature Review

After the systematic literature review, 47 publications were found to be related to FBS. These publications are categorized according to the publication type. The majority of the publications (i.e., 35 of 47 publications) are journal papers. The rest of the publications consists of 3 conference papers, 1 discussion article, 1 closure article, and 1 technical note. Nevertheless, the full text of the six publications could not be accessed. The discussion paper, closure paper, and the six inaccessible publications were excluded from further investigations. Figure 2 shows the names of the journals and conferences and the number of corresponding publications.

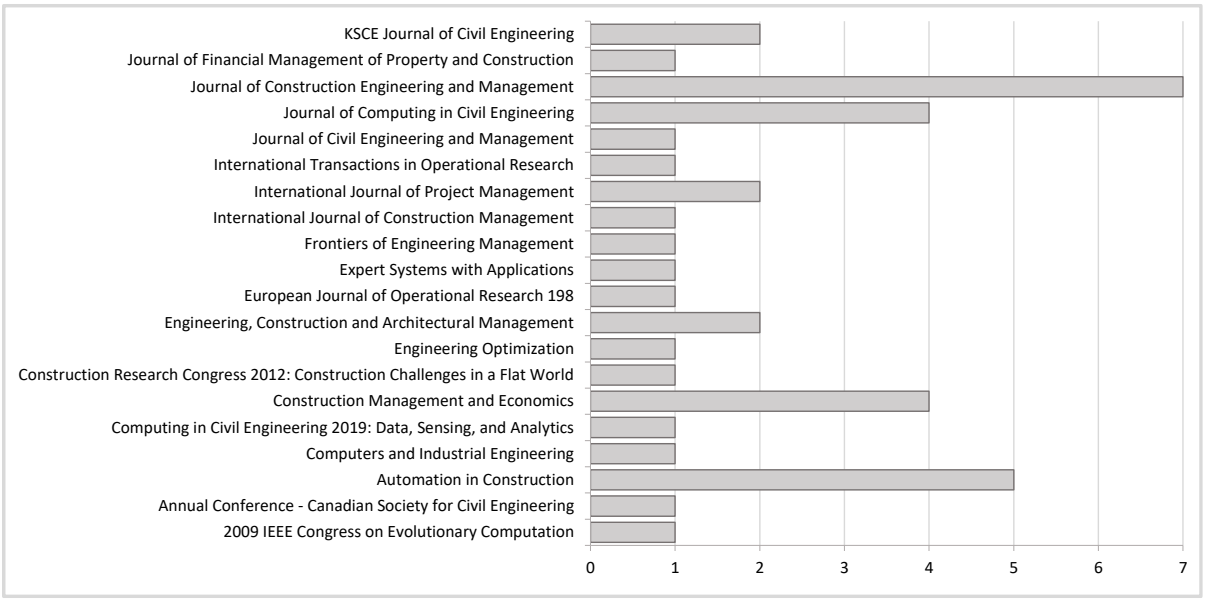

Figure 2: Distribution of the published literature around FBS.

When the algorithms used in the developed models are considered, mathematical algorithms (e.g., Linear Programming, Integer Programming) were used in 10 publications, heuristic algorithms were used in 3 publications, meta-heuristic algorithms (e.g., Shuffled Frog-Leaping Algorithm, Max-Min Ant System) were used in 22 publications, and hybrid algorithms (e.g., Linear Programming/Genetic Algorithm, Mixed-Integer Linear Programming/Heuristic) were used in 3 publications. Additionally, Pareto Optimality Efficiency Network were used in 1 publication (Figure 3). This finding reveals that the researchers frequently prefer meta-heuristic algorithms that can provide near-optimal solutions in a short time due to the need of longer time to solve FBS problems by mathematical algorithms.

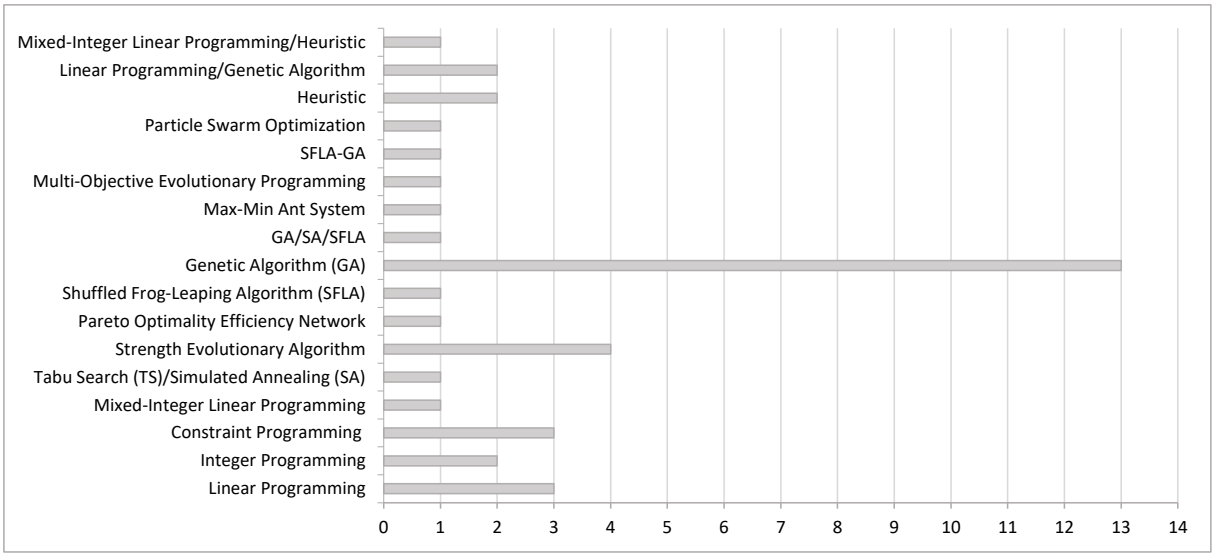

Figure 3: Types of algorithms used in the developed models.

It was observed that different factors are taken into account in development of FBS models (Table 1). While most studies consider portfolios containing a single project, the literature review reveals a limited number of studies that consider portfolios containing more than one project. In addition, there are studies that allows changing the original project duration because there is a need of extending the project duration due to the financial constraints. On the other hand, studies exist proposing models that keep the project duration fixed. In addition, some researchers have modified these FBS models by adding time-cost trade-off or crashing features to allow changing the durations of activities. However, it should be also noted that the original project duration and duration of activities remain unchanged in the FBS models that consider resource leveling. Besides, the FBS models that consider non-cash resource management (e.g., including resource leveling into the model) allow considering only one resource type or multiple resource types.

The literature employs different objective functions (Table 2) to achieve the optimization goals. The objective functions considered in the literature are categorized into four main groups, namely, (1) time, (2) cost and profit, (3) cash, and (4) resources other than cash. It was observed that a significant number of FBS models aim to minimize the increase in the original project duration caused by the finance gap. The FBS models focused on minimizing cost rather than the increase in the original project duration use the minimization of the amount of borrowed credit and the finance cost.

Moreover, the literature review reveals that maximizing the project profit and net present value objectives have been used in a limited number of FBS models. Despite the fact that most of the FBS-related studies have ignored the optimization of resources other than cash, it should be noted that a number of studies have considered objectives (e.g., minimization of resource fluctuations, maximum resource demand) to include management of resources other than cash in FBS models (Table 2).

Parameters and factors considered in the FBS models are presented in Table 3. It was observed that the most frequently used methods in resource management (i.e., resource leveling and resource allocation) are also used in some of the FBS models. For example, "release and re-hire" and "resource idle days" are the optimization parameters considered by

some FBS models for the efficient usage of resources other than cash. Minimizing these two parameters provides a smoother resource usage profile and reduces the maximum resource demand. As far as the financing alternatives are concerned, most of the studies focused on FBS have only used credit line as a financing tool. However, it should be also noted that a limited number of FBS models have considered short-term and long-term credits as financing alternatives.

Conclusion

Finance-based scheduling has been a focus of debate over the last two decades and is of considerable interest to professionals and researchers. Even though researchers have presented quite a volume of academic work on FBS, there has been no attempt to offer a comprehensive review to summarize and critique the existing literature on FBS and to provide suggestions for further research. A systematic literature review has been conducted in this study to identify the research gaps and possible areas for further research. Indeed, the existing models have some shortcomings. For example, many developed models considered the credit line the only financing tool. However, there are many other options to finance a construction project, such as short-term loans (Alavipour & Arditi, 2018a), long-term loans (Alavipour & Arditi, 2018a), balloon payments (Halpin & Senior, 2009), trade financing (Peterson, 2013), and subcontracting (Tabyang and Benjaoran, 2016). In addition, a limited number of FBS models in the literature consider multiple projects simultaneously. The findings of this study also show that researchers ignored using different objective functions when they included resource leveling feature in their FBS model. Moreover, the impact of using different objectives (e.g., net present value) for FBS should be explored to improve existing models. Research on the impacts of using different financing alternatives, objectives, and multiple projects is underway. Until the time this research is completed, it would be prudent for schedulers to keep in mind that these factors may have an impact on their schedules developed via FBS.

Abstract

In this paper construction sector is discussed from a macroeconomic perspective to gain insight into the interaction of the sector with the economy. Hence, it has strong linkages with the other sectors, the responsive characteristics to the macroeconomic conditions, and the potential to absorb an unskilled labor force, it is important to understand the interactions to apply a proper economic policy that serves to reach desired economic development. A set of macroeconomic data i.e., cost of inputs, production and turnover, aggregate output, investments, and monetary tools is analyzed to reveal the effects of the sector on the economy. The results have shown that excessive allocation of resources to the sector and providing support in a way that is incompatible with macroeconomic realities have devastating effects on the economy in the long run.

Keywords: *construction economics, economic growth, GDP, macroeconomics, Turkey.*

Introduction

The construction sector has been considered a prominent catalyst for economic growth and development. Therefore, the relationship between the construction sector and the economy has been the subject of debate for a long time from various perspectives such as economic growth (Yiu et al., 2004; Wilhelmsson & Wigren, 2011; Qabaja & Tenekeci, 2022), capital formation (Esfahani & Ramirez, 2003; Lakshmanan, 2011; Ansar et al. 2016; Ertugrul & Pirgaip, 2021), employment (Wells & Wall, 2003; Chiang et al., 2015; Gulluk-Senesen et al., 2018), sectoral output (Ilhan & Yaman, 2011; Gregori & Pietroforte, 2015; Ali et al., 2019). In these researches, different results have been observed for different countries, time frames, and circumstances yet no consensus has been settled up. These results also prove that the relationship between the construction sector and the economy is more complicated than anticipated.

Infrastructure and housing are the two main outputs of the sector that have a huge impact on economic and social development. Moreover, its strong linkages with other sectors and potential to absorb an unskilled labor force give it political appeal. Consequently,

policymakers use the sector as an economic speculation tool during periods when unemployment and economic stagnation raise.

From another viewpoint, there are discussions about the macroeconomic, spatial, social, and environmental effects of unplanned growth in the sector beyond the economic capacity. These discussions also focus to ensure not postponing real and sustainable economic growth by preventing the excessive transfer of economically scarce resources to the construction sector.

However, it is still not clear how construction-oriented economies can achieve sustainable economic growth and desired development in the long run. This research aims to reveal if a construction-oriented economy provides the expected outcomes to achieve sustainable economic growth or not. Moreover, it indicates how both the excessive incentives provided by the government to the sector and the labor and capital absorbed from other sectors lead to a complete deformation of the economy and misuse of the scarce resources when the expansion of the construction sector exceeds the limits within which efficient production can be achieved. It is assumed that approaching construction as a sub-branch of economics and investigating its interactions with the economy enables us to reveal its effect on sustainable economic growth and desired economic development in the long run, especially in developing countries. Thus, the economic decisions and regulations related to the construction sector can be developed more properly while preventing the misallocation of scarce resources and the establishment of an idle capacity. The evaluation of the construction sector in the Turkish economy between 2000 and 2020 is investigated by examining macroeconomic data from different perspectives to improve our understanding of the interaction between the construction sector and the economy.

The various variables are collected to discuss the relationship between the construction industry and the economy from a multidimensional perspective. The production and turnover, aggregate output, labour force, and investments are selected variables to examine this issue very deeply. The data used in analyses are obtained from the Turkish Statistical Institute (TurkStat).

The time series and scatter diagrams with regression analysis are mainly used to investigate the relationship between selected macroeconomic variables. Then, the outcomes of these analyses are interpreted logically, and the results are presented in the upcoming sections. If the data is published in current prices, it is adjusted to constant prices using a proper deflator to show the real effect, not the nominal. The data obtained from national sources expressed in Turkish Lira, except where indicated otherwise.

Literature Review

Bon (1992, 2000) observed that the share of construction in Gross National Product (GNP) follows an inverted U-shape as a country's economic development level increases. The pathway followed by the construction sector linked with the economic development level of a country is true in relative terms, but not in absolute terms. As a country develops, the construction sector's output still grows, but at a slower rate than the overall economy (Ruddock & Lopes, 2006; Lopes, 2009). From these observations, we may conclude that infrastructure and housing needs in a developing economy lead to a dramatic increase in construction activities relative to the economic scale, but in more mature development stages, the growth rate of the sector slows down, and the sector focuses more on maintenance and

repair activities. This process also indicates a structural change in the sector. However, these results in the literature are not consistent across all developing countries due to different economic structures and capacities of the economies.

Another debate rises from the direction of the causality between construction and the Gross Domestic Product (GDP). Tse and Ganesan (1997) observed that increase in the GDP has a causal effect on construction activity in Hong Kong. On the other hand, Chan (2001) for Singapore and Zheng and Liu (2004) for China observed a bi-directional causal relationship between construction activities and GDP. Lewis (2009) found this relationship ran from GDP to construction during an economic upturn and from construction to GDP during an economic downturn. Moreover, Alaloul et al. (2021) revealed that the output of the agriculture and service sectors influences the construction output level.

Construction can be defined as an assembly activity in that inputs comprise unskilled labour-intensive domestic resources mainly produced by fundamental industries, such as cement and steel manufacturing (World Bank, 1984). This nature of construction activity provides strong backward linkages to itself and thus an expansion of the construction industry increases the demand for the products and services of the other supply industries (Bon et al., 1999).

Pietroforte and Gregori (2003) highlighted the increasing importance of the maintenance and repair sub-sector. More recently, Zhu et al. (2020) discovered the effect of the construction sector becoming weaker to promote economic growth. Moreover, there is still little known about how the adaptive capacities of the other sectors affect the supply of the construction sector (Giang & Peng, 2011).

The construction industry has significant potential to absorb unemployment (Turin, 1978) because it is more labour-intensive and requires a less qualified workforce than many other industries (Hildebrandt, 2000). Therefore, the industry is used as a key tool for employment generation policies in various countries through labour-intensive public works projects, especially when demand diminishes, and unemployment rises (Gruneberg, 1997; Hillebrandt, 2000). The most recent example of the application of this policy was experienced during the 2008 economic crisis. Many governments which hold different economic development levels announced financial packages, including infrastructure projects, to stimulate economic activity and generate employment (Donnges, 2009). However, using the industry as an effortless way to generate employment for the unskilled labour force through unplanned public works could damage both the development of the industry and the entire economy (Turin, 1978). These risks should be managed together with fiscal policy by adjusting the number of public expenditures, and monetary policy by changing the interest rates of loans financing these public works projects (Hildebrandt, 2000).

However, on the other side, increasing construction activity does not necessarily always result in economic growth. Excessive supply of scarce resources to the construction industry and over-estimation of demand for infrastructure relative to economic scale may cause the establishment of idle capacity for both housing and infrastructure (Drewer, 1980; Flyvbjerg, 2008; Balaban, 2012). Economic recessions experienced in Singapore and Trinidad and Tobago in 1985 and Southeast Asia in 1997 are unpleasant examples of this phenomenon (Lewis, 1984; Ganesan, 2000). The irrational growth in the construction industry and housing sector caused high inflation, a decrease in housing purchasing power for low-income groups, and capital outflow from productive sectors in East Asia (Aveline & Li, 2004). It has also been observed that the supply surplus of housing leads to the depreciation of residential

buildings, the situation results in the bankruptcy of companies, as in Taiwan (Hsieh, 2005), or may collapse the mortgage loans and initiate an economic crisis such as experienced in the USA in 2008. Orhangazi and Yeldan (2021) highlighted the negative effects of construction-oriented growth in the Turkish economy. Political factors in decision-making may worsen the situation (Devarajan et al., 1993). The construction industry is commonly used by governments, especially in developing countries, to construct publicly visible projects that help them consolidate their political power while raising the rent through sufficient construction projects and transferring it to ideologically supported equity-owners.

The Economy of Turkey

The evolution of Turkey's construction-based, fragile, and developing economy between 2000 and 2020 is observed to examine the arguments of the two opposing views. Turkey transformed its economic system into an open market economy in the early 1980s. The construction sector then moved full speed ahead and experienced two huge expansion periods between 1982-1988 and 2005-2013. The domestic economic crisis in 1994 and 2001, the global financial crisis in 2008, the Turkish currency and debt crisis in 2018, and more recently the economic impacts of the Covid-19 pandemic suspended these processes, and the sector was the first to suffer. Still, the sector has been perceived as a locomotive sector of the Turkish economy by the government. The government used the construction sector as a key tool to overcome economic stagnation and absorb unemployment after the 2001 and 2008 economic crises. The earthquake hazard mitigation process is subject to rent and environmental debates. Many other "megaprojects" such as the 3rd Bosporus Bridge and the Istanbul Airport were realized within this period. Currently, the Channel Istanbul Project planning to open an artifactual crossing from the Black Sea to the Marmara Sea is at the centre of debates just after the currency crisis in 2018 and 2021.

Turkey has been classified as an "Upper Middle Income" country by the World Bank with its GDP per capita increasing from $4.337 to $8.536, the unemployment rate increasing from 6.5% to 13.11%, and the inflation rate decelerating from 54.91% to 12.28% between 2000 and 2020 (World Bank, 2020). In addition, structural change in the Turkish economy between 1970 and 2020 can be traced to the change in the share of sectors in the GDP. In this process, the share of the agricultural sector dropped dramatically from 37.3% to 6.6%, while the industrial share increased from 17.2% to 22.4% and followed a fluctuating course close to horizontal, and the share of services increased from 37.9% to 54.9% with massive acceleration. Although the share of the construction sector, which is 5.8%, has fallen to 5.1% because of the effects of the pandemic, it has approached the levels of 10% in the 2000s. The transformation of the economy from agriculture to a service economy can be defined as "premature deindustrialization" in which economies of developing countries are turning into service economies without experiencing a proper industrialization process (Rodrik, 2016).

Findings

The Production and Turnover

The production index is generated by multiplying hours worked obtained from construction firms with productivity coefficients obtained from fixed prices sector GDP. It aims to observe the changes in production for a specific period. The dataset is available for the construction sector from 2005-2016 with the base year 2010. TurkStat announced that after completing requiring updates, the dataset is going to be continued to be published in 2018. However, the new dataset has not been published yet. Similarly, the turnover index focuses on revenues generated from operating income. It does not consider non-operating income, VAT, revenues from foreign services, etc. Unlike the production index, it is announced at nominal prices by TurkStat. The dataset is available for the construction sector for 2005-2017 with the base year 2010 and 2009-2020 with the base year 2015. However, these two datasets have different calculation rules, so it is impossible to link them to each other. Moreover, the data represented in these two turnover indices surprisingly follow dissimilar trend lines in real prices.

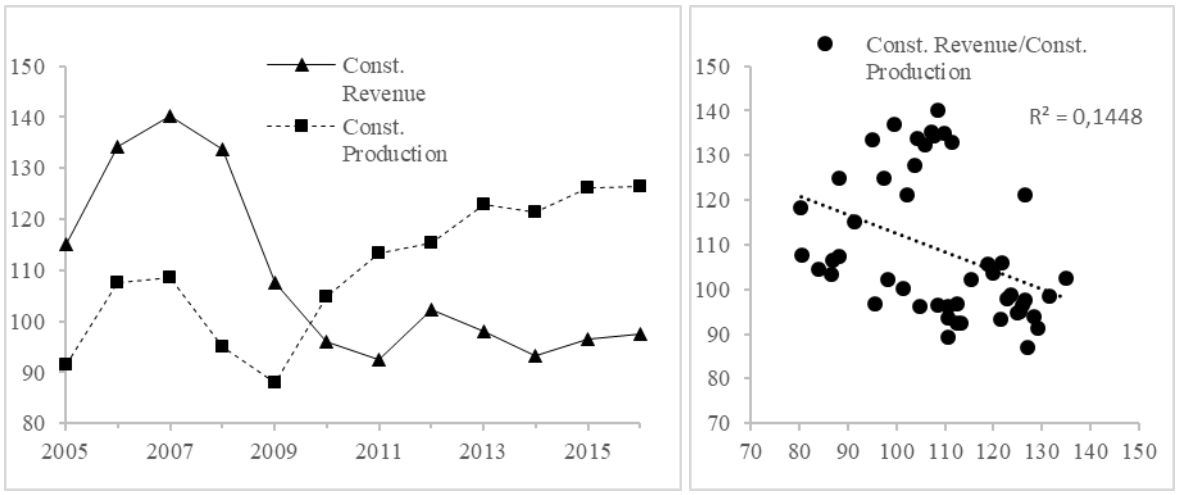

Figure 1a-b: Time series and scatter diagram of the construction revenue and production, respectively.

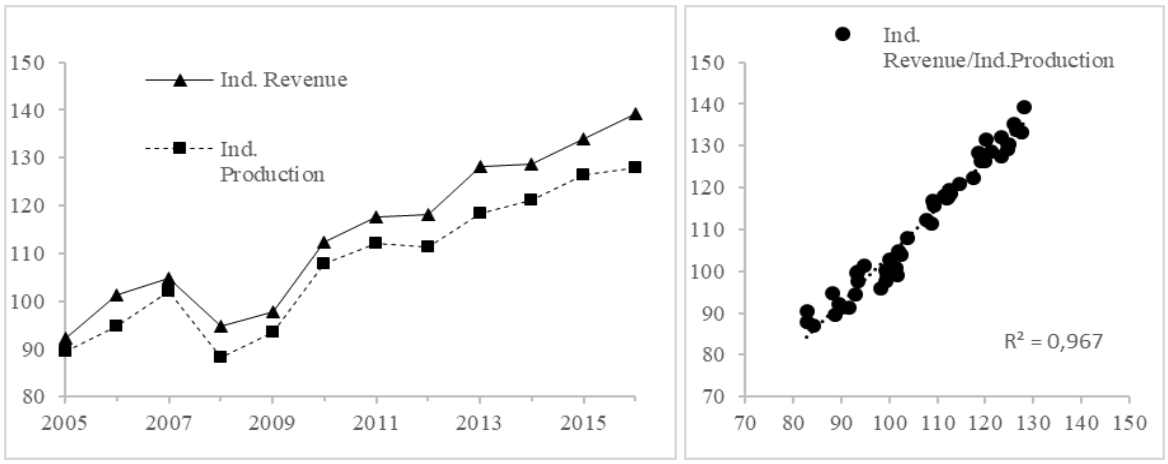

Figure 2a-b: Time series and scatter diagram of the industry revenue and production, respectively.

The negative effects of the 2008 global financial crisis in terms of production and turnover can be tracked for the construction sector in Figure 1a. Both revenues and production reach their peaks in 2007. The construction production index reaches its low in 2009 after two years-long sharp decreases caused by the 2008 crisis, then starts to recover in 2010, and

follows a decreasingly growing pattern until 2016. When the construction turnover index is compared with the construction production index, it reaches its low with two years lag in 2011, thereafter it follows a sideways trend, and it has not given any recovery signal with real prices yet. Figure 1b shows no significant relationship between production and turnover using a simple linear regression model. Moreover, it can be observed that the more the production of construction increases, the total revenue decreases. It means the marginal revenue of the construction output is negative and the average revenue is decreasing. In the short run, an entrepreneur can bear the loss in revenue, but in the long run, producing with negative marginal revenue in a market cannot be maintained without government incentives. Meanwhile, negative marginal revenue expresses the inelastic demand for the construction outputs such as housing and infrastructure. The results show that transferring more factors of production from other sectors to the construction sector or excessive allocation of scarce resources to the sector does not maintain the desired turnover in real terms.

Figure 2a exhibits the industry production and turnover index, both indices reach their peaks in 2007, and after a one-year decrease in 2008, they show steady recovery and follow an almost linear up-trend. This situation implies the industry recovers faster and more proper way when compared with the construction industry. Moreover, a significant relationship between production and turnover can be observed in Figure 2b using a simple linear regression method. This result shows that the marginal revenue of industry outputs is positive in that the increase in industrial production positively affects total revenue.

The Gross Domestic Product and the Share of Construction

The construction sector in Turkey shows rapid growth starting in 2002, just after the 2001 national economic crisis until 2018. The share of the construction output in the GDP increased by 93% and increase from 3.91% in 2002 to 7.53% in 2017 as represented in Figure 5. The global economic crisis in 2008 disturb this process but the sector accomplishes recovery stronger. On the other hand, Figure 3 shows that the share of the industry (excluding the construction sector) remains decidedly fluctuating in a narrow band between 17.69% and 20.04%. The government policies that put the construction sector at the centre of economic growth and development support this situation. The sector is perceived as a “locomotive of the economy” between 2002 and 2018.

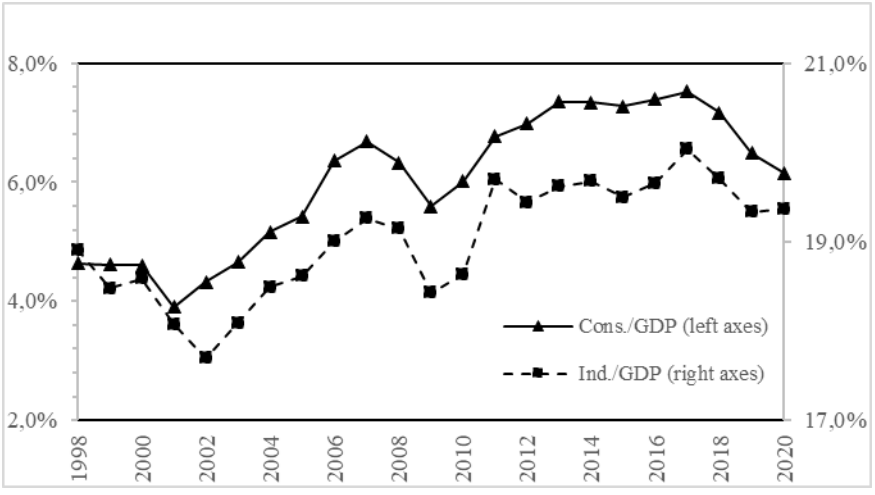

Figure 3: The share of the construction and industry output in the GDP.

Figure 4 exhibits the time-series graph of the GDP (divided by ten to establish scale) and the construction output with seasonally and calendar adjusted 2009 constant prices in Turkish Lira. The GDP and the construction output follow approximately the same pattern until 2018. The devastating effects that began with the Turkish currency and debt crisis in 2018 and continued with the Covid-19 pandemic still affect the sector very deeply. The level of sectoral production began to separate from the economy more significantly than in the economic crisis of 2001 and 2008.

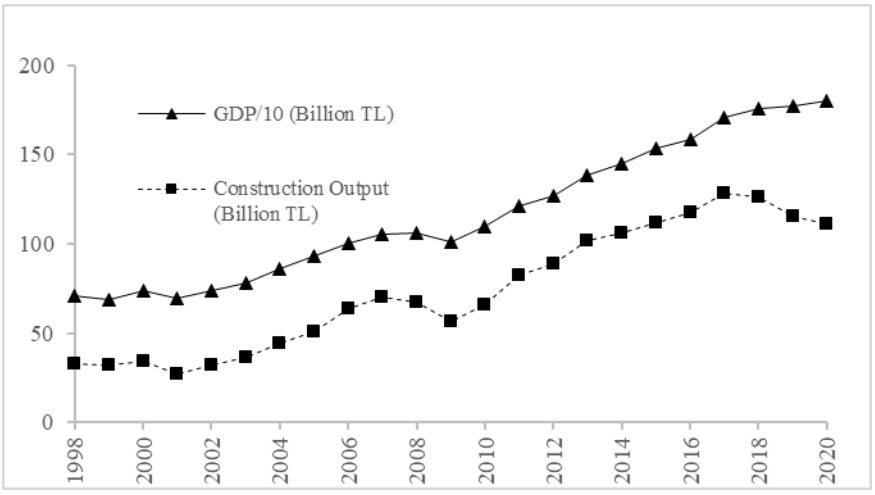

Figure 4: The construction output and the GDP in the Turkish Lira.

However, as can be seen in Figure 5a, the percentage of changes in construction output tends to exaggerate, compared to the GDP, during the booms and slumps accordant with Lewis (2004). On the other hand, Figure 5b represents the percentage of changes in the industrial output that almost follows the GDP. Moreover, no significant lag between the GDP and the construction output is observed yearly. It should be underlined that Birgonul and Ozdogan (1999) observe a nine-month lag in the responsiveness of the construction output in Turkey. That means the construction sector responds rapidly to changes in the economy.

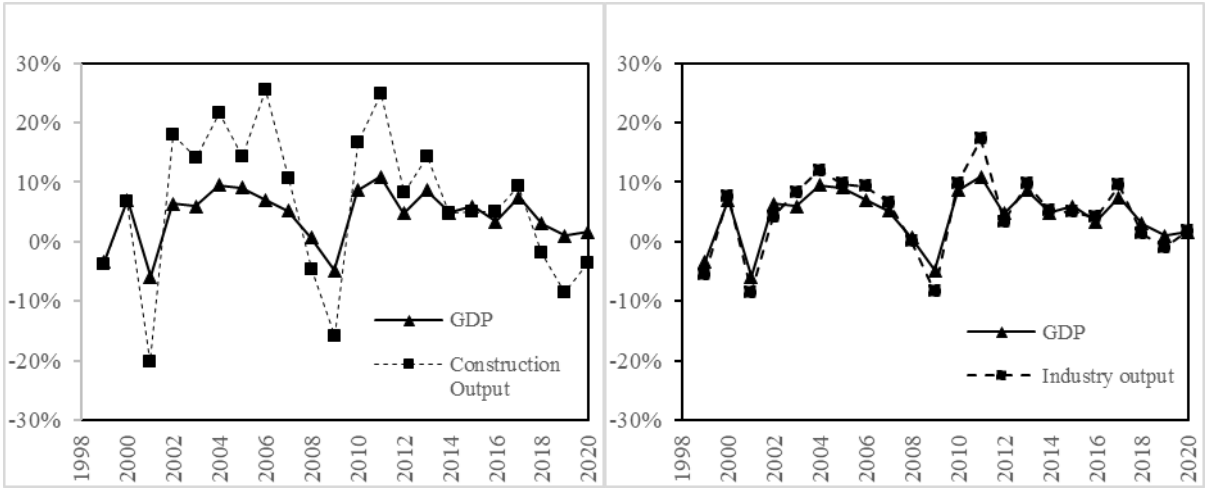

Figure 5a-b: The share of construction and industry in GDP, respectively.

The first reason behind this may be the impact of the public sector's increasing demand for infrastructure projects right after the economic recessions. However, following an economic recession, it may not be easy to find a source of funding for capital-intensive infrastructure projects. In order to overcome this financing problem, governments frequently use the Public-Private Partnership (PPP) as a procurement method. Thus, it transfers financing responsibility to the private sector and supports concessionaires by providing various kinds of guarantees that can be a heavy burden on the public budget. Governments also utilize the output of these projects to consolidate their political position. However, the combined effects of the 2018 crisis and the Covid-19 pandemic on macroeconomic conditions, capacity issues, and previously provided guarantees subject to debates prevent the Turkish government to realize controversial, new infrastructure projects such as the Channel Istanbul Project, so the contribution of the public procurement to the construction demand remains limited.

The second catalyst may be the government intervention in monetary policy through the adjustment of interest rates. The Turkish government tried to keep the demand for housing alive by suppressing the interest rates in the last two quarters of 2020 regardless of the inflation rate and market dynamics. They succeed to create excessive but temporary demand for housing, however, this intervention resulted in heavy damage to the national economy in terms of the exchange rate and inflation. Moreover, increasing demand for mortgage loans with low-interest rates, not by economic conditions, may raise the non-performing loan ratio of the banking system and may cause trouble to the accessibility of financing sources in the future. Consequently, the government had to change all its economic administration and started the raise interest rates dramatically to stabilize macroeconomic conditions.

It should be noted that uncomprehendingly recipes to recover the economy through the construction sector started to become invalid. The breakdown in the construction output level in 2018 differently from the whole economy reveals the need for structural change in the Turkish economy. The “locomotive of the economy” starts to lose its repulsive effect on the economy. The infrastructure investments beyond the economic capacity, limited import opportunities, and low value-added arise from the nature of the construction output, excessive sensitivity to demand conditions, and government interventions to macroeconomic conditions to create demand for the sector begin to cause damage to the economy.

The Construction Labor Force and the Employment

The unemployment and growth rate are the two important indicators that are frequently tracked to monitor the economic outlook of a country. A successful economic policy should focus on both growth potential and employment generation capacity.

The unemployment rate of Turkey follows an increasing trend since the annual average rate of 8.5% was achieved in 2012. This increasing trend also breaks upward in 2019 and reached 13.6% due to the effects of the Turkish currency and debt crisis in 2018 and remains approximately at the same level as the devastating effects of the Covid-19 pandemic on the economy. Figure 6 shows the changes in the unemployment rate, construction employment rate, and industry employment rate (second axes) between 2005 and 2020. Turkstat announced that due to revisions on both population calculations in 2008 and household labour surveys in 2014, it might be deceptive to compare data before and after 2004 (Turkstat, 2020). More notably, the new calculation method has been established at the beginning of 2021, the adjusted series has only been available since 2014, and even worse no guidelines have been

published on how to connect the old and the new series. It is a matter of public debate that these frequent changes made by the TurkStat are a move of manipulation of political power, and the lack of baptism of the institution is questioned.

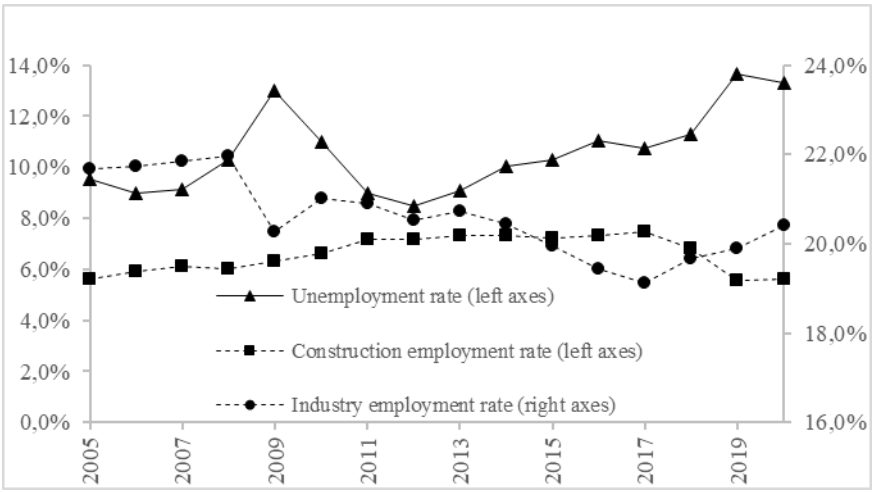

Figure 6: The unemployment rate, the construction, and the industry employment rate.

The construction employment rate increased from a 5.6% annual average rate in 2005 to 7.2% in 2011 and preserve its level until 2017, however it decreases sharply to 5.6% with the effects of the Turkish currency crisis and the Covid-19 pandemic. In the same period, the industry employment rate fluctuates between 19% to 21% annual average rate but shows a regular increase when the construction employment rate decreases significantly between 2018 and 2020.

Figure 7 represents the time-series graph of the construction output and construction employment rate between 2005 and 2020. The construction employment rate and the construction output increased with the same pattern from 2005 to 2011 only disturbed in 2009 by the effects of the global financial crisis in 2008. However, after 2011, the construction employment rate fluctuated around 7.3% although the construction output continued to increase. Since 2018, there has been a regular decline in construction output, while construction employment has fallen by almost 25%. The dataset reveals the differences in the 2008 global financial crisis, the breakdown in the construction sector starting with the Turkish currency crisis and continuing with the Covid-19 pandemic caused more disruptive processes in the construction labour market.

Figure 7: The construction output and the employment rate.

Although the major central banks have resorted to similar expansionary monetary policy tools which were implemented to overcome the 2008 global financial crisis, the depreciation of the Turkish Lira that started in 2018 combined with pandemic restrictions, the resulting increase in the inflation rate, and the insistence behaviour of the CBRT to hold interest rates low could not provide an appreciate environment for the construction sector to support economic growth and to generate employment. Moreover, the temporary, and part-time nature of the construction labour force worsens this situation in terms of unemployment. However, the economic policies established to keep the construction demand alive have some negative consequences if they are not matched with the facts that the economy face. Worse still is that wrong and populist decisions also have an extremely negative impact on the rest of the economy. Moreover, these decisions result in higher inflation, higher interest rates, and a long economic recession.

The Gross Fixed Capital Formation and the Construction Output

Gross fixed capital formation (GFCF) includes all expenditures on fixed capital goods by the public and private sectors. GFCF has two main components: construction, machinery, and equipment. There is a common opinion that emphasizes the strong relationship between economic development and investment level and many studies observed that in developing countries, nearly half of the investments in GFCF comes from construction (Gruneberg, 1997; Hillebrandt, 2000). For that reason, it is necessary to examine the share of construction in GFCF. Figure 8 shows the share of the GFCF in the GDP and the level of GDP.

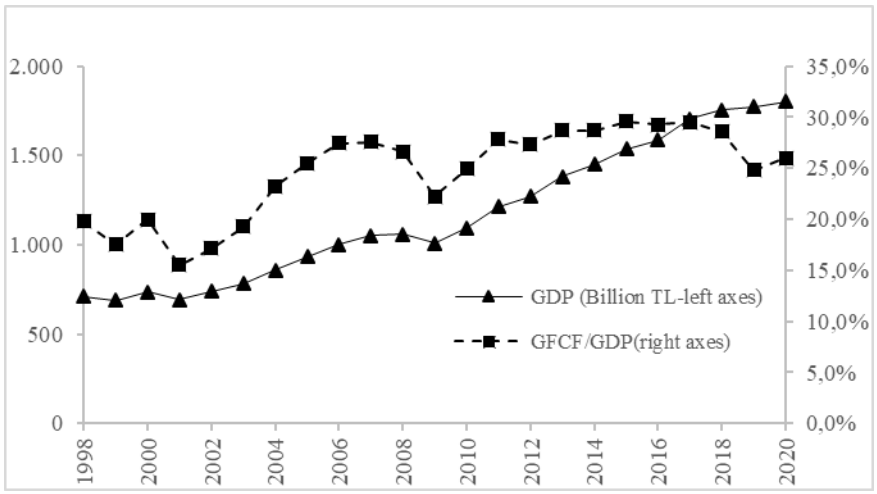

Figure 8: The GDP and the share of the GFCF in the GDP.

The share of the GFCF in the GDP is influenced negatively by the economic crisis in 2001, 2008, and 2018 and bottomed in 2001, 2009, and 2019, respectively. The deteriorating environment of economic trust, rising interest rates, and negative future expectations can be counted as the main reasons. However, the level of investments responds immediately after these breakdowns. During the years that the economy grows, the share of the GFCF in the GDP revolves around 28%. However, these temporary but sharp decreases in the share of GFCF do not have a significant effect on the GDP for that year since the outputs of the investments emerge in the upcoming years. The share of construction in the GFCF between 2009 and 2020 can be observed in Figure 9. The level of construction investments in the GCFC fluctuates around 50%-55% level similar to previously addressed studies for developing countries.

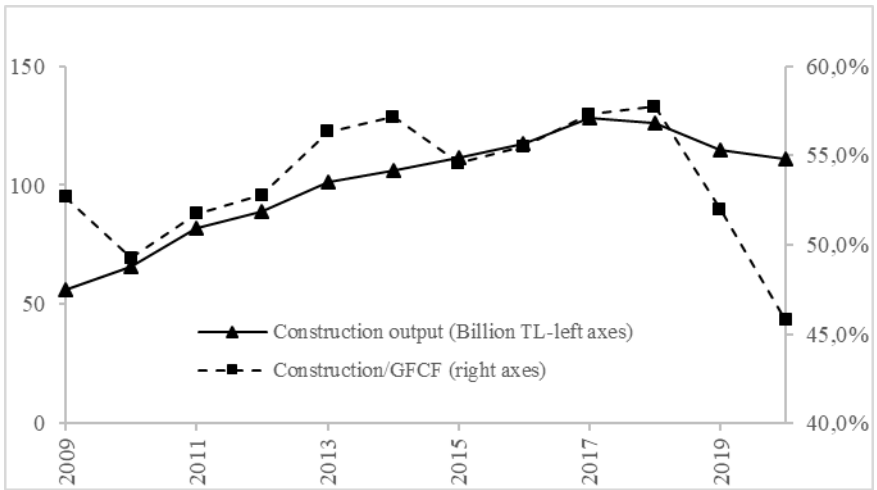

Figure 9: The construction output and the share of construction investments in GFCF.

The negative effects of the 2008 global financial crisis on investments last longer and it bottomed in 2010 with a one-year lag compared with the share of the GFCF in the GDP. A similar scenario is happening after 2018. The GCFC bottomed in 2019 and gives a signal to recover from the bottom despite the ongoing effects of the Covid-19 pandemic on the economy. On the other hand, the construction investments in the GFCF decrease to a lower level in 2020. These observations address that construction investments still suffered after the

2018 currency crisis and decreased by approximately 45% level. It shows that the capital flow to the sector through investments does not provide the expected GDP growth.

Discussion

The evaluation of the Turkish construction industry and its interactions with the Turkish economy during the 2000s are analysed using statistical data published by TurkStat. Economic and social developments and their global impacts make the 2000s an attractive period to investigate the pros and cons of neoliberalism. The global financial crisis in 2008 and the Covid-19 pandemic in 2019 affected the global economic environment as well as the Turkish economy very deeply. Moreover, the national economic crisis in 2001 and the Turkish currency and debt crisis in 2018 increased the burden on the economy. Households and companies have faced rising interest rates, exchange rates, and inflation. In addition, economic stability has deteriorated, confidence in the economy has shrunk, and the country has entered a period of difficulty attracting foreign investors.

The construction sector, whose share in the GDP decelerated to 3.91% in 2002 due to the effects of the national economic crisis in 2001, grew between 14% and 25% annually in the period up to the 2008 global recession and increased its share to 6.68%. There are two main contributors to this fact. First, the high growth rates that Turkey caught after the national economic crisis in 2001 with a steady and relatively low inflation rate caused a decrease in interest rates and an increase in housing demand. The young population of Turkey had a catalyst effect on this process. Second, various kinds of infrastructure projects that were held or excessively supported by the government helped the construction sector to reach extreme growth rates. Although the 2008 global recession briefly interrupted this process, the construction industry has been widely used as a tool to overcome economic recessions due to its strong linkages with other sectors and potential to absorb unemployment. This attitude has been adopted to boost markets after the 2001 national economic crisis and the 2008 global recession by the Turkish government. Moreover, the government has utilized the visible output of the construction sector to strengthen its political position. The governments put into action required legal regulations, provided incentives to the private sector, demanded infrastructure investments, and adjusted interest rates to raise household demand for the housing sector. As a result, the construction sector was mentioned as a “locomotive sector” of the Turkish economy between 2003 and 2017.

However, the excessive support to the sector in terms of the interest rate adjustments and the government demand for infrastructure projects, and the excrescent resource allocation in terms of factors of production such as the capital flow to the sector through investments and the effort of entrepreneurs to enter the sector have not provided expected macroeconomic stability and have accompanied much social and environmental debate. Interest policies that do not coincide with inflation dynamics to encourage construction investments and keep household housing demand alive combined with political and social disputes resulted in an enormous increase in inflation and exchange rate after 2018. Besides that, shifting the leading role in the economy from the production sector to the construction sector, sudden changes in economic management, inconsistent foreign policy actions, and discussions about law and democracy in domestic policy led to a departure from the economic development after 2012.

As a result, in 2018, the construction sector “the locomotive of the Turkish economy” crashed to the exchange rate, inflation, and interest rate spiral. The repayments of private companies

in their foreign exchange debts, the demand for foreign exchange from the household with increasing inflation, controversial issues in foreign policy, and poor economic management turned into a currency and debt crisis. The Turkish Lira lost its value by approximately 130% against the U.S. dollar from the beginning of 2018 to the end of 2020 (CBRT, 2020). This dramatic increase in foreign currency has been affecting traumatically the economy in terms of inflation and interest rates. The upside attacks on the level of exchange rates trigger inflation since the degree of exchange rate pass-through to inflation is relatively high in the Turkish economy. An increasing trend in inflation rate enhances interest rates and the demand for mortgage loans by household decreases significantly. Moreover, instability in the exchange rate and interest rates shakes the trust in the macroeconomic environment and causes a decrease in the level of foreign investments and finance, especially in long-term and complex infrastructure investments. Even worse, the government's persistent opinion of blaming the cause of rising inflation as high-interest rates and its move to further interest rate cuts caused a much bigger exchange rate shock than in 2018. The Turkish lira has lost around 95% of its value against the dollar in just 3 months (CBRT, 2021). Consequently, the government, economic administration, and business world highly debated shifting the direction of the economy from construction to sectors producing value-added products, yet no concrete step has been taken.

The negative and weak correlation between construction revenues and construction production in 2005-2016 signals inefficient production in the sector. Simultaneously, manufacturing revenues and production show a positive and extraordinarily strong correlation. However, construction production rises from approximately 50 billion U.S. dollars to 120 billion U.S dollars. Unfortunately, although the construction sector contributes to the GDP growth during this time, there is no mention of sustainable economic development and continued macroeconomic stability due to the inversely proportional income-production function.

Another important finding that needs to be highlighted is that the construction industry shows a cyclical characteristic. In other words, the sector is impressionable to macroeconomic conditions. During the recessions of 2001, 2009, and 2018, the sector output showed a faster decline than the economy overall. Although the sector recovered its output very quickly after the economic recession in 2001 and 2009, it has not shown any recovery signal in terms of production and labour force in the period starting with the 2018 exchange rate and debt crisis and continuing with the Covid-19 pandemic and the 2021 exchange rate shock. One of the reasons behind this is that despite the economic growth that has been achieved, the relationship between inflation, the exchange rate, and the interest rate has been destroyed by inconsistent monetary policy actions. These policies i.e., decreasing the interest rates incompatible with inflation dynamics were followed to raise household demand in the housing sector and attract investments, however, they cost a heavy bill to the entire economy. Moreover, the need for external financing sources of the sector to finance “megaprojects” in a volatile exchange rate environment and the redundant guarantees that have been provided to these projects by the National Treasury cause a heavy burden on the public budget. Even worse, the allocation of scarce resources in terms of factors of production immoderately to the construction sector may postpone real economic growth.

From the labour market side, it can be observed that the increase in the construction output generates employment until 2011. However, the construction employment rate, which reached a certain level in 2011, has not been able to respond to the increase in the construction output between 2011 and 2018. From 2018 to the present, with the effects of the 2018 Turkish

currency and debt crisis, the Covid-19 pandemic, and the 2021 exchange rate shock, the construction employment rate crashed by around 23% while the construction output loses 13%. The production sector employment rate showed a 7% percent increase in the same period. The different behaviour of the changes in the construction and the production sectors' employment rate reveals the cyclical character of the construction sector once again.

Consequently, the monetary policies have been adjusted to support the sector, and the contingent liabilities to be undertaken raise debates about how sustainable growth can be achieved in an economy where the construction sector is a "locomotive". Moreover, the employment generation in the construction sector is a fact but not unlimited and it is highly sensitive to macroeconomic conditions. Unfortunately, many companies operating in other sectors also shifted their activities to the construction sector to benefit from the government incentives and the high "rent" revenues offered by the construction market. Given this situation and the excessive capital flow through the infrastructure investments to the construction sector has not been realized the expected economic growth and the real economic growth has been offset. In addition, the economy struggles to catch a sustainable growth rate and remains very fragile.

Conclusion

In this study, the relationship between the construction sector and the economy was examined through the case of Turkey between 2000 and 2020 within the framework of two main concepts in the construction economics literature. The first one highlights the construction sector as the driving force of the economy, the sector's backward linkages with the economy, and its potential to absorb unemployment. The second and opposing one focuses on issues in the sector's relationship with the economy, such as its sensitivity to macroeconomic conditions, the problem of idle capacity, and excessive resource allocation.

Classical economic theories emphasize that the main goal of economic development is the achievement of economic growth. Although economic growth is necessary for development, it is not enough on its own (Todaro & Smith, 2015). It is a question mark whether an economic model that focuses on the construction sector is sufficient to achieve this sustainable economic growth. In order to eliminate this question mark, various macroeconomic variables have been selected, analysed, and interpreted logically.

The results show that especially in periods when the construction production-turnover ratio is negative, that is, there is an inefficient production in the sector, transferring more resources to the sector does not provide the desired sustainable and real economic growth. In addition, monetary policies that do not coincide with economic realities to keep demand for the sector alive make the economy fragile and cause currency shocks in countries with high current account deficits, such as Turkey. The high inflation caused by these exchange rate shocks reduces the purchasing power of households and restricts their access to goods and services. This, in turn, decisively affects the quality of life, which is one of the goals of economic development.

In order to prevent all of this, the visible outputs of the sector should not be used as a tool for populist policies. In addition, rent-oriented investments and capital transfer should be prevented and sector outputs should be produced in accordance with the needs of the economy. Although the high financing required by infrastructure projects is transferred from

the public to the private sector through procurement methods such as PPP, the guarantees provided to these projects should be limited in a way that eliminates both the risks on the public budget and the exchange rate risk carried by the private sector.

The data used in this research is mainly obtained from the TurkStat since the TurkStat share limited and not detailed raw data with other data providers such as the OECD, the Eurostat, and the World Bank. The sudden changes in the calculations or the data collection methods and limited or no information about how to link the previous data with the new ones raise some questions and undermine the credibility of the institution. For these reasons, further studies should be conducted with more continuous data for a longer period. Last but not least, the relationship between these indicators should be analysed more deeply from the perspective of causality to validate these findings.

Abstract

Metaverse is a sort of virtual world that creates an atmosphere for people to interact, participate in games, and collaborate. Beyond the unconstrained atmosphere of Metaverse, the function of "make money" has great financial potential for both investors and users. One of the uses of this financial potential is to own the land like a real estate in the "Metaverse" universe and to make profit by designing those plots. For this reason, the factors that determine the land and real estate prices in Metaverse also become crucial issue. This study focuses on the determining factors of land and real estate value on both physical life and Metaverse. This study explains the land and real estate value concept with its factors with traditional approach of physical world. Predictions on real world draw the potentially related factors determining land and real estate value in Metaverse. Collected data using the comparative research method primarily by observation and literature review, and the main goal is to determine similarities and differences between real-world and Metaverse. The significance is understanding for investment values and logic of applications that allow "land-based" crypto trading in the Metaverse, which is seen as the technology of the future.

Keywords: *blockchain technology, land value, metaverse, real estate value*.

Introduction

The metaverse is a computer-based virtual environment where all physical objects, services, families, buildings, world maps, and the universe are located (Brody, 2022). One of the main promises of virtual plots and other purchased virtual assets in the Metaverse is to make money. In addition, since these platforms allow their users to work together and interact, the economic benefits mentioned have potential for various sectors or investors. There have been many studies on concerts, training, and shopping events that are held and have the potential to be realized on Metaverse platforms, but there is very little content about the plots that provide the basis for these sales and create the atmosphere of the productions. In this study, the factors

[1] This paper is based on the author's Master of Architecture thesis.

that determine the financial value of the land on Metaverse are compared with the factors in physical life and evaluated on the examples of three Metaverse platforms.

According to the result obtained from this study, the land and real estate valuation logic in the physical world is similar to the virtual world, but it does not work the same as there are disadvantages such as distance, cost, construction costs, and geographical limitations arising from physical life in the virtual world. On the other hand, there are critical risks such as the volatility of the value of Cryptocoins and the sudden depreciation of the land and real estate owned, despite the possibility of gaining popularity of new platforms to be produced in the future, as Metaverse technology has not yet impacted all our lives and has not been adopted.

The first hypothesis of the study is that the economic values in the physical and virtual worlds will be determined by the value of the currency valid in that world, which is cryptocurrencies in the Metaverse example. At this point, it should be noted that the price of cryptocurrencies is not as stable as the currencies used in physical life. The second hypothesis is that while locational values are important for land valuation, proximity to "central" or "popular" areas that add value to land in the physical world by removing geographic restrictions should not add financial value to land. The idea that physically accessible land is more expensive doesn't make enough sense. Because in the virtual world, users have a feature such as "teleport". For this reason, it can be assumed that physical distances will no longer be an issue. Third, the size of both land in physical life and the Metaverse universe will have a positive impact on land prices. Finally, how "rare" a piece of land is not a comparable issue for the two land types, virtual and physical.

Theoretical Background of the Study

Blockchain technology has evolved since the report on Bitcoin published by Satoshi Nakamoto in 2008 (Nakamoto, 2009). Bitcoin is a digital currency in a decentralized system of networks. It is not real money or commodity value but is somewhere in between, independent of any government or other economic authorities (Baur et al., 2018). Nakamoto (2008) describes Bitcoin as an electronic cash system. According to this definition, Bitcoin can also act as a currency. However, on the other hand, it can be defined as an "asset" as it is an alternative currency. It is not just a currency, but a medium of exchange, a unit of account, and a store of value. In this case, it differs from the concept of "currency" as we know it (Baur et al., 2018).

The economic opportunities offered by blockchain ecosystems are expected to exceed a trillion-dollar market (Bunshnell, 2022). With the correct implementation of the blockchain system, stakeholders can optimize their own activities in line with their own interests and improve service quality (Pazaitis et al., 2017). In that case, it can be said that one of the most important business items of a properly implemented blockchain technology is the establishment of a system-related pricing logic (Lee et al., 2021). Demands for blockchain are evolving and increasing as it creates new business sectors. The scalability logic of blockchain makes it a new ecosystem while improving existing systems (Lee et al., 2021). In this way, new and more reliable business models are proposed.

With the development of technology and Bitcoin, the use of Metaverse has become a growing possibility (Lim et al., 2022). Metaverse refers to a universe powered by the blockchain (Zhao et al., 2022). It is a three-dimensional world that refers to humans and the virtual world they

live in. Thanks to these features, it expands the field of activity of people/users by solving the constraints related to time and resources by getting rid of the problems caused by nature (Momtaz, 2022). With the accessories and other digital assets that users purchase for their avatars, which they use to express their own characters, online virtual asset trading has already begun to change (Fernandez & Hui, 2022). One of these commercial products is land and real estate that allow avatars to spend time

Non-fundable tokens, such as NFTs used within Decentraland, are important not only for online commerce but also for the "Internet of value", where the perception of "value" is reshaped (Goanta, 2020). The Metaverse is closely associated with cryptocurrencies. For example, in The Sandbox, the cryptocoin SAND and in Decentraland, the cryptocoin MANA are important values for purchasing (Vidal-Tomás, 2022).

This study, while determining the pricing determinants of the "lands" traded on Metaverse, makes a comparison with the physical land value determinants known from daily life. It is aimed to determine the tendency of investors and company owners towards the mentioned product by researching the pieces of land sold as Non-Fungible Tokens (NFT) and their market conditions. A framework is presented to understand the relationship between the summary of the determinants that determine the value of physical plots in the literature and the pricing determinants used in the Metaverse. This study is important for investors and potential investors to understand the financial activities that take place on the blockchain. Moreover, due to the size of the NFT asset market and the growth rate it has experienced in recent years, it is important to investigate this topic.

Methodology

With the innovation of Metaverse technology, this study adopts an exploratory research approach, as there are very few studies on the values of the land here. With this methodology, topics that have not been studied before are examined. The steps of the study are to reveal the factors that determine the financial value of the land in Metaverse by comparing it with the physical life through literature review and examples, respectively.

The steps of this approach are as follows. First, blockchain technology, Metaverse, and NFTs will be defined. Based on these definitions, a literature review on Metaverse plots, which are seen as a source of financial income and a review of the three most popular platforms, has been conducted. Meanwhile, the factors that determine land prices in physical life have been determined with the help of the literature, and the physical and virtual land price determinants have been compared. The factors determining the land value in Metaverse were obtained by using a qualitative and exploratory approach (a comprehensive literature review) since the subject in question is new, the application examples are not common, and it promises to be a popular research area. In this way, it aims to establish relations between the land and real estate valuation criteria in the Metaverse platforms, which are the subject of the research, and the criteria in the physical world. The aim of this study is to reveal similar or different land value determinants in Metaverse and physical world lands by comparing them with data in physical life to explain the concept of NFT and the existence of virtual lands and their trading processes. The second is to shed light on Metaverse investors and potential investors by informing them about the details of the issue. The methodology of the research is visualized in Figure 1.

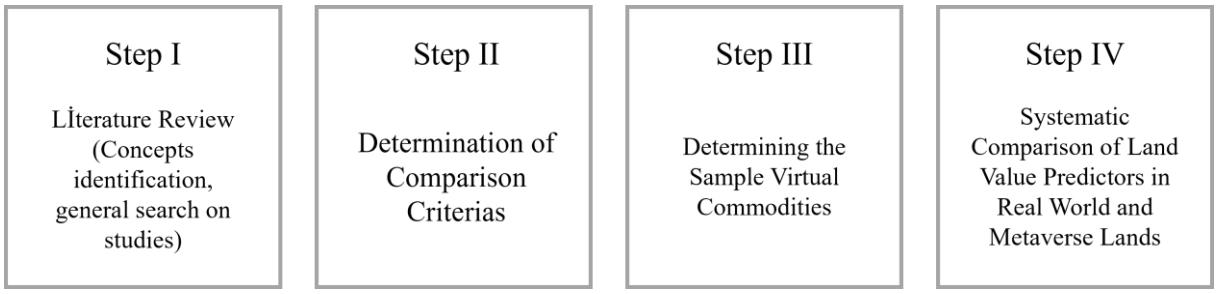

Figure 1: Research methodology.

Lands as Non-Virtual Commodity

In this study, land will be considered a non-virtual commodity and will be associated with the factors that determine the value of land in virtual worlds. For this reason, first, "values" in the physical world gain importance.

Considering that houses consist of reproducible concrete structures and non-reproducible pieces of land, it can be said that the main issue that determines the value of the house is the location of the house, namely the land, and this land capitalizes the market value of the house. In this case, it can be stated that the economic benefits to be produced by the consumption objects built on that land are an important input to understanding land values in the physical world. On the other hand, Davis and Heatcote state that even if the land and the structure on the land are bought and sold together in the housing market, the pricing of the structures and the land will give different reactions to the market conditions (Davis & Heatcote, 2007). According to the study of Yalpır and Bünyan Ünel (2016), the factors that determine the value of land in the physical world are examined under four headings. Legal factors: zoning status and locational factors are expressed as whether the parcel is on the corner or not, whether it is an intermediate parcel, the length and number of facades, the geometric form of the parcel, technical infrastructure, access to roads, and the slope of the surface where the parcel is located. Spatial characteristics are proximity to health, education, security, and other facilities, proximity to public transport facilities, and proximity to waste collection areas. Finally, when local factors are considered, first, population, neighborhood relations, construction density, the development potential of the region, rent, geological characteristics of the region, climate, and pollution rate are expressed. Based on the literature review, the factors that determine the value of the land in the physical world are determined as follows: Zoning and restrictions considered as legal factors. On the other hand, corner parcel, facade length, geometric shape, and technical infrastructure (roads and slope) are the physical factors. Distance to health, education, public institutions, and safety; distance to shopping malls, cultural centers, entertainment centers and green areas; distance to public transport points; distance to waste areas are locational factors. And lastly, population, migration, neighborhood relationships, build-up density, development potential, rent, money making potential, geological features, climate, pollution, considered as local factors.

Virtual Lands as an NFT

Three-dimensional spherical universes have gained popularity in recent years. Virtual worlds have become advantageous, especially by overcoming the limitations created by the

geographical problems of physical life, such as the need to commute. While these environments provide the user with various possibilities, such as elaborately designed graphics, animations, and voice communication facilities, they also have their own virtual economies and currencies (Partala, 2011). Most of the research on NFTs (Ko et al., 2022; Pinto-Guti'errez et al., 2022; Karim et al., 2022; Dowling, 2022) investigated their economic values and characteristics, while a few articles (Goldberg et al., 2021; Dowling, 2022; Nakavachara & Saengchote, 2022) conducted studies on real estate and land on these platforms. Kampakis et al.'s (2022) study examined NFTs as alternative investment instruments. Based on the period in which the research obtained its data, it was concluded that NFTs are an investment instrument that provides financial gain and has its own risk profile.

Designers in virtual worlds take the physical world as their inspiration. Objects, environments, and even all objects in physical life are modeled, and adapted versions of them are created in the virtual world. These designs are simply a three-dimensional re-creation of the physical world in the virtual world. In this case, it can be stated that the similarity of virtual and physical worlds is highly influenced by each other because of their parallelism (Berger et al., 2016). In this case, it can be said that most of the issues that can be discussed and interpreted for the Metaverse platform have their roots in the physical world and the basic logic of these two worlds affect each other. Dowling et al. discovered in their study that the virtual land they examined has the equivalent of a living physical world in the real estate market (Dowling, 2022). In order to determine the land value in the Metaverse, first of all, the factors that determine the value of the NFTs, which are the equivalent of those values, should be known. NFTs earning commercial profits on the Metaverse through programs between applications is a token of value for the market (Momtaz, 2022). According to some academic studies, there are many factors that determine the value of NFTs. One of them is the "scarcity" value, which will contribute to the social status of the owner of the NFT (Lee et al., 2021). On the other hand, being close to the city center, plazas, or business centers for Decentraland parcels is one of the features that increases the value of NFT (Goldberg et al., 2021).

The Sandbox is a universe built on Ethereum blockchain technology. NFT, which represents the ownership of virtual land here, is LAND (Nakavachara & Saengchote, 2022). Here, users can buy LAND. LANDs are the unique digital plots here. These plots come together to form the Metaverse map (VISUAL). All plots here are tradable values (Nakavachara & Saengchote, 2022). There are two main reasons that push users to buy land in Sandbox, OVERLAND, and Decentraland. First, it is aimed at generating income from visitors by establishing various interactions on LANDs; secondly, purchased NFTs can be resold at higher prices in secondary markets (Nakavachara & Saengchote, 2022).

Comparison of Land Value Determinants on Real World and Metaverse

In the Metaverse, the potential income of the land represents the utility of the land and expresses the land value (Huber, 2022). In studies conducted on some platforms in Metaverse, the factors determining the land and real estate values have been explored by many studies (Dowling, 2022; Guven & Ercan, 2022; Goldberg et al, 2022; Nakavachara & Saengchote, 2022; Schonbaum, 2022). The factors identified according to these studies are as follows: cryptocoin's value, location, size of the parcel, popularity, scarcity, memorability.

***Cryptocoin's value*.** The study of Nakavachara & Saengchote (2022) emphasized that the currency used in Metaverse can have an impact on users' buying and selling transactions. For

example, when SAND gains in value significantly compared to other cryptocurrencies, SAND holders will feel richer and will be more willing to buy this cryptocurrency. On the other hand, according to Bunshnell's (2022) research, blockchain systems cannot be protected from global economic forces as they are not resistant to traditional macroeconomic leverage as in global capital markets.

Location. According to Goldberg et al., parcels close to popular buildings, districts, and streets may be affected by the spillover effect of the activities there, and in this way, they may be flooded with visitors (Goldberg et al., 2022). On the other hand, there is no spatially natural reason why one piece of land should be more valuable than another. Because avatars can be teleported in virtual worlds (Morris, 2022). While location is seen as an important factor for virtual lands, it's about being "close" to a place. However, on a platform where users don't walk or travel, "proximity" may not mean anything. In this case, it should be considered that the position change that the teleportable users can perform in one second is not directly related to the distance. On the other hand, the "location" issue starts to gain importance as an activity carried out on a parcel close to or adjacent to a parcel of land will attract users to interact with that area. Hissong stated that plots near the land owned by American rapper Snoop Dogg were selling for much higher prices than expected (Hissong, 2021). Moreover, if you are a fashion entrepreneur, you can benefit from being involved in the digital space where Gucci is located. Moreover, if you want to compete with this brand, you want your land to be as close to that plot as possible (Krion, 2022). This distance will benefit you. Contrary to this view, according to Morris, the idea that geographic space in the virtual world will gain value in the same way as land in the real world is erroneous. Land values in the physical world increase depending on location and utility. Distances are important. Opportunities to overcome those distances are important. It is important in what conditions and when you go to a place in the physical world. These are geographic facts, but in the Metaverse, all distances are faked (Morris, 2022).

Size of parcel. In all three platforms, sales are made in accordance with the determined parcels. The plots used maps are divided into squares. The sales of the parcels are made as 1x1, 3x3, 6x6, 12x12 and 24x24 units. Pricing for each unit is different.

Popularity. Land and real estate in the physical world can be driven by opportunities and constraints. These values become more expensive with their proximity to utilities, communities, and industrial centers, and investors build taller structures to offset the rising density of these regions, which in turn offsets rising land costs (Brody, 2022). Users and investors tend to prefer plots where people are more likely to randomly encounter each other. For this reason, plots close to popular structures are preferred (Goldberg et al., 2021). As the number of people in a region increases, the economy revives, more jobs are created, more people are attracted, and the liquidity of the market increases (Huber, 2022). On the other hand, there is always a risk that new platforms will emerge in the Metaverse supply, but these new platforms cannot be valuable simply by offering more land. These lands are worthless if there is no liquidity, reputation, or utility (Huber, 2022). In this case, it can be stated that the use values and popularity of the owned lands are also important.

Scarcity. Scarcity has a positive correlation with the selling price and a negative correlation with the number of sales (Mekacher et al., 2022). Rare land parcels produced in the metaverse have different prices than rare parcels in real life. While the prices of rare assets in physical life are determined by a market mechanism, prices for artificial rare assets may be limited because, when necessary, an infinite supply of "scarce" assets can be offered (Brody, 2022).

Memorability. According to Goldberg et al., "rememberability" is also a value specifier for virtual lands (Goldberg et al., 2022). This title is about the memorable names of the plots and other memorable factors that can make the plots popular.

Considering these data, the summary table of the factors determining the land value in physical life and in the Metaverse, depending on the main purpose of the study, is summarized in Table 1.

Table 1. Comparison of land valuation factors.

Land Valuation Factors		**Physical World**	**Metaverse**	**Reference**
Legal Factors	zoning and restrictions	Very Important	Very Important	Yalpır & Bünyan Ünel, 2016; Goldberg et al., 2022; Morris, 2022; Hissong, 2021; Krion, 2022
Physical Factors	corner parcel	Very Important	Very Important	Yalpır & Bünyan Ünel, 2016; Goldberg et al., 2022; Morris, 2022
	facade length	Very Important	Very Important	Yalpır & Bünyan Ünel, 2016; Sandbox, 2022; Ovrland, 2022; Decentraland, 2022
	geometric shape	Very Important	Very Important	Yalpır & Bünyan Ünel, 2016; Sandbox, 2022; Ovrland, 2022; Decentraland, 2022
	technical infrastructure (roads and slope)	Very Important	Less Important	Yalpır & Bünyan Ünel, 2016
Locational Factors	distance to public services	Very Important	Less Important	Yalpır & Bünyan Ünel, 2016; Brody, 2022; Goldberg et al. 2021; Huber, 2022
	distance to popular areas	Very Important	Very Important	Yalpır & Bünyan Ünel, 2016; Brody, 2022; Goldberg et al. 2021; Huber, 2022

	memorability	Cannot Evaluate	Very Important	Goldberg et al., 2022

Discussion

The concept that determines the value of land in the Metaverse depends on its potential income (Huber, 2022). This study determined the similarities and differences between the factors that determine the economic value of the lands in the physical world and the factors that determine the economic value of the lands in the Metaverse. Lands in physical life have practical benefits. For example, land can be used for farming or for underground resources. However, there are no natural resources in the Metaverse (Morris, 2022). When we look at the real-life and virtual-life value indicators of land prices, many "problems" are solved by themselves, as there are no obstacles such as geographical restrictions, ecological conditions, space constraints that exist in physical life but do not exist in Metaverse, and the perception of financial value in virtual lands has completely differentiated from that in physical life.

In this case, it is not appropriate for Metaverse to consider legal factors, which are among the factors that determine land value in the physical world, in the context of "zoning and restrictions." In the Metaverse, plots are segregated as platforms see fit, and these NFTs' own legal safeguards are protected by blockchain-based smart contracts. Considering the locational factors, locational advantages such as being in a corner plot have a positive effect only if they increase the popularity of the plot in question, that is, the density of users. Because there are no technical infrastructure needs such as roads and slopes, technical infrastructure remains unimportant in the cyber world. When locational factors are examined, proximity to popular areas is an important factor for both physical and cyber lands. However, since avatars are not affected by environmental pollution, the risks posed by environmental problems do not exist in the Metaverse. In addition, since the transportation of avatars is provided by teleportation, public transportation opportunities are also insignificant. Considering the local factors, the popularity of the area and its money-generating potential are important for both plots. Climate, pollution, and geological conditions are unimportant in cyber worlds.

Our hypothesis that popular lands are valuable but advantages in terms of proximity are effective in the financial value of the lands has been proven through the literature. However, on the other hand, it is equally difficult for the characters with teleportation power to reach popular or unpopular spots. For this reason, physical distances become insignificant. Finally, it has been proven by the work of Mekacher et al. (2022) that the "scarcity" feature increases

the value of plots, although the "rarity" feature is not a comparable phenomenon for physical worlds and cyber worlds as stated in our hypothesis.

It is true that the economic values in the physical worlds and the Metaverse universes vary depending on the currencies prevailing in the universes in question, but this is not exactly proportional to the value of the "plot". While the ability to freely create ancillary transactions outside the control of the ecosystem in any cryptocurrency created by blockchain technology facilitates "digital dollarization," according to Stiligz (2000), this financial liberalization is likely to raise concerns such as creating economic instability. The systems of Metaverse platforms have virtual economies that must be managed very carefully, and the developers of these universes must design by considering the economic balance and constantly closely controlling the system (Nakavachara & Saengchote, 2022).

Conclusion and Future Work

The universe generated in the Metaverse points to a world beyond the physical universe. For this reason, the metaverse will create a great change in every aspect of human beings. People who could rebuild the world are accustomed to reconstructing the city and its values with the new practices they develop. For example, land has now become a symbol that expresses power and material possibilities rather than physical life.

This study investigates the mechanism of the economic value of the plots on the Decentraland, Sandbox, and OVRLAND platforms on the Metaverse by comparing them with the land valuation factors in physical life. This comparative analysis provides insight into the potential of virtual lands. However, it should be noted that the research findings are highly variable as Metaverse technology is a technology that is constantly renewed and open to development. In the Metaverse, land providers can increase the number of products they offer, destroying the "rarity" feature, which is known to increase the value of the land and, in this way, cause the value of the plots to decrease. It can capture users by offering more than their experiences by establishing a platform other than the platforms discussed. The dynamics determined through today's research, the factors that make the parcels "value" economically, may become completely different with a feature to be developed in the next period. These top three platforms, which we have discussed due to the number of users and market volume, may lose their value over time, or even be closed. Therefore, the fields of study in the Metaverse and the possibilities it offers are endless. New studies to be carried out should examine the factors that determine the price balance of these lands in more detail to be able to manage the risks by considering the aforementioned lands as a financial resource.

The Importance of Feasibility Study in Real Estate Investment Projects: Example of a Residential Land

A. Kazaz and H. Esendal
Akdeniz University, Civil Engineering Department, Antalya, Turkey
akazaz@akdeniz.edu.tr, halil.esendal@gmail.com

Abstract

Construction is one of the sectors that require large amounts of capital. The construction sector includes very large-scale sub-units such as residential, commercial, road, and bridges. One of the most important factors in all construction projects is the risks that can occur in the project. Failure to make the right decisions at the beginning of the project leads to negativity in the process, causing project failure at any time, in the range of planned costs, and insufficient quality. Inefficient projects cause companies to fail at the end of the process, and even investors face unintended consequences, such as bankruptcy. The cost analysis of land selection must be done correctly, and the benefit of the project must be determined with all the details in mind. The feasibility study of the land compares the cost required for the investment to be made and the benefit of the project. The criteria for Net Present Value (NPV), Internal Rate of Return (IRR), and benefit/cost analysis must be checked to determine the suitability of the investment to be made. This study covers the feasibility study for a residential project in Antalya province. The study aims to calculate NPV, IRR, and benefit/cost analysis. According to the results obtained, the district with the best Benefit/Cost ratio, NPV, and IRR results was calculated as the Muratpaşa district.

Keywords: *benefits of cost analysis, criteria, decision, housing project, feasibility, IRR, NPV, project, residential land.*

Introduction

Shelter has always been one of the most basic human necessities throughout history. Overcrowding of the population led to the creation of new development areas and the extension of construction outwards from the places designated as settlement centers as the historical process continued. As the population density rose as a result of this circumstance, new zoning areas were determined.

In a rapidly developing world, the basic need for housing and shelter is increasing day by day. This basic need is only for shelter for low-income groups. In addition to shelter, featured and certified dwelling structures are preferred for higher-income groups. The diversification of the housing sector for different income groups and the fact that this need has never diminished and even gradually increased in any period keep the interest of investors in this sector at a high level. Over time, the increase of investors in the housing sector, as well as the expansion

of investment projects in each new project, has prompted other investors from other sectors to gravitate to this sector.

Decision-making process is one of the most critical factors in every sector. Making the appropriate decisions can have a positive or negative impact on every process from start to finish. To reduce uncertainties and ensure the successful completion of the project, it is necessary to think carefully and in detail about the decisions to be made on time, to consider all elements thoroughly, and to examine the options in detail. Every stage in the entire process, from the initial idea of the project to the completion of the project and bringing it to the sector, should be considered thoroughly, and all alternatives should be discussed in all detail in the decisions to be taken.

As in every sector, before investing in the housing sector, the investor considers his/her own capital and thinks thoroughly about which region and with which features he/she will invest in a housing project and decides accordingly. In the decisions taken, many factors such as the development of the district and neighborhood, especially the city where the project will be built, the income levels of the people who prefer the region, housing features such as the preferred indoor space, number of rooms, quality of materials used, etc. play an important role.

If the right decisions are not taken at the beginning or during the project, it is likely that the investor will not make the desired profit, incur losses, or even have undesirable consequences such as bankruptcy. All of the aforementioned negativities are not only project-based but may appear as failures in other investment processes of the investor, and gaining the trust of participants and customers in other projects may negatively affect the investor. The decision-making process should be carried out meticulously to avoid these negativities. Land selection is one of the most important stages of the decision-making process.

During land selection, the cost analysis should be done correctly, and the benefit to be obtained from the project should be determined by considering all the details. The feasibility study of the land enables a comparison of the cost required for the investment to be made and the benefits to be obtained from the project. Net Present Value (NPV), Internal Rate of Return (IRR), and cost/benefit analysis criteria should be checked to determine the suitability of the investment.

In this study, Net Present Value (NPV), Internal Rate of Return (IRR), and cost/benefit criteria were calculated for residential lands in 4 different districts in Antalya province. The lands in question are located in the districts of Mollayusuf Mahallesi- Konyaaltı, Sütçüler Mahallesi- Kepez, Çağlayan Mahallesi- Muratpaşa and Altınkale Mahallesi- Döşemealtı.

Feasibility Study

Capital investment is required for the implementation of a construction project in any region. When the characteristics of the construction sector are analyzed, there is a high level of uncertainty. Therefore, a feasibility study is required before starting any project (Mask & Gaikwad, 2021).

In the study prepared for the preparation and evaluation of investment projects, the issues related to investment and preparation of investment projects were examined in detail, and

investment proposals based on the net present value and internal rate of return methods were discussed (Gedik et al. , 2005).

In the studies, Net Present Value (NPV), Internal Rate of Return (IRR), and cost/benefit analysis were used as commonly used criteria to check the suitability of the project in the feasibility study of a housing project in the Pimpri Chinchwad area in India. The aim of this study was to determine whether the project is feasible or not (Mask & Gaikwad, 2021).

In the study conducted in Malaysia, another country located in Asia, a feasibility study and economic evaluation research was conducted on Green Building projects to help the client decide whether the project is feasible and worth continuing (Halil et al., 2016). In the study conducted in Hanoi, Vietnam, the potential for Construction and Demolition Waste (CDW) recycling facilities was evaluated by estimating the potential supply and demand and assessing the probable costs and benefits. NPV and IRR methods were also utilized in this evaluation (Hoang et al., 2021).

In addition to housing projects, green building projects, and recycling facilities, feasibility studies were also carried out for investment projects such as irrigation canal construction projects and railway construction projects. In one of these studies, a feasibility study was carried out in the research to determine the suitability of the irrigation canal construction project in order to increase the yield in the fields in Indonesia (Zakia et al., 2021). Furthermore, in Tanjung Perak Port, Indonesia, a feasibility study was conducted as an intermediate model for the railway construction project, and the railway construction project was categorized as much as possible by determining the NPV, IRR, and benefit/cost ratios (Arga et al., 2020).

In order to emphasize the importance of feasibility study in the construction sector, due to the delay, cost, and other issues that directly and negatively affect the construction sector in Iraq, as well as other issues that affect the quality of construction projects, a study was conducted to assess the level of awareness of feasibility study in construction projects and to identify the effects of feasibility study in the construction sector, and to identify the causes of feasibility study violations in the construction sector (Mohammed et al., 2019).

If we examine the studies carried out in Turkey country, a thermal hotel project to be developed in Afyonkarahisar region was taken into consideration and SWOT analysis was used in the strategic evaluation of the project and, discounted cash flow method was used in the cost analysis. Net Present Value, Internal Rate of Return were calculated in the study (Taktak et al., 2010). The thesis study was carried out in different regions of the province of Istanbul, and the study was completed with a Financial Analysis study by making Residence, Home - Office, and Hotel Project Development in Kartal-Soğanlık Region and Residence, Office, Shopping Center, and Congress Hotel Project Development in Pendik Region (Çalışkan, 2011).

Studies have been carried out in other sectors apart from the construction sector, and it aimed to produce kaolin from the Balıkesir - Sındırgı field to meet the needs of the ceramic enterprises in the region. It was recommended, that the selection between alternative investment projects should be made according to the NPV criterion (Demirbugan, 2008).

Moreover, research conducted to provide information on economic internal profitability, which is a measure of how much the investment project will contribute to the national

economy, was tested with methods using discounted cash flows, and calculations were made according to the internal profitability ratio, net present value, benefit/cost ratio and net benefit/cost ratio method (Mandacı, 1992). In another study, revenue and expenditure forecasts in investment projects were mentioned. The study, by mentioning that the expenditures made in investment projects were often not completed within a year and that expenditures occur at different times during the project, and that the revenues to be obtained from the project cannot be collected at the same time; it was emphasized that revenues and expenditures were not at the same values. Noting that these value differences should be analyzed over similar time periods, it was explained that some of the valuation methods used in the calculations based on the estimates were Net Present Value (NPV), Internal Rate of Return (IRR), and Benefit/Cost Ratio (Gedik et al., 2005). In a different study, the methods of evaluating the economic efficiency of investment projects for the construction of industrial facilities of industrial organizations under uncertainty and risk were examined. In the study, NPV, and IRR examinations were studied for scenarios (Gayfullina et al., 2021).

The purpose of feasibility study can be listed as follows.

1. Determine the benefit/cost ratio for the project
2. To determine the Net Present Value (NPV) and Internal Rate of Return (IRR) for the project.
3. Analyze the parameters to determine if the proposed project is appropriate.

Net Present Value (NPV)

The Net Present Value (NPV) method is a method of calculating the net value (net) at the present time. The present assumption is to explain that the initial time of the calculation coincides with the time the evaluation is carried out or in the 0 year period in the calculation of investment cash flow (Zakia et al., 2021).

In order for a project to be accepted by this method, it must be equal to or greater than 1. Among alternative projects, the project, which has the largest ratio, is prioritized, with greater than 1. As with the NPV method, the selection and magnitude of the discount ratio to be used in this method affect the analysis results very much. The purpose of the method is to prioritize the project, which has the largest benefit/cost ratio in investments to be made, thus maximizing the investor's B/C ratio. The formula used to calculate the NPV value is:

NPV=PWB – PWC

$$\text{PWB} = \sum_{t-0}^{n} CBt(FEB)t$$
$$\text{PWC} = \sum_{t-0}^{n} CCt(FEB)t$$

PWB = Present Worth of Benefit;
PWC = Present Worth of Cost;
Cb = Cash flow benefit;
Cc = Cash flow cost;
FBP = Present Interest Factor;
n = Investment period;
t = Time period;

If the difference is positive, the project is accepted (NPV > 0). In the case of multiple projects, the project with the NPV high should be preferred. If NPV = 0, it is clear that annual acquisition flows barely cover operating costs and annual investment costs (Gedik et al., 2005).

Internal Rate of Return (IRR)

Internal Rate of Return (IRR) is an interest rate (not bank interest) that describes the level of profit from a project or investment in percentage when the NPV value is equal to zero. IRR is the interest rate that illustrates that the benefits presented are equal to zero (Zakia et al., 2021). The formula used to calculate the IRR is;

$$\text{IRR} = iNPV0 + \frac{NPV0}{(NPV0 + NPV1)} \ (iNPV0 - iNPV1)$$

iNPV0 = interest rate net present value at i0;
iNPV1 = interest rate net present value at I;
NPV0 = net present value at i0;
NPV = net present value at i.

In order for a project to be accepted, the calculated IRR investor must be greater than the minimum discount rate accepted. In a selection between alternative projects, the IRR largest project is prioritized. If the IRR has more than one option higher than the discount rate, the IRR higher investment project will take priority.

Benefit Cost Analysis

Benefit/Cost Ratio is calculated in two different ways. According to the first method, also called the most used profitability index, the Benefit/Cost Ratio is the ratio of the sum of the current values of the benefits (cash inflows) that a project will provide during its economic life, the sum of the costs (investment expenditures and other cash outputs) to the sum of the current values. The second method, called the benefit/cost ratio of investment, is calculated by dividing the total of net reduced cash flows into the reduced investment total.

$$BCR = \frac{PWB}{PWC}$$

PWB = Present Worth of Benefit;
PWC = Present Worth of Cost.

In order for a project to be accepted by this method, it must be equal to or greater than 1. Among alternative projects, the project, which has the largest ratio, is prioritized, with greater than 1. As with the NPV method, the selection and magnitude of the discount ratio to be used in this method affect the analysis results very much. The purpose of the method is to prioritize the project, which has the largest benefit/cost ratio in investments to be made, thus maximizing the investor's B/C ratio (Bostancı, 2008).

Purpose of the Study

One of the most important stages at the beginning of all investment projects in the construction sector is the selection of the land. The benefit to be obtained from the project to be developed on the selected land is one of the most important items in terms of the evaluation of the project by the investor. Therefore, every detail, criterion, and all option must be evaluated in order to make the right decision in land selection. This is the same for housing projects as in other construction branches. In this study, the data required for the feasibility study were determined by literature research and expert opinions, NPV, IRR, and Benefit/Cost ratios were calculated, and the final ranking was made.

Within the scope of the study, 4 parcels where the housing project can be realized were selected. In the selection process, attention was paid to the fact that the lands were parcels designated as residential zoned and that they were located in areas with high housing density and preferred by buyers. For this study, surveys were conducted in the fields and regions, and expert opinions were obtained from previous articles, theses, and studies. With the identified data, NPV, IRR, and Benefit/Cost ratios were calculated on the lands, and the final ranking was aimed.

Location of the Case Study

According to TurkSTAT data published on February 4, 2022, Antalya province is the 5th largest city in Turkey with a population of 2,612,834 people and its surface area is approximately 20,177 km². According to TurkSTAT data published on February 4, 2022, there are 19 districts and districts including Akseki, Aksu, Alanya, Demre, Döşemealtı, Elmalı, Finike, Gazipaşa, Gündoğmuş, İbradı, Kaş, Kemer, Kepez, Konyaaltı, Korkuteli, Kumluca, Manavgat, Muratpaşa, Serik, and a total of 914 neighborhoods in these distributions.

As in Turkey in general, the demand for shelter is increasing day by day due to the growing population in Antalya. Due to important factors such as tourism, local and foreign settlers prefer Antalya province. An analysis of TurkSTAT data shows that the number of residential building permits issued by the issuance in 2021 in the districts where the study was carried out among 19 districts constitutes approximately 34% of the province in general and 45% of the occupancy permit.

Density maps according to the sales made on the basis of independent sections on a district basis for 2021 are given below. A part of the Konyaaltı district is shown in Figure 1, a part of the Döşemealtı district in Figure 2, a part of the Kepez district in Figure 3, and a part of the Muratpaşa district in Figure 4.

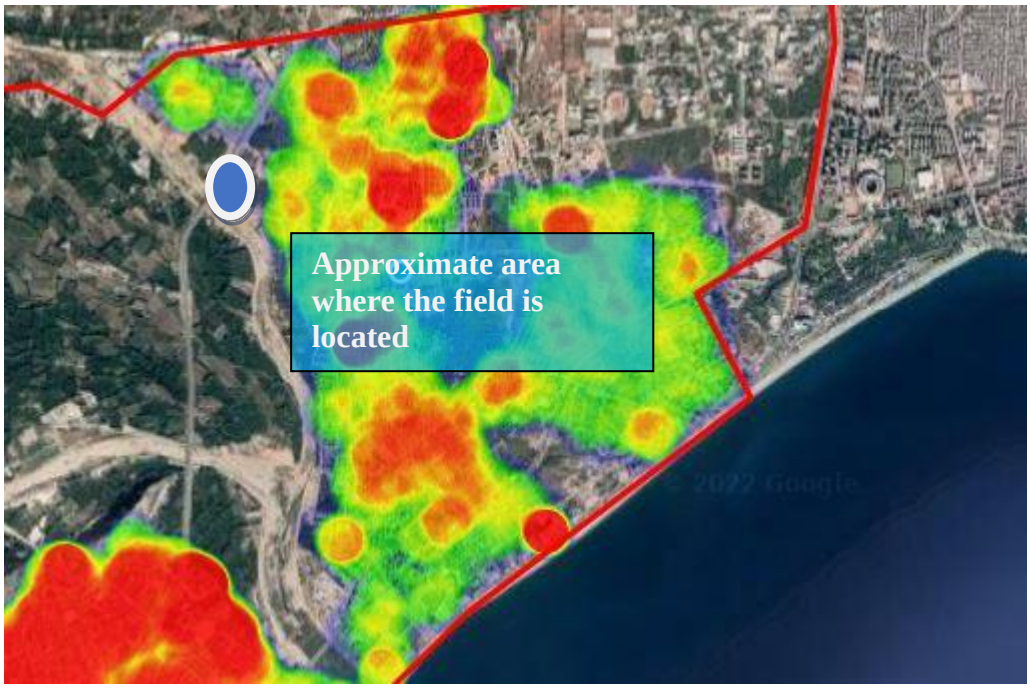

Figure 1: Konyaaltı district independent division density map for 2021 (Reference: parselsorgu.tkgm.gov.tr).

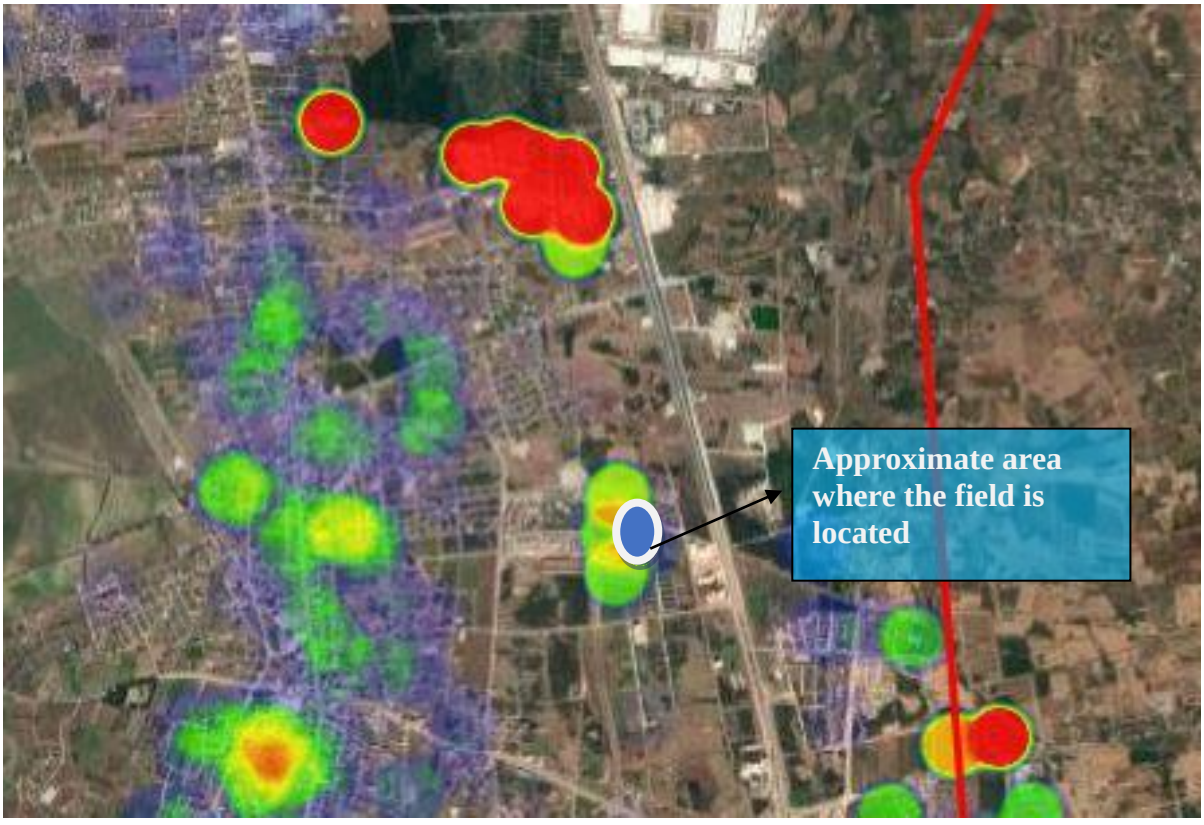

Figure 2: Döşemealtı district independent division density map for 2021 (Reference: parselsorgu.tkgm.gov.tr).

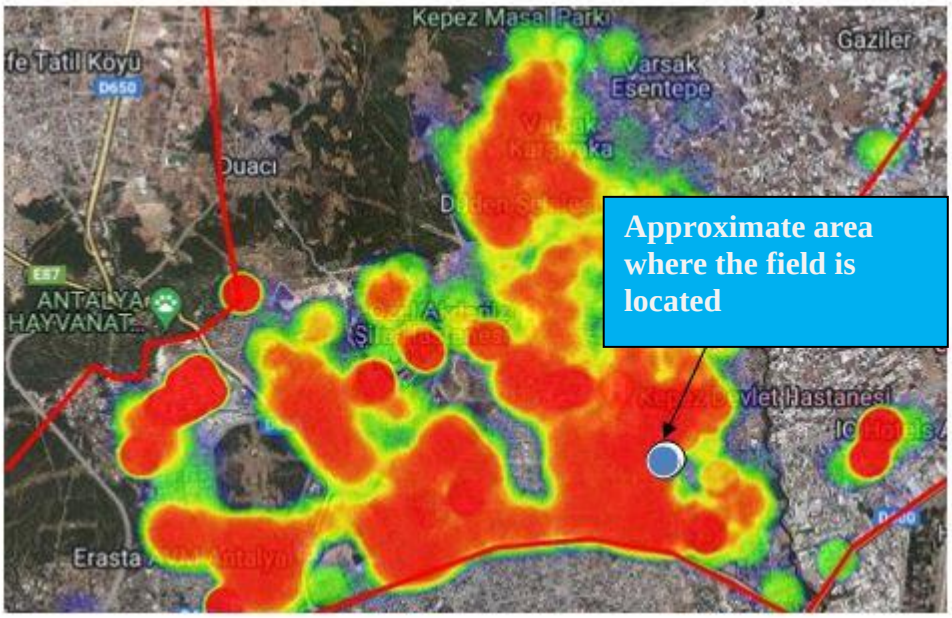

Figure 3: Kepez district independent division density map for 2021 (Reference: parselsorgu.tkgm.gov.tr).

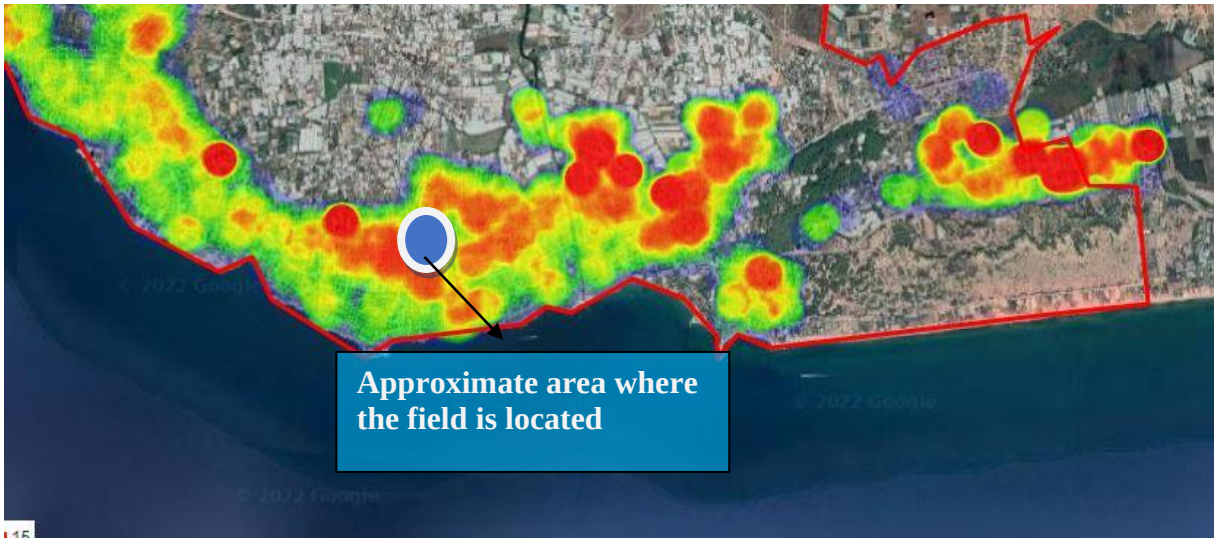

Figure 4. Muratpaşa district independent division density map for 2021 (Reference: parselsorgu.tkgm.gov.tr).

Comparative Feasibility Assessment of the Predicted Housing Zones

NPV, IRR, and Benefit/Cost ratios were studied for the four parcels specified in the study area. The acceptances and assumptions made in the studies are as follows;

-In the determination of the Construction Area, the precedent rights determined for the lands and 30% of the area excluding the precedent were taken into consideration.

-For the Saleable Area, 20% of the construction area was deducted from the approximate construction area with the assumption that the common areas will be more

because the immovables in Konyaaltı and Muratpaşa are qualified, 10% because the immovable in Döşemealtı is a villa, and 10% with the assumption that the common area of the immovable in Kepez district will be lower.

-For the cost item that constitutes the expense item, considering that the buildings to be built in Konyaaltı, Muratpaşa and Döşemealtı will be of higher quality, the 4-C construction class was taken, and the average of the 3-A and 3-B construction class was taken for the construction in Kepez district. Due to the inflation after February 18, 2022, when the unit prices were published, the unit^{m2} price was increased by approximately 35-40%.

-In the sales figures that make up the income, zero housing price averages were taken, taking into account the research made in the region. 23,000 TL/m^2 for Muratpaşa, 8,500 TL/m^2 for Kepez, 20,000 TL/m^2 for Konyaalti, and 17,000 TL/m^2 for Döşemealtı were foreseen.

- The percentage of contractors in the regions is 40% for Muratpasa, 50% for Kepez, 44% for Konyaaltı, 45% for Dosemealti.

-The reduction rate for NPV is taken as 10%.

The results of the work carried out are as follows.

Table 1. Results obtained.

	MURATPAŞA	KEPEZ	KONYAALTI	DÖŞEMEALTI
BENEFIT/COST	36%	11%	30%	27%
NPV (USD)	777.509 USD	12.038 USD	682.278 USD	558.283 USD
NPV (TL)	12.051.391 ₺	186.601 ₺	10.575.315 ₺	8.653.395 ₺
IRR	28%	11%	22%	22%

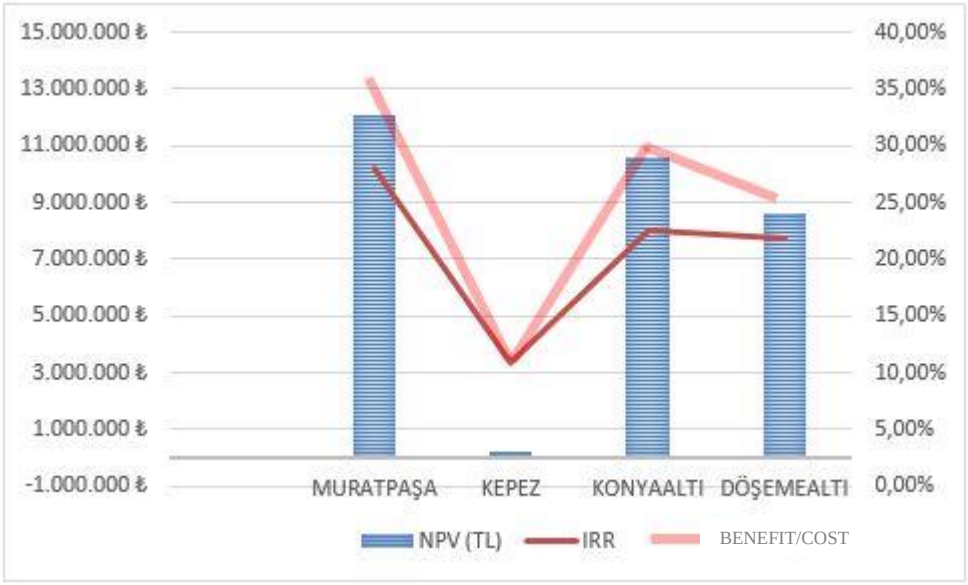

Figure 4: Graphical display of results.

Table 1 shows the data obtained as a result of the study. Figure-4 is the graphical representation of the results obtained.

As can be seen from the results obtained, the district with the best Benefit/Cost ratio, NPV, and IRR results was calculated as Muratpaşa district.

Results

Within the scope of the research aiming at the selection of residential land, first of all, all the criteria that should be considered in the selection of an investment land were identified through other articles, research, theses, publications and interviews with experts.

Considering that housing projects were developed for all lands, NPV, IRR, and Benefit/Cost Ratios were determined by taking into account the income to be obtained from the lands in case of completion of the projects and the costs to be spent and ranking was made among the regions. As a result of the feasibility study, it was seen that the best alternative could be the land in Muratpaşa district.

Research and studies have shown that the proximity of the land to the center, the completion of the infrastructure and especially the high turnover to be obtained from the sale of housing, which constitutes the income item of the project, can be important items in the selection of the land.

When the NPV, IRR and Benefit/Cost Ratios are analyzed; it is contemplated that the investment can be considered for the land in Konyaaltı and Döşemealtı districts in addition to the land in Muratpaşa district. Due to the development of the Döşemealtı district, the increase in interest recently, and the expansion of detached housing throughout the country, it is thought that better results may be obtained in new studies to be conducted in the coming period.

In this study, the criteria are considered in terms of deciding on land selection at the beginning of a project have been shown with sample applications. The criteria, calculations, and acceptances in the study have been taken into account by considering the four selected lands, and do not cover the districts in general. All the details in the study are specific to the field and the process in which the research was conducted.

Finally, in all studies, including the decision-making to be carried out in these districts, land-specific criteria should be determined, research should be carried out, and a project-specific decision should be considered. In addition, the study was conducted on the data identified during the research process, and therefore, future research is recommended even for the same lands, during the investment decision-making process for the process outside the research.

Consumer Based Perceived Quality in Real Estate 4.0

Ç. Karabağ and G. Özkaptan Alptekin
İstanbul Kultur University, Department of Architecture, İstanbul, Turkey
cigdemkarabag@superonline.com, g.alptekin@iku.edu.tr

Abstract

It is important to perceive the quality and evaluate the service outputs in the competitive environment in the real estate sector. Since the quality perceived by the consumer has a subjective conceptual structure, it is very difficult to define and measure. In consumer-oriented perceived quality, which is characterized as the relationship between expectations and alternatives, pre-purchase expectations, service process experiences, and after-sales services are considered as a whole. Perceived quality creates a reason to buy for customers and provides value to customers by differentiating the existing branded product from its competitors. In this context, various methods are used in the measurement of perceived quality with a consumer approach. In the study, the perceived quality principles of the "Consumer (behavior) Based Brand Equivalence" model, which is used frequently among the measurement methods of consumer-based perceived quality, can be evaluated within the scope of Real Estate 4.0, developed by David A. Aker in 1991, and in addition to the principles of Real Estate 4.0 has been integrated. Determined perceived quality principles were questioned by a survey of 204 people, specifically for the XX brand, which is one of the leading companies in branded housing projects in the real estate sector. With the analysis of the answers to the questions created as a result of the analysis of the concepts and approaches corresponding to the perceived quality components of the XX brand, it was determined which criteria were primarily perceived by the consumer, and the results were discussed.

Keywords: *brand value, consumer based brand equality, perceived quality, real estate, real estate 4.0.*

Introduction

As change accelerates and intensifies with globalization, the importance of information technologies is gradually increasing. The level of information technologies is defined by the concept of Industry 4.0 with the integration of the internet into the industrial value chain (Kartal & Şentürk, 2020). This concept, which is the new paradigm of production, covers many fileds as finance/investment, business management, law, construction, marketing, etc. (Yıldırım, 2020). These transformations also affected lifestyles, demands, tastes, and habits. Worldwide communication opportunities, increasing consumer expectations, and a large number of actors in the construction market increase competition. The competitive environment of the real estate sector has led to the emergence of branded real estate projects (Yetkin & Coşkun, 2021). Functional, innovative, and technological approaches, which put

user profiles at the forefront and which are realized for changing needs, gained value (https://blog.kpmg.lu/four-tech-upgrades-featured-in-real-estate-4-0/). High demand for the real estate projects, has been a driving force for being recognized, to be chosen, and brought mix use projects and other typologies have brought quality within the competitive environment. The reflections of industrial revolutions in the real estate sector are evaluated under the concept of Real Estate 4.0, which has just started to be mentioned (https://yapidergisi.com/mimarlik-ve-endustri-4-0-eslesmesi/). In this context, it is become important for companies to understand the "consumer trends" both on a global scale and local scale, and to make their investment-related analysis and planning in the light of these data (Öztürk, 2016). For this purpose, companies make investments more than before for their corporate and project-based brands in order to maintain their position and increase their market shares. It is of great importance that the marketing studies start from the planning and programming phases within the scope of feasibility studies during the initiative phase, the correct determination of the project scope, and the creation of brand value (Kotler et al., 2017). For the companies developing real estate projects; classification of the customers according to geographical, demographic, psychographic, and behavioral features is seen as one of the most important factors affecting project sales and consumer approaches. In recent years the majority of the investments consist of housing projects, and competition is increasing especially under the "Branded Housing" projects for the middle and middle-upper user group (Çınar & Çako, 2012).

The new marketing strategies that emerged with Industry 4.0 require focusing directly on consumer needs and putting forward innovative solutions for these needs (Yaprak, 2021). In the case of Real Estate 4.0, it has gained importance to have the advantage of consumer/user satisfaction, brand assurance, sales, and after-sales services, and national/international brand competition. Especially in the housing sector, the fact that quality has special importance brings to the fore the housing brands that are compatible with modern technology, have earthquake safety, will protect/increase their economic value, and are presented as investment tools. In this direction, being in the mind of the consumer/user has become a great necessity for companies (Dönmez, 2008). Branding and brand management, which is a professional field of work, should be applied consciously to real estate companies and projects by analyzing market conditions, consumer behavior/demands, positioning in the market, and by creating studies that will provide individual and social benefits (Öztürk, 2016). In this context, the concept of perceived quality has gained importance in the emergence of different concepts with the effects of brands on consumers' minds. Companies achieve quality when they can offer reliable, robust products/services that meet consumer expectations. By this way, trust, utility, function, and value are provided to the consumer (Marcouse et al., 2016).

Quality is an identifiable and measurable variable. Quality management is primarily based on the creation of a system that responds to consumer expectations (Nelson, 2006). By using the conceptual models in the literature, the effect of the brand and brand value on the quality perceived by the consumer can be measured in the real estate sector as well. In 1991, David A. Aaker's "Consumer (behavior) based brand equity model" gained importance in this dimension as one of the important factors in transforming the consumer's choice in favor of the company. However, although there are many scientific studies carried out on brand value in companies in different sectors, sufficient studies have not been found in the real estate sector yet. In this context, the study aims to reveal the factors affecting the 'perceived quality', which is one of the dimensions of brand value, and to reveal the evaluations of the consumers on the subject by exemplifying the counterparts of the factors through an exemplary real estate firm and the projects it produces.

Branding in Real Estate 4.0

In the real estate sector, companies trying to manage their marketing and brand management processes by considering issues such as competition, quality, perception management, retention, and association (Gül & Acar, 2014). The brand concept, which consumers are familiar with in all areas of life, entered the construction industry later. The opportunities offered by Industry 4.0 for strategic marketing have triggered a significant transformation in Real Estate 4.0 in the competitive environment in the sector (Önder, 2021). Among the reasons why product and service-oriented branding works enter the construction sector much later than other industrial production sectors and different service sectors, various problems caused by the internal dynamics of the construction sector arising from project-type production, multi-stakeholder, and multi-stage fragmented structure, and the control of the service and production process are among the reasons. Challenges related to the building are the high demand for the building and the large number of small-scale and non-institutionalized contractors in the market (Karabağ, 2021). However, the rise in user expectations and the efforts to exist in the competitive conditions in the global market has been the driving force for brand studies in the construction industry. The willingness to lead, to leave the competition behind, and to give the best to employees and customers are cited as the most important reasons for companies to benefit from branding (Wheer, 2013).

Nowadays, due to the increase in user expectations and competition conditions in the market, real estate projects, developed for the middle, upper-middle, and upper- income groups, need to be nourishing with some abstract values beyond traditional expectations in order to prominent in the market and meet with the right consumers. At this point, the major values are directing the consumer perception, memorability, and building trust. These values also constitute components of the concept of "brand" (Kocatürk, 2017). In this context, it is necessary to plan marketing and sales strategies based on branding in real estate projects that are prominent with their investment value today. While it is known that traditional management approaches bring traditional results, creative, developing and innovative solutions are expected from brands, avoiding prejudging with more instinctive behavior, believing in the spirit of the brand with corporate employees, working with empathy, and being intertwined with the brand.

Real estate investments strive to establish a long-term trust relationship with the user by prioritizing the benefit/value and satisfaction of the consumer/user, who has gained brand value or is advancing rapidly towards branding. Depending on changing lifestyles and evolving needs, conversions take place on the axis of the consumer/user (Ertuğrul & Deniz, 2018). Quality construction for the consumer is related with meeting expectations such as performance, functionality, reliability, durability, utility, aesthetic requirements in physical dimension (Sümer et al., 2015); also includes abstract values such as socio-cultural environment, status, image, reputation, value and psychological factors in the perceived quality dimension.

Brand Value and Consumer Based Brand Equity

Brand value is a remarkable marketing concept for practitioners and researchers, as it offers companies the advantage of differentiation with high sales and profit margins, and provides the opportunity to develop products/services and protect the brand from competitors (Taşçı & Baş, 2018; Keller, 2003). After the concept of financial valuation, which first came to the fore during company acquisitions or mergers, the increase, and protection of brand assets, etc. are measured for different reasons (Çelik, 2006). Thus, brand consumers; create a value proposition centered on functional, emotional, and personal benefits. The brand value increases brand preference and plays an active role in making the product/service affordable in consumers' minds. Brand equity is also considered an important marketing strategy that companies focus on, with the brand loyalty provided by ensuring trust in the brand, perceiving the products and services as high quality, and reducing all the perceived risks associated with it (Koçoğlu, 2017).

The dictionary definition of “Brand equity” is; In addition to the physical features purchased by the consumer, it is expressed as a brand that is built with an emotional connection, personality, and a satisfying mixture (Aktuğlu, 2011). In terms of brand value measurement, a common measurement model has not been developed yet, since it has a complex structure that combines abstract and tangible elements. The concept of "brand value", which is one of the most critical areas of marketing management, is measured through financial, consumer (behavior) based, and mixed methods. Financially based brand equity means the financial returns of the brand. Consumer-based brand equity, on the other hand, includes abstract components that cover what the consumer learns, hears, sees, and thinks about the brand in the process (Atıgan, 2017; Tosun, 2017). Brand value is the ultimate goal that is desired to be achieved as a result of branding studies. Many factors create brand value. These factors are listed as; brand loyalty, brand awareness, perceived quality, brand associations, owner assets, and competitive advantages (Aktuğlu, 2011). The main source of brand value is consumers. At this point, the brand value taken into consideration is evaluated based on individual consumers (Avcılar, 2008).

Evaluations from the consumer's point of view form a basis for the qualitative assessment of brand equity (Uyar et al., 2018). In the literature, the consumer (behavior) based brand equity model put forward by D. A. Aaker (1991); consists of four components: brand awareness, brand association, perceived quality, and brand loyalty (Figure 1).

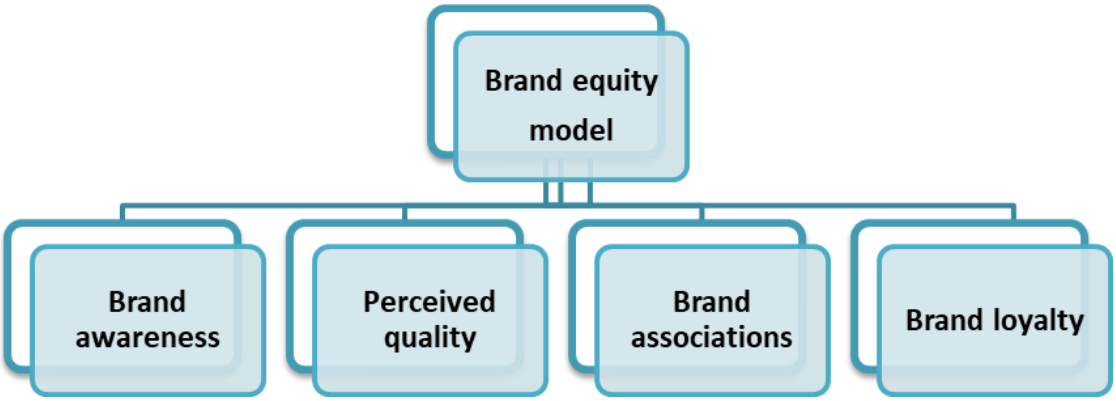

Figure 1: Aaker’s (1991) consumer based brand equity model.

Brand awareness, perceived quality, brand associations, and brand loyalty that are located in the minds of consumers are all combinations of positive and negative thoughts and feelings.

(Biyan, 2019). Today, one of the foundations of the success of companies with high brand value is that the products or services of the brand are perceived as high quality by consumers. The increase in perceived quality, which expresses the quality perception of the consumers, increases the brand value of the companies, as well as the increase in the purchase intention of the consumers, the market share, and profitability of the companies shows the perceived quality importance (Kocatürk, 2017). In this context, the study is examined in terms of perceived quality and dimensions.

Perceived Quality in Consumer Based Brand Equity Model

The perceived quality phenomenon, which is characterized as the relationship between expectations and alternatives, can be defined as the general quality perception of the consumer (Aaker, 1991). The concept of quality is a subject of interest these days, and also concerns all companies. However, quality and perceived quality are different concepts from each other. While quality is objective or product-based, perceived quality is subjective and customer-based. This situation has led companies to intangible benefits that create value and include cognitive and emotional leading associations rather than concrete benefits in providing a competitive advantage (Toksarı & İnal, 2012). It is quite difficult to determine and measure the quality, the reason of subjective concept, and differentiation according to perceptions. Therefore, it is seen that companies attach importance to consumer-focused quality (Atıgan, 2017). Perceived quality is also expressed as a concept that is suitable for the wishes and requirements of the target audience and meets their expectations (Sağlam, 2014).

For many brands, perceived quality defines the competitive environment and their position in it (Aaker, 1996). Consisting of the total perception, quality includes judgments about what is substantial to the customer. Perceived quality is different than attitude. Many low-quality products can generate a positive attitude, as they are not expensive. Therefore, perceptions of quality are subjective (Erdil and Uzun, 2010). In the measurements of perceived quality which are answered by consumers; the use of the X brand is comfortable/easy/hassle-free, the X brand is reliable and durable/robust, and the X brand is of high quality, the maintenance service of the X brand is very good, the answers to the questions are taken and the measurements take place.

Perceived quality creates a reason to buy for customers and provides value to customers by differentiating the existing brand from its rivals (Sağlam, 2014). For the reason perceived quality cannot be determined objectively, it includes consumer judgments about what is important and what is not (Aaker, 1991). For brands, perceived quality defines the competitive environment and their position in this area Aaker (1991); five key factors increase the value of perceived quality (Figure 2).

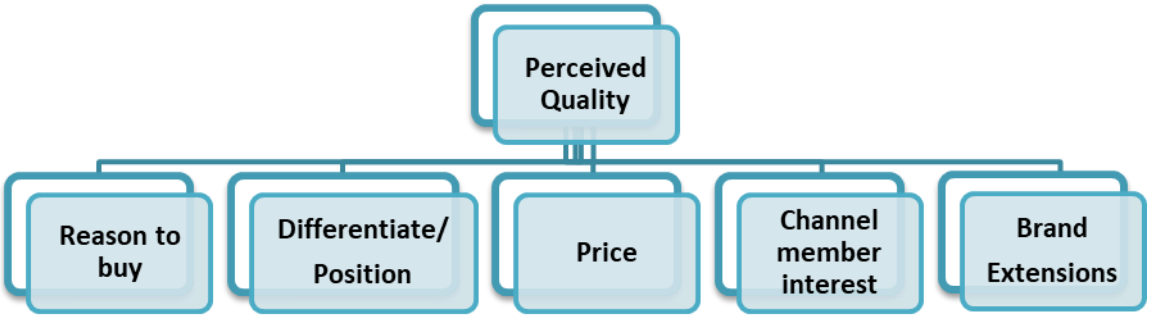

Figure 2: Perceived quality in consumer based brand equity model.

Reason to Buy

Perceived quality is directly related to purchasing decisions. Perceived quality becomes the center of the consumer when consumers do not have knowledge about the product/service or do not have the source and ability to obtain the information (Aaker, 1991). In this case, the perceived quality of the brand, rather than the actual quality of the brand, can be transformed into purchasing behavior by the consumer. The perceived quality of the brand significantly affects the purchasing decisions of consumers. When consumers make their final decisions, they choose the option that offers the highest benefit and acts in this direction. As long as this choice can afford consumer expectations, it affects customer satisfaction and the probability of the customer's repurchase (Kotler & Keller, 2018).

Differentiate/Position

The fundamental positioning feature of a brand is its position in the perceived quality dimension, regardless of the product/service definition (Aaker, 1991). Thus, the brand differentiates itself from its opponents and is positioned in a distinct place in the minds of consumers. Functionally brand positioning targets to create the desired perception in the consumer's minds. It is the work of creating a positive effect, feeling, and story in the mind of the potential customer regarding the product/service. It is hard to create a positive effect on consumers' perceived quality with the not perceived differentiation and looks similar to others. In this context, in a heavily communicative society, positioning can be defined as, a set of ideas that take communication problems seriously (Reis & Trout, 2019). Brands are expected to look different from others, and to position based on difference.

Price

Perceived quality presents advantageous pricing and options to sell the product. This price difference increases profits, and they can be used in research development activities. This resource provided also strengthens perceived quality (Aaker, 1991). Due to the high perceived quality of the brand, selling the product at a high price creates a price difference from its competitors (Sağlam, 2014). The perception of high quality provided to the consumers justifies the price of the product/service and also ensures prestige and social status. Particularly in housing projects, the concepts of status, image, and value are important

concepts in the perception of the brand. With different project concepts, the perception that the price is due to the difference in the project can be an important basis for price comparisons among consumers. At the same time, working with well-known designers/architects creates the impression on the consumer's side that the price is deserved.

Chanel Member Interest

Perceived quality creates importance for retailers, distributors, and other companies. Thus, channel members help distribution channels to win (Aaker, 1991). Channel members also prefer existing brands that were requested by the consumers. In this direction, it contributes to acquiring a distribution advantage for the company. In the real estate sector; real estate advisors, real estate sales sites on the internet, print media, TV shows, social media project promotions, etc. fields can be defined as the channels of the sector. Channel members prefer to have the brand that consumers want. Thus, in new project promotions, the quality perception of the brand can take place in different channels. Thus, in new project promotions, the quality perception of the brand can take place in different channels.

Brand Extension

Brands that have strong in terms of perceived quality can achieve a higher chance of success by expanding further (Aaker, 1991). By using the brand name with high perceived quality in other product/service groups, it takes advantage of the existing brand name and saves the cost of new brand promotion (Erdil & Uzun, 2010). Companies can create value by using the perceived quality of their brand in different products and services. At the point of responding to rival moves, brands, hold a place in the minds of potential customers with a “single-location” strategy rather than a multi-brand strategy (Reis & Trout, 2019). In this way, they can use the same quality perception in other products/services by taking advantage of the existing brand name.

Search Methods

The brand value obtained as a result of branding, in the real estate construction sector significantly affects consumer’s purchasing decisions. The general quality perception of the consumers/users can be evaluated as the superiority of the product/service compared to its alternatives and its suitability for usage expectations (Keller, 2019). Brand value of the real estate projects are interrelated with the brand value of the construction company by which they are developed. In order to analyze the factors affecting brand value, perceived by the consumers for the real estate projects, a survey is prepared. The survey is designed to gather information according to a particular real estate company, considering its projects at all. For this reason, a real estate company with the brand XX is selected because of its branding approach and success both in corporate level and project level, at home and abroad. Survey questions were formed on the dimensions of "Perceived Quality" developed by Aaker for the XX brand in the consumer (behavior) based brand equity model.

Consumer Based Brand Equity Analysis of Brand XX

The determination of brand value and its degree could be determined by the values which existed formed in the mind of the consumer. In this context, survey questions regarding the XX brand were asked within the framework of the components of Aaker's consumer-based perceived quality model, for people who have heard/seen the XX brand at least once. The surveys have been reached via e-mail and a short message (SMS) from the business environment, the close circle, and social media. In the survey, a total of 253 people accessed and 204 participants answered the questions. XX brand, which included Aaker's consumer (behavior) based brand equity measurement model components with the; Perceived quality, the reason for purchase, positioning, price difference, channel member interest, and brand extension have been analyzed on a company-specific basis.

In the first part of the survey, questions have asked to determine the demographic characteristics of the participants, and in the second part, to reveal the consumer-based perceived quality value. Questions oriented to consumer-based brand equity components were asked with a 5-point Likert scale, and while calculating the weighted averages, the option I strongly disagree with was multiplied by 0 and not included in the mean. It is weighted by 'Disagree' 1, 'Partially agree' 2, 'Agree' 3, and 'Strongly Agree' 4 points. Analysis of the results has shown with weighted average tables and graphics. Tables that contain weighted means, for easy reading of the positively and negatively weighted scores, the highest score has shown with a color code starting from dark blue and the lowest score being white.

In the survey study, primarily the findings related to the demographic characteristics of the participants were evaluated. The findings related to gender, age, education level, and occupations have given in Table 1. 51% (130 people) of the participants are mostly men. In the age group part, 32% of the participants (68 people) are in the 46-55 age range. The participants' average age has been detected as 46. Regarding the education status question, participants; 58.02% (123 people) university graduates and 50.47% (107 people) stated as doctors/engineers/architects.

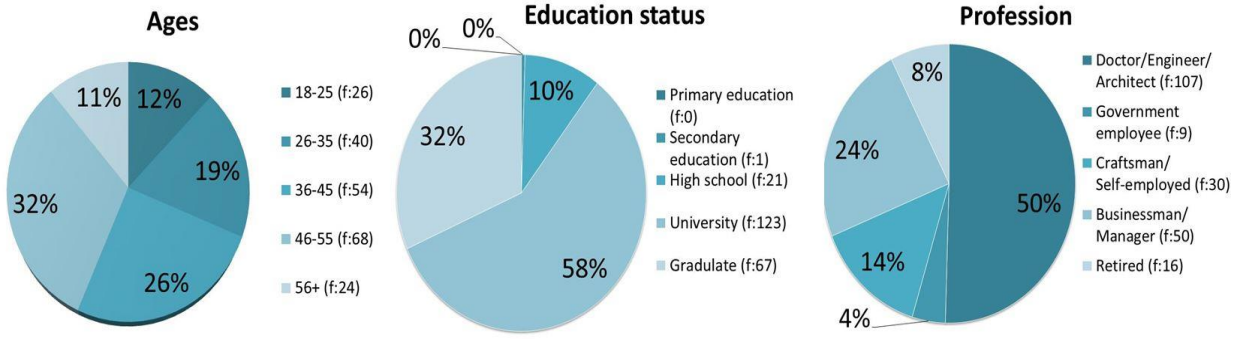

Figure 3. Demographic characteristics of survey participants.

Primarily, when 204 participants were asked to indicate the first three words that came to their minds about the XX brand; the word "brand" took first place with a rate of 65% (127 people). While "High price" was in second place with a rate of 42% (81 People), "Different architectural design" was in third place with a rate of 38% (74 People), (Table 1). In this context, since the additional price that consumers are willing to pay in return for the product and service is an evaluation of perceived quality, XX brand, provides the perception of quality with the values in "brand" and "high price" concepts. Another approach to perceived quality is the judgment of consumers that the quality of a high-priced product will also be high. At this point, the company takes the first place with its brand concept and high price proportions. The

concept of different architectural designs and luxury also supports the perceived quality of the company. There is a direct relationship between the companies that produce luxury goods and services and the perceived quality of the brand (Atıgan, 2017). On the other hand, it has been seen that the patent designs and foundation works, which the company prioritizes in its promotions, lag in creating perception/awareness on the consumer side.

Table 1. Evaluations of the first three concepts that come to mind with XX brand.

WHAT'S ON YOUR MIND ABOUT BRAND XX WİTH THE FIRST THREE WORDS	FREQUENCY	PERCENT
Brand	113	68,48
High price	70	42,42
Different Architectural Design	64	38,79
Luxury	45	27,27
Investment/Value	43	26,06

The average weight evaluations of the questions regarding the brand position in the minds of consumers and the perceived quality model adapted to the sector are given in Table 3, 4, 5, 6, 7. Evaluation that constitutes the reason to the buy of XX brand, "XX brand uses quality building materials" scored 59.92 points above the average (Table 2).

Table 2. Reason to purchase in consumer based perceived quality in XX brand.

Reason to buy								
	The number of responden ts	Strongly disagree %(0)	Disagre e %(1)	Partially agree %(2)	Agree %(3)	Strongly agree %(4)	Weighted average of responses (out of 4)	Weighted average of responses (out of 100)
XX brand uses quality building materials	179	1,68	8,94	44,69	37,43	7,26	2,40	59,92
When I evaluate XX, the concept of quality is in the top 3.	177	3,39	14,69	37,85	34,46	9,60	2,32	58,05
XX brand produces projects with famous architect and designer groups	175	2,86	13,71	44,57	30,86	8,00	2,27	56,86
						AVERAGE		**58,27**

The average positioning value of the XX brand is 61.02 points. “The images of the projects presented by the XX brand are of high-quality” expression received the highest weighted average value with 67.12 points (Table 3).

Table 3. Positioning in consumer based perceived quality in XX brand.

Positioning								
	The number of respondents	Strongly disagree %(0)	Disagree %(1)	Partially agree %(2)	Agree %(3)	Strongly agree %(4)	Weighted average of responses (out of 4)	Weighted average of responses (out of 100)
XX is a high-quality brand	179	2,23	10,61	46,37	34,08	6,70	2,32	58,10
XX brand produces projects in accordance to consumer demands	169	2,37	7,69	52,07	31,95	5,92	2,31	57,84
Project images provided by XX are of high quality	165	1,82	8,48	29,70	39,39	20,61	2,68	67,12
						AVERAGE		**61,02**

In the ranking of the first three words that come to mind about the XX brand, brand and quality are seen as the priority value, while the rate of participation in the statement "I accept to pay a higher price than other projects in order to have a project with XX brand quality" received a score below the average with 41.52 (Table 4). As a result, it has been observed that while consumers perceive XX Company as high quality with its brand value, they do not accept to pay high prices for the brand in particular.

Table 4. Price in consumer based perceived quality in XX brand.

Price								
	The number of respondents	Strongly disagree %(0)	Disagree %(1)	Partially agree %(2)	Agree %(3)	Strongly agree %(4)	Weighted average of responses (out of 4)	Weighted average of responses (out of 100)
I agree to pay a higher price than other projects in order to have a project in the XX brand	168	13,69	31,55	34,52	15,48	4,76	1,66	41,52
						AVERAGE		**41,52**

Channel member interest in consumer-based perceived quality has got a 58.21 average value. The statement "XX brand advertisements and promotions create a high quality connotation" received 64.27 points, and it was concluded that it strengthens the perception of quality with advertisements and promotions (Table 5).

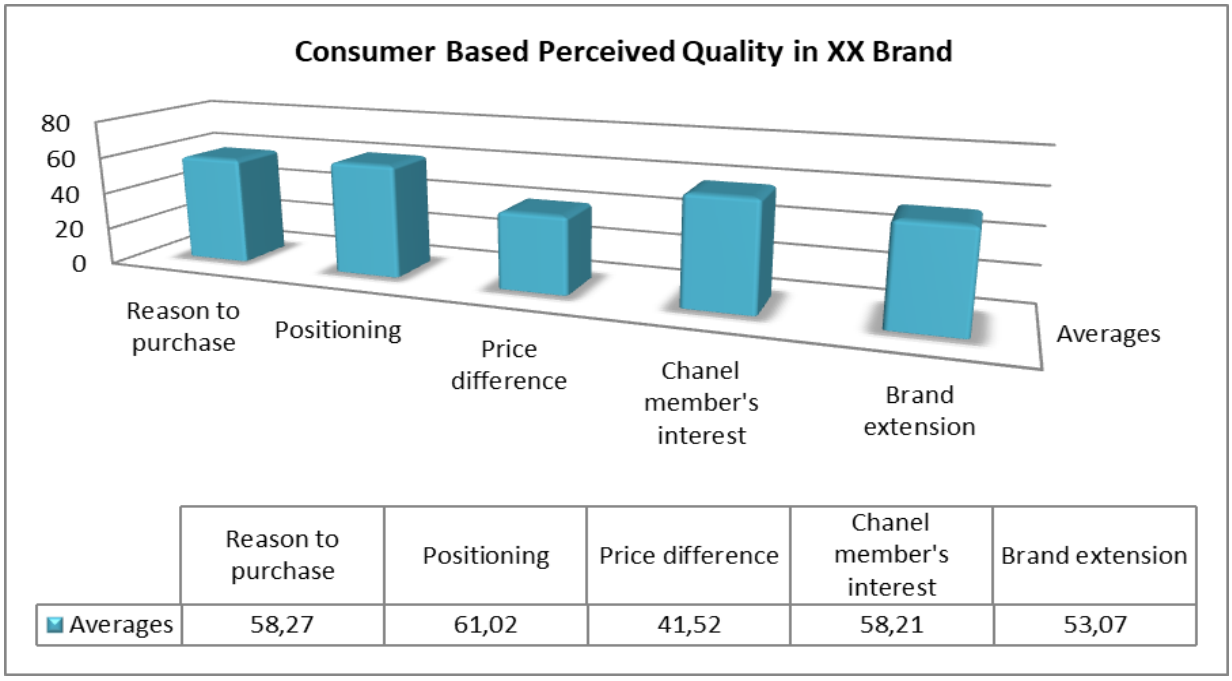
Table 5. Channel member interest in consumer based perceived quality in XX brand.

Channel member interest

	The number of respondents	Strongly disagree %(0)	Disagree %(1)	Partially agree %(2)	Agree %(3)	Strongly agree %(4)	Weighted average of responses (out of 4)	Weighted average of responses (out of 100)
XX creates a high quality connotation in advertisements and promotions.	177	3,95	9,60	25,99	46,33	14,12	2,57	64,27
Brand XX advertises too often	179	2,79	16,20	31,84	38,55	10,61	2,38	59,50
The fact that XX is involved in different real estate and promotion channels helps me think that it is a quality company.	171	7,02	25,73	30,99	29,24	7,02	2,04	50,88
						AVERAGE		**58,21**

XX brand extension in consumer-based perceived quality has got a 53,7 average value. The statement "XX brand advertisements and promotions create a high quality connotation" received 64.27 points, and it was concluded that it strengthens the perception of quality with advertisements and promotions (Table 6).

Table 6. Brand extension in consumer based perceived quality in XX brand.



Brand extension								
	The number of respondents	Strongly disagree %(0)	Disagree %(1)	Partially agree %(2)	Agree %(3)	Strongly agree %(4)	Weighted average of responses (out of 4)	Weighted average of responses (out of 100)
Patented products offered by XX create a perception of high quality	169	2,96	15,38	43,20	32,54	5,92	2,23	55,77
Developing projects in different regions makes XX think that the company is of high quality.	169	5,92	23,67	37,28	24,26	8,88	2,07	51,63
						AVERAGE		**53,7**

In the study, the perceived quality dimensions and their equivalents were determined as a result of the evaluations of people who have heard/seen the XX brand at least once;

- ***Reason to buy.*** Among the factors affecting the quality perception of the brand, the comment that the brand uses high quality building materials has the highest score with 59.92 points. The consumer/user gave an average of 58.27 points to their reason for purchasing (Table 2).
- ***Positioning.*** Among the perceived quality factors of the XX brand, quality positioning got the highest value with an average of 61.02. The quality of the project images presented by the brand provided the highest value for consumers with 67.12 points (Table 3).

- ***Price.*** While various project awards such as the highest quality and most prestigious housing awards received by the XX brand contribute to the perception of quality, they also play a role in increasing the profit margin in project sales prices. Among all the factors affecting the perception of quality, the price-based assessment which was directed to the consumer, with 41.52 points took the lowest value (Table 4).
- ***Channel member interest.*** It is seen that, the promotions carried out by the brand through social media and different real estate channels have created a high-quality perception among consumers, with a high score of 64.27. It can be said that the brand's frequent advertising and presence in different real estate channels create a high-quality perception with an average of 58.21 points (Table 5).
- ***Brand extension.*** It is seen that, the brand is aiming for high market share with different project segments, non-governmental organizations, and social projects under its corporate structure. While the brand extension factor, which affects the perceived quality of the brand, scored with an average of 53.7 points, may be interpreted as patented design products created a higher quality perception, and that project developments in different regions had a slightly lower effect on quality perception (Table 6).

Table7. Consumer based perceived quality in XX brand.

	Reason to purchase	Positioning	Price difference	Chanel member's interest	Brand extension
Averages	58,27	61,02	41,52	58,21	53,07

As a result, the perceived quality average is 54.41 in return for the marketing strategies developed by XX firm within the scope of Real Estate 4.0 (Table 7). Approaches that are effective in the formation of consumer/user-based perceived quality; The use of quality building materials, the quality of project visuals, advertisements and promotions, projects which are located in the real estate channels, and patented products, can create a quality connotation for the brand by contributing to the perception of the brand as high quality in consumers/users.

Results

The "Perceived quality" dimension, which is under the title of consumer (behavior)-based brand value, has gained a significant value today. Consumer-based brand equity is seen as one of the important factors in transforming the consumer's choice in favor of the firm. The concept of "Perceived quality", which is defined as the general quality perception of consumers / users, is a subject that attracts intense attention by all companies today.

For this purpose in this study, the "Consumer (behavior) based brand equity" model was integrated with real estate 4.0. The factors that play an important role in consumers' purchasing decisions and affect "Perceived Quality" are determined through a real estate firm and the perception of the consumers'/users on this issue has been trying to be measured. Like the general perception of branded products, branded housing is perceived as high quality by the consumers and the persistence of this perception affect the brand value positively. Within the scope of the evaluated XX real estate company's branded housing projects, it is seen that producing and presenting projects that meet the needs/demands of the consumer/user, especially with the dimension of "positioning", can make significant contributions to the perceived quality. However, as a result of the research, although the brands create high connotations, real estate consumers are within the dilemma of quality and price, and it has been concluded that the price difference is strong enough to change the brand orientation. In this respect, the fact that real estate development companies should offer price positioning strategies and project promotions as equivalents within the dimensions of quality perception can provide important contributions to the company.

Abstract

Generally, residential projects are planned (scheduled) according to construction companies' institutional data and standard man-hours data provided by governmental agencies. And the construction duration appeared from these schedules. And in the contract phase, the determined construction duration is an obligatory variable. These projects are carried out in accordance with the schedule. However, some residential projects are also carried out by the building owners or their partners. Even if the project starts within planning, some deviations between as-built and as-planned situations can occur, and it can be difficult to predict how the project will progress due to reasons such as resource problems, economic situations of contractors, or environmental factors. In this study, some residential projects made by contractors, the building owners or their partners are categorized and discussed. Project information such as start/end dates, license date, building inspection information, construction area, and construction cost are examined.

Keywords: *estimating, planning, residential projects.*

Introduction

Before starting the construction projects, cost, quality, and time planning are made. However, since each construction project has its unique structure, deviations may occur in these plans. It is expected to occur more in private construction projects. Because situations such as slow resource transfer or excessive time are seen more frequently. Although there are no such problems with resource transfer or planning in public buildings, the construction process may not go as planned due to special situations that will be encountered in practice. Seasonal factors, the economic situation of the country, the situation of the contractor performing the work, a situation related to the legislation, or another external factor can be shown as the reason for this. Success factors are inputs that directly or indirectly affect the success or outcome of the project (Duy Nguyen et al., 2004; Masrom et al., 2015). The success of a

project also depends on factors such as project complexity, technical expertise, organizational competence, and risk management (Doloi et al., 2011).

Residential projects are at the forefront of private construction projects. The construction process of residential projects is completed by either the contractors or the landowner. There are building inspection firms that follow the process of residential projects in Turkey. These firms are assigned to residential projects by a government agency (Provincial Directorate of Environmental, Urbanism and Climate Change), and this building inspection firm is obliged to conduct interest inspections throughout the construction process. These building inspection firms receive money from the relevant government agency according to the completion percentage of the construction in return for this service. This fee is calculated according to the total cost of the construction. Money flows to the state institution by the owner of the building. Then, the building inspection firm receives this money for certain periods according to the completion percentage of the construction. The sample progress payment related to the completion percentage of the construction prepared by the Provincial Directorate of Environment, Urbanization and Climate Change is shown in Table 1 below.

Table 1. Sample progress payment report for the inspection service fee.

Table 1 contains general information about the sample project. There are details such as the owner of the building, the license date of the building, the detailed address of the building, the building inspection information, the construction area and the cost of the building. As seen in Table 1, a certain amount of construction must be completed for the building inspection firm to receive progress payment. These; a) Project Inspection Fee to be Paid at the Stage of License Obtaining (10%), b) Excavation and Foundation Up to the Upper Level (10%), c) Structural System (40%), d) Part of the Building Prepared for Plastering, Including Roof Cover, Fill Wall, Door and Window Frames, Installation Infrastructure (20%), e) Mechanical and Electrical Installation and the Remaining Structure Section (15%), and f) Approval of the Work Completion Report by the Relevant Administration (5%). The building inspection firm may request the progress payment of more than one completed stage from the relevant directorate at the end of each stage or cumulatively. The relevant directorate, on the other hand, approves the progress payment after examining it and makes the payment to the building inspection firm. This payment to be made is called level progress payment.

Within the scope of this study, a progress payment report of 249 inspection service fees by Bitlis Provincial Directorate of Environment, Urbanization and Climate Change is examined. In the next stages of the study, more emphasis will be placed on estimation. Within the scope of this study, however, is limited to the classification of these reports only. We also thank the employees of the relevant directorate for allowing this data to be shared for an academic study.

Results

Various classifications have been made for 249 different residential projects. These classifications are related to the building construction area, construction cost, the month in which the construction began and project duration of the building. The input variables are listed as below.

- Building construction area: the area of total project that includes all stories of buildings.
- Construction cost: The total declared cost of the buildings.
- The month of the project's beginning: The month and the season supposed to affect the project progress so that this variable is considered as input of the model.

Building Construction Area

Building construction areas are included in the related database. The construction areas range between 186 m^2 and 11440 m^2.
Figure **1** shows the distribution of construction areas.

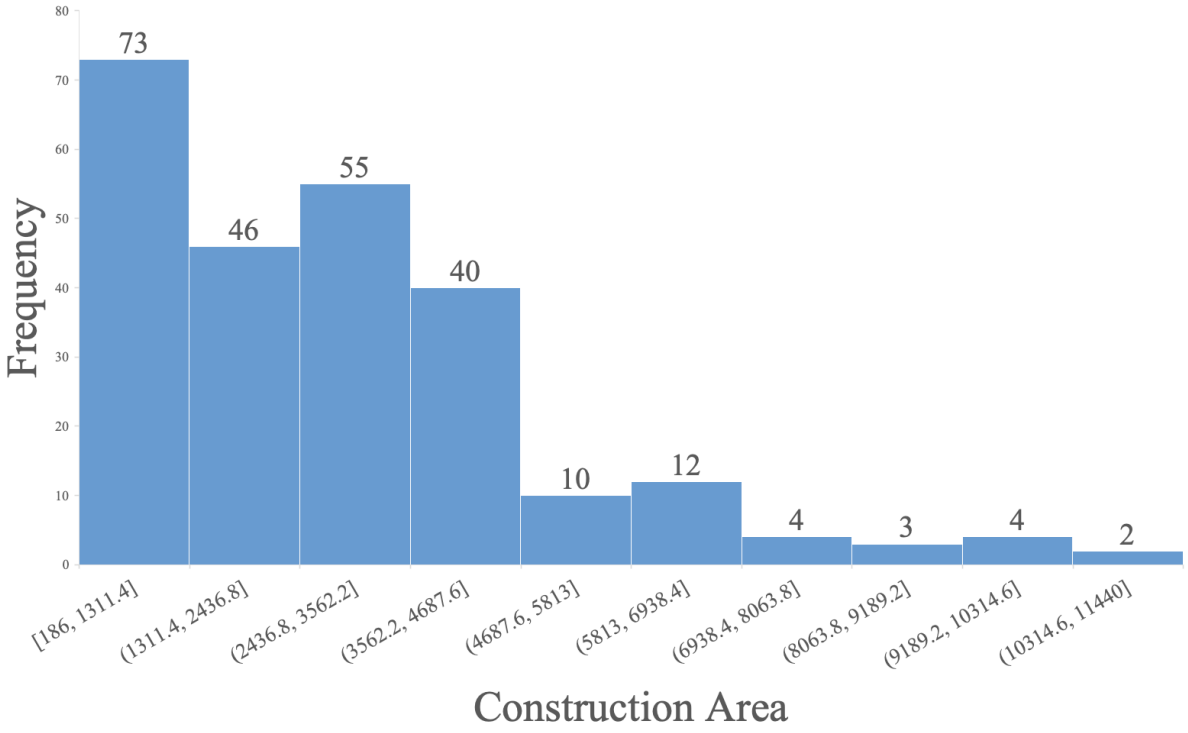

Figure 1: Distribution of construction areas.

Construction Cost

The construction costs are included for each construction project. These cost values are declared costs to the governmental agencies. The range of the costs distributed between ৳206,963.00 and ৳ 37,054,160.00. Figure 2 shows the distribution of the construction costs in the related location. From the graph, it can be asserted that from both Figures 1 and 2, the distributions are skewed to left.

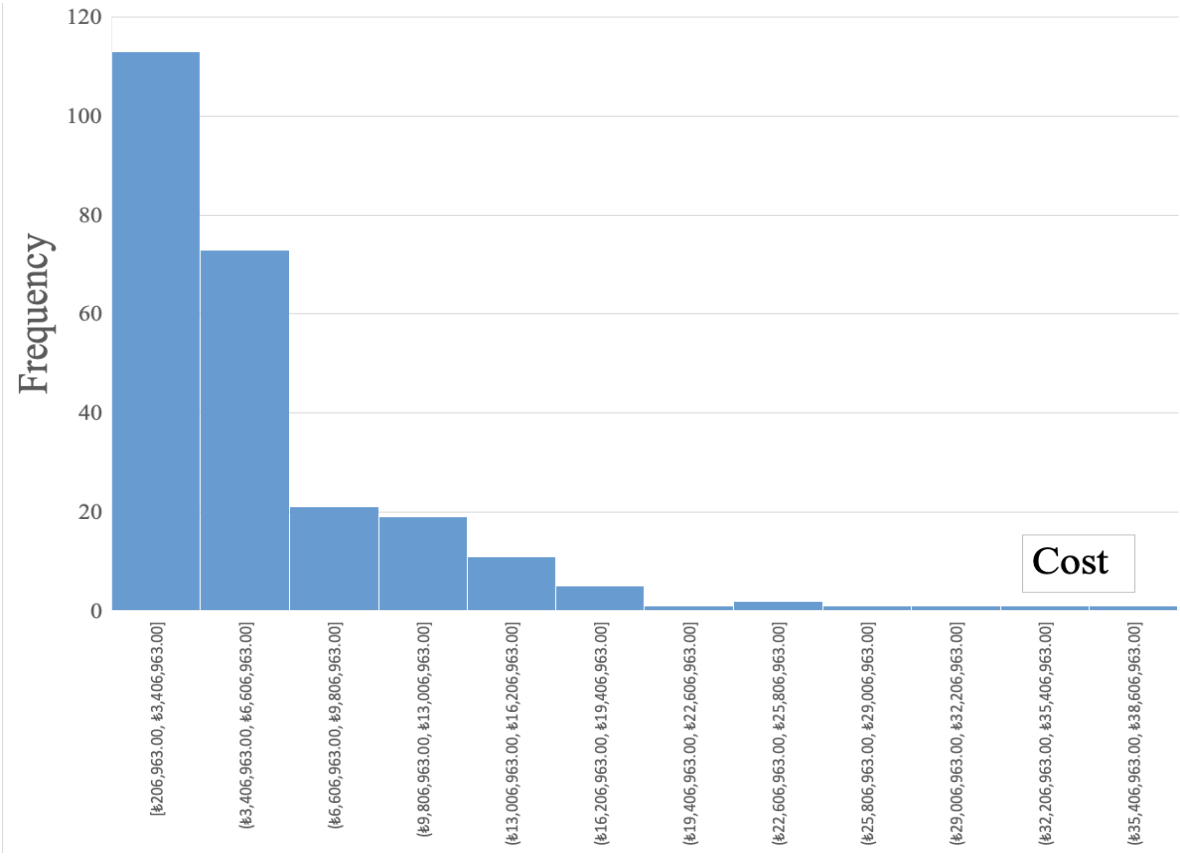

Figure 2: The distribution of construction costs.

The Month in which the Construction Began

For these 249 projects, the start month is collected to see the distribution of the starting season. The variable stored as a discrete variable, figure 3 shows the distribution of starting month of these 249 projects.

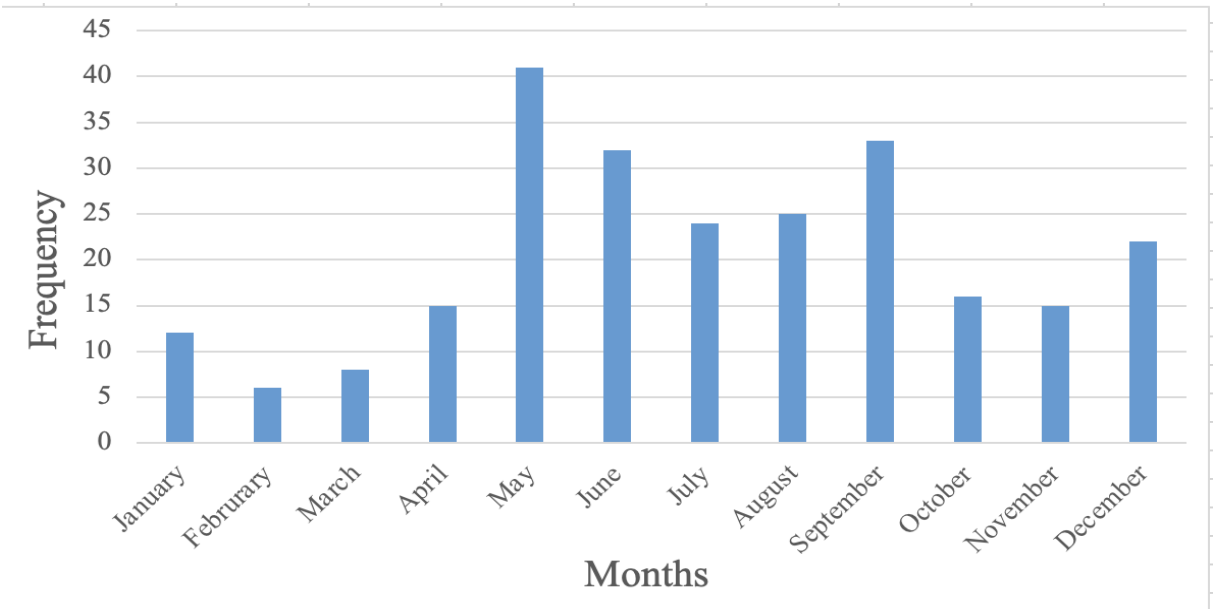

Figure 3: The distribution of starting months of constructions.

Correlation between Project Duration and Costs

In this study, the relationship between the construction costs and project durations is searched. Figure **4** gives the relationship between costs and durations. In the figure, there is no rational correlation appears. However, there are a few partial linear relationships appear.

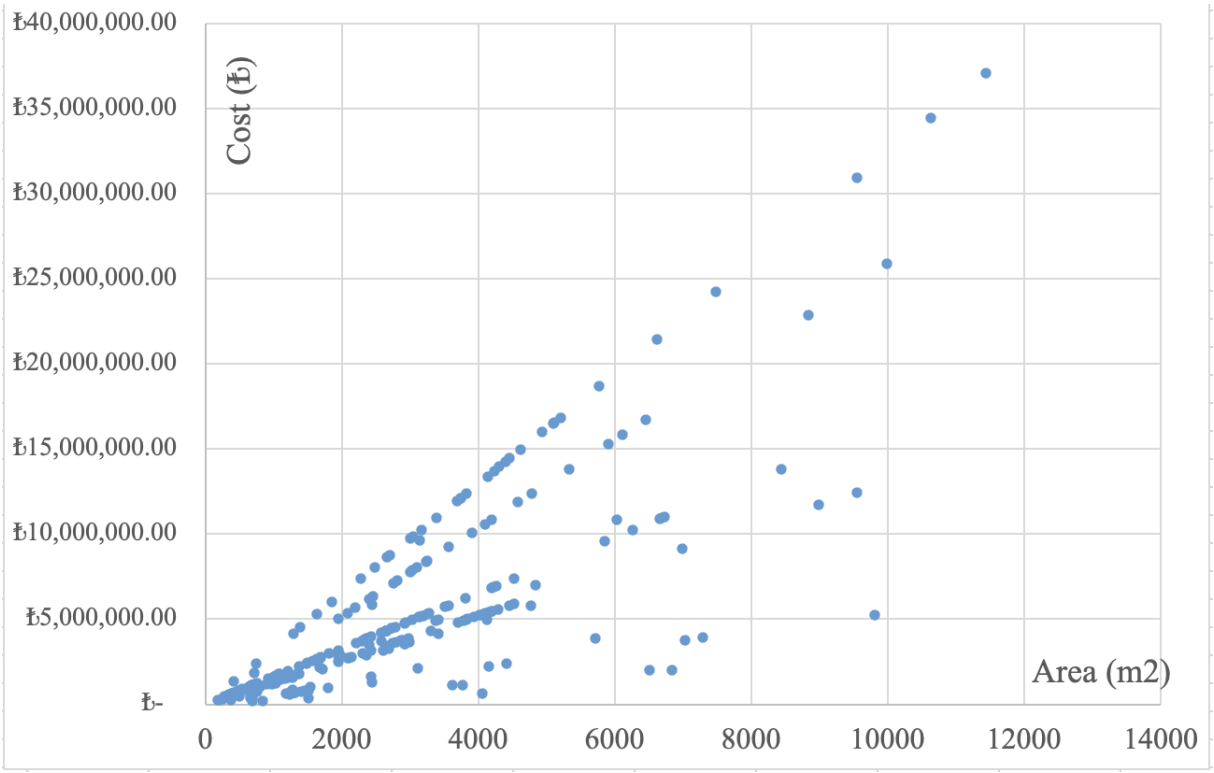

Figure 4: Relationship between construction cost and area.

Conclusion

Since construction projects are specific projects, each stage must be well planned. In special projects such as residential projects, this planning is more important. Because, for example, failure to deliver a house sold during the land period or during the construction phase can lead to various problems. Therefore, issues such as the size of the building construction area, the cost of the building, and the season in which the building will start may become important. The next stage of this study will be to calculate the estimated completion times of the construction based on these issues. In other studies, there are various studies on the factors affecting project success (Al-Tmeemy et al., 2011; Aslan et al., 2021; Chan et al., 2002; Dang et al., 2012; Duy Nguyen et al., 2004; Iyer & Jha, 2006; Mukhtar et al., 2017; Xiang et al., 2013; Yong & Mustaffa, 2013). At the end of this study, the effects of different factors on the project will also be discussed. Naturally, there is the project duration specified in the project, but the important thing is to estimate how many deviations will occur. In this way, both the owner of the building and the buyer or the building inspection firm will learn the estimated completion times and act accordingly.

Abstract

Advertisement is critical for the companies to convey their messages to their customers. Although the construction companies were not one of the main advertisers in the past, now they have spent a large amount of money on advertisements with increasing competition among companies. However, most of the advertisements of the construction companies are not effective as expected due to their traditional competition strategies. Therefore, the construction companies should understand how they can improve the effectiveness of their advertisements to avoid the waste of money spent on advertisements. In this study, the effectiveness of the luxury real estate advertisements is investigated considering the age factor, which is considered as one of the important factors that affects the effectiveness of the advertisements. Firstly, four advertisements whose have different advertisement appeals were identified. These advertisements were selected to eliminate the effects of other factors, such as duration and type. Then, a questionnaire survey was prepared . The first part is related to the demographic structure of the respondents, and the other is about the effectiveness of the four advertisements. After the questionnaire survey, a dataset which consists of 216 data was collected. This dataset was analysed using t-test to identify the effects of age on the effectiveness of the real estate advertisements.

Keywords: *luxury real estate advertisements, advertisement effectiveness, age.*

Introduction

Advertisements are an important medium for companies to convey their important messages to the customers. Therefore, the companies spend a large amount of money on advertisements for each year. For instance, in 2021, the companies spent $780.59 billion for advertisement. This amount is close to the total gross domestic product of Turkey in 2021 ($806.8 billion). Also, construction companies have become important advertisers in recent years (Cheng et al., 2016). For instance, based on a review of sector-related television commercials, the construction industry in Turkey had the third-longest amount of ad time in 2017 with 1369 hours. Besides, the construction sector ranks first with 233,516 spots in advertising spots

(MediaCat, 2018). However, advertisement effectiveness is a critical issue for the companies (Maheshwari et al., 2014), since, unfortunately, all the spending money on advertisements does not provide the expected benefits to the companies. Therefore, the companies should understand advertisement effectiveness to allocate their marketing budgets effectively (Bendixen, 1993). Although advertisement effectiveness is a popular topic in the literature, the studies about the construction industry generally overlook this subject. Therefore, limited studies are related to advertisement effectiveness in the construction management.

Advertisement effectiveness is also affected by different factors. Especially, previous studies have shown that the demographic factors should be considered while investigating the advertisement effectiveness (Ansu-Mensah et al., 2013; Keshari & Jain, 2016). Therefore, the companies should understand the demographic differences to have more effective advertisement campaigns. Especially, the effect of age is widely emphasized in the literature since the human beings confront with sensory functioning (vision, hearing, smell and taste, touch), cognitive system (working memory, long-term memory, knowledge-based memory, source memory) and affect and motivation with ageing (Drolet et al., 2019). Therefore, the people with different ages have different thinking structure on decision making (Keshari & Jain, 2016). For instance, opposed to older age groups of people, younger people tend to be persuaded more quickly (Srivastava, 2010). Similarly, different aged customers have different shopping methods. For instance, while younger generations view internet shopping as the most convenient way to acquire anything, older consumers believe that conventional shopping is the most dependable technique (Suman et al., 2019). Consequently, the age factor is a critical factor and should be investigated to reveal the differences between different age groups.

The main objective of this study is to study the effect of age on advertisement effectiveness. In the first part of the study, a literature review is provided for advertisement effectiveness to reveal how the advertisement effectiveness can be measured. Then, the research methodology used in this study is described elaborately. The findings of the analyses performed to understand the relationship between the age groups and advertisement effectiveness are discussed.

Advertisement Effectiveness

Companies always want to measure the effectiveness of their advertisements. Therefore, advertisement effectiveness has been investigated in the literature for a long time. There are different methods for measuring the advertisement effectiveness. One of the earliest studies was conducted by Strong Jr (1925). He proposed a hierarchical model composed of four parameters, namely attention, interest, desire, and action. According to Strong Jr (1925), the advertisement should firstly take the attention of the customer. After achieving the first stage, then it should make the customer interested in the message of the advertisement. Then, it should awake a desire to purchase the product, so the act of buying can start. Lavidge and Steiner (1961) also followed hierarchical logic, unlike the other study, they mentioned three components, namely, cognitive component, the emotional component, and the motivating stage in their model. Based on this model, firstly, the advertisement should address the human logic by conveying the information, then this information should trigger the emotions of the customers. At the last stage, based on how the customer receives the information, the advertisement can affect the customer positively or negatively. This model was also used by sticking to the main structure of the model in other studies such as Kiani (1998), Wisker et al. (2019), and Kong et al. (2019). Alternatively, some of the authors proposed that advertisement

effectiveness should be measured by determining how successfully the advertisement achieve the targets. Schultz et al. (1994) stated three advertisement targets, namely, sales volume, behavioral effects and communication effects. Similarly, Neal and Bathe (1997) suggested that the advertisement effectiveness should be measured by determining the number of customers who prefer this product.

Some tests have been developed to measure the advertisement effectiveness. Starch (1923) proposed a test that consists of three tests, namely, attention test, headline test, and test of text. Wells (1964) also developed another test that measures the emotional appeal. Beerli and Santana (1999) developed a copy test that consists of tests for measuring the memory and attitude. To measure, the memory, they used four tests, namely, unaided recall, aided recall, verbal recognition, and visual recognition. They also measured the attitude toward the advertisement using three tests, namely, liking, emotional quotient and reaction profile.

Research Methodology

The following figure shows the methodology followed in this study. Firstly, a literature survey was performed to determine the tests used to measure the advertisement effectiveness. TV advertisements were selected. Then, a questionnaire was prepared according to the advertisement effectiveness tests used in this study. Data were collected using this questionnaire. At the last stage of this study, t-test analysis was performed using the collected data.

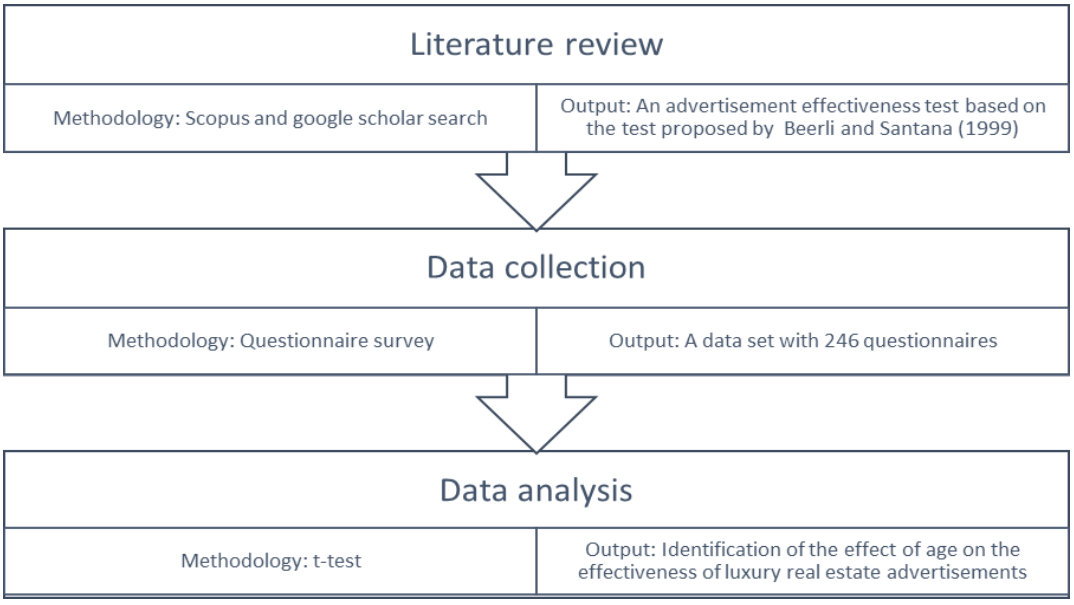

Figure 1: Research methodology.

Questionnaire

In this study, a questionnaire survey was performed to collect the data. The most important part of this questionnaire was developing a test to measure the advertisement effectiveness. In this study, the approach developed by Beerli and Santana (1999) was used. Based on Beerli and Santana (1999), the advertisement effectiveness should be measured by considering the

cognitive and affective effects of the advertisements, therefore in this study, the tests that can measure the cognitive and affective effects of advertisements were considered. Beerli and Santana (1999) used memory tests to measure the cognitive effects. Among the memory tests used by Beerli and Santana (1999), unaided recall test was used in this study. In the unaided recall test, the respondents rate how well they remember the features of the real estate project with a Likert scale from 1 to 7. 1 means that "I remember nothing about the features of the project shown in the advertisement" and 7 means that "I remember all the features of the project shown in the advertisement." For measuring the emotional effects of advertisements, Beerli and Santana (1999) used three tests, namely, liking, emotional quotient, and reaction test. In this study, liking and emotional quotient tests were used to measure the emotional effects of the advertisements. The respondent was asked to rate how much s/he liked each individual advertisement on a 7-point Likert scale to determine the liking level. For measuring the emotional quotient, Wells (1964)'s scale that a widely known and very reliable measure, was applied following the Beerli and Santana (1999)'s study. Besides, the other superiority of this scale is its two-dimensionality (emotional and cognitive components). In this test, 12 statements are given to the customers. The customers can agree or disagree with these statements. While some statements are in favor of the advertisement, on the other hand, some of them are against the advertisement. When the customer agrees to a favorable statement or disagrees to an unfavorable statement, it is considered a positive emotion against the advertisement. Therefore, the number of agreements on favorable statements and the number of disagreements on unfavorable statements are added to each other, then the sum is divided by 12 and multiplied by 100 to produce a score between 0 and 100. However, some of the original statements are not appropriate for evaluating the luxury real estate TV advertisements, therefore, these statements were modified. The following table shows the final list of these statements. Consequently, in the questionnaire, 14 questions were determined to measure the advertisement effectiveness. Also, the age of the respondents was asked. At the end of questionnaire survey, three scores would be obtained for each advertisement. These scores are liking, recall and emotional quotient.

Table 1. The statements used in the questionnaire.

1	This ad is very appealing to me.
2	I would probably skip this ad if I saw on TV.
3	This is a heart-warming ad.
4	This ad makes me want to buy the real estate shown.
5	This ad does not arouse my interest.
6	I don't like this ad.
7	This ad makes me feel good.
8	This is a wonderful ad.
9	This is the kind of ad you can easily forget.
10	This is a fascinating ad.
11	I'm tired of these kinds of ads.
12	This ad turned me off from the idea of buying a real estate.

The other important stage of this research was the identification of the advertisements which would be used in this study. To determine the most appropriate advertisements, two criteria were identified. Firstly, each advertisement should have different advertisement appeals. In this study, the advertisement appeal classification proposed by Davies (1993) was used. According to Davies (1993), there are two main categories for advertisement appeals, namely, rational/informative and emotional/psychological. In this study, two advertisements

representing these two advertisement appeals were used. Secondly, the duration of the advertisements should be longer than 20 seconds to ensure that these advertisements are long enough to inform the customers or invoke emotions of the customers. Based on these criteria, two advertisements were identified. Information on these advertisements is provided in Table 2. The first advertisement represents the rational advertisement appeal because it follows evidence-based marketing and uses an expert's insights to prove the high quality of their product. The other advertisement is an example of an emotional advertisement appeal, and it uses an emotive-based marketing strategy.

Table 2. The advertisements used in this study.

Advertisement	Advertisement appeal	Web link
Queen Central Park Bomonti	Rational	https://www.youtube.com/watch?v=Om9SO9O5MJE
Emlak Konut	Emotional	https://www.youtube.com/watch?v=qyxa_WgWK-w

Data Collection

In this study, the questionnaires were applied face to face to avoid any misunderstandings by providing immediate feedback. In the questionnaire application, at the first step, the first advertisement was shown to the respondent. After watching the advertisement, the respondents filled out the first questionnaire form. The procedure of the first advertisement was over by filling in the questionnaire. The same procedure was followed for the second advertisement. This questionnaire was administered among 221 people living in Istanbul, and the respondents were identified using the convenience sampling method. Following the data collection process, each questionnaire was evaluated, and 5 of the 221 surveys were removed because they gave identical responses to every question. The remaining 216 questionnaires formed the dataset used in this study.

Data Analysis

To examine the effect of age on luxury real estate TV advertisements, independent t-test was performed. Two age groups were identified to perform the analyses. The first group is the age group of 20–35 and the second group is the age group of 35–50. Before applying the independent t-test, the appropriateness of the data for independent t-test should be checked. According to Laerd (2018), the data should comply with six assumptions. The first three assumptions have already been achieved while collecting the data. The remaining three assumptions were also tested. The first assumption is about "no significant outliers." To test this assumption, boxplot method was used. For each age group vs test scores, boxplots were drawn. According to the drawn boxplots, no outlier could not be detected in the dataset. Secondly, the normality of the dataset was tested Shapiro-Wilk test of normality that is more appropriate for small sample sizes. According to the test, unfortunately, none of the data was identified as normal distributed (sig. >0.05). However, independent t-test is quite robust to violations of normality (Laerd, 2018). Therefore, the last assumption was also checked to decide whether the dataset was appropriate for the independent t-test. Levene's test for homogeneity of variances was used to control for this assumption. The following table shows the result of Levene's test. According to the table, only two variables meet the assumption of homogeneity of variance, namely, emotional quotient for ads 1 and 2. However, the

independent t-test also provides results for the variables that violated the assumption of homogeneity of variance. Therefore, in this study, the t-test scores calculated with no equal variance's assumption for these variables were used. Consequently, this dataset was decided to be appropriate for the independent t-test.

Table 3. Levene's test results.

Test scores	F	Sig.
Liking for ad 1	7.518	.007
Recall for ad 1	13.578	<.001
Emotional quotient for ad 1	.671	.414
Liking for ad 2	13.304	<.001
Recall for ad 2	10.326	.002
Emotional quotient for ad 2	2.831	.094

Finally, an independent t-test was applied for each advertisement, and the outputs of this test are shown in Table 3. Also, in this table, the averages of recall, liking, and emotional attraction test scores are shown for each age group with their standard deviations. According to this table, a significant difference between the two age groups in terms of liking was observed for advertisement 1, however, there is no significant difference in terms of liking between the age groups for advertisement 2. The liking level of the younger age group is significantly lower than that of the older age group for advertisement 1.

Both age groups stated that they could recall most of the features of real estate projects. And the differences between the age groups in terms of recall for both advertisements are not significant. Lastly, for advertisement 1, there is a significant difference between the age groups in terms of emotional attraction for advertisement 1. However, this significant difference cannot be observed for advertisement 2. In other words, both groups stated that they were attracted by this advertisement emotionally at a similar level.

Table 4: Independent t-test results.

		20-35		35-50		
		Mean	Std. Dev.	Mean	Std. Dev.	Sig.
Ad 1	Liking	3.37	1.73	3.93	2.01	0.031
	Recall	4.85	1.63	4.52	2.16	0.202
	Emotional Attraction	33.50	27.20	49.16	25.80	0.000
Ad 2	Liking	5.19	1.61	5.00	1.91	0.443
	Recall	5.19	1.45	5.44	1.76	0.238
	Emotional Attraction	55.22	34.91	60.61	31.52	0.235

Also, to investigate the relationship between age and advertisement effectiveness by excluding the advertisement appeal effect, the ANCOVA test was performed by combining the separate test results of these two advertisements. The similar assumptions required for the t-test are also required to perform ANCOVA, therefore this dataset was also determined to be appropriate for this analysis. The result of this test is shown in Table 4. According to this table, the only significant difference between the age groups is observed only in terms of emotional attraction. On the other, no significant differences are observed in terms of liking and recall.

Table 5. ANCOVA Test Results.

		20-35		35-50		
		Mean	Std. Dev.	Mean	Std. Dev.	Sig.
Ad 1 + Ad 2	Liking	4.28	1.90	4.46	2.03	0.294
	Recall	5.02	1.55	4.98	2.02	0.828
	Emotional Attraction	44.36	33.06	54.88	29.30	0.000

Discussion of the Findings

In this study, the effect of age on advertisement effectiveness was investigated. According to the t-test results, the significant effect of age on the advertisement can be observed in one dimension, namely, emotional attraction. However, in other dimensions, no effect can be observed. Therefore, age has a limited effect on advertisement effectiveness. Moreover, in the literature, some conflicting conclusions about the relationship between age and advertisement effectiveness can be seen. For instance, Keshari and Jain (2016) proposed that the age of the respondent does not have any effect on their response to the advertisements. However, Srivastava (2010) stated that age and advertisement impact is correlated strongly.

According to Table 5, the advertisements attract the older age group more emotionally. This effect can be explained by the changes in people's decision-making with aging (Djafarova & Rushworth, 2017). This conclusion does not comply with some studies since they stated that younger people are influenced more quickly compared to older-age groups (Srivastava, 2010). This can be explained by investigating these advertisements separately. Based on Table 4, the emotional attraction score of the young generation is much lower than that of the old generation. This shows that the rationally fragmented advertisement is not emotionally attractive to the young generation. Therefore, the effect of age on advertisement effectiveness should be examined considering the effects of different advertisement appeals. Besides, when the rationally fragmented advertisement is considered, there are significant differences between age groups in terms of liking and emotional attraction. However, no significant differences are observed in any test for emotionally fragmented advertisements. Consequently, to reveal the age effect, the advertisement appeals should also be considered with the effects of advertisement effectiveness.

Based on Table 4, the younger generation does not like the rationally fragmented advertisement compared to the older generation. As stated above, this advertisement uses celebrity endorsement to prove the luxury of the real estate project. This celebrity is an old queen, and the young generation cannot easily perceive her as their ideal self-image and role model. Although studies show that the young generation is more easily persuaded by celebrity endorsers compared to the old generation (Chan & Fan, 2022), the selection of the celebrity is also critical for persuading the younger generation. To persuade the young generation, the celebrity should be selected by considering whether this celebrity can be idolized by the young generation. However, the old generation likes this advertisement more compared to the young generation. Since buying a new real estate is also considered an important investment, the rationally fragmented advertisement is expected to be more effective among the old generation. However, the liking level of this advertisement is moderate. The moderate liking level can be the result of the selection of the celebrity since the respondents can question the realism of the

advertisement and they do not believe that the celebrity will actually live in this real estate project. Whereas customers are more likely to purchase a product if they think the celebrity who is endorsing it genuinely uses it (Jamil & Rameez ul Hassan, 2014). Therefore, in real estate advertisements, a global celebrity endorsement can be an ineffective strategy. Instead of global endorsers, an endorsement of a local celebrity who has popularity, credibility, and a positive image in the target market can be a more effective strategy for the rationally fragmented advertisements in the real estate market. However, in emotionally fragmented advertisements, both age groups are affected at the same level. Also, all test scores of this advertisement are high for both age groups. This shows that the advertisements that trigger emotions are more effective in both age groups. The reason for this finding can be that real estate is more than an investment for many people, and they see their real estate as a relaxed and comfortable haven that can protect them from the dangers around (Madigan & Munro, 1996). Consequently, real estate companies should prefer emotionally fragmented advertisements to increase their advertisement effectiveness.

Conclusion

In this study, the relationship between age and advertisement effectiveness is examined for luxury real estate TV advertisements. The findings show that the effect of age on these advertisements is limited. There are no significant differences between the age groups in terms of liking and recall in these advertisements. In other words, old and young age groups like these advertisements and recall the features of the advertised real projects at a similar level. However, only the emotional attraction test score is determined significantly different between these age groups. The reason for this finding can be explained explicitly when the advertisement appeal is also considered. Therefore, the effect of age on advertisement appeal should be examined considering the advertisement appeal.

In this study, two advertisements with two different advertisement appeals are examined to reveal the effects of age on advertisement effectiveness. This study shows that the effect of age can vary among the different advertisement appeals. In the rationally fragmented advertisement, age was identified as a critical factor that affects advertisement effectiveness. However, such a relationship could not be identified in the emotionally fragmented advertisement. The old generation liked the rationally fragmented advertisement more compared to the young generation. Therefore, real estate companies could use rationally fragmented advertisements when they are targeting the old generation. However, the celebrity used in these advertisements is critical, since when the audiences feel that the possibility of using the advertised product by the celebrity is low, the realism of the advertisement decreases, which in turn decreases the advertisement effectiveness. However, emotionally fragmented advertisements were identified as an effective strategy for both groups. Therefore, the real estate companies can prefer this advertisement appeal to have more effective advertisements.

Finally, this study has some limitations and can be improved by further studies. Firstly, this study was conducted by targeting Turkish customers. Therefore, different findings can be revealed for different countries due to the cultural and economic diversity. Secondly, luxury real estate projects were considered in this study, therefore other studies that focus on budget real estate projects can reach different conclusions. Besides, this study used only the main advertisement appeals, however, there are also subcategories for advertisement appeals. This study can be repeated for more advertisements that have these advertisement appeals; thus, the effects of age can be examined more elaborately. Finally, the selection of celebrities was

identified as a critical factor in the study. This study does not elaborately investigate the effect of celebrity on advertisement effectiveness. Therefore, the effects of celebrity endorsements can also be investigated to select the most appropriate celebrity for different advertisement appeals.

Investigation of Intended Use of Digital Transformation Applications throughout Construction Projects' Lifecycle

C. Yalnız, İ. G. Erol and H. Aladağ
Yildiz Technical University, Department of Civil Engineering, İstanbul, Turkey
ylnz.cns@gmail.com, incierdal95@ gmail.com, haladag@ yildiz.edu.tr

Abstract

While digitalization has brought radical changes in all sectors, it has also created important transformations in the construction industry. Digitization tools such as BIM, RFID, CPS, IoT, AR-VR, etc., have provided many opportunities to manage construction projects. Especially in large-scale construction projects, digital tools emerge as efficient solutions to problems such as high project workload, the presence of many disciplines and sub-disciplines that need to work together, and the large construction site that needs to be managed. In this context, determining digital tools that are used in the construction industry and revealing their intended use in construction projects throughout the project's lifecycle constitutes the aim of this study. In accordance with the study's aim, a comprehensive literature review was conducted to determine digital tool usage in the lifecycle of construction projects. Findings related to digital tool usage were compiled under eight stages that are strategic definition, preparation and briefing, concept design, spatial coordination, technical design, manufacturing and construction, handover and close out, and in-use stages, respectively. In each stage, samples and estimations that show how the digitization tools use were presented in detail. Results show that even though some digital tools are still in the testing phase or utilized less than expected, the construction industry will be bound to adapt due to the provided opportunities by innovations soon.

Keywords: *construction industry, construction project, digital transformation, digitalization tools, digitization, project management.*

Introduction

Digitization is defined as utilizing digital technologies to change a business model and provide new income and value-creating opportunities (Gartner, 2021). Digitization can also provide better real-time monitoring of operations and results by integrating structured and unstructured data, providing better views of organizational data, and integrating data from other sources (Maskuriy et al., 2019). Digitization has changed many companies' organizational and operational processes due to technology adaptation, and it is also defined as the ability to transform existing products and services into digital versions. In this direction, various advantages are provided by the digitization of the tangible product (Parviainen et al., 2017). The fact that digital data is easily accessible and calculable creates a chance for fast and accurate analysis in many subjects. This approach has simplified business processes in many areas (Kane et al., 2015).

Furthermore, especially in the construction industry, digital tool usage provides simultaneous data distribution, prevention of repetitive work, and faster project deliveries with more efficient tools. These improvements have facilitated cooperation and increased performance in projects with different manufacturing tracking tools. The development of digital tools has prevented wasting time, cost, and material. New employment areas have emerged in the construction industry due to utilizing new digital tools. Digitalization also transforms the leadership in the construction industry. Influential digital leaders in research from MIT Sloan Management Review and Deloitte (2015) are defined as leaders who provide vision and purpose to their organization, create conditions for experimentation, encourage people to think differently, and support people to collaborate beyond their borders. Some companies have managed the transition process by including digital leaders in their teams and developing team members through various training to accelerate digital transformation. While digitalization has brought about radical changes in all sectors, it has also created some transformations in the construction project lifecycle. During that process, many digital tools have been produced as indicated below:

- Simulation and Modelling
- Building Information Modelling (BIM)
- Augmented Reality (AR) - Virtual Reality (VR) - Mixed Reality (MR)
- Cyber-Physical Systems (CPS)
- Radio-Frequency Recognition Systems (RFID)
- Product Lifecycle Management
- Internet of Things (IoT)
- Additive Manufacturing
- Robotics
- Cloud Computing Systems, and
- Big Data (Oesterreich & Teuteberg, 2016).

Although digital tools provide many opportunities for managing high project workload, multi-disciplinary working, and large-scale construction sites, many companies still do not have a holistic transformation approach. Furthermore, many digital tools are still in the testing process. Therefore, the study aims to investigate the intended use of digital transformation applications throughout the construction projects' life cycle.

Digital Transformation Applications in Construction Industry

Advancement in technology provides many digital applications in the construction industry. In this section, all relevant applications have been examined.

- Simulation and Modeling: Simulation can be defined as an area where animations are made from the models, created in line with accurate data. The animations can be made for visual presentation purposes or to create a basis for technical analysis. In addition, the model can measure real effects with simulation programs (Ndekugri & Lansley, 1992).
- BIM: BIM, defined as the digital reflection of a facility's physical and functional characteristics, is used in project decision-making, planning and programming, cost management, and facility maintenance processes (Rokooei, 2015). The BIM model is produced by modelling the building elements in three dimensions and entering the relevant data into the parameters of the model elements. In addition to modelling,

interdisciplinary coordination can also be done on this platform. As Lahdou and Zetterman (2011) stated, BIM enables interdisciplinary work not only with a single model but also by integrating many models. Architectural, static, electrical, and mechanical models are integrated into the main model, and the necessary coordination can be quickly done.

- AR, VR, and MR: The Augmented Reality statement allows "virtual data created in the digital environment to be displayed synchronously on the real world (Şen, 2021). It is a type of experience that is created by combining images of the physical world and interacts with changes in the environment in real-time, adhering to predetermined software limits." With the further development of systems such as BIM and the transition of designs from 2D to 3D, AR technology will become frequently used. Virtual Reality is a set of systems in which the real-world environment can be presented to the person with different alternatives with the help of virtual design space and digital systems in the 3D model made by the designer. The user can experience the designed environment emotionally with the help of electronic devices (Şen, 2021). Mixed Reality is a mixture of the physical world and the digital world. In mixed reality, digital information is represented by holograms (objects made of light and sound) that appear in the space around you (Lindgren & Johnson-Glenberg, 2013).
- CPS: Cyber-physical systems use operating systems, sensors, and actuators to control machines that exist in traditional construction processes. The motion data generated in the machines are received with the help of sensor-like tools and are easily reported. These systems allow computer systems to be integrated into physical systems to maintain, operate and manage production and usage processes more securely and efficiently. The main components are mobile devices, machines, and tools (Eggenreiter, 2021).
- RFID: A radio frequency identification system tracks objects, animals, and people. The RFID system is similar to a kind of barcoding system. RFID Readers receive data over the frequencies emitted by the RFID tags attached to the objects. Supply Chain management, customer relationship management, warehouse management systems, and enterprise resource planning are the processes that utilize the obtained data from the RFID system. RFID technology components include an RFID tag, RFID Printer, RFID reader, and programming tool (Lee et al., 2013).
- Product Lifecycle Management: Product Lifecycle Management is a multi-disciplinary computer-aided technology organization that supports recording the data belonging to a product and the processes from the idea stage to the end of its useful life in the computer environment. This information is quickly accessed and used efficiently (Ötleş et al., 2015).
- IoT: IoT is a structure formed by connecting physical structures to the internet. An existing object receives and transfers data with its IP; in this direction, the objects become usable over the Internet. All objects in the IoT are connected to the internet with a live data transferring system. Technologies such as detection technologies, identification and recognition technologies, hardware, software and cloud platforms, communication technologies and networks, software and algorithms, location technologies, data processing solutions, power and energy storage, and security mechanisms can be defined as IoT tools (Işıkdağ, 2015).
- Additive Manufacturing: Additive manufacturing is generally the production of 3D objects layer by layer. The part designed in the digital environment is converted into the required format and separated into layers, and additive manufacturing machines fuse these layers by creating them additively. The purposes of additive manufacturing systems can be listed as reducing production investment costs, reducing

manufacturing times, manufacturing complex geometries, and being suitable for small-scale and unique production (Sürmen, 2019).

- Robotics: Construction Industry is affected by the rapid advancement of artificial intelligence. Robot creation provides many opportunities in the industry and may achieve successful results in repetitive tasks in a controlled area. On the other hand, the uncontrolled area at the construction sites has risks since robots to adaption. Despite the mentioned obstacles, robotic systems and artificial intelligence solutions are used in construction projects. The most used of these can be listed as 3D printers, drones, and demolition robots (Kafadar, 2021).
- Cloud Computing: Cloud computing is the general name for internet-based adjustable information technologies with high processing power, such as shared data processing, storage, and calculation, which can be used at any time with a computer or mobile device. In this respect, cloud computing is not a product but a service. Cloud Computing technology has a significant contribution in terms of cost, speed, performance, and security. In addition, it reduces expenses such as purchasing software and hardware and setting up data centres (Keleş & Keleş, 2018).
- Big Data: Big data is the collection of data from different sources such as media shares, blogs, photographs, videos, and three-dimensional models produced in the computer environment or 2D drawings, converted into a meaningful and workable format. This technology has been used increasingly in construction and other industries recently. For example, sensors on buildings can collect hundreds of data that help evaluate building performance. In line with that, advanced automation and integration to measure, monitor, control, and optimize building operations and maintenance can be provided (Bilal et al., 2016; Kaya, 2016).

With the indicated tools above, many opportunities have been occurring in the project lifecycle processes in the construction industry. However, every digital application or device has different capabilities in different stages. Therefore, the user should know which tools can be utilized in which stages. Thus, the following section categorizes the utilization of the tools based on the stages.

Investigation of Digital Transformation Applications in Project Management Phases

Royal Institute of British Architects (RIBA) is investigated in various studies to standardize architectural and construction project processes. "Plan of Work" document has been produced to standardize work planning since 2013. As the project processes get more complex, especially the project scales getting bigger, different perspectives on process planning will be involved, which may lead to the emergence of many project management methods. This multi-perspective situation risks creating unsustainable and incorrect planning results in some cases. Therefore, RIBA has standardized the steps related to the work plan processes by examining the approach of many countries. Since the study aims to analyse digital application usage in defined construction processes comprehensively, the standardized process of RIBA was used as a base. Project planning process stages that emerged in line with this approach: 1) Strategic Definition Phase, 2) Preparation and Briefing Phase, 3) Concept Design Phase, 4) Spatial Coordination Phase, 5) Technical Design Phase, 6) Manufacturing and Construction Phase, 7) Handover Phase and 8) Use Phase (RIBA Plan of Work, 2020). Each stage includes procurement strategy, information exchange process, project strategy, protection strategy, cost strategy, fire safety strategy, health and safety strategy, inclusive design strategy, planning

strategy, plan of use strategy, and sustainably organized in line with the energy strategy phases.

RIBA has examined many country approaches to construction and created a standard process for the construction projects. In line with the study's aim that is investigation of intended use of digital transformation applications throughout construction projects' lifecycle Tablo 1 has been produced as a result of literature review (Şapcı & Pektaş, 2021; White et al., 2021; Rokooei, 2015; Lahdou & Zetterman, 2011; Şen, 2021; Ofluoğlu, 2016; Eggenreiter, 2021; Lee et al., 2013; Ötleş et al., 2015; Işıkdağ, 2015; Sürmen, 2019; Kafadar, 2021; Keleş & Keleş, 2018; Bilal et al., 2016; Kaya, 2016).

Table 1. Digital application usage throughout construction projects' lifecycle.

	Strategic Definition	Preparation and Briefing	Concept Design	Spatial Coordination	Technical Design	Manufacturing and Construction	Handover	Use
Simulation and Modeling	X	X	X	X	X	X		
BIM	X	X	X	X	X	X	X	X
AR /VR /MR			X	X	X	X	X	
CPS						X	X	X
RFID						X	X	X
Product Lifecycle Management								X
Iot / IoS						X	X	X
Additive Manufacturing			X			X		
Robotics						X		X
Cloud Computing Systems	X	X	X	X	X	X	X	X
Big Data								X

As seen in the Table 1, almost all indicated digital tools can be utilized in the manufacturing and construction phases. Besides, BIM and cloud computing systems can be utilized in all phases of construction project management phases. On the other hand, big data seems to be utilized in the only use phase. However, considering the indirect usage potential, big data can be also utilized for other projects' comparative analysis or first feasibility studies as a sample. Detailed explanations related to which digital applications can utilize in which phase can be found below:

- Strategic Definition Phase: At this stage, it is essential to define the employer requirements in detail rather than the design and details. In this direction, strategic thinking, management consultancy, life analysis, sustainability studies, financial modelling, and design thinking are becoming crucial (RIBA Plan of Work, 2020). During this stage, it is seen that using simulation and modelling tools for environmental analyses provides an opportunity for a better understanding of the environment. For example, the digital twin of the Docklands has been created, and the digital twin has provided a better understanding of the city's circulation, usage, and topography with simulations while the new projects are created. This opportunity provides the proper decision-making for the new project creations. Besides, making the correct estimates for the possible revenues obtained and measuring the budget performance value is more manageable with the digital twins. In addition, the fact that estimations related to logistics can be made will ensure that correct estimations about logistics expenses can be made from the beginning of the project. The created opportunities will increase productivity and improve the quality and performance of

the project. In addition, determining the employer's requirements with a holistic perspective by making the necessary analyses will save time in future processes (Ndekugri & Lansley, 1992; Şapcı & Pektaş, 2021; White et al., 2021). When the use of BIM is examined, modelling the project area provides an opportunity to make various analyses. For example, Geographic Information System (GIS) models provide a better understanding of the environment. Such models can be transferred into BIM software and are useful for creating the design, especially if similar projects with the same function plan have been done before in the project area; examining them can indirectly provide ease at this stage. For example, if a multiple-apartment project needs to be implemented in a residential area with a digital twin model, examining similar multiple-apartment BIM projects nearby will ease the determination of the employer's demands. The fact that the data can be easily obtained from digital data models and the analysis can be done easily creates the advantage of accessing the right data and provides time savings (Rokooei, 2015; Lahdou & Zetterman, 2011; Şen, 2021; Ofluoğlu, 2016; White et al., 2021). Cloud computing is a system that facilitates the storage and sharing of building-related data at all stages of the construction processes and the coordination of all teams in data access. It enables the employer to quickly communicate with the team during the strategic definition phase and to share data simultaneously. As a result, the project team can review the data, necessary updates on the subjects can be provided interactively, and the project's performance increases due to the advantages provided by this interactivity (Keleş & Keleş, 2018).

- Preparation and Briefing Phase: It is necessary to prepare a more detailed summary of the project that was decided in the previous stage. The summary should include the necessary information for the concept design stage. In addition, feasibility studies are done, and following that, whether the area and the planned project are compatible with the client's requirements is checked. It is crucial to make the relevant analyses with the employer team, examine the spatial requirements, associate them with the project budget, and specify them as a summary because the preliminary feasibility study will refer to the project's ongoing processes. Besides, it is necessary to consider new digital technologies and include the information for asset management after the transfer process. The client should determine who will control the compliance with the project in line with the project construction processes. Resources are determined, and the project schedule and execution plan are made at this stage (RIBA Plan of Work, 2020). Simulation and modelling programs can enhance cooperation with the analysis opportunities when we examine the digital applications in the Preparation and Summarization phase. Since the resources are determined, the program is made, and the execution plan is prepared in this stage, the design team is also included in the process to make strategic design decisions. For example, to design an energy-efficient building, the design team can start to determine how to use the sun and natural ventilation methods by examining the area and alternative mass designs. Such approaches have the potential to prevent waste at this stage indirectly (Ndekugri & Lansley, 1992; Şapcı & Pektaş, 2021; White et al., 2021). BIM usage in the preparation and summarization phase provides holistic advancement. Besides, the feasibility of the building can be obtained more easily with the BIM model. Design ideas can be converted into masses as sketch models, and more successful estimations can be made by taking quantities from models in line with requested materials and costs. Since a holistic study is carried out in this process, interdisciplinary cooperation is supported, performance increases, and timesaving is achieved (Rokooei, 2015; Lahdou & Zetterman, 2011; Şen, 2021; Ofluoğlu, 2016; White et al, 2021). The cloud computing system provides simultaneous access to data, data storage, and data sharing

facilities. Besides, the communication of every team member can be achieved easily. Also, the client can efficiently communicate with his team and the design team during the preparation and summary stages. In this direction, the necessary coordination and progress can be achieved, and the project performance increases accordingly (Keleş & Keleş 2018).

- Concept Design Phase: This stage aims to produce the design concept correctly in line with the previous stage's data and create the project in line with the Client's requirements. The most critical issue at this level is determining the information requirements necessary for successfully creating the concept. In addition, making some basic engineering calculations about circulation, toilet usage, and the usage of stairs provides more successful progress in the process. In addition, the concept needs to be decided by the Client. At this stage, providing the detail packages for the complex parts of the project, such as the facade details, is essential for the following chapters (RIBA Plan of Work, 2020). As in the other stages, simulation and modelling tool usage facilitate design-related analysis, coordination, and presentation processes. Besides, design presentations can be easily presented to the Client by showing the project simulation. In addition, the simulation and model can establish a common ground for the project discussions. Therefore, it facilitates the decision-making process and offers the opportunity to produce and examine many more alternatives. Thus, simulation and modelling tools increase project productivity, quality, and performance (Ndekugri & Lansley, 1992; Şapcı & Pektaş, 2021; White et al., 2021). BIM usage in the concept design process provides many opportunities as in the previous stages. For example, creating and presenting many alternative design options according to the analyses, easing coordination and decision-making processes, monitoring quantification changes, and providing many outputs for value engineering processes can be considered BIM benefits in the concept design process. In addition, since the project drawings are obtained from 3D models. Each modelled element, section, plan, and elevation view is updated simultaneously in all drawings, thus providing timesaving (Rokooei, 2015; Lahdou & Zetterman, 2011; Şen, 2021; Ofluoğlu, 2016; White et al., 2021). AR, VR, and MR technologies provide a suitable marketing method for presenting the design to the Client. In addition, these tools ease clarifying the problems to the relevant responsible person due to the visual presentation. The use of additive manufacturing is a positive tool for presenting the work during the concept design phase, especially in presentations to the Client. An Architectural 3D model created from the 3D printers can be presented to explain the design (Çalışkan & Arpacıoğlu, 2020). In this phase, cloud computing systems also will encourage communication, allowing all disciplines to access the design and changes simultaneously through the models in cloud systems (Keleş & Keleş, 2018).
- Spatial Coordination Phase: The most critical issue at this stage is the completion of the coordination prior to the manufacturing and construction process. At this stage, the necessary coordination should be done in detail to avoid returning to the coordination stage. Decisions of room and function changes regarding the venue must have been completed in the previous process. This process should not be started before the room locations are finalized (RIBA Plan of Work, 2020). In this process, simulation and modelling tools facilitate data transfer and provide data analysis on models related to problem areas. Since the modelling mentioned here is schematic modelling created with 3D modelling programs independent of BIM processes, the benefit of the overlap tests for the project cannot be mentioned at this stage. However, it can be considered a tool that simplifies the process of defining the problematic area in 3D and transferring it to the people in the team. In this direction, it increases performance and

productivity. The site simulations can be prepared at this stage. These simulations can be used while providing and developing occupational health and safety training. These benefits provide better time management, especially in large-scale projects (Ndekugri & Lansley, 1992; Şapcı & Pektaş, 2021; White et al., 2021). BIM usage in this process enables the prediction of construction-related issues. İnterdisciplinary coordination with clash tests provides error minimization before manufacturing. Decision-making is done efficiently, and action is taken fast. Considering the complex nature of large-scale projects, the holistic approach provided by BIM occurs easily controllable projects in terms of cost, time, and occupational health and safety (Rokooei, 2015; Lahdou & Zetterman, 2011; Şen, 2021; Ofluoğlu, 2016; White et al., 2021). AR/VR/MR usage in this stage effects that facilitate interdisciplinary cooperation in the site and office regarding coordination issues can be revealed. Problems related to coordination issues in design can be examined through models with the help of VR glasses. While this situation supports communication between stakeholders, time can be gained indirectly. Especially when conducting on-site inspections, comparisons of the model and current situation can be made with augmented reality tools (Şen, 2021; Özdemir, 2019). In the spatial coordination phase, using Cloud computing systems has time-saving advantages such as interdisciplinary coordination, simultaneous analysis, tracking change, publishing problems online via add-on programs over models in the cloud, and providing coordination with online discussions. Especially in large-scale projects, the problem of crowded project teams making it difficult to follow and coordinate can be easily avoided with cloud computing systems (Keleş & Keleş, 2018).

- Technical Design Phase: In this section, where the necessary information for the manufacturing and construction phases is produced, the subcontractors employed by the contractor together with the design team detail their projects. At this stage, it is essential to involve the relevant subcontractors in the project so that the necessary field inquiries and audit and reporting processes can progress (RIBA Plan of Work, 2020). The involvement of all subcontractors in the technical design process has risks in terms of control, especially in large-scale projects. Simulation programs can be used in OHS training related to the adaptation process of subcontractors to the field. Using simulation and modelling tools increases efficiency, especially when making logistics plans related to the manufacturing and construction process while determining time-based logistic coordination, determining circulation areas, and making plans related to occupational health and safety (Ndekugri & Lansley, 1992; Şapcı & Pektaş, 2021; White et al., 2021). At this stage, possible changes can be followed simultaneously via BIM models. The revisions required by the technical design and quantity changes can be easily followed through the models, and stakeholder management can be done efficiently (Rokooei, 2015; Lahdou & Zetterman, 2011; Şen, 2021; Ofluoğlu, 2016; White et al., 2021). AR/VR/MR usage in this stage effects that facilitate interdisciplinary regarding occurred issues can be revealed (Şen, 2021; Özdemir, 2019). Using cloud computing systems at the technical design stage facilitates interdisciplinary coordination and has many opportunities for timesaving and increases cooperation such as simultaneous review, tracking of change, online issue publishing through add-on programs over models in the cloud, and coordination with online discussions. Especially in large-scale projects, due to the crowded project teams, follow-up and coordination become difficult. Therefore, cloud computing systems are becoming crucial (Keleş & Keleş, 2018).
- Manufacturing and Construction Phase: Manufacturing and construction phases take place in this phase. Design works have been completed in the previous stage. Output

can be the completed building structure in line with the drawings as in the traditional process. Also, there can be building information models that include every relevant data for asset management maintenance and use with the completed building. The data in the models must follow the client requirements indicated in the contracts. In addition, inspections related to construction processes are carried out during this process (RIBA Plan of Work, 2020). Real-time monitoring regarding the construction status can be achieved through the simulation models. Besides, logistical coordination and health and safety training can be better managed due to visualization capability. Furthermore, monitoring the project performance, collaborating with the project stakeholders in case of possible delays, and revising the field program with correct data provide an opportunity for gaining time and cost (Ndekugri & Lansley, 1992; Şapcı & Pektaş, 2021; White et al., 2021). BIM in this stage provides the site team to pursue the project, and the team can quickly determine possible changes due to the model and real-status comparison. In addition, the client's inspections are also eased for the same reason. Project and real situation comparisons can also be made with point cloud models, and possible issues are quickly detected. Thus, time and cost-saving can be achieved (Rokooei, 2015; Lahdou & Zetterman, 2011; Şen, 2021; Ofluoğlu, 2016; White et al., 2021). Regardless of the stage, VR, AR, and MR tool usage provides better management due to real-time monitoring capability. For example, due to the location indicator barcodes at the site, if the site engineer has a digital tablet, she can easily reach the information model for the appropriate location and review it. In line with that, it provides interdisciplinary cooperation opportunities and prevents possible issues (Şen, 2021; Özdemir, 2019). Laser scanning systems can be given as examples of cyber-physical systems. By adding the data scanned from the construction sites with the laser scanner, linked into the models for comparing the actual situation and the requested situation can be made easily (Eggenreiter et al., 2019; Kan & Anumba, 2019; Akanmu et al., 2013). Material tracking during the Manufacturing and Construction phase, controlling the warehouses, and providing warning systems related to occupational safety are managed more efficiently with the RFID systems. For example, controlling the status regarding the reinforcement in the concrete and making material counting in the warehouses are possible with the RFID system. Besides, developing alarm systems when the dangerous equipment on the site works close to the workers using the RFID tags on the helmets can provide better HSE management. In addition, considering the user errors in the indicated process, especially in large-scale construction projects, it is seen that RFID tag systems eliminate these risks with automation (Akanmu et al., 2013; Uygunoğlu & Topçu, 2020; Lee et al., 2013). Internet of Things (IoT) in the manufacturing and construction phase is described as an effective tool for tracking the amount and location of materials on the site using RFID tags. For example, the data received from the RFID tags are transferred from the RFID readers to the databases using IoT. In addition, considering the digital twin of the city of Docklands, created data with sensors is transferred to the database with IoT (White et al., 2021; Uygunoğlu & Topçu, 2020; Işıkdağ, 2015; Ghosh et al. 2020). Additive manufacturing in this phase provides an advantage in producing the building elements, such as precast or modular facade elements. In addition, building elements produced with a 3D printer indirectly saves time and increases project productivity (Sürmen, 2019; Çalışkan & Arpacıoğlu, 2020). The use of robotics in construction and manufacturing processes is not expected since construction sites are considered complex for using robots. 3D printers and drones are the robotic systems that are utilized in construction. Drones facilitate site monitoring and obtaining up-to-date data for site conditions. In addition, structural elements such

as roofs and bridges can also be made with 3d printers (Kafadar, 2021; Sürmen, 2019). Especially in the large-scale projects, cloud computing systems provide convenience in reporting the actual situation on the site, reporting the problems, delivering the reports simultaneously to all stakeholders, notifying the possible revisions to the site, and supporting the stakeholder management, enabling the project to be built with better performance. Besides, with cloud computing systems, tracking can be done simultaneously without being in the working area. In addition, control systems can be created over cloud areas related to material tracking, distribution, and manufacturing tracking (Keleş & Keleş, 2018).

- Handover Phase: In this phase, the building must be completed in line with the requirements specified in the contract. To achieve a successful handover process, the relevant activities can begin at the previous stage. The building is transferred to the client after the occupancy assessment is made (RIBA Plan of Work, 2020). The BIM model produced during the handover process enables process-related controls, and the point clouds obtained by laser scanning make it easier to control the compliance processes with the project. In addition, the As-Built BIM model can be utilized for lighting, noise, etc., reviews. Besides the BIM model and VR-AR devices, new approval processes can be developed without going to the site using the point clouds. In line with that, the approval process can be standardized (Rokooei, 2015; Lahdou & Zetterman, 2011; Şen, 2021; Ofluoğlu, 2016; White et al., 2021). VR-AR devices can facilitate the handover process for the relevant controls. Furthermore, regarding compliance with the project, productions can be easily checked over the digital drawings at site using VR-AR devices (Şen, 2021; Özdemir, 2019). Cyber-physical systems can be utilized in the handover processes of large-scale buildings since the controls are more complex than the small-scale project while making mechanical and electrical system tests. For example, while performing a noise, fire alarm, and lighting tests, data can be tracked more easily with the CPS systems. Especially in green building handover processes, data reflected on digital twins from CPS systems can be utilized while checking whether the building works in line with required performance values in each season (Eggenreiter, 2021; Kan & Anumba, 2019; Akanmu et al.,2013). During the handover phase, the control of the building elements on the site can be done quickly with the help of RFID tags. Furthermore, if the tags have been attached to the construction elements and model element ID numbers have been defined, the detection of problematic equipment and relevant stakeholder can be managed better. Thus, handover process can be sped up (Akanmu et al., 2013; Uygunoğlu & Topçu, 2020; Lee et al., 2013). Manufactured elements data on the site are transferred to the digital area via the IoT and relevant devices. Besides, RFID tags and readers make controlling the produced elements easier. For example, in the digital twin of the city of Docklands in Dublin, flood analysis in the city has been made using the digital twin. Furthermore, every citizen has a connection with the digital twin to add a comment via applications. User usage and comments are also followed via devices. Development projects can be created based on the data obtained from the analysis. IoT provides better management to ease the data transfer from the sensors or devices for the handover process (White et al., 2021; Uygunoğlu & Topçu, 2020; Işıkdağ, 2015; Ghosh et al. 2020). During the handover phase, cloud computing systems achieve significance with the simultaneous distribution of information regarding the reporting and tracking issues. Due to the time management in large-scale projects approving processes can be quickly in the cloud system (Keleş & Keleş, 2018).
- Use Phase: This process is defined as the period of the building being in use until the end of its life. The project team finalizes their tasks, and the contract is completed. If

requested, separate contracts are prepared to complete After Use Assessment or provide longer-term customer advice. If the building does not meet the customer's expectations during this stage, a new process regarding the renovation or transformation of the building should be started. This situation needs to be considered in the first stage. The client team can request foreseen information about the dismantling or renovation of the structure (RIBA Plan of Work, 2020). The asset information is entered into the BIM model elements during the BIM processes. All data in the model can be easily tracked, assets can be classified, and analyses can be made quickly through these classifications. In line with these data, stakeholders follow building lifecycle and maintenance requirements. Especially in large-scale projects, when the number and diversity of model elements are considered, the importance of holistic tracking, control, and analysis opportunities provided by digitalization becomes crucial (Rokooei, 2015; Lahdou & Zetterman, 2011; Şen, 2021; Ofluoğlu, 2016; White et al., 2021). Cyber-physical system applications can provide an opportunity to analyse the building lifecycle. For example, smart home thermal, maintenance, and energy usage processes can be analysed via data obtained from sensors. Another sample is Docklands, where the city has the digital twin. Many detections are made in line with the data obtained by the sensors and users' mobile devices, which are used for city development. Since data collection in large-scale projects is more comprehensive and complex than in small-scale ones, increasing cyber-physical system usage in large-scale projects is inevitable (Eggenreiter, 2021; Kan & Anumba, 2019; Akanmu et al., 2013). RFID tags provide a complementary approach in this phase. When the maintenance period comes, RFID tags can be utilized to find the element in the large-scale construction area with RFID readers. In addition, material life cycles can be monitored through RFID tags. RFID tags are also essential for the creation of digital twins due to provide a connection between the digital twin and the building. Increasing the project performance, waste-minimization, and facilitation of the follow-up process can be considered the benefits of RFID usage (Akanmu et al., 2013; Uygunoğlu & Topçu, 2020; Lee et al., 2013). IoT creates efficiency in this phase due to providing connections between electronic devices such as RFID, sensors, computer and etc. Besides, when a building is not in use, smart systems regarding heat, light, and ventilation can be controlled from the outside. In addition, various software can automatically adjust the settings of the building when it is not in use, in line with the data obtained with the sensors. Such systems show the importance of IoT in the construction industry due to supporting energy efficiency systems (White et al., 2021; Uygunoğlu & Topçu, 2020; Işıkdağ, 2015; Ghosh et al. 2020). The product lifecycle management process is essential in monitoring the life of the building elements and making the necessary applications for the maintenance and modification processes related to the building easily through this follow-up. In addition to increasing performance, it supports cooperation by making the data available to all stakeholders. Besides, waste minimization can be achieved by following the material processes in the building and extending their life if necessary with the proper intervention (Ötleş et al., 2015; Eigner, 2014; Filik & Yeşilay, 2020; Terzi et al., 2010; Xin & Ojanen, 2017; Li et al., 2015). Robotics systems can be utilized for collecting data regarding the status of the building. Data collection via drones for digital twins can be a sample from this process (Kafadar, 2021). In this phase, cloud systems can be defined as the area that shares and stores process-related analyses and reports simultaneously for every relevant discipline (Keleş & Keleş, 2018). Big data technology is used in the construction industry to monitor fuel consumption and equipment usage. Big data improves many activities in this phase,

such as facility (assets and equipment) management, risk minimization, preventive maintenance, pre-construction foresight evaluation, construction site organization, supply process, and security. With the development of technology and the widespread use of digital tools, the importance of big data will increase much more, and the processes will be advanced in line with the analysis of these data (Bilal et al., 2016; Kaya, 2016).

Conclusion

Rapid advancement in technology affected the construction industry. As a result of digital transformation, many applications have been created, such as BIM, RFID, CPS, IoT, and AR-VR. Furthermore, digital applications have provided many opportunities such as time and cost efficiency, real-time monitoring, and waste-minimization during construction (Oesterreich & Teuteberg, 2016). In the study, the effects of digital transformation on construction have been compiled under the RIBA "Plan of work" stages. It is determined that, as seen in Table 1, the "Manufacturing and Construction Phase" is the most appropriate for digital transformation, and nine digital tools can be utilized. Besides, the "Strategic Definition Phase" and "Preparation and Briefing Phase" are less appropriate due to the three digital tools that can be utilized. On the other hand, BIM and Cloud Computing systems are utilized more than other digital tools in the construction stages. Considering the rapid digital transformation in all sectors, managing this transforming process in construction is becoming crucial. Therefore, a holistic examination of the capability of the digital application compiled on the standardized project processes has formed a basis for better consultation. The study can guide companies and employees trying to adapt to digitalization processes. For example, a firm that expertise in concept design can get an idea by examining the use of digital tools in the "Concept Design" section of the table. The table can also guide digital tool developers to improve or create new tools considering the stage requirements due to RIBA having already defined them (RIBA Plan of Work, 2020). On the other hand, even though digitalization in the construction industry has much potential, still traditional methods have been selected. Therefore, for future development, the construction industry can be examined by comparison of the indicated digital application utilization potentials in Table 1 and the current utilization status. In line with that, every "Plan of Work" stage can be examined in more detail with case works considering cost and time effects. For example, the cost and time difference between the "Manufacturing and Construction Phase" utilizing Cloud Computing Systems or not utilizing them can be researched to inform the Construction Industry.

Abstract

Building Information Modeling is capable of responding the expectations of well-managed complex design and construction processes, enhanced sustainability, low cost and high efficiency, and effective building operation and maintenance in contrast to traditional project delivery process. Owing to the benefits it provides, BIM has been highly adopted in many developed countries and its adoption rate is increasing in developing countries. As in many developing countries, the implementation rate of BIM in the Turkish AEC industry is increasing, but many difficulties are still encountered in BIM implementation. Therefore, this research aims to determine the critical challenges of BIM implementation in Turkish AEC industry. To achieve this aim, the objectives are to; identify the BIM implementation influencing challenges (ICs) and determine the critical challenges of BIM implementation. Through a systematic literature review of 563 articles, 46 ICs were identified under four categories: BIM practices (13 items), BIM awareness (9 items), BIM organization (18 items), BIM education (6 items). The questionnaire was designed by the 46 ICs with 5-point Likert scale as measuring instrument and applied to 600 architects and engineers occupied at construction companies that do not use BIM technology. A total of 141 valid questionnaire were returned, representing a 23.5% response rate. Obtained data analyzed using reliability analysis, and mean score ranking. Mean score ranking was conducted to each group individually to identify the critical challenges specific to category, and among the 46 ICs, 24 of them determined as critical challenges for BIM implementation in AEC industry in Turkey. Considering these critical challenges, the suggestions have been developed to improve the current situation.

Keywords: *building information modeling (BIM), critical BIM challenges, BIM implementation, Turkish AEC industry.*

Introduction

The rapid growth in the AEC industry is an important factor in the formation of an intense competitive environment. The intense competition environment in the AEC industry increases the importance of completing construction projects with maximum efficiency in minimum cost and time. The competitive environment requires companies/project stakeholders in the industry to follow technological developments and to benefit from them by adapting to technological innovations.

Building Information Modeling (BIM) enables the creation of digital models that can contain all data of life cycle processes of a facility. With this aspect, it facilitates information management and sharing, supports interdisciplinary communication and interoperability of project stakeholders, and that provides better management of complex design and construction processes (Sacks et al., 2018), can be described as an information management system (Alizadehsalehi et al., 2020). BIM technology, with its advanced sustainability with nD models, schedule time planning, cost estimation and many features, while provides safe construction processes and providing a solution to the need for low cost and high efficiency, also with as-built modeling it is effective in building operation and maintenance.

BIM has the potential to meet the expectations for the AEC industry and competitive environment with the possibilities it offers. With its potential to meet expectations, the adoption of BIM has been high in many developed countries and this rate is increasing in developing countries in recent years. Mandatory use in public projects by various countries (Finland, Norway); publication of various guides (USA, UK); the creation of programs for the gradual transition (Germany, Italy); (McGraw Hill, 2014) that was realized by the government's awareness of the benefits of BIM implementation.

While the adoption of BIM in the global AEC industry is increasing rapidly, the Turkish AEC industry is still in its infancy (Aladag et al., 2016; Elmalı & Bayram, 2022). Although Turkey ranked 2nd in terms of the number of companies in the list of the world's largest contracting companies between 2017-2019, the targeted growth could not be achieved, and it ranked 3rd in 2020. In this case, the effect of the pandemic is obvious and should not be ignored, but it is necessary to follow the technological developments and innovative approaches in the national and international competitive environment. For the Turkish construction industry, increasing the communication and cooperation between the project stakeholders and ensuring the high level of coordination of the activities are among the important development goals. However, it is important to closely follow the technological developments in the world and to determine various strategies by adapting them to the conditions of the country. Among the strategic solutions to be determined for the sector, the areas of activities for research and development should be determined as a priority. (Construction, Engineering-Architecture, Technical Consultancy and Contracting Services, Specialization Commission Report, 2018). At this point, BIM is among the technologies that are of vital importance for the Turkish AEC industry to remain competitive in parallel with the global trend (Ezcan et al., 2013). It is necessary to expand its use by ensuring the adaptation of the sector as soon as possible. In this respect, it is important to investigate the influencing and critical challenges that BIM implementation, especially in countries where the adoption rate of BIM technology is low.

The prevalence of BIM adoption and use in developed countries (i.e., United States of America, Canada, United Kingdom, France etc.) has significantly extensive. As in many developing countries (i.e., Iran, Malaysia, Nigeria, Pakistan etc.), the rate of BIM implementation in the Turkish AEC industry is increasing, but many challenges are still encountered in BIM implementation. Although there are many studies on BIM in Turkey, especially on the adoption of BIM technology, there are limited studies on identifying the main challenges of BIM implementation in Turkey. Therefore, this research aims to identify the critical challenges of BIM implementation in the Turkish AEC industry. The current study identified the influencing challenges (ICs) in 4 categories through a systematic literature review to identify the limitations of BIM implementation, and the critical challenges (CCs) by ranking the mean score for each category.

Based on this background, the main objectives at the current study are threefold: (1) determining the critical challenges of BIM implementation. (2) identifying the importance of each critical challenge for the construction industry. Identified critical challenges can contribute to action plans to overcome the difficulties encountered in the implementation of BIM. Finally (3), addressing the research and knowledge gap by identifying the critical challenges of BIM implementation at Turkish construction industry which can be generalised to almost all developing countries.

Research method

To determine and emphasize the critical challenges of BIM implementation in Turkey, a quantitative research design was carried on. Following a four-staged methodological framework potential influencing challenges were determined, the questionnaire was designed and administrated, data were collected and statistically analysis were carried out to reach the study's aim.

Identifying the Potential Influencing Challenges Restricting the BIM Implementation

The first stage of current study was the identification of the ICs that effect of BIM implementation for all building life cycle phases regarding BIM practices, BIM awareness, BIM organization, BIM education. Conducting systematic literature review (SLR) the comprehensive literature is examined into.

Web of Science database was used to access scientific papers related to BIM. The search parameters in the database were determined using keywords. The search parameters were assigned as keywords: (1) for population, "construction professionals"; (2) for outcomes, "BIM adoption challenges", "BIM adoption obstacles", "construction industry" publications with a range of 2007-2020.

A total of 563 journal articles were found in the initial search and by filtering to certain fields, this number was decreased. Based on Web of Science categories, engineering civil, construction building technology, management, engineering multidisciplinary, and architecture were selected as search fields. There were 426 articles residual after filtering. The corresponding author then reviewed and examined each of the 426 articles abstract, introduction, and conclusion parts. The journal articles were removed when the study aim was irrelevant or did not fit. Finally, 40 articles were chosen for a thorough examination for identifying the influencing challenges. The 40 selected articles coded to regarding the key study findings to specific challenges categories taking into consideration BIM practices, BIM awareness, BIM organization, BIM education. Finally, 46 ICs that are directly related to these four categories were determined (Table 1).

Table 1. Influencing challenges ICs limiting the BIM implementation.

Challenges Categories	Coded as	Challenges	Sources
Challenges related to BIM practices	P1	The thought that BIM technology will increase to design duration and cost	[1- 5]
	P2	The thought that workflow, productivity, and efficiency will be affected in the transition to BIM technology	[2], [6-9]
	P3	Fear of abandoning the traditional project delivery system	[2], [5], [9-13]

	P4	Lack of government support for BIM technology/lack of obligation with legal legislation	[5], [7], [9], [11], [13-24]
	P5	Lack of government-led initiatives to promote BIM technology	[15], [17-18], [20-22]
	P6	Stakeholders/companies and subcontractors he works with have little/no use of BIM technology	[5], [8-9], [13], [17], [19-20], [25]
	P7	Require BIM technology knowledge sharing within stakeholders	[2], [4-5], [7], [9], [18-20], [26]
	P8	Requires the participation, coordination, and control of the project stakeholders in the project at the design stage	[2-5], [7], [20-21], [25], [27-29]
	P9	Difficulty of learning BIM-based programs	[8], [11-12], [20-21], [24- 25]
	P10	License problem of BIM-based programs	[8], [13], [21], [25-26]
	P11	Possibility of data loss in file transfer between different BIM-based programs	[2], [5], [9-10], [14], [23], [26]
	P12	Increasing the workload due to BIM library preparation at the beginning of the project	[9], [19], [24],
	P13	Possibility of occurring difficulties in version control due to model updates	[7-10], [16], [21], [25], [27]
Challenges related to BIM awareness	A1	Unknown accessibility of design, schedule, and budget data during the design stage with the BIM technology	[1], [3-4], [20], [24]
	A2	Unknown accessibility of quality, schedule, and cost data during the construction stage with BIM technology	[1], [3-4], [20], [24]
	A3	Unknown accessibility of performance, usability, and financial data during the management stage with BIM technology	[1], [3-4], [20], [24], [28]
	A4	Unknown that alternative design options can be analyzed, and the most suitable project can be selected with BIM	[1-4], [20-21], [30-31]
	A5	Unknowing improve the quality of work in and adaptation to the planned time can be achieved with BIM technology, accurate quantity and cost estimation can be made with the building information model	[1-3], [20-21], [31]
	A6	Unknown clash detection capabilities of BIM technology between project	[2-3], [7], [21-22], [27], [32]
	A7	Unknowing the possibility of controlling all systems instantly and automatically in 3D model with BIM technology	[1], [3], [20], [27]
	A8	Unknown ability of BIM to standardize the information structure and support for a wide range of file formats	[7], [26], [28]
	A9	Unknown with BIM technology adaptability to graphically illustrate potential failures, leaks, evacuation plans, etc.	[1-3], [12], [24]
Challenges related to BIM organization	O1	Not supporting the use of BIM technology by top and mid management	[7-8], [11], [16], [19-22], [31], [33-35]
	O2	Not being yet include in use of BIM technology to competitive environment in the industry	[2], [5], [11], [20], [32], [36]
	O3	Too few be qualified personnel who can use BIM technology	[7], [9-10], [16-21], [37]
	O4	Additional expenditures of consultant support required for the use of BIM technology	[16], [26-28], [33], [37]
	O5	Seeing/considering the need for BIM training for personnel within organization as an extra expenditure and waste of time	[2], [13-14], [18], [27], [35]
	O6	High of initial investment cost (software, hardware, training) and inadequate financial resources of the organization for the transition to BIM technology	[2], [7], [9], [13], [20-21], [27], [35], [38]
	O7	Probability that the investment made for the transition to BIM technology cannot respond the expected economic impact (return on investment)	[14], [19], [27], [39]
	O8	Require individual and group motivation from top management to the lowest level employee in the organization for BIM adoption	[9], [11],[18], [20], [22], [34]
	O9	Thought difficult of adoption of personnel to BIM technology	[11-13], [18]
	O10	Client's/user's not enough BIM technology knowledge and demand	[2], [13], [17-18], [20], [31], [33], [36-39]
	O11	Need to significant change in the organizational structure for integration into BIM technology (size of the organization type, structure, culture, etc.)	[8], [18], [20], [27]
	O12	BIM use/new business model causing a change in the decision mechanism and workload distribution	[9-10], [12]
	O13	Lack of dedicate time for learning and developing BIM technology due to fast paced nature of the construction industry, work overload and tight deadlines	[8-9], [12-13], [25]
	O14	Lack of able immediately pass implementation after the trainings of during the transition to BIM	[8], [17], [29]

	O15	Legal disputes, software updates and require additional funds for other expenses	[5], [7], [16], [20], [27]
	O16	Rising the workload with data transfer after the transition to BIM technology	[2], [7], [16], [27]
	O17	Lack of organization's BIM project experience and the possibility of negative consequences	[5], [7], [16-17], [19-21], [27]
	O18	Desire to switch to BIM technology, however, the lack of/low number of units to provide consultancy or training on this subject	[11], [15], [17], [39]
Challenges related to BIM education	E1	Unavailable or not enough courses for BIM technology in the education programs of the architecture/engineering departments of universities	[2], [13], [17], [40]
	E2	Lack of faculty members who have knowledge of BIM applications/technology in universities	[2], [10], [13], [26]
	E3	Insufficient studies aimed at understanding the differences in the design process of the traditional methods and BIM applications of the professional bodies related to the construction sector in the country	[6], [13], [24]
	E4	Insufficient studies of the professional bodies/government regarding the construction sector in the country for introduce the transition process to BIM technology to companies	[5], [17], [22], [26]
	E5	Being inadequate Turkish resources on BIM technology	[12-13], [17], [40]
	E6	Lack of sectoral or academic training opportunities related to BIM in the city he lives in	[2], [13], [17-18], [28]

P: practices, A: awareness, O: organization, E: education

Organizing and Administrating the Questionnaire

Based on SLR, a questionnaire was composed for architects and engineers current working in architectural offices and construction companies that do not have BIM implementation in Turkey and was conducted. To measure all the challenges affecting the prevalence of BIM implementation, the survey is consisted of four sections that can be summarized regarding BIM practices, BIM awareness, BIM organization and BIM education, and demographic variables. The survey contained 46 ICs (13 for practices, 9 for awareness, 18 for organization and 6 for education) to be rated on a 5-point Likert-type scale, with a “not severe” limitation represented by 1 and a “most severe” limitation represented by 5.

The sample group contains architects and engineers who working companies that do not use BIM. The questionnaires were sent to 600 people via e-mail, consisting of architects and engineers from 07.07.2020 to 14.11.2020. A total of 152 questionnaires were returned that 11 of them extracted due to missing data, finally 141 completely completed were used as material of the current study that represents a response rate of 25.3%.

Data Analysis

First the responses of the participants were coded, and then various statistical tests, including reliability analysis and mean score ranking were analysed using the Statistical Package for Social Sciences (SPSS).

To determine the internal consistency among questions as using the Likert scale in a survey, reliability should be measured (Nunnally & Bernstein, 2007). Cronbach’s alpha (α)

coefficient was used to determine the statistical reliability and validity of participants' replies. The α coefficient values range from "0" to "1"; the minimum acceptable reliability threshold was determined as 0.7 (Cronbach, 1951; Tavakol & Dennick, 2011).

It was important to determine the ranking of ICs of BIM implementation, to realize the main objective of this study. Therefore, the mean score ranking method was used. Furthermore, normalized mean values (NMVs) are significant to determine the criticalities of the 46 ICs for BIM implementation. The calculation of NMVs for each success ICs follows Eq 1. Any challenge with an NMV exceeding 0.5 is considered to be an CC (Liao & Teo, 2017; Zhou et al., 2019). Four groups of the dataset were normalised to the interval (0-1) to identify the ICs ranked as most critical to BIM practices, BIM awareness, organisation, and BIM education.

$$Normalized\ mean\ value = \frac{(mean\ of\ IC - lowest\ mean)}{(highest\ mean - lowest\ mean)} \quad (1)$$

ICs with normalized mean values not less than 0.50 are identified as the CCs.

Findings

To determine the internal consistency of the questionnaire reliability analysis was conducted using Cronbach α coefficient. The α coefficient of the data set for the 46 ICs affecting the BIM implementation was determined to be 0.961, which is above the minimum threshold of 0.7 (Tavakol & Dennick, 2011).

Mean score ranking was conducted to each group individually to identify the critical challenges specific to category. When the findings of this study analyzed, it is determined that among the 46 ICs, 24 (6 of practices, 7 of awareness, 7 of organization, 4 of education) of them determined as critical challenges (challenges with normalization values ≥ 0.50) for BIM implementation in AEC industry in Turkey (Table 2-5).

Regarding the BIM practice critical challenges, the means, normalized mean values (NMV) and standard deviations (SD) of ICs related to BIM practices were computed to responses of questionnaire (Table 2).

Table 2. Ranking of ICs related to BIM practices.

Challenges Categories	Coded as	Challenges	Mean	Sd	NMV[a]	Ranking
Challenges related to BIM practices	P1	The thought that BIM technology will increase to design duration and cost	2,49	1,252	0,000	13
	P2	The thought that workflow, productivity, and efficiency will be affected in the transition to BIM technology	2,67	1,308	0,165	12
	P3	Fear of abandoning the traditional project delivery system	3,07	1,35	0,532[b]	6
	P4	Lack of government support for BIM technology/lack of obligation with legal legislation	3,2	1,408	0,651[b]	4
	P5	Lack of government-led initiatives to promote BIM technology	3,46	1,393	0,890[b]	2
	P6	Stakeholders/companies and subcontractors he works with have little/no use of BIM technology	3,58	1,335	1,000[b]	1
	P7	Require BIM technology knowledge sharing within stakeholders	3	1,429	0,468	7
	P8	Requires the participation, coordination, and control of the project stakeholders in the project at the design stage	2,86	1,353	0,339	10

	P9	Difficulty of learning BIM-based programs	2,88	1,363	0,358	8
	P10	License problem of BIM-based programs	3,32	1,5	0,761[b]	3
	P11	Possibility of data loss in file transfer between different BIM-based programs	2,76	1,282	0,248	11
	P12	Increasing the workload due to BIM library preparation at the beginning of the project	3,07	1,272	0,532[b]	5
	P13	Possibility of occurring difficulties in version control due to model updates	2,85	1,198	0,330	9

Sd = Standard deviation, NMV[a] = normalized mean value = (mean - minimum mean)/ (maximum mean - minimum mean)
[b]Indicate the challenge is a critical challenge (normalization value ≥ 0.50)

The results show that the ICs of the criticality of the challenge range from 2.49 to 3.58. Challenges with NMVs not less than 0.50 are identified at the CCs. The results indicate that six challenges have normalized values greater than 0.50 in this group among 13 challenges, therefore, assumed as CCs. "Non-use of BIM technology by stakeholders" (P6) is determined as the most critical challenge for BIM practice (Table 2).

The means, NMV and SD of ICs related to BIM awareness were computed to responses of questionnaire and presented at Table 3.

Table 3. Ranking of ICs related to BIM awareness.

Challenges Categories	Coded as	Challenges	Mean	Sd	NMV[a]	Ranking
Challenges related to BIM awareness	A1	Unknown accessibility of design, schedule, and budget data during the design stage with the BIM technology	2,89	1,249	0,000	9
	A2	Unknown accessibility of quality, schedule, and cost data during the construction stage with BIM technology	2,93	1,232	0,095	8
	A3	Unknown accessibility of performance, usability, and financial data during the management stage with BIM technology	3,24	1,271	0,833[b]	3
	A4	Unknown that alternative design options can be analyzed, and the most suitable project can be selected with BIM	3,31	1,231	1,000[b]	1
	A5	Unknowing improve the quality of work in and adaptation to the planned time can be achieved with BIM technology, accurate quantity and cost estimation can be made with the building information model	3,25	1,322	0,857[b]	2
	A6	Unknown clash detection capabilities of BIM technology between project	3,13	1,233	0,571[b]	6
	A7	Unknowing the possibility of controlling all systems instantly and automatically in 3D model with BIM technology	3,19	1,299	0,714[b]	4
	A8	Unknown ability of BIM to standardize the information structure and support for a wide range of file formats	3,14	1,22	0,595[b]	5
	A9	Unknown with BIM technology adaptability to graphically illustrate potential failures, leaks, evacuation plans, etc.	3,1	1,281	0,500[b]	7

Sd = Standard deviation, NMV[a] = normalized mean value = (mean - minimum mean)/ (maximum mean - minimum mean)
[b]Indicate the challenge is a critical challenge (normalization value ≥ 0.50)

The results show that the ICs of the criticality of the challenge range from 2.89 to 3.31. The results indicate that seven challenges have NMVs not less than 0.50 in this group among nine challenges, therefore, assumed as CCs. "Not knowing the alternative design options can be analysed and the most suitable project can be selected with BIM" (A4) is determined as the most critical challenge for BIM awareness (Table 3).

To identify the critical challenge regarding the BIM organization the means, NMV and SD of ICs related to BIM organization were computed to responses of questionnaire (Table 4).

Table 4. Ranking of ICs related to BIM organization.

Challenges Categories	Coded as	Challenges	Mean	Sd	NMV[a]	Ranking
Challenges related to BIM organization	O1	Not supporting the use of BIM technology by top and mid management	3,24	1,212	0,283	13
	O2	Not being yet include in use of BIM technology to competitive environment in the industry	3,25	1,179	0,300	12
	O3	Too few be qualified personnel who can use BIM technology	3,61	1,144	0,900[b]	2
	O4	Additional expenditures of consultant support required for the use of BIM technology	3,48	1,167	0,683[b]	5
	O5	Seeing/considering the need for BIM training for personnel within organization as an extra expenditure and waste of time	3,52	1,197	0,750[b]	4
	O6	High of initial investment cost (software, hardware, training) and inadequate financial resources of the organization for the transition to BIM technology	3,45	1,203	0,633[b]	6
	O7	Probability that the investment made for the transition to BIM technology cannot respond the expected economic impact (return on investment)	3,35	1,201	0,467	8
	O8	Require individual and group motivation from top management to the lowest level employee in the organization for BIM adoption	3,2	1,252	0,217	17
	O9	Thought difficult of adoption of personnel to BIM technology	3,33	1,163	0,433	9
	O10	Client's/user's not enough BIM technology knowledge and demand	3,55	1,194	0,800[b]	3
	O11	Need to significant change in the organizational structure for integration into BIM technology (size of the organization type, structure, culture, etc.)	3,42	1,088	0,583[b]	7
	O12	BIM use/new business model causing a change in the decision mechanism and workload distribution	3,21	1,207	0,233	15
	O13	Lack of dedicate time for learning and developing BIM technology due to fast paced nature of the construction industry, work overload and tight deadlines	3,67	1,263	1,000[b]	1
	O14	Lack of able immediately pass implementation after the trainings of during the transition to BIM	3,31	1,17	0,400	10
	O15	Legal disputes, software updates and require additional funds for other expenses	3,31	1,22	0,400	11
	O16	Rising the workload with data transfer after the transition to BIM technology	3,07	1,249	0,000	18
	O17	Lack of organization's BIM project experience and the possibility of negative consequences	3,2	1,155	0,217	16
	O18	Desire to switch to BIM technology, however, the lack of/low number of units to provide consultancy or training on this subject	3,24	1,249	0,283	14

Sd = Standard deviation, NMV[a] = normalized mean value = (mean - minimum mean)/ (maximum mean - minimum mean)
[b]Indicate the challenge is a critical challenge (normalization value ≥ 0.50)

The results show that the ICs of the criticality of the challenge range from 3.07 to 3.67. The results indicate that seven challenges have normalized values not less than 0.50 in this group among 18 challenges, therefore, assumed as CCs. “Lack of time to learn and develop BIM” (O13) is determined as the most critical challenge for BIM organization (Table 4).

The means, NV and SD of ICs related to BIM education were computed to responses of questionnaire (Table 5).

Table 5. Ranking of ICs related to BIM education.

Challenges Categories	Coded as	Challenges	Mean	Sd	NMV[a]	Ranking
Challenges related to BIM	E1	Unavailable or not enough courses for BIM technology in the education programs of the architecture/engineering departments of universities	3,75	1,308	1,000[b]	1

	E2	Lack of faculty members who have knowledge of BIM applications/technology in universities	3,74	1,296	0,967[b]	2
	E3	Insufficient studies aimed at understanding the differences in the design process of the traditional methods and BIM applications of the professional bodies related to the construction sector in the country	3,71	1,251	0,867[b]	3
	E4	Insufficient studies of the professional bodies/government regarding the construction sector in the country for introduce the transition process to BIM technology to companies	3,69	1,153	0,800[b]	4
	E5	Being inadequate Turkish resources on BIM technology	3,45	1,277	0,000	5
	E6	Lack of sectoral or academic training opportunities related to BIM in the city he lives in	3,45	1,374	0,000	6

Sd = Standard deviation, NV[a] = normalized mean value = (mean - minimum mean)/ (maximum mean - minimum mean)
[b]Indicate the challenge is a critical challenge (normalization value ≥ 0.50)

The results show that the ICs of the criticality of the challenge range from 3.45 to 3.75. The results indicate that four challenges have normalized values not less than 0.50 in this group among six challenges, therefore, assumed as CCs. “Lack of courses on BIM applications in the architecture and engineering curriculums” (E1) is determined as the most critical challenge for BIM education (Table 5).

Conclusion

Current study reveals the critical challenges of the implementation of BIM in the Turkish AEC industry in terms of challenges in use of BIM technology by architects and engineers who working in companies that do not have BIM implementation using data from 141 questionnaire respondents in industry.

Through a systematic literature review, 46 ICs were identified under four categories: BIM practices (13 items), BIM awareness (9 items), BIM organization (18 items), BIM education (6 items). Among the 46 ICs, 24 of them identified as CCs by mean score ranking analysis.

“Non-use of BIM technology by stakeholders” (P6) is determined as the most critical challenge for BIM practice, in this group among 13 challenges. Since the construction process is a complex process with different levels and many participants, the relationships between the participants at each stage of this process is significant. Indeed, use of BIM technology by stakeholders/companies and subcontractors is essential to ensure the successful implementation of BIM technology.

“Not knowing the alternative design options can be analyzed and the most suitable project can be selected with BIM” (A4) is determined as the most critical challenge for BIM awareness, in this group among nine challenges. The most suitable project can be selected via evaluating alternative design options, energy, thermal, acoustic, environmental analysis, and simulations such as air flow, water, carbon emissions (Attarzadeh et al., 2015) over the building information model created with BIM implementation. In addition, Aladag et al. (2016) states that "efficient monitoring and reporting" and "advanced budgeting and cost estimation" capabilities are the most important factors among the project gains achieved by BIM implementation. Recognize the ability of the sector to use BIM to achieve maximum quality at minimum cost and time is an important factor in the adoption of BIM technology.

“Lack of time to learn and develop BIM” (O13) is determined as the most critical challenge for BIM organization, in this group among 18 challenges. Time, cost, and quality are very

significant factors for the stakeholders in the project delivery process in the construction industry. Due to the fast-paced nature of project construction, heavy workload, and tight deadlines, it is often not possible for staff to devote time to learning and developing BIM technology. Furthermore, Aibinu and Ventkatesh (2014) remarked the necessity of learning time for BIM adoption.

"Lack of courses on BIM applications in the architecture and engineering curriculums" (E1) is determined as the most critical challenge for BIM education, in this group among six challenges. It has been determined that having BIM knowledge and training in education life before entering professional life has a significant effect on the prevalence of use in the current study.

It can be concluded from these findings that there are several critical challenges for BIM implementation in Turkish construction industry. With regard to these findings;

- First, universities and the government should take responsibility for BIM education. Related departments of universities, particularly architecture and engineering departments, should update their education curricula and increase the number of BIM-related courses. Higher education institutions and the government should collaborate to develop a national BIM curriculum to fulfil the need for BIM proficiency among graduates entering the workforce.
- It is recommended that the up-down management create a dedicated BIM department to handle or support BIM deployment in their projects in the long run. Moreover, top management in construction organizations are urged to address gaps in their employees' skill sets by supporting them in attending appropriate BIM seminars, workshops, or conferences to improve their BIM capacity and knowledge.

Analysis of Industry 4.0 Technologies from a Lean Construction Perspective

M. Cesur and E. F. Taş
Istanbul Technical University, Department of Architecture, İstanbul, Turkey
cesurm@itu.edu.tr, tase@itu.edu.tr

Abstract

The concept of lean production, which is the basis of lean management, was first introduced with jidoka in 1930s and emerged in the manufacturing sector. The relationship of lean production with the construction sector was established in 1992 and started to be expressed in the construction sector approximately 60 years later. It took a long time to adapt to construction practices. Although targets such as reducing waste, increasing customer satisfaction by optimizing time, cost and quality, etc. are thought to be approaches that will increase productivity for the construction sector. The term Industry 4.0 was first mentioned in 2011. Informatics and industrial applications are brought together. It has been developed in order to keep up with the changes experienced on a global scale and to provide a competitive advantage in the increasing competitive conditions. It is aimed to reduce production time, costs, increase production quantity and quality. With the development of technology, Industry 4.0 has begun to be considered together with lean construction applications since the goals of lean construction and industry 4.0 are similar. In this study, it is aimed to explain Industry 4.0 technologies and to reveal how they can benefit from lean construction with a literature study.

Keywords: *construction industry, industry 4.0, lean construction, technology.*

Introduction

With the correct use of rapidly increasing technological developments, many sectors have benefited, gained competitive advantage and increased their productivity. Especially thanks to the industry 4.0 revolution that emerged in the manufacturing sector, the direction of technological developments has changed, automation of machinery and processes has been ensured, and progress has been made on digitalization and integration of digital systems. On the other hand, lean construction helps to reduce waste, increase productivity and ensure customer satisfaction. The construction sector is lagging behind other sectors in accepting technological developments. Considering the benefits it provides; it is foreseen that the application of lean construction principles and the use of industry 4.0 technologies will provide advantages to the construction project processes since industry 4.0 and lean construction have similar goals. There are literature studies that bring these two issues together and examine their integration. However, in many studies, industry 4.0 technologies have been studied on a large scale and their scope has been broadened. No study has been found that examines how industry 4.0 technologies will benefit against the waste of lean, in

terms of industry 4.0, where the technologies were born, construction and lean construction by examining more deeply.

This study consists of 6 chapters. After this introduction section, there is the lean construction section. Information about lean construction, its development process, waste and principles are explained. In the third chapter, the industry 4.0 development process and its benefits are emphasized. In the fourth section, the method is explained, and in the fifth section, the literature study is included. Finally, the sixth chapter is the conclusion part of the study.

Lean Construction

According to Lean Construction Institute's the last studies, thanks to the use of lean methods in production, the waste rate in the manufacturing sector decreased to 26% and the waste rate in the construction sector to 57% (Bajjou & Chafi, 2020). The concept of lean first emerged in the manufacturing sector and then began to spread in other sectors. The oil crisis in 1973 dealt a great blow to the entire world economy. Unlike other companies, Toyota Motor Company in Japan survived this crisis with a high profit rate. It has reached a high profit rate from companies in both Japan and countries such as Europe and USA. Toyota attracted the attention of the whole world and there were people from different countries who came to examine it. It is described as the Toyota Production System in 1988 (Paslawski & Rudnicki, 2021; Pereira et al., 2019). Just-in-time production (1950s-to prevent overstock) and jidoko (1930s-autonomation-to prevent error in the production line) formed the cornerstones of this system (Paslawski & Rudnicki, 2021). In this system, it is aimed to keep the cost, time, equipment and space usage at the lowest level, to spend less effort and to make maximum production (Womack & Jones, 2003). Later, its name started to be used as "lean production" (Pereira et al., 2019).

In order to increase efficiency in lean production, it is aimed to reduce activities that do not add value. There are 8 types of waste that lean manufacturing defines. ***Overproduction;*** these are the wastes that are produced more than necessary and are considered as surplus production. ***Unnecessary transportation;*** refers to inefficient workflows, unnecessary transportation of machinery, equipment, and materials. ***Unnecessary motion;*** it refers to unnecessary movements of workers in their daily work due to poorly organized work areas. ***Excess inventory;*** this includes anything that is more than necessary for the work. ***Waiting;*** it represents all kinds of waste that will require waiting, such as the lack of resources such as workers, materials, equipment. ***Defects;*** re-manufacturing in production, repair, etc. works is a type of waste that negatively affects time, cost and efficiency. ***Over-processing;*** all kinds of unnecessary high-quality actions that do not create added value in the production processes and do not create value for the customer are in this waste group. ***Unused employee creativity;*** means that the talents, development and learning opportunities of the employees are not used efficiently. (Bajjou & Chafi, 2020; Liker, 2004; Nassereddine et al., 2022-a).

It was revealed by Koskela (1992) that wastes defined for lean production, in other words, activities that do not produce added value, also cause low productivity in the construction sector. Koskela (1992) published a report on the application of lean manufacturing methods in construction. He stated that this method, which provides a competitive advantage in the production sector and reduces waste, should also be applied in the construction sector. "Major development efforts in construction, like industrialization, computer integrated construction and construction automation have to be redefined to acknowledge the need to balance flow

improvement and conversion improvement" (Koskela, 1992). Thus, the concept of lean construction emerged.

Lean construction has 5 principles. The first of these is ***specify value***. Identifying activities that add and do not add value for the customer. The second principle is ***value stream mapping***. It is determining how value is generated, when it is delivered, and where improvements can be made. It allows to identify where the waste occurs. The third principle is to create a ***continuous stream of value***. It is to make the flow continuous by reducing unnecessary waiting, movement, error, etc. wastes. The fourth principle is ***pull value***. It means the delivery of necessary materials, workers, information in construction, on time. It is to pull the necessary material in case of need instead of a continuous stacking situation. The fifth and final principle is to ***pursue excellence***. It means continuous improvement by eliminating waste and increasing transparency on construction sites (Aziz & Hafez, 2013; Bajjou & Chafi, 2020; Womack & Jones, 2003).

Technological developments are taking place in the construction sector that will facilitate the use of lean methods, make the lean construction process efficient, reduce the waste defined by lean, and facilitate the realization of lean principles. Industry 4.0 technologies will contribute to the implementation of lean principles in construction.

Industry 4.0

The term Industry 4.0 (Fourth Industrial Revolution) was first used in 2011 at the Hannover Fair. In 2013, a report was prepared and officially announced that it was a revolutionary initiative in the manufacturing industry (Xu et al., 2018). There is no standard definition of industry 4.0 in the literature. Industry 4.0 enables the development, access and integration of information and communication technologies with automation technologies in order to ensure complete system integration (Ferreira et al., 2020). It facilitates access to technology, enables price reduction and the use of sensors in value chains, and removes barriers to supply chain integration and management (Ferreira et al., 2020).

In order to understand the development process of the fourth industrial revolution, the first three revolutions are mentioned in this study. ***The First Industrial Revolution*** emerged towards the end of the 18th century. In this revolution, mechanical production systems using water and steam power began to be used. ***The Second Industrial Revolution*** emerged in the late 19th century. With the use of electrical energy, mass production has begun. ***The Third Industrial Revolution*** emerged in the middle of the 20th century. Automation and microelectronic technology have started to be used in the production sector. The use of computer aided systems has started. Finally, ***The Fourth Industrial Revolution*** emerged at the beginning of the 21st century. With the contribution of cyber physical system and internet of things, it has developed in the automation of machines and processes. It focuses on digitization and integration of digital systems (Xu et al., 2018). In the cyber physical system, the physical and digital components are intertwined, integrated and coordinated. Thanks to the cyber physical system, communication is established between the machines and the control system becomes decentralized to ensure efficiency in production. Thanks to the Internet of things, virtual networks are created between objects and their integration is ensured (Xu et al., 2018).

Industry 4.0 technologies shorten the development process and increases innovation skills. It provides flexibility in production processes. It helps to use resources efficiently and increase production and efficiency (Lasi et al., 2014). It provides standardization, thus preventing mistakes and misunderstandings (Xu et al., 2018). Such benefits of industry 4.0 technologies show that they will contribute to lean construction. Both lean construction and industry 4.0 technologies aim to increase efficiency and standardization and reduce waste.

Methodology

Aim. It is foreseen that lean construction applications will be facilitated with some industry 4.0 technologies and these technologies will benefit construction projects. For this reason, studies that relate these two concepts in the literature have been examined.

Scope. There are many industry 4.0 technologies in the literature. Within the scope of this study, industry 4.0 technologies, which facilitate the realization of construction projects according to lean principles, which are suitable for construction projects in terms of way of doing business, and which are the most mentioned and emphasized in the literature, have been examined. These technologies are simulation, RFID, AR.

Method. In the literature study, the Scopus database was searched. The words "lean construction" and "industry 4.0" were scanned together. Industry 4.0 technologies such as simulation, Radio Frequency Identification (RFID) and Augmented Reality (AR) have been encountered the most in use with lean construction. With this method, articles related to the subject were reached. Later, in some sections, other articles related to the subject were obtained from the references of the relevant articles.

Literature Review

In this part of the study, industry 4.0 technologies, which are most frequently associated with lean construction in the literature and where lean principles are most applicable, are examined. In this review, first of all, lean construction and industry 4.0 concepts were searched together and frequently encountered technologies in the literature were revealed. After the industry 4.0 technologies were determined, the concepts of "simulation", "RFID", "Augmented Reality" were searched one by one along with the concept of "lean construction". For each of them, what these technologies mean in terms of industry 4.0 is explained in the first paragraph, the use of this technology in the construction sector is explained in the second paragraph, and these technologies are examined together with lean construction in the third paragraph.

Simulation

Simulation means "a model of a set of problems or events that can be used to teach someone how to do something, or the process of making such a model" in Cambridge Dictionary (URL-1, 2022). Scheidegger et al. (2018) defines simulation as the real or hypothetical model for analyzing and describing the system's behaviors. In this definition, modeling refers to the model production process; the model is a simplified and abstract representation of the real; the system is the analyzed process; process refers to elements that are related to each other;

simulation refers to the operation of the model over time. Thanks to the simulation, products, processes and system design that have not yet been physically produced are experienced. It helps in decision making, reducing costs and cycles, and shortening time before materialization (Negahban & Smith, 2014). Ferreira et al. (2020) said that in addition to these, simulation enables companies to see the obstacles to implementation, costs, risks, and the impact on their performance.

In the construction industry, simulation technology is used for many purposes. Some of these are risk analysis, maintenance operations, planning, process developments, and claims. Simulation in construction projects helps to test decisions virtually before real-life implementation and to support construction project management (Abdelmegid et al., 2019). According to Bajjou and Chafi (2020) simulation enables decision-making construction professionals to experiment with a low-cost and controllable system, enabling processes to be effectively designed, analyzed and improved. Thanks to the simulation, the workflow is better understood. In addition to Abdelmegid et al. (2019) and Bajjou and Chafi (2020), Fischer et al (2021) also stated that simulation benefits visualization in construction projects, it can be used in weather forecasting, field logistics and routing strategies can be tested by visualizing, the productivity of workers can be monitored, and possible errors can be predicted.

In the literature, there are studies in which simulation technology and lean construction are used together. Nassereddine et al. (2022-a) stated that the most effective way to see the impact of lean construction principles on construction processes is simulation. In addition, Halpin and Kueckmann (2002) stated that lean thinking and simulation are very similar. It is efficient to analyze and test processes before they happen so that non-value-added activities can be defined and reduced. According to Bajjou and Chafi (2020), the two main reasons for applying the simulation are to identify and measure the waste in the construction process, to reveal possible improvements and developments in risk, cost and time. In Paslawski and Rudnicki (2021)'s study, in addition to lean construction, distance and road type possibilities were evaluated by using simulation to reach the construction site. These two differing cases are analysed to reveal how the efficiency of the concrete pavement set is at the highest level. Thanks to the simulation, productivity increased by 56%, the implementation process was improved, and the pull feature of lean construction was also used by placing orders without interruption in deliveries. Halpin and Kueckmann (2002) made case studies by simulating the movements of crane and crews to ensure minimum waste in wall frame assembly and to pour concrete in the wastewater treatment plant with lean construction methods.

In many literature studies, it is stated that thanks to the simulation technology applied with lean construction, it increases the productivity, flexibility, provides continuous improvement, time and cost savings, increases communication and information sharing (Bajjou & Chafi, 2020). The simulation provides accurate quantitative information such as the duration of the cycle, the amount of work to be done per day, productivity, team utilization. By revealing this information, wastes of lean construction (unnecessary transportation, waiting, unnecessary movement, etc.) can be measured. Activities that do not add value are identified and eliminated (Halpin & Kueckmann 2002; Pereira et al., 2019).

RFID

Radio Frequency Identification (RFID) means “a system of fixing a small electronic device to something or someone that sends out a radio signal, so that a computer can find out where they are or other information about them” (URL-2, 2022). RFID technology is used in the recognition and tracking of all kinds of living and inanimate objects from a distance without touching them (Uygunoğlu & Topçu, 2020). RFID technology is generally used in logistics management and inventory control (Liu et al., 2022). Thanks to RFID, communication between tags and readers can be achieved without line of sight, unlike traditional barcodes and codes (Liu et al., 2022). RFID system usually consists of tags, reader(s) and backend server. Every physical object in the system has a tag and this ID is unique. In order to automatically perform inventory management with RFID, the IDs of all tags in the system are defined and the need for intensive manual processing is reduced (Liu et al., 2022). For example; suppose a manufacturer wants to take back the faulty goods it produces after it is shipped to the warehouse. If the labels of these faulty products are known, they will be able to access the products easily. In RFID technology, there are three categories in inventory processes: tag identification, tag detection (missing or unknown) and tag search. With tag identification, it is ensured that all tag IDs entered into the system are defined correctly. With tag detection, missing and unknown tags in the information stored in the database are revealed. With the tag search, it is possible to find the desired tags from the system (Liu et al., 2022). The work done with RFID technology reduces the costs considerably, speeds up the workflows, and increases efficiency and quality (Uygunoğlu & Topçu, 2020).

It has been explained in the literature that RFID is used for many purposes in the construction industry.

- The first purpose is on supply systems. Ju et al. (2012) stated that it can be used in the distribution of materials brought to the construction site to the relevant locations. The usage area in material distribution gains importance especially in precast structures. Cai et al. (2014) stated that RFID technologies are used successfully in precast elements. It provides the opportunity to reduce costs, to show the originality and quality of the product to the customer. Real-time data on the condition of each precast element can be accessed, inventory and quality information is recorded, and this technology can be used in product shipment (Cai et al., 2014).
- The second purpose is on quality management (Wang, 2008). Lee et al. (2009) stated that the tracking of deformation in reinforced concrete structures, the quality of concrete, the corrosion status of reinforcements in reinforced concrete can be tracked with RFID tags. In Turkey, before the concrete is poured, RFID chips are placed in the mold and the concrete quality is collected electronically in the ministry system (Uygunoğlu & Topçu, 2020).
- Another purpose is determining the materials inside the building and their usage areas, and in defining the places of duty of people (Montaser & Moselhi, 2014).
- At last, the field of occupational health and safety is also included in the purposes. Kelm et al. (2013) stated that by attaching RFID tags to the helmet used by the workers and the tools and equipment that cause the accident, they contribute to the worker's health and safety in the construction, the workers are warned when they are in the risky area and the accidents are minimized.

In the literature, there are studies in which RFID technology and lean construction are used together.

- Sahin et al. (2017) examined the use of lean construction and RFID technology in supply systems of small to medium size construction companies. In this study, it is aimed to reveal how the communication and information flow between the main

office, construction site, factory area and suppliers can be coordinated with RFID. For this, firstly, 3D drawings were made and barcodes were created for the ducts and pipes, and their information was entered in the computer. By monitoring the ducts and pipes produced in the factory with these barcodes, it is aimed to ensure the supply-demand balance between the field and the factory during the procurement process. It was also desired to prevent excess stock, which lean construction defines as waste. In addition, with the pull principle of lean construction, it is aimed to produce just in time and to bring the material to the construction site when necessary. It has been concluded that it has advantages such as real-time tracking and visualization, the delay of the work decreases, the average completion time of the work decreases, the average completed work increases, and the annual investment costs decrease (Sahin et al,. 2017).

- Chen et al. (2019) also worked on improving the coordination of prefabricated elements with the factory and field, such as Sahin et al. (2017). Chen et al. (2019) conducted a study at the local level by examining this issue on the basis of China. In Chen et al. (2019)'s case study, a 3D model was created during the design phase of the project, the combined use of 3D model and RFID technology in prefabricated production was examined, and simulation technology was used to evaluate the risk situation related to the schedule. As a result of this study, it was informed that productivity can be increased, uncertainty can be reduced, and waste, which is one of the principles of lean construction, can be prevented thanks to the combined use of 3D model and RFID technology.
- Li et al. (2018) also examined lean construction with RFID in prefabricated elements such as Sahin et al. (2017) and Chen et al. (2019). Simulation technology was used in this examination. In the simulation, the process of bringing prefabricated elements from the factory to the site and assembling them is tested with the traditional method in the first part, and with the lean construction principles, RFID and 3D modeling in the second part. In the second part of the simulation, it has been concluded that it has the advantages of providing real-time tracking, reducing uncertainties and complexity, facilitating information transfer, and shorter cost and time.

In many literature studies, it is stated that thanks to the RFID technology applied with lean construction, time and cost savings are achieved, uncertainty and complexity are reduced, RFID tags attached to materials or workers provide ease of tracking, and faulty and overproduction, excess inventory, and waiting, which are wastes of lean, can be prevented.

Augmented Reality

Augmented reality (AR) means that reality is modified and augmented by computer. Unlike virtual reality, which creates a virtual environment instead of the real one, AR strengthens the virtual information by bringing it to the real world. AR means that reality is modified and augmented by computer. Unlike virtual reality, which creates a virtual environment instead of the real one, AR strengthens the virtual information by bringing it to the real World. The information produced and created in the computer environment is transferred to the user's view in the real World. AR not only allows users to passively view information on the computer, but also to interact with published information and collaborate with people on the other side of the computer in real time. AR can be applied in different sectors such as gaming, pharmaceuticals, military, automotive, entertainment, engineering, construction,

manufacturing and aerospace and provides users with a competitive advantage (Nassereddine et al., 2022a).

As Nassereddin et al (2022a) mentioned, AR can be applied in construction industry. In the literature, there are studies describing what AR technology can be used for in construction projects and what benefits it will provide to construction projects. Thomas et al. (1998) designed a wearable system for visual navigation aid at the construction site, thereby facilitating on-site navigation. Dunston et al. (2000) designed an AR system integrated into a two-dimensional drawing program to assist in the design of the mechanics discipline. Park and Kim (2013) integrated AR and geolocation and tracking technologies to ensure occupational safety in the construction field. Nassereddine et al. (2022a) stated that with the use of AR during the construction phase, different discipline elements can be coordinated, mock-ups can be seen, it will be possible to see how the drawings on the computer will look in the field, the construction process can be visualized and followed, the integration between the field and the factory can be ensured, It allows planning how heavy and difficult to transport elements can be placed before transportation, detecting defaults and monitoring the material supply in the field. All these areas of use have allowed the construction projects to be produced leaner.

In the literature, there are studies in which AR technology and lean construction are used together. AR technology can be used to correctly implement geometrically drawn projects in the computer environment and to establish a correct relationship with space. Although it can be seen in three dimensions on the computer, mistakes can be made in the field during the manufacturing phase. AR can be integrated with the drawing on the computer to detect or avoid errors. Thus, it prevents the waste of faulty manufacturing defined by lean construction (Oskouie et al., 2012). AR provides monitoring and visualization of business processes. The progress of each construction activity can be monitored and proactive action can be taken in case of delay. (Nassereddine, 2022b). Waiting, which is one of the wastes of lean, is reduced (Dallasega et al., 2020). Thanks to visualization, repeatable works in activities can be revealed and flow can be created. Another benefit; It facilitates different suppliers working for the same field to understand the common area, visually perceive their scope of work and facilitate cooperation with other suppliers (Nassereddine, 2022b).

Conclusion

It has been stated in many studies in the literature that when lean construction principles are applied in construction projects, efficiency will increase, waste will be reduced, and customer satisfaction will increase. Industry 4.0 technologies emerge in the manufacturing sector and provide benefits for other sectors as well, increasing efficiency and facilitating business methods. Within the scope of this study, lean construction applications in construction projects and industry 4.0 technologies, which are most frequently mentioned with lean in the literature, were examined together. And these studies have revealed that construction projects will save time and cost, reduce the rate of uncertainty and complexity, reduce the waste defined by lean, increase visibility and visualization, provide more accurate results, increase coordination between teams, and ensure continuous improvement and development.

Today, there may be some obstacles in using these two methods together in construction projects. In construction projects, the number of stakeholders is high, there are different contractual relations and different interests. It can be difficult to get everyone to agree and

implement a new method. The lifetime of construction projects may be short for technological structuring. Companies may avoid this technology as the initial investment cost may be high and it may take a long time to explain the lean construction practices to all project teams and to ensure the correct application. For this reason, the coexistence of stakeholders who have worked together before and are familiar with lean construction practices and have experienced these practices will be factors that will facilitate the implementation in projects that will take longer than an average construction project (such as large-scale projects). This is true for today. But technology is developing day by day. As it develops, it both becomes cheaper and spreads in the sector. Technological advances increase exponentially, then exploding. It is thought that lean construction practices and industry 4.0 technologies can be applied together in all types of construction projects in the future, and this study is encouraged for construction companies to experience these applications.

In this study, lean construction is discussed with 3 technologies, but there are many other industry 4.0 technologies. Construction companies should follow the developing technologies and improve their business practices by keeping up with the developing technologies.

Abstract

New technological production forms have emerged with the development of the concept of Industry 4.0. While the digitalization of production systems has been improved in all areas, the construction industry has also been affected by this situation; the concept of construction 4.0 has emerged. Construction 4.0 involves the digitalization of the construction industry by working together with different technologies such as the internet, sensors, software, lasers, and drones. The widespread use of construction 4.0 technologies in the construction industry, which has a production network that is becoming more complex day by day, will allow the solution of possible problems in the project process and the efficient execution of the processes by the desired quality & occupational safety standards. The scope of the study is to determine the awareness of construction 4.0 technologies by surveying senior employees such as architects and civil engineers from the construction industry in Kayseri, Turkiye. The determination of awareness will be utilized to reveal the aspects where Construction 4.0 can be developed in the industry. Thus, a perspective for the future can be developed. It is aimed that the findings will contribute to the management actions such as planning, design, decision-making, control, and communication in the project production process at the national and international levels.

Keywords: *industry 4.0, construction 4.0, construction industry, project management, Kayseri.*

Introduction

The change in economy, environment, and civilization has a significant impact on the construction industry that shapes the built environment. In recent years, with the advancement of technology and the differentiation of needs that determine the quality of life, construction projects have also become more complex; while quality potentials have grown, budget and program weights have increased. However, when compared to different industries, the construction industry generally gets behind in integrating the innovations brought by technology (Alaloul et al., 2018). This situation reduces the efficiency of the construction project management processes. The fact that the construction industry is not integrated with advanced technologies such as computer-aided construction, automation, prefabrication, and the lack of attention to research and development (R&D) studies are the most important causes of productivity losses (Oesterreich & Teuberg, 2016; Razkenari et al., 2018).

Construction 4.0 technologies such as building information modelling (BIM), prefabrication, modular systems, cyber-physical systems, internet of things (IoT), robots, augmented reality/virtual reality (AR/VR), 3D printers, big data, cloud computing systems, and drones should be adapted to the construction industry in order to increase the productivity. As these modern technologies will be adapted in the industry, sustainable construction practices will increase, time and cost savings will be achieved, occupational safety precautions will be taken, occupational accidents will be reduced, waste generation will be minimized, and communication problems between project parties will be eliminated, and real-time data will be obtained with minimum error and high accuracy (Osunsanmi et al., 2018).

Within the scope of the study, the technologies discussed in the context of construction 4.0 were determined by literature review, and the relationship of these technologies with construction project management was examined. In the next stage of the study, a survey was conducted with senior employees working in the construction industry in Kayseri, which is the most investment-friendly province of the construction industry in the Central Anatolia Region. In the survey study, the participants' awareness of construction 4.0 technologies and their use of technology were determined and their views on the effects of technologies on project management were determined. This study, which is specific to the Kayseri construction industry, aims to increase the efficiency in the construction project management processes with the use of technology in the construction industry at national and international levels.

Construction 4.0 Technologies

Technological and scientific opportunities have been increased with the development of Industry 4.0, which focuses on the integration of computer and cyber-physical systems. The construction industry has also benefited from these developments and the term “Construction 4.0”, which has gained importance in recent years, has emerged (Forcael et al., 2020). The concept of Construction 4.0 is that all equipment in the construction worksite is connected to the internet and each other; it is based on the creation of a digital construction site where each part of the construction project can be monitored and managed through different technologies. In this context, Construction 4.0 is the digitalization of the construction industry and the use of all digital technologies in building products in communication and interaction with each other (Oesterreich & Teuteberg, 2016).

Significant improvements have been observed in the technologies that form the basis of Construction 4.0. However, it is difficult to generalize its widespread use in the construction industry. Therefore, it is necessary to examine the interaction between technologies and their application dynamics in other areas to improve this situation (Karmakar and Delhi, 2021). BIM technology includes design, planning, decision-making, performance estimation, cost estimation, scheduling, etc. Three-dimensional models are used to operate the building throughout the construction lifecycle. It enables the collection of data and their communication (Çetiner, 2010). Three-dimensional printing of buildings via 3D printers is a challenge between the countries. Big data on the other hand is the conversion of all data collected from different sources on the internet into a meaningful and workable format. Cloud computing is the storage of data and applications in the source on a server called a cloud (EBSO, 2015). Cyber-physical systems are the connection between interconnected computers and physical systems. Radiofrequency identification is a technology in which data is carried through radio waves (EBSO, 2015). Augmented reality (AR) and virtual reality (VR) technologies combine real and virtual objects and provide simultaneous interaction between them (Parlak Biçer et al., 2021). The internet of things (IoT), on the other hand, is that smart objects with digital networks and the internet gain a virtual identity and interact with their environment in a physical and social context (EBSO, 2015).

There are limited studies in the literature that describe and classify Construction 4.0 basic technologies (Perrier, 2020). Oesterreich and Teuteberg (2016) classified the technologies for Construction 4.0 and divided them into three groups: smart factory, simulation, and modeling, digitization, and virtualization (Figure 1). According to Oesterreich and Teuteberg (2016), technologies in the smart factory group are the technologies for creating “smart construction sites”. Technologies in the simulation and modeling group are aimed at improving complex “construction operations” such as worker performance, supply, and weather. Technologies in the third group are technologies for managing construction documents in real-time and improving “communication” between project stakeholders (Oesterreich & Teuteberg, 2016).

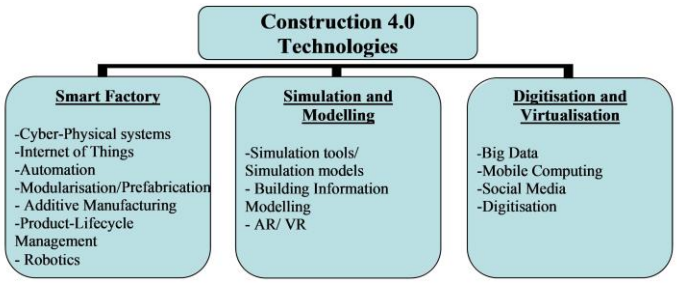

Figure 1: Construction 4.0 technologies (Edited from Oesterreich & Teuteberg, 2016).

Dallasega et al. (2018) divided the construction 4.0 technologies into six basic groups in their study. These were classified as digitization, cloud computing, BIM, 3D printing, tracking & localization, and e-supply chain management. The application examples from the construction companies were discussed by considering the organizational, geographical, and cognitive contexts of technologies (Dallasega et al., 2018). Forcael et al. (2020) classified the Construction 4.0 technologies as BIM, common data environment (CDE), drones, cloud-based project management, AR/VR, artificial intelligence (AI), cyber security, cyber-physical systems, big data and analytics, block chain and laser scans (Forcael et al., 2020). Boton et al. (2021) stated that BIM is the main source in the digitalization of the construction industry. The other technologies were classified as 3D printers, big data, cloud computing, cyber-

physical systems, cloud computing, radio frequency identification, AR/VR, and the IoT, (Figure 2).

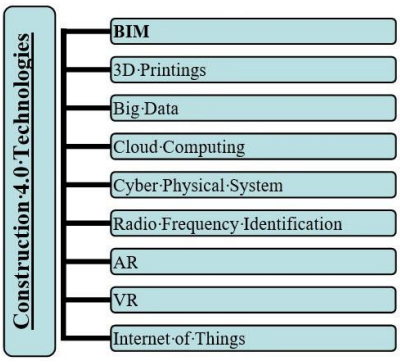

Figure 2: Construction 4.0 technologies (Edited from Boton et al., 2021).

Many studies in the literature classify technologies for Construction 4.0 and discuss their contribution to the construction industry as mentioned. It can be concluded that the basic technologies for Construction 4.0 are BIM, cyber-physical systems, VR/AR, IoT, cloud computing, big data, radio frequency identification, 3D printers, drones, and robots. Apart from these, it has been observed that wearable technologies and autonomous robots are also included in a limited number of studies (Forcael et al., 2020; Gao et al., 2022). In this context, in the survey study conducted within the scope of the study, research was conducted on the awareness, use, and benefits of these technologies in the project management processes in the Kayseri construction industry.

Impacts of Construction 4.0 Technologies on Project Management

Project management is the planning, implementation, and control of all the steps necessary for the project to reach the determined time, scope, quality, and cost targets. Different organizations are required for the project to reach its goal by the duration, quality, cost, and size of the project (Kömürlü & Toltar, 2018). The importance of project management in the construction industry has increased since different disciplines are involved in construction projects. The projects are unique, and their complexity is increasing. Basically, the project management process consists of actions and factors (Figure 3). In this process, actions and factors are in a constantly transforming relationship with the building design, production, and use. However, currently, the use of traditional project management methodologies, especially in the production of large-scale structures, has begun to be insufficient to optimize the process. It has become a necessity for building production processes to adapt to the transformations and technologies brought by Construction 4.0 for this reason (Taner & Parlak Biçer, 2021).

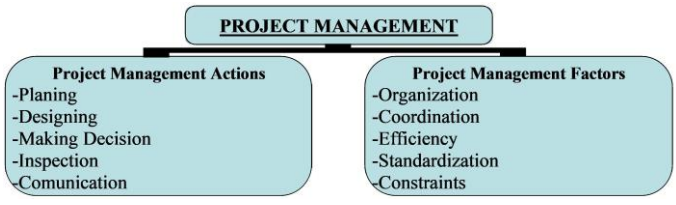

Figure 3: Actions and factors in the project management (Edited from Gültekin, 2007).

The goal of project management is to efficiently build and deliver a construction project. The efficiency of the project is the ratio of resources (inputs) to the products (outputs) (Akbıyıklı & Dikmen, 2019). The most common problems in the construction industry are low productivity due to delays, budget overruns, and unskilled labour; less frequently experienced problems are remakes and metering errors due to quality problems (Gürkan, 2019). Alaloul et al. (2020) underline that productivity in the construction industry can be improved through construction 4.0. Soto et al. (2020), on the other hand, state that with the widespread use of technology, new opportunities can be created such as reducing waste and repetition, as well as improving quality, reducing time, and completing projects within budget.

Construction project management starts with the analysis of large amounts of data (inputs) obtained during the planning process of the project before the design process (Schönbeck et al., 2020). Perrier et al. (2020) state in their study that real-time processing of collected data will increase efficiency. In this context, it is important to use big data technology that processes data and draws conclusions from it and to create a virtual construction site with BIM in the process of building. In addition, continuous digital processing of building data from planning to delivery of the building with cloud computing and radio frequency identification can identify delays and contribute to project management processes by preventing time and financial losses (Schönbeck et al., 2020; Hamledari et al., 2018).

According to Schönbeck et al. (2020), Construction 4.0 concepts cover not only new technologies but also project management factors such as organizations, management, and processes. However, there will be difficulties at the beginning, as the implementation of these factors will require extensive changes and new skills. The application potentials of different technologies in project management actions such as operation, planning, design, decision-making, and construction should be well investigated to overcome these difficulties. The widespread use of construction 4.0 technologies in project management actions will contribute to project management factors and thus to the entire project process. For this purpose, the potentials were analyzed by classifying different construction 4.0 technologies into three groups. (Figure 4). As a result, labor and material losses decreased; it has been stated that a long-lasting life cycle is provided (Schönbeck et al., 2020).

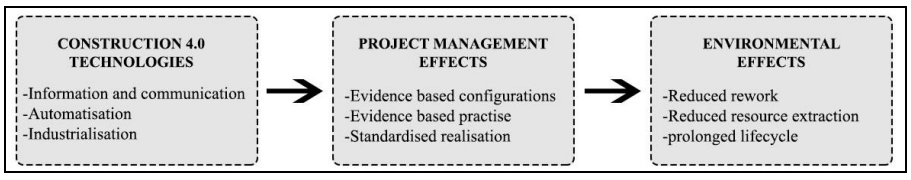

Figure 4: Impact of construction 4.0 technologies on project management (Edited from Schönbeck et al., 2020).

In the context of construction projects, the value of digital processes, automation, and technology remains unexplored. It is predicted that the widespread use of Construction 4.0 technologies in construction project management actions and factors will increase the quality in the construction sector and reduce time and cost.

Research Methodology

Kayseri has a rich potential in terms of capital accumulation, industrial opportunities, transportation modes, underground resources, labor force, consumption habits, and housing

needs. In Kayseri, one-fourth of the total industrialists invest to the construction industry. The importance of occupations related to the construction industry in the province of Kayseri continues to increase over the years (ORAN, 2014).

A survey study on the awareness, use, and possible contributions of Construction 4.0 technologies to the construction industry were applied in the province of Kayseri. 39 people, including 21 architects, 16 civil engineers, and 2 civil technicians, participated in the survey study. Although the survey study was sent to more employees, the returns did not exceed the specified numbers. Therefore, even if this situation is seen as a weak aspect of the study, the study will contribute to this field. The results obtained from the survey are examined in the findings section.

Within the scope of the study, a questionnaire form was used as a data collection tool. The questionnaire form was created by using the literature and was prepared via Google forms. The relevant link has been conveyed to the employees of the construction industry in Kayseri. The contact information of the participants obtained from the relevant professional chambers was used. Within this scope, a total of 46 questions were asked to the participants related to the level of awareness of Construction 4.0 technologies, the use of Construction 4.0 technologies in the workplace, and the contribution of Construction 4.0 to project management. The survey study consists of four sections. In the first section, 10 questions related to the demographic characteristics of the participants were prepared. In the second section, 12 questions were asked related to the level of awareness about Construction 4.0 technologies. In the third section, 12 questions about the use of Construction 4.0 technologies by workplaces are included. In the fourth and last section, 12 questions were prepared about the impact of Construction 4.0 on project management. In the survey study, the questions were prepared using a five-point Likert scale. The statistical data of the survey were calculated with the MS Excel 2016 software and visualized in graphics. The data obtained were presented under the figures.

Findings

The sample consists of 54% (21) architects, 41% (16) civil engineers, and 5% (2) civil technicians. 46% of the participants are male, and 54% are female. 26% of the participants work in the public sector and 74% in the private sector. 31% of the participants are in the managerial position, 31% in the employer position, and 38% in the employee position. 2% of the participants are between 20 and 25 years old, 13% are between 26 and 30 years old, 41% are between 31 and 35 years old, 15% are between 36 and 40 years old, and 28% are 41 and older. 5% of the participants have associate degrees, 41% undergraduate, 33% master's degrees, and 21% doctorate degrees. 13% of the participants have 1-5 years, 31% 6-10 years, 25% 11-15 years, 8% 16-20 years, and 23% have 21 or more years of professional experience. 51% of the workplaces of the participants operate in housing/mass housing, 5% in industrial buildings, 20% in commercial and institutional buildings, 3% in infrastructure projects, and 21% in other projects. In this case, it can be stated that the workplaces of the participants are more active in housing/mass housing projects. The 44% of the workplaces of the participants are in the local sector, 18% in the regional sector, 23% in the national sector, and 15% in the international sector. The 23% of the participants' workplaces have been operating in the sector for 1-5 years, 23% for 6-10 years, 16% for 11-15 years, 5% for 16-20 years, and 33% for 21 years or more. Considering the data obtained here, the fact that the participants of the survey

study have valuable experience in the field and that they have been in the sector for a long time. This situation increases the reliability of the study.

In the second section of the survey study, the awareness levels of the participants for Construction 4.0 technologies were measured. The opinions of the participants about BIM technology are as follows: 16% completely know, 46% know, 10% neutral, 23% do not know, and 5% never know. For cyber-physical systems technology, they responded as follows: 5% completely know, 18% know, 8% neutral, 31% do not know, and 38% never know. For virtual reality/augmented reality (VR/AR) technologies, they responded as follows: 10% completely know, 54% know, 8% neutral, 15% do not know, and 13% never know. For internet of things (IoT) technology, they responded as follows: 8% completely know, 36% know, 23% neutral, 15% do not know, and 18% never know. For cloud computing technology, they responded as follows: 10% completely know, 54 % know, 8% neutral, 13 % do not know, and 15% never know. For big data technology, they responded as follows: 10% completely know, 41% know, 18% neutral, 10% do not know, and 21% never know. For radio frequency identification technology, they responded as follows: 5% completely know, 26% know, 23% neutral, 28% do not know, and 18% never know. For additive manufacturing/3D printing technology, they responded as follows: 13% completely know, 21% know, 15% neutral, 20% do not know, and 31% never know. For autonomous vehicles technology, they responded as follows: 8% completely know, 41% know, 18% neutral, 18% do not know, and 15% never know. For wearable technologies, they responded as follows: 13% completely know, 54% know, 5% neutral, 13% do not know, and 15% never know. For drones, they responded as follows: 25% completely know, 49% know, 10% neutral, 8% do not know, and 8% never know. For robots, they responded as follows: 21% completely know, 56% know, 8% neutral, 5% do not know, and 10% never know (Figure 5).

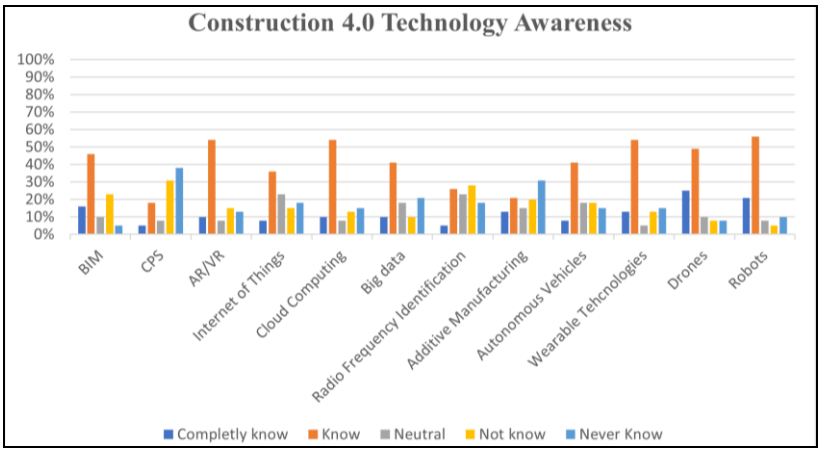

Figure 5: Awareness of construction 4.0 technologies according to the survey study.

In the third section of the survey, the use of Construction 4.0 technologies in the workplaces of the participants was evaluated. Accordingly, the opinions of the participants about the BIM technology are as follows: 20% want to use for the future project, 21% use, 28% neutral, 10% do not want to use, and 21% never want to use. For cyber-physical systems technology, they responded as follows: 10% want to use for the future project, 5% use, 41% neutral, 16% do not want to use, and 28% never want to use. For virtual reality/augmented reality (VR/AR) technologies, they responded as follows: 23% want to use for the future project, 20% use, 26% neutral, 8% do not want to use, and 23% never want to use. For internet of things (ıoT) technology, they responded as follows: 18% want to use for the future project, 10% use, 36%

neutral, 13% do not want to use, and 23% never want to use. For cloud computing technology, they responded as follows: 26% want to use for the future project, 18% use, 26% neutral, 10% do not want to use, and 20% never want to use. For big data technology, they responded as follows: 23% want to use for the future project, 13% use, 28% neutral, 13% do not want to use, and 23% never want to use. For radio frequency identification technology, they responded as follows: 15% want to use it for the future project, 8% use it, 36% neutral, 15% do not want to use, and 26% never want to use it. For additive manufacturing technology, they responded as follows: 21% want to use for the future project, 15% use, 26% neutral, 15% do not want to use, and 23% never want to use. For autonomous vehicles technology, they responded as follows: 15% want to use for the future project, 8% use, 38% neutral, 13% do not want to use, and 26% never want to use. For wearable technologies, they responded as follows: 18% want to use for the future project, 18% use, 28% neutral, 13% do not want to use, and 23% never want to use. For drones, they responded as follows: 31% want to use for the future project, 13% use, 28% neutral, 8% do not want to use, and 20% never want to use. For robots, they responded as follows: 23% want to use for the future project, 21% use, 20% neutral, 10% do not want to use, and 26% never want to use (Figure 6).

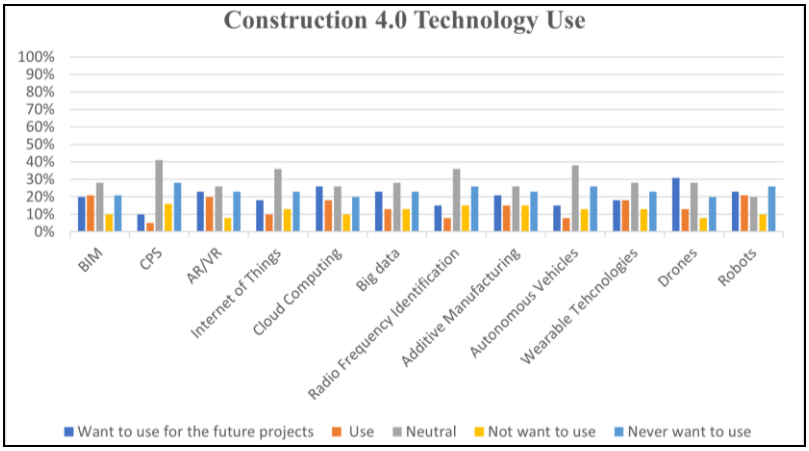

Figure 6: Usage rates of construction 4.0 technologies according to the survey study.

Within the scope of the survey, the Relative Importance Index (RII) method was used for the answers responded to each question, to determine the relative importance perceptions of the sub-dimensions of the section "The impact of Construction 4.0 on project management". RII values were calculated using the following formula (Gündüz et al., 2013):

$$R\ddot{O}E = \frac{\sum W}{AxN} = \frac{5n_5 + 4n_4 + 3n_3 + 2n_2 + 1n_1}{5xN} \quad (1)$$

Where;
W: The weight value of the answers given to each question (between 1 and 5),
A: The highest weighting coefficient (5 in this study), and
N: the total number of samples.

The degrees of importance are as follows: RII<0.6 low indicator, 0.6≤RII<0.8 medium indicator, and 0.8≤RII ≤ 1 high indicator (Artan İlter, 2017). In the last section of the

application, participants were asked to evaluate the impact of Construction 4.0 on project management. In line with the answers given, the degrees of importance were determined.

According to Figure 7, the most significant factors within the scope of the impact of Construction 4.0 on project management are respectively; making construction 4.0 technologies easier to plan, design, monitor and execute projects (Question 3, RII=0.83), improving the quality of the building by preventing errors in the early stages with the use of BIM and other simulation technologies (Question 12, RII=0,82), improving communication, coordination and collaboration among project stakeholders of big data and cloud-based project management tools use (Question 4, RII=0,81), decreasing project delivery time/contributing to budget with the use of BIM (Question 11, RII=0,81) and determining production standards with the use of BIM/Additive manufacturing/Augmented reality technologies (Question 6, RII=0,80), have been determined. The medium indicators of importance, respectively; managing highly complex technical projects with Construction 4.0 technologies (Question 2, RII=0,78), increasing the security of AR/VR-based education and wearable technologies (Question 8, RII=0,78), preventing the problems experienced in machine and workforce by using autonomous robots in the building production process (Question 5, RII=0,77), minimally affecting the management process from external factors with the use of cloud computing/additive manufacturing systems (Question 7, RII=0,77), obtaining real-time data of building components and workers by using the internet of things (Question 9, RII=0,77), protecting information on product standards with the use of cyber-security systems (Question 10, RII=0,77), and identifying and solving of problems in real-time with construction 4.0 technologies (Question 1, RII=0,75), have been determined. As seen in Figure 7, the importance index of all sub-dimensions is between the 75%-85% band. According to these findings, the factors have high and medium importance (Figure 7).

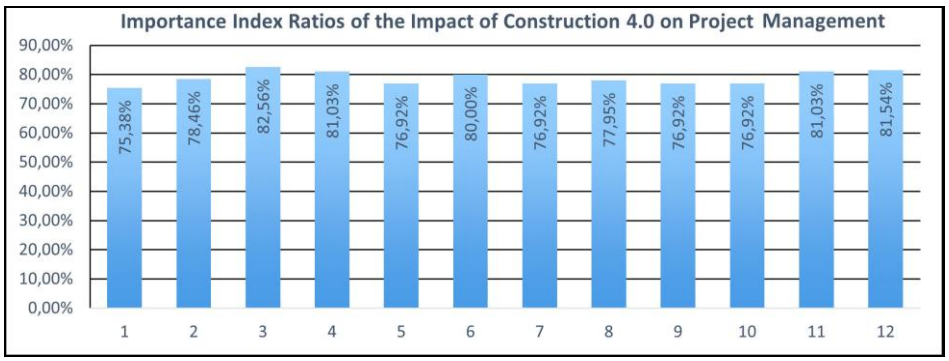

Figure 7: Impact of Construction 4.0 technologies on project management.

Discussion

There are a number of increasing studies discussing the use of Construction 4.0 technologies and their effects on project management processes. Ebrahimi (2019) conducted a survey with construction professionals in her work on the integration of Industry 4.0 technologies into the construction industry. The findings indicated that although the awareness of Industry 4.0 technologies is low, BIM technologies and smart factory technologies are widely used in the industry. As a result of her work, Ebrahimi (2019) has proposed a five-stage roadmap that covers industrial transformation and implementation from a technical and strategic point of view.

Adepoju and Aigbavboa (2020) examined the threats and opportunities of Construction 4.0 technologies in the construction industry in their study. Within the scope of the study, a survey was conducted with 40 project managers and project supervisors. As a result, the use of BIM and prefabrication technologies creates new opportunities for collaboration, creativity, and employee productivity. However, it has also revealed negative consequences such as a decrease in the workforce. In the study, it is suggested that construction 4.0 technologies become widespread in practice, but it is emphasized that it should be controlled by laws. Nagy et al. (2021), on the other hand, stated that Construction 4.0 is not only a technology but also a management and strategic challenge. To overcome these difficulties and make the construction industry more sustainable, management strategies for Construction 4.0 should be established. In this context, a survey was conducted with construction industry professionals. As a result, technologies not only create opportunities in the sector but also create new problems in the context of human resources, management knowledge, and competence, organization. In the solution to these problems, sector managers and the government should work together to produce new value chains.

Results

This study was carried out to examine the awareness of the Construction 4.0 technologies concepts in the construction industry of Kayseri, their use in the public and private sectors, and their effects on project management. For this purpose, a survey consisting of 46 questions was applied to architects, civil engineers, and construction technicians. Considering the 12 concepts in which the awareness level of construction 4.0 technologies is determined, the most known technologies by the participants are respectively; robots, drones, wearable technologies, cloud computing, augmented reality/virtual reality (AR/VR), building information modeling (BIM), big data, autonomous vehicles, internet of things (IoT), additive manufacturing, radio frequency identification and cyber-physical systems. In the third section of the study, the use of Construction 4.0 technologies by the participants was evaluated. The top five technologies that workplaces use and intend to use are as follows: drones, robots, cloud computing, AR/VR, and BIM. In the last section of the study, the effect of Construction 4.0 on project management was evaluated with 12 questions asked to the participants. While making this evaluation, the Relative Important Index (RII) values were taken into consideration, and it was concluded that 5 of the 12 sub-dimensions were of high importance. The highly important effects of technologies are respectively; easier planning/designing/monitoring of projects, increasing the quality of the building by preventing errors in the early stages, improving communication/coordination/cooperation among project stakeholders, reducing project delivery time/helping budget, and determining production standards, is in the form.

It is obvious that the widespread use of Construction 4.0 technologies will contribute to project management actions such as planning, designing, decision-making, supervision, and communication, and factors such as organization, coordination, standardization, and productivity. For this, the managers of the construction industry should make an effort and the managers of the country should support this. This study, which contributes to the studies to be carried out on this subject, is important in this respect. Despite the low number of responses to the survey sent as the weakness of the study, it is seen as the strength of this study that it contributes in terms of quality and practice, especially due to the small number of studies in the field. It is thought that the data obtained from this study, which was applied on a

provincial basis and conducted for the occupational groups in the sector, is valuable in terms of being encouraging and creating a resource for future studies.

In this study, an original study was carried out in terms of the awareness of technologies in the construction industry of Kayseri, Turkiye. Moreover, this research, it is significant in terms of determining the benefits of technology to project management processes and raising awareness of its use in the industry. It is aimed that this study will contribute to future similar scientific studies.

BIM Based Automated Code Compliance Checking System: TRegCheck Program

B. A. Temel and H. B. Başağa
Karadeniz Technical University, Department of Civil Engineering, Trabzon, Turkey
bayramali.temel@ktu.edu.tr, hasanbb@ktu.edu.tr

Abstract

In this study, the presentation of the TRegCheck (Turkish Regulation Checking System) program, which automatically performs the code compliance checking of the BIM based residential architectural projects according to the rules determined from the building legislation in Turkey is presented. TRegCheck is a rule-based control system that automatically checks compliance with the legislation by computer, considering the IFC data of the building model drawn based on BIM and the rules of the relevant building regulations. With this program, story height calculation, Building Coverage Ratio (TAKS) calculation, Floor Area Ratio (KAKS) calculation, minimum building parking area calculation and minimum building shelter area calculation are made according to the relevant regulation, and compliance with the legislation is automatically checked. The TRegCheck program provides convenience to both architects and engineers at the design stage and especially those working in the municipality, in the automated code compliance checking of BIM based designed buildings.

Keywords: *automated code compliance checking, BIM, IFC.*

Introduction

In the architecture, engineering, and construction (AEC) industry, checking the compliance of a building's architectural design with building codes is a manual process that often depends on the experience and skills of the inspector. This process requires considerable effort and time and is error prone. In addition, uncertainties, and inconsistencies in the evaluation of the auditor cause delays in the construction process. Automatically checking the compliance of the building design according to the regulations is a process that includes faster, more consistent, and more transparent audit procedures.

The ability to automatically check compliance with the regulation of a building in the design phase comes to the fore and is realized with BIM, which started a digital transformation and technological revolution in the AEC sector today. BIM can be defined as a digital representation of a building, an object-based three-dimensional model, or a digital repository of project information to facilitate interoperability and information exchange between related software applications (Miettinen & Paavola 2014). Interoperability and digital information exchange between BIM programs is possible with the IFC data file (Nisbet et al., 2009). With the IFC data file, it has provided a standard method and generally agreed upon protocol for

the computable representation of a building (Nawari, 2018). In this way, necessary data can be obtained from the BIM model for rule control. Advances in BIM technology and the availability of the IFC data file also provide opportunities for new software tools that can perform automated regulatory compliance checks. With this opportunity, the efficiency and accuracy of the compliance control processes of a project designed for designers such as architects, engineers and control staff working in administrative institutions such as municipalities will also increase. Thus, in the near future, BIM will become an important digital asset not only in design, but also in software that automatically checks compliance with regulations and obtaining building permit approval from legal institutions such as municipalities (Raslan & Davies, 2006).

Advances in BIM technology and the availability of the IFC data file also offer opportunities for new software tools that can do ACCC. In this way, designers and administrative institutions will increase the efficiency and accuracy of control processes, especially for municipalities. Thus, in the future, BIM will become an important digital asset not only in design, but also in software that automatically checks compliance with regulations and obtaining approval from legal institutions (such as municipalities) (Raslan & Davies, 2006).

The first successful attempt in the AEC industry to automate the control of design conformity was the application of a decision table representing the standard specifications of the American Institute of Steel Construction (AISC) carried out by Fenves in 1966. After this study, various control systems have been developed in the field of ACCC in many different countries until today (Pesquera et al., 1984; Noland & Bedel, 1985; Jaeger & Harelik, 1985; Fenves et al., 1987; Huuskonen & Kaarela, 1995; SMC, 2021; Han et al., 1998; NovaCITYNETS, 2002; Han et al., 2002; Haraldsen et al., 2004; Ding et al., 2006; AEC, 2006; Eastman et al., 2009; Tan et al., 2010; Fiatech, 2012; Kim et al., 2013; Lee et al., 2016; Dimyadi et al., 2018; Beach et al., 2020). These systems developed in the field of ACCC are generally country-based, and each system has been developed by their own countries, either by private or public institutions. In addition, although the target of all these systems is building regulations, many of them deal with specific regulations (fire, security, occupancy permit, zoning, wheelchair access regulation, etc.) or non-regulatory issues (design automation, bridge design, etc.). For example, Han et al. (2002) a simulation approach for accessibility control for the use of wheelchairs by persons with disabilities according to the American Disability Act (ADA); Eastman et al. (2009), on the other hand, the Design Assessment Toll (DAT) was developed for the circulation and security of courthouses in the USA.

In addition to the important studies carried out worldwide on automatic regulatory compliance inspection systems, there are limited academic studies in this field in Turkey (Balaban, 2012; Macit, 2014; Türkyılmaz, 2016; Yapıcı Topuz, 2018; Akbaş, 2019; Demir Altıntaş, 2020; Bayer, 2020; Balku, 2021; Işıklı Aktaş, 2021; Aydın, 2021).

According to the current academic studies in the literature, research on BIM-based automatic regulatory compliance auditing systems in many developed countries dates back years. As a result of these researches, there are many systems that have been developed and started to be used. However, these systems either took the legislation of the countries where they were developed as reference or allowed simple rules to be defined manually. Many developing countries such as Turkey have started to develop automatic regulatory compliance audit systems for their own building legislation in recent years; however, it has not been actively

implemented yet. When the studies are examined, it is seen that the developed systems are made within the framework of simple rules.

Aim of the Research and Methodology

In this study, it is aimed to introduce the program that automatically performs regulatory compliance audits of residential architectural projects drawn on the basis of BIM, according to the rules determined from the Turkish building legislation. This program named TRegCheck (Turkish Regulation Checking System) covers the floor height calculation, building coverage ratio (TAKS) calculation, Floor Area Ratio (KAKS) calculation, minimum building parking lot and shelter calculation rules selected from the Planned Areas Zoning Regulation (PAZR), Parking Lot and Shelter Regulations included in the building legislation in Turkey.

With the developed program, an automation system infrastructure will be created that will eliminate the time-consuming, error-prone, paper-based, and manual compliance inspection process of two-dimensional CAD projects drawn with traditional methods, and instead instantly evaluate and report the compliance of BIM-based projects according to the legislation. Thanks to the automatic regulatory compliance audit, the audit of the designed projects will be carried out in a short time and without errors.

In the study, first of all, the existing building legislation concerning the construction sector in Turkey was examined in detail and the rules that could be automatically checked for compliance with the legislation were selected from these legislations. Afterwards, drawing rules to be followed while creating BIM models were determined in order to perform automatic regulatory compliance checks over IFC data files of BIM-based building projects. At the same time, the content and relationships of the IFC data files of BIM-based building models were analysed. Thus, it has been determined where and in what order the data required for automatic regulatory compliance audits are generated in the IFC file. According to the information obtained, algorithms have been created in order to extract the necessary data from the IFC file and to carry out compliance checks for the determined rules. As a result, TRegCheck program, which is a program with an interface, has been developed, tested and its efficiency has been determined to demonstrate its effectiveness.

In this context, Figure 1 shows that TRegCheck program checks the rules of which legislation and which calculation subjects.

Figure 1: The rules that TRegCheck program checks.

Rules Selected from the Building Legislation and Reasons for Choosing

The rule sentences for the control of building floor heights in PAZR are simple and understandable. With these aspects, it is easy to integrate into the TRegCheck program and sets an example for the process and stages of adapting the controls of all other simple and understandable rules in the building legislation to the program. For example, floor height calculation and control has been chosen as an example of how this and similar type of rules can be controlled easily with a single rule expression such as door, window, corridor widths and do not have logical and computational relations with other rules.

In PAZR, KAKS is defined as "the ratio of the total of all the floor areas of the building to the area of the zoning plot", and the principles and rules for the calculation of KAKS are detailed in various parts of the building legislation. KAKS is the calculation subject that has the most complex and open to interpretation rules in the building legislation and is the most likely to make mistakes.

In PAZR, TAKS is defined as "the ratio of the floor area to the area of the zoning parcel", and the principles and rules for TAKS calculation are detailed in various parts of the building legislation. TAKS calculation was chosen because it has the most complex rules after KAKS calculation in PAZR and contains the most time-consuming and error-prone set of rules.

When we come to the minimum building parking area calculation and minimum building shelter area calculation rules, since these calculation rules have the rules based on the most logical relations between the various articles of the regulation and the annexes of the regulation, and checking these calculations takes more time and error-prone than the other rules in the relevant regulation. Minimum building parking area calculation and minimum building shelter area calculation rules were chosen because they contain a clear set of rules.

Creating BIM Based Building Models

Autodesk Revit software was used to create BIM models and IFC data files of building projects within the scope of the program. In order to carry out error-free compliance checks in TRegCheck program, a BIM model of a building must be created with the Revit program according to some drawing rules. All the determined drawing rules were given to 3 people, an interior architect, an architect, and a civil engineer, who can make BIM-based designs, and they were asked to design the building with Revit. In this way, the final version of the rules was created by correcting the incomprehensible, missing, or incorrect parts of the determined rules.

Analysis of IFC Data File

First of all, it is necessary to determine which data is needed from the IFC file of the BIM model in order to carry out the checks for the calculation rules selected from the building legislation.

Explanations on what data is needed from the IFC file of the building model in order to carry out automatic regulatory compliance checks for the rules of the calculation subjects selected from the building legislation with the TRegCheck program are given in Table 1.

Table 1. Information to be obtained from the IFC data file according to the calculation subjects selected from the building legislation in order to carry out compliance checks with the TRegCheck program.

Information from the IFC data file	**Calculation Topics**				
	Story height	TAKS	KAKS	Minimum building parking area	Minimum building shelter area
Story names	+	+	+	+	+
Story height values	+				
Floor building construction area names		+	+		
Floor building construction area values		+	+		
Zone (space) names		+	+	+	+
Zone (space) area values		+	+	+	+
Single space names		+	+	+	+
Single space area values		+	+	+	+
Tree data structure (Hierarchical structure)	+	+	+	+	+

In order to develop a system that performs automatic regulatory compliance checks of BIM-based building projects, it is necessary to analyse the IFC data file of the BIM model, that is, to know the file structure, the meaning of the data in the file and the relations of the data with each other. Because the necessary information about the building to automate regulatory compliance audits is contained in the IFC data file. This information, on the other hand, can be filtered with the software coding to be developed and extracted out of the file, and conformity checks can be made according to the rules determined within the building legislation.

As the drawing detail level of the BIM model of any building project created with Revit increases, the content volume of the IFC data file increases in direct proportion. Data lines with unique parametric encodings in the ".ifc" extension data file of each object such as columns, beams, walls, doors, windows, stairs, floors, and each feature such as the name and material defined for these objects, belonging to the BIM model created in Revit, and IFC entities are formed within these data rows.

Each IFC entity created in the IFC data file has a meaning, attributes that make up this entity, and relationships with other entities. For example, any location defined in the BIM model has a corresponding IFCSPACE in the IFC data file. Each part separated by commas between the two parentheses following the entity in the data line defines the attributes of that entity. Attributes of the IFC entity that start with # between the two parentheses refer to the entities in the relevant data rows in the file.

A view of the content of the data file with the ".ifc" extension of any building design whose BIM model was created with the Autodesk Revit program is shown in Figure 2.

The referencing structure in the IFC data file describes the order in which the components that make up the building come together. For example, the project consists of the land, the land from the buildings, the building from the floors, the floors from the quarters, columns, walls, doors, etc. It creates a tree data structure (hierarchical spatial breakdown) showing that it

consists of a sub-elements in the form of a tree. In the IFC data file, the tree data structure of the BIM model is formed by the IFCRELAGGREGATES entity.

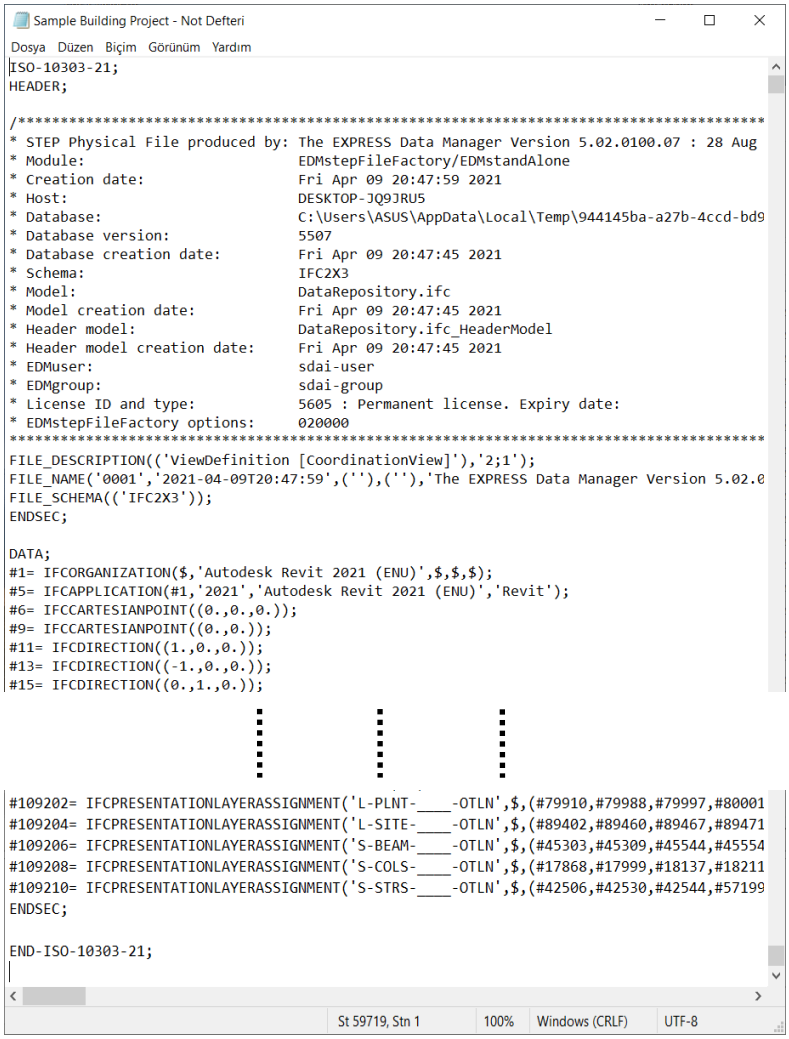

Figure 2: An example view of the ".ifc" extension data file.

If we talk briefly about the features of the IFCRELAGGREGATES entity:
- This entity consists of 6 attributes separated by commas between two parentheses.
- The 5th attribute defines which object to collect the elements,
- The 6th attribute indicates which elements will be collected.

The numerical information and properties of each element of the building modelled in Revit are accessed by the IFCRELDEFINESBYPROPERTIES entity in the IFC data file.
This entity consists of 6 attributes.
- 5th attribute to which objects or object the property definition will be applied,
- The 6th attribute refers to the set of properties that will be applied to the target object or objects.

In the floor plan of an example building project shown in Figure 3, the branching representation of how to reach the area value of 3.24 m² for the area named "BATH (BB01)" and which assets and which attributes are required are shown in Figure 3.

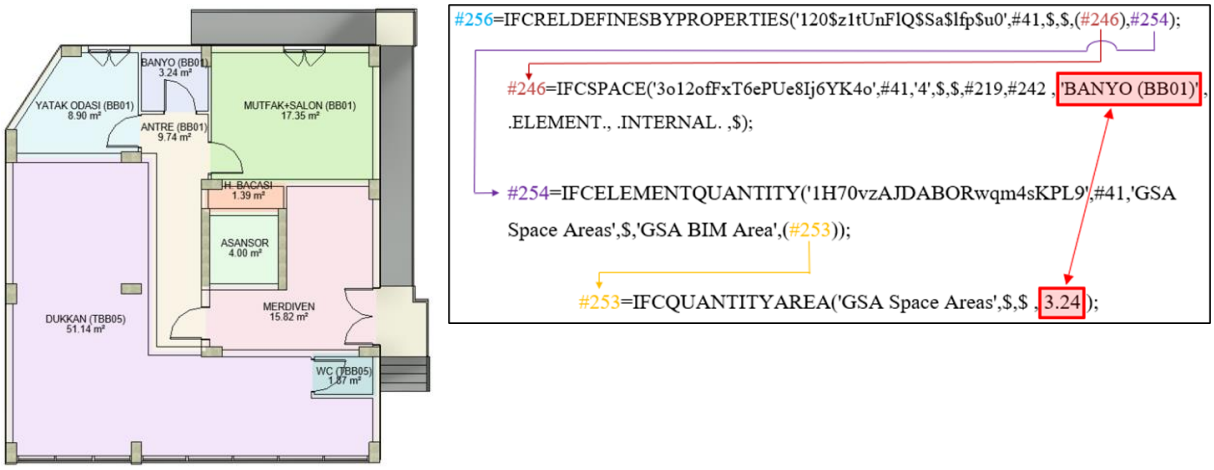

Figure 3: Branching display of how to reach the area value of 3.24 m² for the area named "BATH (BB01)" in the floor plan of a sample building project and which assets and which attributes are required.

Shortly, the desired data from the IFC data file of the BIM model can be transferred to the outside of the file with the software prepared by establishing algorithms based on these examinations described above. Thus, with the TRegCheck program for the control of the determined rules, the data of the BIM model, which is the most important step for automatic regulatory compliance control, is obtained.

Development of TRegCheck Program

The algorithms established for the software coding running in the background of the TRegCheck program were carried out in two stages. In the first step, in the Analysis of the IFC Data File section, based on the analysis and branching algorithms, all the lines in the IFC data file are read one by one within the scope of the information obtained from the IFC entities and relationships to be considered in the IFC data file, and the data lines containing the required IFC assets are automatically found from the IFC file. It is filtered out of the file and separated to be used in calculations and controls at a later stage. In this context, all IFC assets required from the IFC data file of BIM models are ".txt." extension Notepad files are filtered according to a certain order in order to retrieve the necessary data from the IFC entity. According to the algorithms performed in this way, all the data that should be taken from the IFC file of the BIM model were obtained by using the data in the lines separated in each txt file and in line with the relationships between the entities.

In the second stage, software operations were carried out by establishing algorithms for each calculation topic selected within the scope of the thesis for the realization of the calculation, audit and result reports of the TRegCheck program with the data obtained in the first stage.

A view of the Compliance Check/Data Entry section, which is opened when the Conformity Check icon is clicked on the vertical ribbon menu on the left after the user login of the TRegCheck program is given in Figure 4.

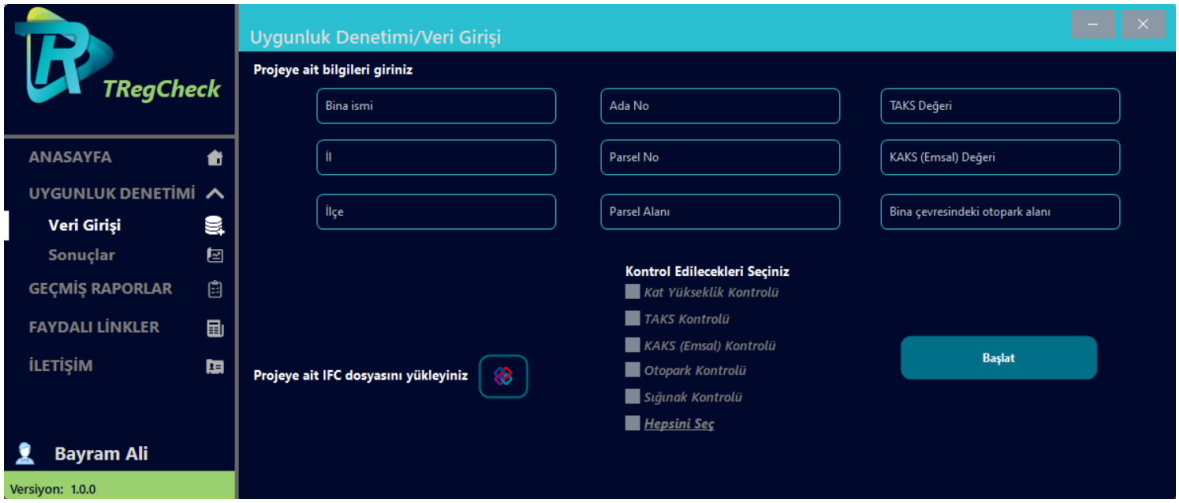

Figure 4: A view of the Compliance Check/Data Entry section of the TRegCheck program

In the data entry section, data entry cells where the information about the project to be checked for compliance will be entered; file upload section for uploading the project's ".ifc" extension file to the program; In order to determine which calculation rules the compliance audit is for, there is a selection section of the items to be checked and a Start button to start the compliance audit processes.

Testing the TRegCheck Program

At this stage, studies were carried out to test the TRegCheck Program, that is, to determine the accuracy of the results obtained from the compliance audits of the program. For this purpose, four building projects that had previously obtained construction permits were determined within the scope of the thesis and BIM models were created with the Revit program.

After the BIM models of the projects determined within the scope of the thesis were created with Revit, automatic regulatory compliance checks were carried out with the TRegCheck program over IFC data files, and both the program's operation was checked, and the calculation and audit results were obtained. Afterwards, these four building projects were manually calculated and checked in Microsoft Excel program. The results obtained both with the TRegCheck program and manually were the same.

Results and Discussions

With the TRegCheck program, the auditing process, which is more time-consuming, prone to errors, and carried out manually by traditional methods, can be carried out automatically within seconds and error-free for BIM-based projects prepared in the computer environment.

It is thought that manipulations and abuses encountered in compliance audits by municipalities will be reduced with TRegCheck, and pressure by third parties to approve building projects that do not comply with the legislation by the people working in the municipality.

With the TRegCheck program, convenience is provided for both architects and engineers at the design stage, and especially for those working in the municipality, in the automatic regulatory compliance inspection of buildings.

With the TRegCheck program, the building permit and building occupancy permit inspection will be carried out by the municipalities in a short time, and both the employees will lose less time in the project review task during the working hours and the demands of the citizens waiting for service will be answered earlier.

It is thought that the problems faced by designers and controllers in understanding the updated rules and not being able to follow the updated articles in the building legislation will be at the lowest level with the TRegCheck program.

Thanks to the developable and updatable feature of the TRegCheck program, the regulations for the control of the changing rules in the legislation and other rules to be selected according to the requests by the users will be easily defined by the program administrators to the system.

Handling Imbalanced Data in Building Energy Benchmarking

S. Bolluk and S. Seyis
Özyeğin University, Department of Civil Engineering, İstanbul, Turkey
said.bolluk@ozu.edu.tr, senem.seyis@ozyegin.edu.tr

Abstract

The energy demand of the building stocks reached a critical value by almost covering 30% of the world's overall energy consumption. Therefore, the importance of building energy benchmarking gains importance. Building energy benchmarking might suffer from imbalanced datasets as a classification model. Using an existing dataset to observe the effectiveness of several machine learning models in predicting the energy benchmark label of the buildings in Seattle, several classification algorithms are first utilized to predict the buildings' energy benchmark label over an imbalanced dataset. Cost-sensitive loss functions and several decision thresholds are then introduced to the artificial neural network (ANN) models, and their effectiveness in handling imbalanced data is examined. Finally, several classification evaluation metrics are analyzed. The results display that the cost-sensitive approach with an empirical decision threshold slightly improved the loss of the ANN models and classification of the minority class. This study shows that the cost-sensitivity concept in ANN is a promising study field, and significant improvements in loss reduction can be achieved through empirical testing. Another prominent result is that machine learning could render building energy benchmarking possible at the urban scale as their results are repeatable for different scopes and regions. Therefore, this study underlines the importance of data-driven methods in district energy performance assessment.

Keywords: *automation in construction, building energy benchmarking, cost-sensitive learning, machine learning.*

Introduction

Building energy performance assessment emerges as a necessity considering the massive greenhouse gas (GHG) emissions caused by the built environment (Hong et al., 2020). Owing to the population growth and consequently the expansion of cities, the energy demand of the building stocks reached a critical threshold by almost covering 30% of the world's overall energy consumption (Ritchie, 2018). This brings the following questions: Is it possible to correctly forecast the consumption behavior of the built environment in urban areas, and if so, how to conduct the energy estimation of the urban building stocks with various characteristics? Even though the answer is ambiguous, one thing is certain that the digital twins of the urban building stock with the real-time consumption patterns would potentiate the sustainable environment practices over the retrofit and urban planning actions. Here, one of the essential actors is the building energy benchmark models. Building energy benchmarking is a process that evaluates the internal and external performance of a building

and whether the building complies with the relevant regulations (Ohlsson & Olofsson, 2021). This forms a classification task for the modelers with the features of the building's energy-related parameters and the target variable, showing the building's energy benchmark label. Classification models in machine learning suffer from imbalanced datasets. While training such models, the imbalanced distribution of the class labels might induce misclassification. This is due to the update of the model parameters occurs inevitably according to specific classes with numerical superiority (Khan et al., 2015). Despite the rapid advancements in the deep learning domain, the class imbalance problem, which is frequent in real-world data collection scenarios, remains challenging for most classification tasks. In the literature, the research on the class imbalance problem is investigated from two central angles: Data Level Approach and Algorithm Level Approach (Hou et al., 2021). In data-level approaches, balanced datasets are acquired via either oversampling the minority classes or undersampling the majority classes. On the other hand, algorithm-level approaches operate in the training phase and try to amplify the effect of minority class representation in the optimization process. Loss functions are critical components of every optimization problem, as they define an objective on which the model's performance is evaluated. Loss functions measure the overall distance, or error, between the estimated and actual value of a specific input set. Based on this evaluation, internal updates of the model weights are affected when performing backpropagation in artificial neural network (ANN) models. Depending on the scenario, different loss functions are used for developing a well-defined objective. Therefore, there is no ground truth in concatenating loss functions to algorithms in machine learning. The most important factors to be considered when deriving a loss function are the selected model, the optimization approach with the derivatives' property, and the dataset's characteristics. One of the most popular loss functions used in machine learning is cross-entropy loss, a metric used to evaluate classifier performance. However, as mentioned above, the cross-entropy loss might be paralyzed when handling imbalanced datasets. As an algorithm-level approach to dealing with an imbalanced dataset, cost-sensitive loss functions might be an alternative. The cost-sensitive approach minds the distribution of the class labels in a dataset and calculates the error of the model's prediction regarding those distributions (Takase et al., 2018). With this approach, cost-sensitive models can classify the datasets through a balanced training process. For example, Focal Loss, which is a modified version of the cross-entropy loss, down-weights the examples that are easy to train (majority classes) and focuses on learning complex examples (instances from minority classes) with tunable controlling parameters (hyperparameters) (Lin et al., 2017).

Using an existing dataset, this study analyzes the relationship between the building-specific parameters and the energy efficiency and performs the followings: (1) Data preprocessing is applied to remove the unnecessary features and outliers. (2) Several classification algorithms are then performed to predict the buildings' energy benchmark label over imbalanced data. (3) Cost-sensitive loss functions with several decision thresholds are introduced to the ANN models, and their effectiveness in handling imbalanced data is examined. (4) Finally, several classification evaluation metrics are analyzed to determine the optimal classifier.

Methodology

Data Preprocessing

A building energy benchmarking dataset was obtained from an open-source platform by the city of Seattle (2020 Building Energy Benchmarking, n.d.). The recordings are from 2020, with 3628 specific buildings and 42 energy-related features. Although there are similar datasets in the same platform between 2015 and 2019, the 2020 dataset reserves the richest content with more buildings and features. In the data imputation part, mean and median values of the relevant features were used to deal with the missing values of the numerical features, including the largest property use type and the site energy use. The categorical variables were then encoded into binary expressions since the classification algorithms could only work with numerical values. In this sense, the target variable, concluding whether or not a building is compliant for energy benchmarking, is transformed into one (1) for compliant and zero (0) for not compliant. The next topic was the distribution of the classes. In the dataset, 97.2% of the instances were compliant, while 2.8% were not compliant. This indicates that the dataset is highly imbalanced. Such imbalanced distributions might cause undertraining of the model for the minority class, zeros, since the model's parameters are destined to be updated according to the majority class, ones. To lessen this issue's effect, 60% of the classes with compliance statutes were removed from the model. The updated distributions were 93% and 7% for the compliant and not compliant classes. Even though the numbers are still imbalanced, decreasing the number of the dataset might induce additional problems. Plus, this study aims to observe the power of different machine learning models in handling imbalanced data. Therefore, the authors assumed this distribution well enough to perform the following classification task. Finally, the processed dataset was divided into the training and test sets as 25% of the data for testing purposes.

Model Development

The classification models examined in this study are as follows: Support Vector Machine (SVM), Multinomial Naive Bayes, Logistic Regression, K-Nearest Neighbors, Decision Tree, Random Forest, and Multilayer Perceptron (MLP). These classifiers have various settings and parameters that may lead to utterly different outputs. Therefore, automating the process and obtaining the best hyperparameter settings for each classifier was necessary. To do this, the grid search procedure was utilized. A grid search is a framework that analyzes the power of the machine learning models according to their hyperparameters enabling statistical calculations. It performs cross-validation over the distinct parameters and provides the users with the optimal settings. The grid search mechanisms were established for each model according to their characteristics, and the classification process was initiated. The analysis was performed in Python using the following libraries: ***Scikit-learn*** for the classical machine learning models and ***PyTorch*** for the MLP models.

The first model was the SVM Classifier. SVM models create a hyperplane that discriminates different classes in the best manner (Shalev-Shwartz & Ben-David, 2014). This separation is achieved using a loss function that maximizes the distance between each class's hyperplane and extreme data points. The regularization parameters and kernel types were the hyperparameters evaluated in the grid search. Here, the regularization parameters, ranging between 0.01-1.0, form the minimum threshold for the algorithm to make an accurate

prediction, while the kernel types (e.g., linear or polynomial) determine the numerical approach that the algorithm will follow. The second model was the Multinomial Naïve Bayes Classifier. The Bayes decision theory is based on observing the prior distributions of classes to derive posterior distributions. It is a very naïve assumption that the data dataset has a particular distribution and the features are statistically independent (Alpaydın, 2020). In the case of this study, neither the dataset had a particular distribution nor the features are not correlated. Therefore, the Multinomial Naïve Bayes model was employed since it can handle multinomially distributed data. Next, the Logistic Regression model was created and tested in the grid search. Logistic Regression models calculate the probability of occurrence of classes using the sigmoid function. The output for each class is a probability ratio. The model updates its parameters using the gradient of the calculated loss calculated between the output and the actual probabilities. The tested hyperparameters of the Logistic Regression were the regularization parameters, ranging from 0.01-0.6, and the solver parameters used in result optimization. The third model was the K-Neighbors Classifier. The grid search observed the following hyperparameters: the number of neighborhoods and the measurement tools for the weight and metric. The class label of a data point is determined according to the nearest points' label with a certain number of neighbors set in this classification model. The uniform or distance weights identify the method used in calculating the impact of the nearest data points on the observed data. Finally, the metrics, such as Euclidean, Manhattan, and Minkowski, indicate the methods used in calculating the distance between data points. The fourth model was the Decision Tree Classifier. Decision Trees are non-parametric models that evaluate the dataset in a hierarchical order. This means that the model sets some initial weights over the first observed data points, increases the number of weights, and updates their values as it progresses on more data points. Each iteration generates decision boundaries for the model (Hastie et al., 2009). The hyperparameters tuned in grid search were the criterion that calculates the loss of each split, the splitter strategy according to the calculated loss, and the class weights that balance the learning process. The Random Forest Classifier was the following algorithm analyzed through the grid search. The parameters observed in the mechanism were the number of estimators and the criterion types for data splitting. The number of the estimator, ranging between 10-100, is the number of trees (decision trees) created by the model to split the data points into clusters and measure the aggregated accuracy. The criterion parameters, such as the Gini Index and entropy, are used to detect the impurity level of the dataset (Hastie et al., 2009).

The final model was the MLP Classifier. MLP is the perceptron algorithm having multiple hidden layers. This is also called Artificial Neural Network (ANN) model. MLP functions differently than most other machine learning models. In MLP, features are evaluated as single sets (input layers) rather than the dataset as a whole (Figure 2). This enables MLP to update model weights in each iteration according to the loss calculated over the utilization of each input layer. This process is called Online Learning (Alpaydın, 2020). For a classification task in machine learning, let us say a set of x represents the inputs of a single instance, the set of w represents the corresponding weights, and the n represents the total number of data points, then the probability of each output y is calculated using Equation 1:

$$y_i = \sum_{j=1}^{n} w_{ij} x_j + w_{i0} \quad (1)$$

The weighted sums are then placed in activation functions that transform the relationship into a non-linear form. Following this path, the final process is to put the activated sums into the

final activation function, which will return a value specific to the aim of the analysis. For example, if the analysis is a regression, the final activation layer should return a linear value, whereas if it is classification, the final outputs might be a probability value for each class. After calculating the possible outcomes in forward-pass calculations, the MLP model determines the loss between the outcomes and actual values and updates the model parameters using Stochastic Gradient Descent. This is called backpropagation (Dong & Yang, 2018) (Jeewajee & Kaelbling, 2020). This update lasts until achieving a certain amount of convergence. In the grid search structure, several hyperparameters of the MLP model were tested to create a baseline model. The hidden layer size and the number of units in each hidden layer determine the complexity of the MLP model. In this study, considering the computational complexity, the authors decided to develop a simple layer setting with nine hidden units. However, an empirical analysis should be done with the advanced test setups to decide the optimal layer settings.

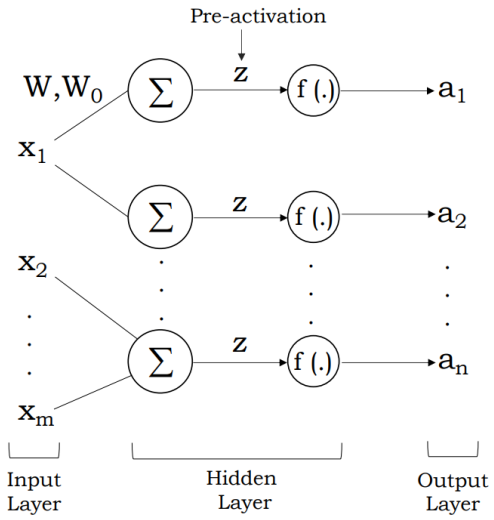

Figure 1: Multilayer perceptron (MLP) architecture.

Once creating a baseline architecture for the MLP, the aim was to increase the accuracy of the classification of the imbalanced dataset through a more advanced hyperparameter tuning. This tuning includes the following hyperparameters: the activation function, learning rate, weight initialization, momentum, and loss function. The activations functions were the sigmoid and tanh functions. Learning rate α is the parameter ranging between 0-1.0 that determines the scope of the update along with the gradient of the loss (Equation 2):

$$\Delta w_i = -\alpha \times \frac{\partial Loss}{\partial w_i} \tag{2}$$

To initialize the weights of the MLP, three different initializations were tested. The first was the random initialization that creates weights according to the Gaussian distribution with zero mean and one standard deviation. The second one is Xavier initialization which produces a uniform distribution with an exponential term based on the number of inputs (He et al., 2015). The last one is the He Initialization generating weights according to the Gaussian distribution, where the mean and standard deviation are both the square root of the input numbers (He et al., 2015). Weight generalization in ANN is a crucial topic since initial weights might have an enormous effect on the results. For example, a proper initialization might yield faster

convergence. On the contrary, randomly initializing the weight in deep networks might cause a vanishing gradient problem (Marion et al., 2022). When this happens, the model's loss stops improving, and the weights get stuck at certain values. Therefore, these three methods in weight initialization were tested in this study. Another hyperparameter tested in multiple scenarios was momentum. When the weights update for each iteration varies significantly from the others, the change in the model's loss exhibits fluctuant patterns. Momentum helps prevent this fluctuation and provides a stable convergence. The value for the momentum is usually taken between 0.5-1.0 (Alpaydın, 2020).

Finally, and most importantly, different loss functions were evaluated to understand the cost-sensitivity concept in ANN. The most common loss function for classification is the Cross-Entropy (CE) Loss. Assume that n is the number of classes, which is two in our case, r is the target (actual) label, and y is the predicted label. Then, the binary CE Loss for each iteration is calculated using Equation 3:

$$\text{CE Loss} = \sum_{i=1}^{n=2} r_i \times log(y_i) \tag{3}$$

CE Loss provides an efficient learning process for classification problems. However, when the data is imbalanced, the model cannot update its parameters according to the minority class, zeros. Even though the accuracy might be high, the cost raised by the misclassification of the minority class would cause some significant problems. For example, the effect of misclassification can be more evident in cancer detection (Qader et al., n.d.) or fraud detection in the banking sector (de La Bourdonnaye & Daniel, 2022). There are some cost-sensitive approaches in the literature accordingly. One of the most famous cost-sensitive loss functions is called Focal Loss (Lin et al., 2017). Focal Loss is created through an empirical process, and its assumption is based on a random constant updating the loss, called gamma γ (Equation 4):

$$\text{Focal Loss} = (1 - e^{-CE\ Loss})^{\gamma} \times CE\ Loss \tag{4}$$

To improve both the CE Loss and Focal Loss, two distinct class ratios were derived from the class distribution of the dataset: *one-ratio* (0.933) and *zero-ratio* (0.067). These ratios were then used in different loss functions. According to the efficiency of the tested functions, the authors chose to continue with only one loss function: Cost-Sensitive Exponential CE Loss (Equation 5):

$$\text{Cost-Sensitive Exponential CE Loss} = \begin{cases} CE\ Loss^{(1+zero_{ratio})}, & r = 1 \\ CE\ Loss^{(1-one_{ratio})}, & r = 0 \end{cases} \tag{5}$$

It should be remembered that the update of the ANN models is performed over the gradient of the loss, and the cross-entropy loss is a function of the model's pre-activated output. If the class ratios are introduced in the loss function as exponential terms, the gradient term would have two constants with two class ratios. In this case, on the assumption that z is the pre-activated output, and the target label r is one, the multiplier term aims to increase the loss where the exponential term gets negative and has a decreasing effect (Equation 6). However, as the class distributions are getting more imbalanced, this exponential term cannot decrease the overall loss but balance the increment of the loss caused by the multiplier. Thus, it might provide an adaptive and more balance learning process. The inverse effect of this assumption applies to the cases when the target label is zero.

$$\frac{\partial CE}{\partial w_i} = (1 + zero_{ratio}) \times f(z)^{(-zero_{ratio})} \times \frac{\partial f(z)}{\partial z} \times \frac{\partial z}{\partial w_i} \quad (6)$$

In addition to the loss functions, ANN models were equipped with different decision thresholds. In machine learning, estimations are made over probabilistic terms. In the case of binary classification, as in this study, the estimator determines the class labels if the occurrence probability of a class is bigger than the other. In other words, the instance is labeled according to the class whose occurrence probability is higher than 0.5. Considering our dataset is highly imbalanced, a 0.5 decision threshold might be useless. After experimenting with several scenarios, the authors decided to continue with a 0.65 decision threshold. This way, ANN models only make estimations when the calculated probability of the majority class (ones) is higher than %65. This might restrain the misclassification of zeros as the models favor ones only when they are confident.

Classification Evaluation Metrics

Evaluating the reliability of classification models with imbalanced data requires intense attention that is far beyond merely examining the accuracy of the results. This is because the models' behavior might result in favor of the majority classes. In such cases, as in our case, the class label of the truly and falsely predicted labels might be more important than the absolute accuracy of the model. Therefore, one should consult multiple evaluation metrics to comprehend the reliability of the classification. To that end, the authors read the classification results over the following metrics: Accuracy, F1 Score, and Brier Score Loss (Table 1). Lastly, confusion matrices were introduced as visual tools to summarize the classification, showing the truly predicted labels in the diagonals.

Table 1. Classification evaluation metrics.

Evaluation Metric	Formula
Accuracy	$\frac{1}{n_{samples}} \times \sum_{i=1}^{n_{samples}} \begin{cases} 1, & y_i = r_i \\ 0, & y_i \neq r_i \end{cases}$
F1 Score	$\frac{TP}{TP + \frac{1}{2}(FP + FN)}$
Brier Score Loss (Mean-Square Difference)	$p_i = \Pr(y_i = r_i)$ $\frac{1}{n_{samples}} \times \sum_{i=1}^{n_{samples}} (r_i - p_i)^2$

Results

In the first part of the analysis, six classical machine learning models were initiated with their optimal hyperparameters, and their performance in classifying the imbalanced dataset was observed. For each classification metric, including the Accuracy, F1 Score, and Brier Score, the Random Forest Classifier outperformed the other eight classifiers (Table 2). However, these metrics cannot be merely sufficient to interpret the misclassification of different classes. Therefore, the confusion matrices should also be examined.

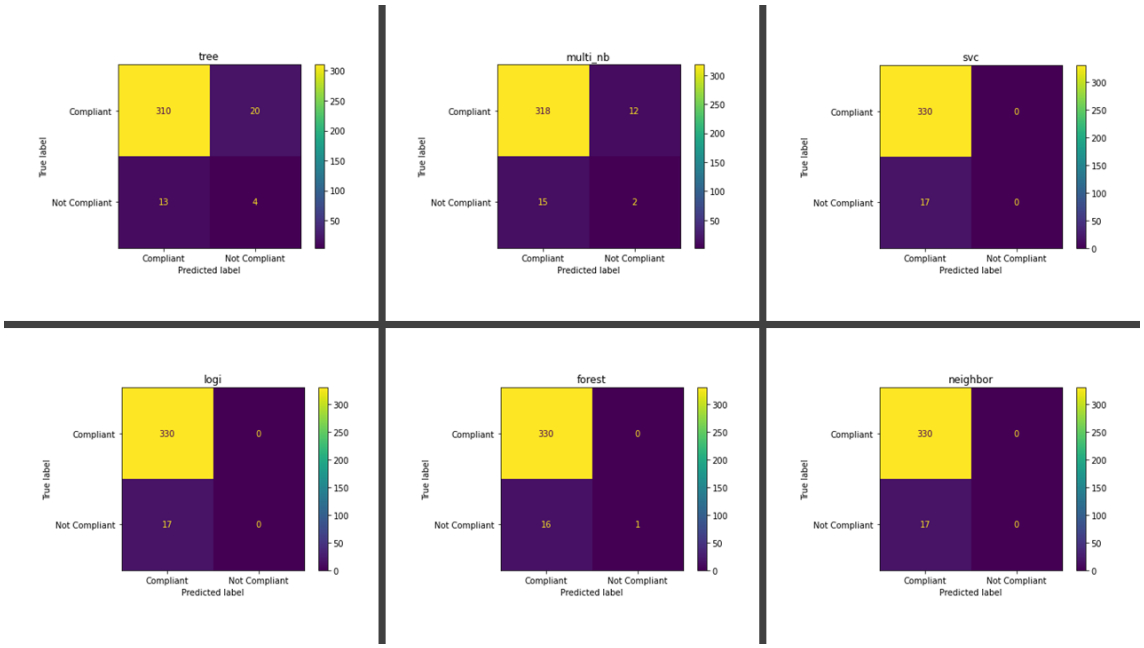

Figure 2: Confusion matrices of the classical models.

Even though the classical models exhibited satisfactory results in terms of standard evaluation metrics, it is seen that most models poorly predicted the labels of the minority class, zeros (Figure 2). These models falsely predicted most zeros since the models considered a specific distribution (e.g., Gaussian) and made estimations over the distribution parameters, where the assumed distribution was not perfectly Gaussian for each feature distribution. Plus, it was almost impossible to manipulate their framework in calculating the final loss. This is very natural because these models were trained based on the weights of the ones as they occurred almost fourteen times more than the zeros in the analysis. However, there are outliers for the classical models: The Decision Tree and Multinomial Naïve Bayes. These models performed slightly balanced in predicting different class labels. For example, the Decision Tree classifier faintly learned the weights in favor of the minority class, zeros, as it predicted four (4) true negatives (Figure 2). Nevertheless, it only predicted 310 true positives, significantly affecting the model's overall accuracy (Table 2). On the other hand, the MLP models were not the optimal ones in terms of standard evaluation metrics (Table 2). However, considering the number of true positives and true negatives, MLP models provided the most balanced distribution between classes (Figure 3). This is because the ANN structure enables modelers to conduct extensive hyperparameter tuning. In this study, an empirical analysis was performed for the hyperparameters of the MLP models, including the loss functions and decision thresholds. The MLP models were trained to classify labels for the benefit of the minority class, zeros. These models were integrated with loss functions that penalize the final loss when the instance label is one. This way, they can update the weights according to the minority class, zeros. Plus, an experimental decision threshold of %65 enabled models to make classifications only when they were confident. It should be noted that experimental decision thresholds were also assessed for the classical machine learning models. However, the authors did not record any improvement for the models with such an arrangement. In this context, it can be said that MLP models are more inclined to learn the instances from the minority class, zeros, owing to the cost-sensitive loss functions. Among the MLP models, the one with cost-sensitive exponential loss produced the best results. It predicted three (3) true negatives and 320 true positives (Figure 3).

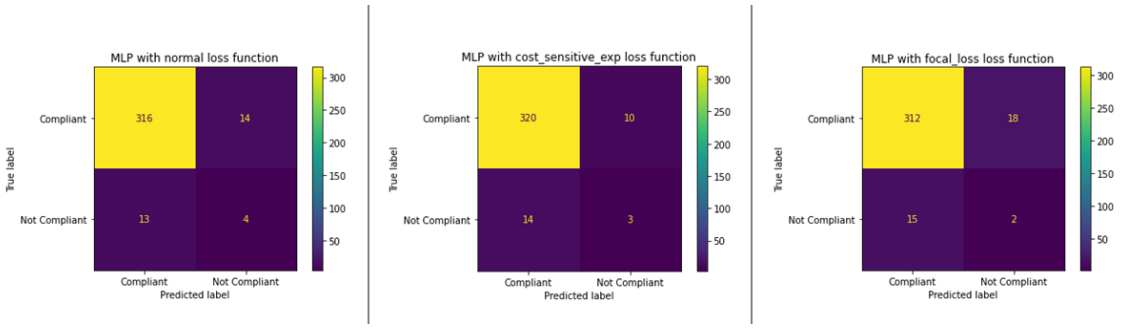

Figure 3: Confusion matrices of the MLP models with different loss functions.

Table 2. Classification results.

Classifier	**Accuracy**	**F1 Score**	**Brier Score**	**TP**	**FP**
Support Vector Machine	0.951	0.975	0.048	330	0
Multinomial Naive Bayes	0.951	0.975	0.047	318	2
Logistic Regression	0.951	0.975	0.047	330	0
K-Nearest Neighbors	0.951	0.975	0.052	330	0
Decision Tree	0.905	0.949	0.095	310	4
Random Forest	0.954	0.976	0.045	330	1
MLP with Normal Loss	0.922	0.959	0.105	316	4
MLP with Focal Loss	0.905	0.95	0.127	312	2
MLP with Cost Sensitive Exponential Loss	0.931	0.964	0.103	320	3

Discussion

This study utilized different classification metrics and confusion matrices to interpret the results. Among the classification evaluation metrics, the Brier Score Loss appears to be the most reasonable metric to compare the results. This is because the Brier Score evaluates the probability of the class labels that the models make and in calculating the loss. Such a loss value holds excellent insights into the confidence level of the models in making predictions. Hence, looking at the Brier Score Loss, it is evident that the Random Forest Classifier outperformed the other models in classifying the building energy benchmark label. However, considering the estimations on the minority class, the MLP models, especially the one with cost-sensitive exponential CE loss, exhibited the most balanced distribution between classes (Figure 3). In this sense, it is evident that MLP models are powerful in handling imbalanced datasets.

This study contains some limitations. The first one is the lack of computational power. When developing MLP models with optimal hyperparameters, more than 300 million scenarios can be tested over several hyperparameters, including the learning rate, initialization type,

activation functions, number of epochs, momentum, hidden layer size, and loss functions. ANN is a nascent field that offers independence in performing empirical studies. This makes it possible to improve the model's predictive capacity via hyperparameter tuning. However, in this study, only a limited number of scenarios were tested on the model's hyperparameter settings. The authors believe the results could display remarkable improvements with sufficient computational power. The other limitation is the size of the dataset. Available datasets are separated into training, validation, and test sets in machine learning studies. At first, the model is trained using a training set, and its performance is observed over the validation set. This part generates the validation curve (Figure 4), which is very helpful in analyzing the change in the loss calculated for each epoch. Once the optimal hyperparameters are determined, and the model is trained once more using these hyperparameters. The trained model's weights are then used to analyze the model's performance over the test set. This is the final process where the analysis report with the accuracy curve (Figure 4) is published using the test results. In our case, the original dataset had around 3300 instances. This number was reduced to around 1400 instances to balance the class distribution slightly. Due to the limited data and, more importantly, the size of the minority class (zeros), this study only divided the datasets into training and test sets. Then, the test set was both used in model validation and testing. This assumption forms an internal consistency for the results as it can represent the training and test sets fairly. However, when new instances are appended to the model, the predictions might not cover the actual labels, and thus the generalization capacity of the model might suffer. This suggests that the dataset should be big enough to be divided into training, validation, and test sets to provide an external consistency for the model's results.

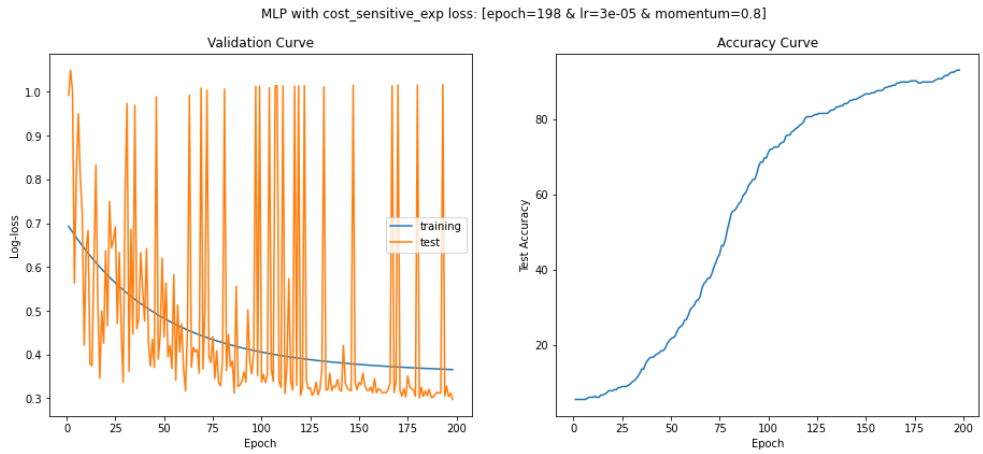

Figure 4: Validation and accuracy curves of the MLP model with cost-sensitive exponential CE loss.

There is a significant fluctuation in the validation curve in Figure 4. Most features in the dataset do not have the Gaussian distribution, and they include many outliers. This complicates the accurate prediction of the labels with the parametric approach, analyzing the distribution parameters (e.g., mean and variance) and making estimations accordingly. Moreover, the size of the test set is significantly small. When the variance of the test set is high due to the small number of samples, the trained model cannot fit the test set, and steady patterns in the loss reduction cannot be observed for the test set. This explains the oscillation in the validation curve. Creating synthetic data to increase the number of samples or employing non-parametric methods, which do not require information derived from the feature distributions, might solve this problem.

Conclusion

Building energy benchmark labels were predicted via several classification models in this study. Six different machine learning models were tested with their optimal hyperparameters settings, which were automatically found via the grid search. The MLP models were then manually examined to decide on the best hyperparameters. Here, the most significant part was to analyze the power of different cost functions in handling imbalanced data. To do this, three MLP models were integrated with different loss functions. Overall result interpretation was performed using different classification metrics. Here, the Random Forest was the best model from the point of the standard evaluation metrics (Table 2), where the MLP models were the winning models in truly predicting instances from the minority class, zeros (Figure 3). This study showed that the cost-sensitivity concept in ANN is a promising study field, and significant improvements in loss reduction can be achieved through empirical testing. Even though the number of accurate predictions for the minority class by the cost-sensitive loss functions is not great, the assumption of this study can be comprehensible and enhanced with a large dataset. Therefore, a possible future work of this study could be working with a large dataset to decrease the variance between training and test sets and increase the generalization power of the classification. Another future work could be utilizing an advanced computational configuration to conduct extensive hyperparameter tuning for the MLP models. This study also showed that machine learning models could make accurate building energy benchmarking. Therefore, this study underlines the importance of data-driven methods in district energy performance assessment.

Contributions of Augmented Reality Applications During Sustainable Building Life Cycle

C. Bedur Doğruöz and İ. Erbaş
Akdeniz University, Faculty of Architecture, Department of Architecture, Antalya, Turkey
dogruozcanan@gmail.com, ierbas@akdeniz.edu.tr

Abstract

Completion of the projects in the construction industry within the predetermined quality, time, and costs both ensures the achievement of the project goals and supports sustainable development. The length of manufacturing and usage processes in the construction industry causes the industry to intervene the environment too much. Therefore, sustainable development is also important in the construction industry. "Augmented Reality" is defined as the enrichment of real-world products, systems or environments by making use of virtual data. Augmented reality applications while widely used in many industries such as education, health and manufacturing, it has only recently been used in the construction industry. The purpose of this study; to reveal the contributions of the use of augmented reality applications during the construction phase in the sustainable building life cycle. Within the scope of the study, augmented reality applications under construction were examined. SWOT analysis was carried out with the samples examined and the results of the analysis were evaluated together with the sustainability goals. As a result of the study, it has been revealed that augmented reality applications during the construction phase are in line with the goals of the concept of sustainability.

Keywords: *augmented reality, building life cycle, sustainability, swot analysis.*

Introduction

Multidisciplinary structure of the construction industry; requires cooperation and coordination. Each step depends on the previous action step, and it affects the next action step. The correct and efficient implementation of construction activities from start to finish is dependent on this cooperation and coordination. For this reason, the margin of error should be as low as possible, and compliance should be ensured between approved projects and implementation projects. Hence, project manufacturing processes can be completed within the anticipated time and cost, with high quality. In addition to all of these, construction industry is one of the industries with high energy and resource consumption when compared with other industries. When the usage process of the resulting product is taken into consideration, it is understood how long the activities of the construction industry affect the environment in which it is situated. Increasing environmental problems have revealed the requirement for a sustainable approach in the construction industry as well as in every other field (Huovila & Koskela, 1998). Adopting sustainable construction principles, starting from the design stage of the buildings, throughout their lifetime and beyond will contribute to sustainable

development processes (Kibert, 2005). In addition, that the limitation of the natural resources, energy and raw material is a global problem, so this shows that the adoption of sustainable development is a necessity. For this reason, ensuring sustainability in the construction industry is becoming a global goal (Gökçe et al., 2018).

Augmented reality applications are defined as enriching real-world products, systems, or environments by using computer-assisted data and presenting them to the user experience; While it is widely used in many industries such as education, health and manufacturing, it has only recently been used in the construction industry (Altınpulluk, 2015).

It can be stated that the augmented reality applications in the construction industry are in line with the sustainable construction goals in terms of ensuring the compliance between the approved project and the application project, protecting the resource consumption with the least intervention to the environment, and contributing to the field of occupational health and safety. In the literature, there are various studies on sustainability in the construction industry (Geçim, 2018; Hoşkara, 2007; Huovila & Koskela, 1998; Kibert, 2005; Sev, 2009; Şenel, 2010). Some studies have also addressed augmented reality applications in the building industry (Arslan et al., 2019; Behzadan & Kamat, 2009; Behzadan & Kamat, 2013; Chen et al., 2013; Chi et al., 2013; Fazel & Izadi, 2018; Kwon et al., 2014; Lee et al., 2011; Park et al., 2013; Talmaki et al., 2010; Tsai, 2014; Wang, 2007; Wang & Dunston, 2007; Wang et al., 2013). However, there is not enough study in the literature that deals with sustainability and augmented reality applications in the construction industry together. Hence, the purpose of this study is to reveal the contributions of the use of augmented reality applications during the construction phase in the sustainable building life cycle. Within the scope of the study, the augmented reality applications that are used in the construction industry were examined and SWOT analysis was made about these applications. Sustainable building life stage is examined in three stages: pre-construction phase, construction phase and post- construction phase. Scope of the study were determined as the construction phase applications in the building phase. It is important to state that augmented reality applications are related to their contribution to the construction phase and sustainability goals.

Material and Method

The purpose of this study is to reveal the contributions of the use of augmented reality applications in the construction phase of the sustainable building life cycle consists of 4 stages. In the first stage, the concept of "sustainability" has been discussed and the concepts of "sustainable architecture" and "sustainable construction" were mentioned in relation to the concept of sustainability. Building life cycle, being one of the three principles of the concept of sustainable construction, has been examined. Concepts of traditional building life cycle and sustainable building life cycle, which are two different approaches in the building life cycle, are explained and the importance of sustainable building life cycle is emphasized. Within the scope of the study, the "construction phase", which includes construction site applications, was discussed within the scope of the "construction phase", being one of the phases in the sustainable building life cycle. In the second stage, the concept of augmented reality was explained and augmented reality applications in the construction industry were discussed with examples. In the third stage, SWOT analysis was performed by the authors according to the second stage analysis. Within the scope in the SWOT analysis, only augmented reality applications were evaluated during the construction phase. In fourth stage, results of third stage and first stage were evaluated together.

Concept of Sustainability

The concept of “sustainability” has the meaning of "continuity" and "sustainability", which was first discussed on a global scale at the United Nations Conference on Environment and Development held in Stockholm in year 1972 and entered the literature at this point (Durmuş, 2010). The concept of sustainability, which deals with the need to evaluate "environment" and "development" together, was defined by the World Commission on Environment and Development (WCED) in year 1987 as "the ability of humanity to continue with its development with the needs of present generations without compromising the needs of future generations" (WCED, 1987).

The concept of sustainability has three dimensions as economic, social and environmental. The situation where all three dimensions can be evaluated together is defined as the most ideal situation (Sev, 2009). Environmental sustainability is an approach purposing to protect the natural environment as much as possible and to interfere with it at the least. Environmental sustainability is to leave the earth to future generations in a much better way than its current state (Sev, 2009). Social sustainability means leaving the necessary resources to the future so that future generations can protect and sustain their existence by ensuring equality between generations. According to this understanding, both the needs of today's societies will be met and the right to life of future generations will be protected. (Sev, 2009; Şenel, 2010). Economic sustainability is defined as providing high performance growth by using less resources against increasing population and industrial manufacturing. Economic sustainability is related with ensuring a regular public and private investment flow with effective use and management of resources, evaluating economic efficiency with social criteria instead of operating profitability (Hoşkara, 2007; Sev, 2009).

The concept of sustainable architecture came to the fore within the scope of sustainable development. In addition to the manufacturing of design and construction processes with a certain time, quality and cost, it also anticipates that the buildings should be environmentally friendly, consuming less energy, not polluting the environment, and increasing the quality of life of the users. The concept of “sustainable construction” that emerged in this case is defined as the equivalent of sustainable development in building design and construction. Sustainable construction offers a holistic approach to the construction and management of the built environment together with the building life cycle framework (Şenel, 2010). The concept of sustainable construction is considered as a response given by the construction industry in the sustainable development process (Huovila & Koskela, 1998). Sev (2009) specified that design and construction in sustainable architecture is comprised of three basic principles: resource management, life cycle design and design for human beings. This study focuses on the construction phase in the building life cycle.

Building Life Cycle

In the traditional sense, the building life cycle is a linear process consisting of design, construction, use-maintenance, and demolition stages (Geçim, 2018). In the traditional approach, as factors such as the environmental effects that occur during the material construction phase of the building life cycle, the lack of waste management, and the ignoring of recycling after the use phase are realized, in the building life cycle, the need for a

sustainable approach has emerged. In the concept of sustainable building life cycle, the environmental effects and consequences of all processes, from the acquisition of resources in nature to their return to nature after their useful life is over, are taken into account. The principle of sustainable building life cycle is based on the understanding that resources can transform from one form in which they will be beneficial to another form in which they will be beneficial and that their useful life can continue without ending (Şenel, 2010).

The life cycle of a structure is examined in three phases as pre-construction, construction, and post-construction. The pre-construction phase is comprised of stages of design, construction phase; construction and use, and post-construction phase is comprised of stages of destruction and recycling in the post-construction phase (Sev, 2009). Within the scope of sustainable architecture, the methods that should be applied at the construction stage in the building life cycle can be listed as reducing the impact of construction site works and equipment on the environment, waste management, preventing environmental pollution, ensuring the health and safety of workers in construction, using non-toxic maintenance and repair materials, and choosing materials that will not harm the health of users. (Sev, 2009; Şenel 2010).

The construction phase, that starts with the phase where the building is produced in the building life cycle process is the process that continues with the use of the building (Şenel, 2010). During the construction phase, considering that the structure is built permanently and has been in use for many years, it can be said that this phase has an important place in the sustainable building life cycle.

Augmented Reality

Augmented reality is achieved by enriching real-world objects and spaces through virtual items produced in computer systems. As Altınpulluk (2015) quotes from Craig (2013), Augmented reality is not just a technology, it is an environment that contains some components and values and has artistic and philosophical value. From this perspective, it can be stated that defining augmented reality only as technology is equivalent to limiting the possibilities of augmented reality.

In the theory which Milgram and Kishino (1994) name as “Reality-Virtualism Continuity”; the concepts of virtual reality, augmented reality and mixed reality are expressed (Figure 1). While there is a world that we perceive with the naked eye without using any hardware at one end of this continuum, there is a completely computer-generated world at the other end (Arslan et al., 2019). As per these concepts, virtual reality (VR) can be defined as an environment encountered in computer-based three-dimensional games, where the user's relationship with the world completely disappears when he enters this environment. Augmented reality (AR) can be expressed as an environment that maintains its connection with the real world, where data and images can be added to real world images and enables real and virtual objects to be perceived together in the same environment (İçten & Bal, 2017b). While virtual reality is based on the virtual world, augmented reality is based on the real world (İçten & Bal, 2017a).

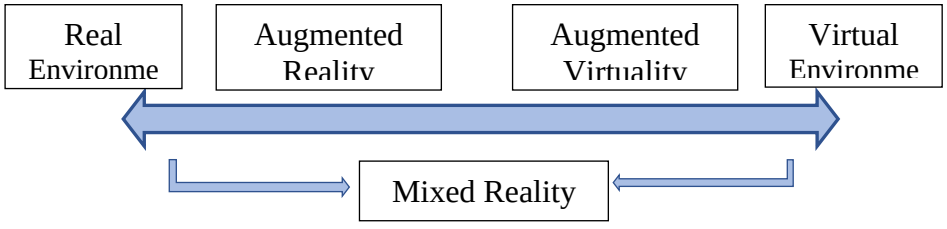

Figure 1: Milgram's reality-virtuality continuity (İçten & Bal, 2017a).

Augmented Reality in Construction Industry

Although the studies on the application of augmented reality technology in the construction industry have increased in the last few years (Li et al., 2018; Wang, 2007), the construction industry is one of the industries that have not used this new generation technology adequately, yet (Arslan et al., 2019).

As quoted by Arslan et al. (2019) from Van Berlo et al. (2009), augmented reality can be used in 3 main categories being on-site experience, on-site verification and on-site warning system. With on-site experience, it is possible to predict how a building will be settled in the place where it will be built before it is constructed, with the conditions and geography surrounding it. With on-site verification, a 3D building model is fitted with a virtual image on the constructed building relative to a given reference point. Hence, it can be controlled whether the application project is compatible with the designed project or not. With the on-site warning system, in the presence of potential hazards at the construction sites, the warning signs on the construction site become more attractive and their safety can be increased by being warned as necessary. With the use of augmented reality by means of these three methods, the suitability of the project for its purpose, the harmony between the approved project and the application project, the quality of the application project, its compatibility with its environment, and occupational health and safety can be managed effectively in real time (Arslan et al., 2019). In Figure 2, on-site experience, on-site verification and on-site warning system and augmented reality application examples are seen respectively.

Figure 2: Respectively; on-site experience, on-site verification and on-site warning system and augmented reality application examples (Arslan et al., 2019).

As quoted by Arslan et al. (2019) from Hammad (2002), Hammad has developed MARSIFT for site engineers and technicians working on infrastructure projects and checking the location of structural members. By means of this system, the necessary information can be obtained in real time within the scope of the work to be done depending on the users' locations and duties. The use of augmented reality applications in the planning of virtual construction site environments was revealed by Wang (2007). Wang predicted that with augmented reality, planning errors could be prevented, and productivity will increase in this process. Again, Wang and Dunston (2007) purposed to train the operator in a real construction site equipped with real construction equipment, virtual materials, and virtual targets, instead of impractical real field training, with the augmented reality model called ARTS which they developed. One

of the situations frequently encountered during excavation works at the construction site is related with the damage occurring in relation to infrastructure systems. In order to minimize negative situations, Behzadan and Kamat (2009) integrate augmented reality and GPS; They superimposed live video of real images with CAD models of infrastructure facilities. Thus, the equipment operator will be able to view the virtual images of the infrastructure systems in real time at the real excavation site and ensure that the excavation operations are carried out without damaging the infrastructure systems. As quoted by Arslan et al. (2019) from Han (2009), Han (2009) created a formula according to OSHA standards, arranged augmented reality over real pictures and used it for occupational health and safety training. Talmaki et al. (2010) used augmented reality applications to increase the safety conditions of workers who were excavating in the city. Lee and Akın (2011) aimed to increase the field performance of construction equipment with the AROMA-FF model they developed by using augmented reality applications. Again, as Arslan et al. (2019) quoted from Zhao (2012); Zhao (2012) used augmented reality applications to prevent electrical accidents in construction works. As Arslan et al. (2019) quoted from Kim et al. (2012), Kim et al. (2012) modelled the possible scenarios of construction equipment on construction sites with augmented reality applications and predicted that these models could provide potential improvements in the construction planning process. Chen et al. (2013) designed a program called SAVES with augmented reality applications. In this program, firstly, various risks in the construction site were determined and classified. Afterwards, a model of the construction site was prepared with building information modelling (BIM) and was used to raise awareness of workers on occupational safety with various training scenarios. Behzadan and Kamat (2013) organized occupational health and safety training targeting civil engineering students by making use of augmented reality applications. Park et al. (2013) developed a security management and visualization system (SMVS) by integrating augmented reality, GPS, BIM and gaming technologies. In this way, it is purposed to be aware of the accidents that may occur at the construction site and to avoid the accident. Chi et al. (2013) investigated potential future application areas of augmented reality applications in the construction industry. According to the results of the research, it is stated that the use of mobile devices will be more effective and cost-effective in the future, and the applications of augmented reality applications on these devices will increase. A model where augmented reality applications are integrated with BIM, was put forward by Wang et al. (2013). In this model, it is focused on how augmented reality applications can realize real-time communication on construction sites. Tsai (2014) developed a system called MERIS. This system includes the workers working in the open air to ask for help with their mobile phones when they are faced with a dangerous situation or work accident. The research conducted by Kwon et al. (2014) is one of the studies carried out for quality control in construction projects. With this system, it is purposed to control the dimensional errors of the construction site productions during the construction phase. Kwon et al. (2014) stated that the limitations of augmented reality applications can be avoided by adapting more advanced technologies to the system. Fazel and Izadi (2018) built modular surfaces on construction sites by using augmented reality applications. Figure 3 shows the modular surface construction at the construction site.

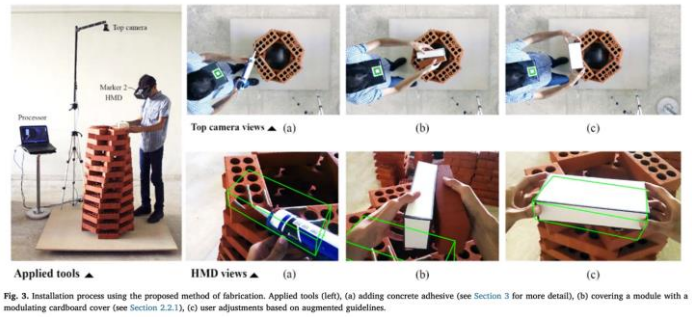

Fig. 3. Installation process using the proposed method of fabrication. Applied tools (left), (a) adding concrete adhesive (see Section 3 for more detail), (b) covering a module with a modulating cardboard cover (see Section 2.2.1), (c) user adjustments based on augmented guidelines.

Figure 3: Construction of modular surface construction at the site (Fazel & Izadi, 2018).

Arslan et al. (2019) have developed a system that will minimize errors during the application phase of the project with the combination of point cloud display and AR application. Figure 4 shows the overlapping of the approved project and the application project in real and virtual environments.

Figure 4: Overlapping of project applied with approved project in real environment and virtual environment (Arslan et al., 2019).

Results

In this section, SWOT analysis of augmented reality applications was made during the construction phase. SWOT analysis was performed by the authors in line with the examined samples. SWOT Analysis is a technique used to identify the strengths and weaknesses of the institution, organization, project, or situation where the analysis will be conducted, and to identify opportunities and threats that may arise from the external environment (Erol, 2019). In this study, a SWOT analysis was carried out in order to reveal the current situation of augmented reality applications within the scope of the construction industry. The current contributions of augmented reality applications constitute the strength of the system. Strengths benefit the operation of processes and the whole industry. Weaknesses are aspects that need improvement and can take their place in the system as strengths when developed. Opportunities reveal other possibilities that can be achieved Through augmented reality, in a sense, it reveals the potential of augmented reality applications. The threats indicate situations where action should be taken beyond the weaknesses of the system. Strengths, weaknesses, opportunities and threats of augmented reality applications in construction are discussed in line with the examples included in the study. Table 1 shows the results of the SWOT analysis.

Table 1. SWOT Analysis.

STRENGTHS	WEAKNESSES
• Ability to view the building model in real time • Ability to quickly and accurately detect errors between the approved project and the application project • Real-time alignment between the approved project and the application project • Minimum margin of error • Progress in project construction processes without the need for on-site solutions • Less control needed in approved project-application project processes • Minimal intervention to the land • To be able to complete occupational health and safety training more effectively • To be able to benefit from occupational health and safety measures more effectively	• Due to being a new generation technology, encountering various technical problems • Continuously meeting the energy needs of the devices • The need to transfer data to the system correctly • The margin of error is related to the user experience
OPPORTUNITIES	**THREATS**
• It is predicted that the use of augmented reality applications in the construction industry will become widespread in the future and will become more specialized according to the needs. • Facilitating multidisciplinary studies • To be able to benefit from advanced technology opportunities in the construction industry efficiently • Contributing to the technology-human relationship in the construction industry • Setting an example for other industries	• Decrease in employment • Software security requirement • Being open to technological vulnerabilities • Excessive reliance on technology • The need to adapt to constantly renewed technology • Obligatory dependence on technology • Difficulty returning to previous systems in case of failure to adapt to updated technology and devices

One of the strengths of augmented reality applications under construction is the real-time viewing feature, which is one of the main features of augmented reality applications. In this way, real-time visualization of the building model is provided. Through real-time imaging, the differences between the approved project and the application project are detected quickly and accurately, and high-quality construction can be achieved with minimum error margin. Again with the real-time viewing feature, real-time viewing is provided between the approved project and the application project. With the rapid detection of differences between the approved project and the application project with augmented reality applications, progress is achieved without the need for an on-site solution based only on the application. The need for less control in the project manufacturing process is also one of the strengths of augmented reality applications. With the use of augmented reality applications during the application of the building to the land, it is possible to interfere with the land at minimum level. Again, in the field of occupational health and safety, it is possible to complete the trainings in real time and in a wide variety of scenarios with low cost and shorter time, and to benefit from occupational health and safety measures more effectively. All of these constitute the strengths

of augmented reality applications in the construction industry. Through these strengths, it is possible to complete the projects within the stipulated time and cost, with high quality.

In addition to all these strengths, augmented reality applications in the construction industry also have weaknesses. Due to the new generation technology, various technical problems can be encountered. In addition, meeting the constantly existing energy needs of the devices can be considered as one of the weaknesses of the system. The more accurately the data is transferred to the system in augmented reality, the more smoothly the processes will proceed. For this reason, it is very important to transfer the data to the system correctly. As errors in data transfer will cause for augmented reality applications to affect the accuracy of the results, precision required in data transfer is also one of the weaknesses of the system. User experience is also one of the factors affecting the results of augmented reality applications. This is because of the fact that the margin of error depending on the user experience can also be counted as one of the weaknesses of the system. Elimination of all these weaknesses will increase the strengths of the system.

Existing applications of augmented reality applications in the construction industry also includes potentials for the future. These potentials can be considered as opportunities for augmented reality applications in the construction industry. For example, it is foreseen that the use of augmented reality applications in the construction industry will become widespread in the future, as in every industry, and it will become more specialized according to the needs. With the widespread use of augmented reality applications in the construction industry, it can be counted as an important step for efficient use of advanced technology opportunities in the construction industry and for digital transformation in the industry. In this way, it is foreseen that it will contribute to the human-technology relationship in the long run. Just as augmented reality applications in other industries set an example for the construction industry; In the future, the construction industry will set an example for other industries.

Apart from the above-mentioned strengths, opportunities and weaknesses that need to be eliminated, there are also threats to consider. With the spread of augmented reality applications in the construction industry, there is less need for people and the decrease in employment constitutes one of the risks. With the widespread use of technology, being open to technological vulnerabilities and ensuring software security are also factors that threaten the system. With the widespread use of technology, it is possible for the workers in the field to rely too much on technology and accordingly become more insensitive about the tasks they have to do and the precautions they should take. The need to adapt to the constantly renewed technology and depending on this technology, the difficulty of returning to the previous systems in case of not adapting to the updated technology and devices are among the factors that threaten the system.

Discussion

With augmented reality applications during the construction phase, high quality construction, cost and time completed within the stipulated limits, it is ensured that the construction activities reach their targets efficiently. Staying within the scope of the foreseen cost and time also provides benefits such as preventing unnecessary resource use and minimal intervention to the environment. Behzadan and Kamat (2009); have shown that the excavation process can be advanced by minimally intervening in the field with the augmented reality applications they applied during the excavation works. Chen et al. (2013) have revealed that occupational

health and safety measures can be implemented effectively by using augmented reality applications. In this and similar studies in the literature, it is seen that augmented reality applications contribute to the effective resource use phase. Since the effective use of resources is among the principles of sustainable construction, it can be said that augmented reality applications contribute to sustainable construction through their strengths.

Since augmented reality applications are still new technologies in the construction industry, encountering technical problems has been identified as the weakness of these applications. In addition, it is necessary to work meticulously at every stage to reach the end product of augmented reality applications without errors. In this case, user experience is very important. In their study, Kwon et al. (2014) have revealed that user experience affects the end product. With the development of technology, elimination of technical problems and meticulous work in the use of the system, the weaknesses of augmented reality applications can evolve into strengths. It is thought that it will contribute more to the principles of the sustainable building phase by evolving the weak aspects into strengths.

When sustainable building phase principles are associated with the opportunities of augmented reality applications in construction, it should be considered that augmented reality applications are still developing technologies. In the future, as technology develops, augmented reality applications will also be developed, and their contribution to the construction phase in the construction industry will increase and become more efficient. In their study, Fazel and Izadi (2018) have revealed that they have succeeded in providing construction with less margin of error with augmented reality applications. In addition, in the application phase of projects with augmented reality applications, Arslan et al. (2019) have demonstrated that construction compatible with the approved project can be achieved. The increase in the use of augmented reality applications in the construction stages with the developing technology in the future will prepare a common ground for the stakeholders participating in the industry from many different fields. This holistic approach that augmented reality applications provide to the construction phase can be associated with the holistic nature of sustainable building phases.

With regards to the sustainable building phase principles, when augmented reality applications under construction are associated with threats, the need to become dependent on technology and to be technologically secure comes to the fore. In all the examples examined, it is seen that the augmented reality applications contribute to the construction phase with the technological infrastructure. It is predicted that with the spread of augmented reality applications in the construction industry, commitment and dependence on technology will increase. While augmented reality applications are used in the construction phase and are developed in line with the sustainable building phase principles, these threats should also be taken into consideration.

Conclusion

In this study, regarding the contribution of augmented reality applications to the construction phase within the scope of the sustainable building life cycle, academic studies examining augmented reality applications in the construction phase were examined and a SWOT analysis was made. As a result of the study, it has been determined that augmented reality applications during the construction phase have significant contributions to the building phase in terms of time, cost, and quality within the scope of the sustainable building life cycle. Although

augmented reality applications have contributed to the construction phase, the technological weaknesses and threats that emerged as a result of the SWOT analysis should also be considered.

This study reveals that augmented reality applications during construction contribute to the field within the scope of sustainable building life cycle. The limitation of the study is the construction stage in the building phase within the scope of the building life cycle. Dealing with the subject throughout the cycle or at different stages would provide a different perspective to the field.

There isn`t enough study in the literature that deals with the relationship between augmented reality applications in construction and sustainability. Therefore, it is thought that revealing the relationship between the augmented reality applications in the construction phase and the sustainability building life principles could contribute to the field of science.

Abstract

Obtaining timely and accurate host country information is vital for an effective and successful country risk assessment of international construction projects. This information may appear in the form of unstructured textual data such as news, editorials, reports, and official documents and could be extracted from documents available on the Internet. There are several methods of acquiring country data for use in the assessment process. These contain tedious processes and necessitate qualitative and quantitative assessments that depend on hundreds of factors. Getting current and accurate information is required throughout the project's lifecycle. However, current country risk models may fail to properly contain countries' continually changing economic and political environment, especially in the construction industry. Furthermore, it mainly relies on subjective appraisal and is prone to subjective interpretation, misunderstanding, and biased judgment. In order to minimize human errors and to facilitate the country risk assessment, an automated process can be utilized. Despite the promising results of previous approaches to automating the process of extracting useful information and facilitating information retrieval processes, there is insufficient research on the country information acquisition from the Internet for country risk assessment. This research questioned effective country risk acquisition methods and proposed usage of web crawling. In this paper, the web crawling algorithm, designed for repetitive actions so that browsing is automated, was explained, and its potential for country risk assessment was discussed. A demonstrative case was given to reveal its benefits and challenges. Utilization of web crawling is expected to contribute to collecting and organizing the latest and most accurate country information and facilitate an in-depth understanding of country-related documents.

Keywords: *automation, country risk assessment, international construction, web crawling.*

Introduction

Information is the most significant input for any assessment process (Lehner & Maier, 2000). For an effective and successful country risk assessment of international construction projects, obtaining timely and accurate host country information is crucial. The related country information and the knowledge can be in different formats (in the form of structured and mostly

unstructured textual data). These data could be extracted from the documents in companies' databases, from institutes that provide country-related information, and from the documents available on the Internet (e.g., news, articles, editorials, research papers, interviews, reports, and official documents) (Moon et al., 2018; Shin, 2015; Pathirage et al., 2007).

There are various methods for gathering country information for use in the assessment process. Specifically, documents from the Internet may be utilized as one of the most valuable resources for an effective risk assessment of a country (Pathirage et al., 2007). As a result of the rapid growth of the Internet, a large amount of country data has been collected, and the volume of the related country data is continuing to increase over time (Shin, 2015; Hjelt & Björk, 2006). On the other hand, manually obtaining timely, precise, and accurate information about host countries from the Internet can be challenging, contain tedious processes, require qualitative and quantitative assessments that depend on hundreds of factors, also is prone to errors (Moon et al., 2018).

Despite the promising results of previous approaches to automating the process of extracting useful information and improving information retrieval processes, there is insufficient research on information acquisition from the Internet specifically for the country risk assessment. An automated process of gathering data from Internet websites (i.e., web crawling) needs to be utilized to minimize errors and facilitate the country risk assessment. While some research has been carried out on web crawling for the construction industry, no studies have been found focusing on using web crawling in country risk assessment. This research aims to propose web crawling as one of the emerging technologies for effective country risk identification to get a better country risk assessment process. In this paper, first, web crawling and its procedure were explained, and then the potential of web crawling was discussed. Finally, a demonstrative example was illustrated to explain how country-related data is automatically retrieved by web crawling.

Web Crawling

A web crawler (also referred to as a robot or a spider) is a program that automatically collects and stores Webpages' content from the Internet. It automatically searches information pertinent to a selected particular subject by visiting/navigating the Web on demand while keeping the indexes (Pinkerton, 1994; Cho, 2001; Olston & Najork, 2010).

Basically, the web crawling procedure has two parts: list page parsing and target page parsing, which can be seen in Figure 1 (Manning et al., 2008; Moon et al., 2018). The list page parsing process includes retrieving target pages' URLs from the Web. Following this step, the actual data on the webpage (data from target pages), which is built using Hypertext Markup Language (HTML), is retrieved throughout the target page parsing process. (Moon et al., 2018). This process is based on accessing page content via HTML, a standard language to define the structure of websites' content. HTML assigns each element a certain tag on a web page. Thus, the crawler may extract particular information from the target elements as long as it is able to access the website's structure (Moon et al., 2018).

In other words, when a set of URLs is provided, all of which are kept and prioritized, the web crawler visit all web pages addressed by those URLs and collects hyperlinks from those pages. It downloads the webpages' content iteratively until it finally stops when the predefined criteria are satisfied (Cho, 2001; Olston & Najork, 2010).

In more detail, a web crawler performs according to several policies, including a "selection policy" that sets out which pages to download, an "e-visit policy" that specifies when to check for page changes, a "politeness policy" that defines how to prevent overloading Web sites, and a "parallelization policy" that specifies how to coordinate distributed web crawlers. (Castillo, 2004).

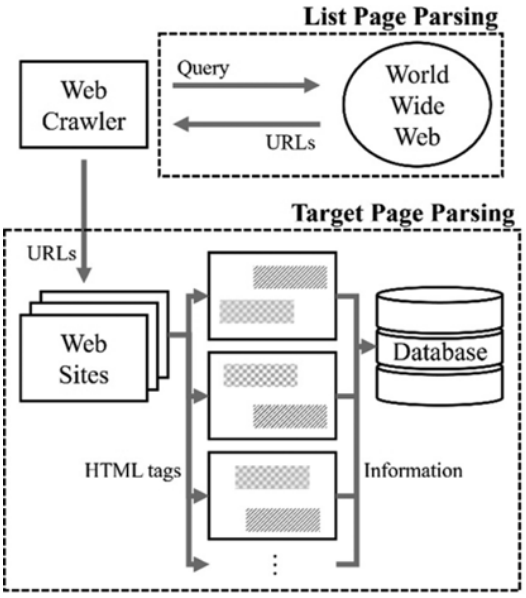

Figure 1: Procedure of Web Crawling (Moon et al., 2018).

Related Work

Web crawlers have had a variety of uses, commonly as a Web search engine, since the 1990s (Patil & Patil, 2016). General-purpose crawlers (e.g., Historical web crawlers, in-house web crawlers, commercial web crawlers, open-source crawlers), their architectures, and the implementation details which are out of the scope of this paper, have been frequently discussed in the related literature. As the main focus of this paper, potential applications of web crawling in the construction management area are investigated.

Although extensive research has been carried out in general, the potential of web crawling is not revealed yet in the construction research area, and there have been only a limited number of studies. The amount of data on the Web relating to construction has rapidly expanded due to a significant increase in construction-focused websites. Thus, it is not easy to identify and gather up-to-date Internet data relating to the global construction market; therefore, automated data collection methods are required to accelerate the procedure and benefit the construction sector.

To date, study of Moon et al. (2018) is the only study on utilisation of web crawling for international projects. They have attempted to investigate the usage of web crawling algorithms to obtain country information. They created a construction document management system for information acquisition of international construction projects for global contracts. They sought to gather the most recent information on the target country in the international construction market in a timely manner. Therefore, they utilized the web crawling algorithm in their developed system to promptly acquire text data that includes the latest information.

Kim et al. (2021) explored patterns and causes related to fire accidents on construction sites. Through web crawling and deep learning approaches, they identified the fire accident factors in construction accidents using news media data (i.e., news reports) on various fire accidents on construction sites. Hong et al. (2019) focused on sustainable development issues and green building certifications, mainly related to information management of building materials. They presented an automated approach for gathering and categorizing Green Building Material Information (GBMI) utilizing web crawling and ontology to increase productivity, improve work efficiency, reduce human mistakes, and decrease the time needed for material information management. Jeon et al. (2021) focused on the Purdue Indicator for Construction (Pi-C), a composite index comprised of five factors to examine the situation of the construction sector and support/assist data-driven decision-making. They stated that there are still missing in Pi-C. To find new metrics for the development and quality factors of the Pi-C, they developed a Latent Dirichlet Allocation-based method. To this end, they employed a web crawler to gather more than ten thousand abstracts of research papers from academic search engines. Dou et al. (2019) presented a new media-driven metric for the prefabricated construction (PC) industry's level of development in China. They claimed that the absence of PC-related statistics might prevent related study, so data gathered from new media (e.g., Weibo and WeChat) may be utilized. As a result, they used web crawling and text segmentation using Python programming language in order to get index data. Zhou et al. (2021) reported that the majority of building codes are kept in unstructured text-based documents and introduced a method that automatically acquires and formalizes building codes and transforms them into a knowledge graph representation. Web crawling was performed in their study to obtain building codes from the Web automatically.

So far, very little attention has been paid to implementing web crawling as a method for identifying country risks to assist the *country risk assessment* process in international markets. Within the scope of this research, potential usage of web crawling was investigated for the assessment of country risks considering the information about the global market. A demonstrative example is illustrated below to explain how web crawling automatically obtains country-related data.

An Application of Web Crawling

A hypothetical case will be used to demonstrate how web crawling can be used for country risk assessment. It is assumed that company professionals want to investigate country conditions to understand what and how country-related factors may affect project success or lead to failure. Therefore, they need to assess identified country risks considering the country-specific information. In a traditional way, company professionals enter and browse all related websites one by one, to find a particular information and then enter the retrieved information down on a spreadsheet manually, which is tedious, time-consuming, also prone to mistakes. In this example, rather than manually searching and collecting the necessary country data, web crawling was used which would provide a more efficient and faster way.

It is assumed that responsible departments such as risk management, business development or bidding identified the URLs of websites where country-specific information exists. Beautiful Soup, a popular Python library for pulling data out of HTML, was used (Hajba, 2018). Two data sources were chosen for demonstrative purposes: International Monetary Fund (IMF) website and The World Fact Book in Central Intelligence Agency (CIA) website, considering

that they address up-to-date and comprehensive country-related data regarding the international construction market. XPath expressions were used in this example to easily find any element in an HTML DOM page.

In this example, information on “climate”, “location”, and “projected real GDP (% Change)” were planned to be extracted from the data sources, identifying “Turkey” as the country in which the case company aims to collect information about. First, the selected country-related web pages and their URLs were determined by investigating the structure of the web page (in HTML). Then, by inputting URLs and XPaths, the programmed web crawler accessed each data page, parsed and processed the webpage to “crawl” the target data needed, and then collected relevant data from the page. Finally, the data was saved in a CSV format to be more readable in Microsoft Excel. Each website’s data extraction date ranged from 21 March 2022 to 01 Sep 2022. The screenshots of the webpages that were used for data sources (Figure 2, Figure 3, and Figure 4) can be seen below.

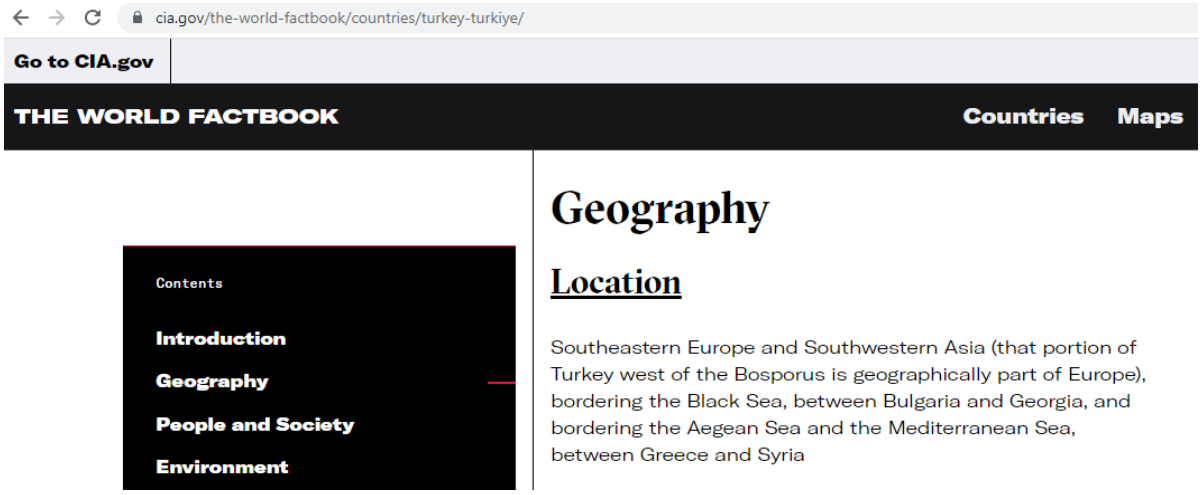

Figure 2: Information on the “location” from CIA website.

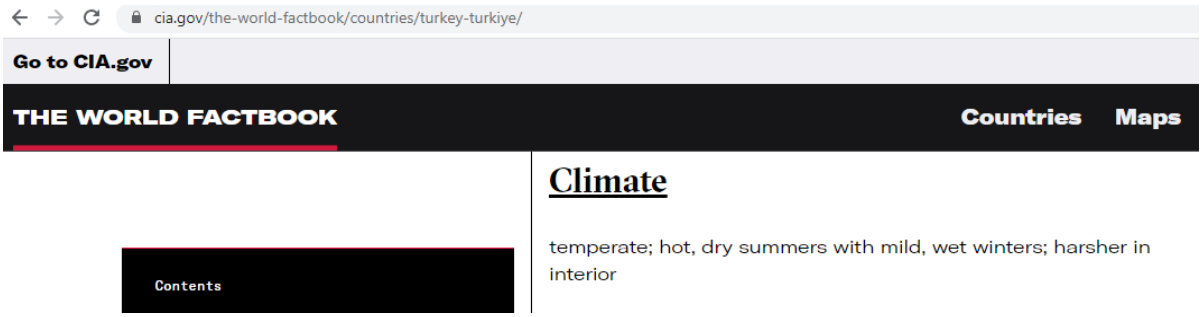

Figure 3: Information on the “climate” from CIA website.

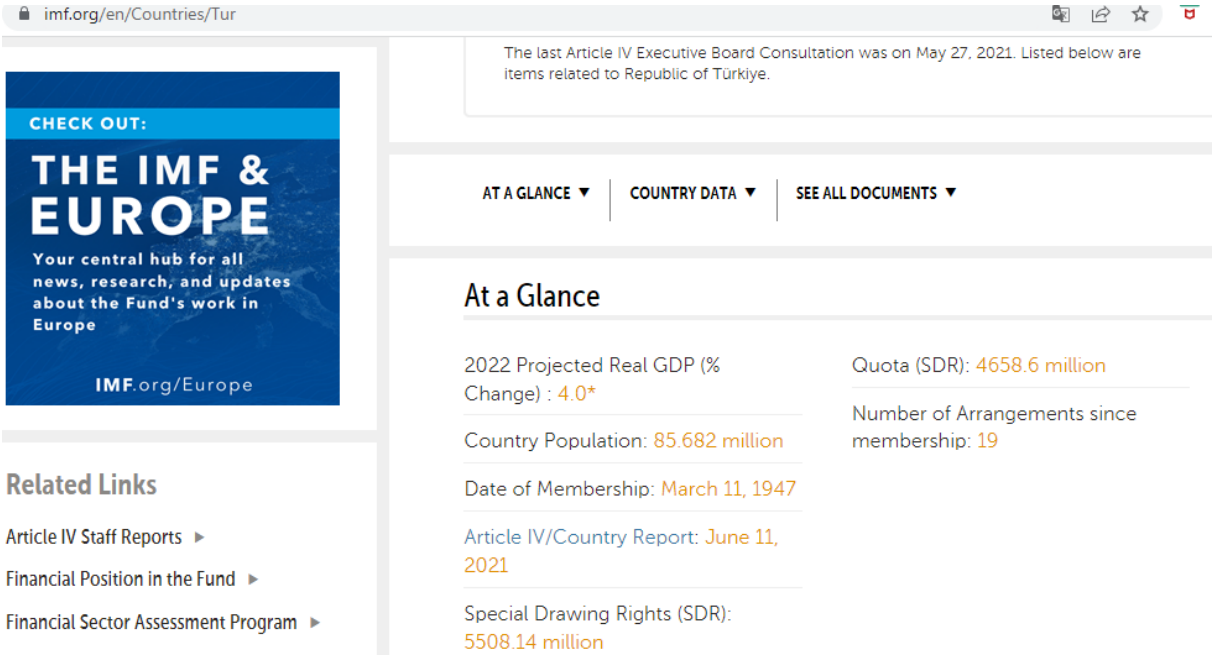

Figure 4: Information on the "projected real GDP (% Change)" from IMF website.

The output of this simple example is given below (in Table 1) to be used in the country assessment process to help users to understand the country's current situation.

Table 1. The output of web crawling, for the example of Turkey.

Country	**Turkey**
Location	"Southeastern Europe and Southwestern Asia (that portion of Turkey west of the Bosporus is geographically part of Europe), bordering the Black Sea, between Bulgaria and Georgia, and bordering the Aegean Sea and the Mediterranean Sea, between Greece and Syria"
Climate	"hot, dry summers with mild, wet winters
GDP (% change)	4.0

Web crawling may help company professionals to gain access to the information of several countries at the same time, in case there is more than one target country and make comparisons. To demonstrate this, the web crawling algorithm was used to get information from multiple countries, URLs of the websites were formatted using text placeholders to be replaced of specific country codes (e.g., IND for India and DZA for Algeria).

When the URLs of the data sources websites and country codes were supplied to the web crawling algorithms, the web crawler generated results of related countries' data. The output of multiple countries was received and grouped in an automated manner. Comparative results are presented in Table 2.

Table 2. Comparative results of Algeria and India.

Country	Location	Climate	GDP (% change)
Algeria	"Northern Africa, bordering the Mediterranean Sea, between Morocco and Tunisia"	“arid to semiarid; mild, wet winters with hot, dry summers along coast; drier with cold winters and hot summers on high plateau; sirocco is a hot, dust/sand-laden wind especially common in summer"	2.4
India	“Southern Asia, bordering the Arabian Sea and the Bay of Bengal, between Burma and Pakistan"	“varies from tropical monsoon in south to temperate in north"	7.4

Similar comparative tables could also be prepared considering data that belongs to different years to see the trends. It is apparent that more data would be needed for risk assessment such as political, economic and social indicators, which can be easily done using the same web crawling algorithm.

Discussions

The hypothetical case study demonstrates that, by using web crawling, searching on websites and extracting the related information from the related webpages can be performed automatically among the massive amount of information existing on the Internet.

In order to use the data automatically gathered with web crawling for the purposes of risk management, first a country risk taxonomy should be defined, and then indicators corresponding these risks should be identified. After determining the web sources that contain data/information about these indicators, web crawling can be used to automate information gathering process and facilitate risk assessment. For example, the data about climate can be used to assess “weather risk” and location can be used to assess accessibility and logistics risks. Similarly, % change in GDP can be used as an indicator of economic conditions whereas a time series of GDP values could be used to assess economic stability. More research is needed about potential utilisation of web crawling for risk management purposes.

Conclusions

Acquiring recent and accurate information is highly required, especially for the country risk assessment of international construction projects under countries’ continually changing economic, social, and political environments. Up to now, automated data gathering through web crawling has not received much attention in the construction management literature. Similarly, the application of web crawling for use in *country risk assessment* of international construction projects has not been investigated.

By employing an automated web crawling process, useful information during international construction projects could be extracted, collected, sorted, and analysed systematically. Besides, it can be repeatedly updated and utilized at any time in construction phases by the construction companies' professionals.

We assert that, rather than manually gathering country data, web crawling can be more efficient and faster. It facilitates the planners and managers to review web pages in the country risk assessment, which enhances the project management processes. In the example in this paper, only three country information categories ("climate", "location", and "projected real GDP (% Change)") were selected to demonstrate how web crawling could be employed easily. More comprehensive applications could be made, and more studies on how web crawling may be used to support risk-informed decisions can be conducted in future studies.

Web crawling may appear to be a good method of breadth-first-search; however, there are various difficulties and concerns, such as management of very large data structures, the decision of what pages the crawler should download as data sources, and the frequency of revisiting the content sources in the web pages (Olston & Najork, 2010). Furthermore, the HTML structure of the selected websites may change, and/or data retrieving may be blocked/restricted by the webpage server provider. In addition, finding the answers to theoretical questions of web crawling implementation might also be another issue for construction company professionals. Additionally, designing a robust web crawler may be challenging since the data on the Web is large, and continually growing.

In this study, attention has been paid to copyright issues. Similarly, while applying web crawling in the future, websites and the target data should be selected with due consideration to copyright. The web crawler method in this paper required the data based on human input, which determined the necessary details. In the future, web crawlers could be commonly utilized more automatically and properly.

volkanarslan@beun.edu.tr, ulubeyli@beun.edu.tr

Abstract

A new technology concept, Internet of Things (IoT), has drawn a significant interest in several industries. This technology is a network of sensors, actuators, or machines to facilitate real-time communications between these items in the environment of computer applications. The construction industry may have a great potential to experience IoT's advantages in several aspects. However, studies on IoT in the construction industry are relatively new. The purpose of this research is to analyze the IoT technology and its application in the construction industry from the perspective of health and safety issues. To this aim, a detailed literature review was conducted, and current applications of IoT on health and safety implications were revealed. Thus, the results obtained are expected to be beneficial for both industrial practitioners and academic researchers to adopt the IoT technology and to improve the health and safety performance of the construction industry.

Keywords: *construction industry, health and safety, internet of things.*

Introduction

The Internet of Things (IoT) has been widely investigated with the development of sensor technology and wireless internet. This technology interconnects intelligent objects or devices such as sensors, communication devices, and computing devices through wired and wireless communication networks to collect, share, and utilize information without human intervention (Kim et al., 2019). Moreover, the IoT is a network of sensors, actuators, or machines to facilitate real-time communications between these items in the environment of computer applications. It has been applied to many industries such as health care, production logistics, manufacturing, and mining, as well as the construction industry (Yeo et al., 2020). The construction industry may have a great potential to experience IoT's advantages in several aspects. It is a novel technology and has a potential to be used in the construction industry to improve several issues under the construction management topic (Arslan et al., 2019). However, studies on IoT in the construction industry are relatively new. IoT network technology has been applied in various types of workspaces such as warehouses, exhibition centers, and commercial buildings, however, there is a lack of discussions on the application of this technology to the construction site in terms of health and safety (Chung et al., 2020). Although various IoT technologies have been studied for safety management, their applications on construction sites have stagnated (Yeo et al., 2020). The purpose of this research is to analyze the IoT technology and its application in the construction industry from

the perspective of health and safety issues. To this aim, a detailed literature review was conducted, and current applications of IoT on health and safety implications were revealed.

The IoT Concept

IoT is a network of physical objects. The IoT concept was coined by a member of the Radio Frequency Identification (RFID) development community in 1999, and it has recently become more relevant to the practical world largely because of the growth of mobile devices, embedded and ubiquitous communication, cloud computing and data analytics (Patel et al., 2016). IoT is a connection of three things: (i) people to people, (ii) people to machine/things, (iii) things/machine to things/machine. The goal of the IoT is to enable things to be connected anytime, anyplace, with anything and anyone ideally using any path/network and any service (Fig. 1).

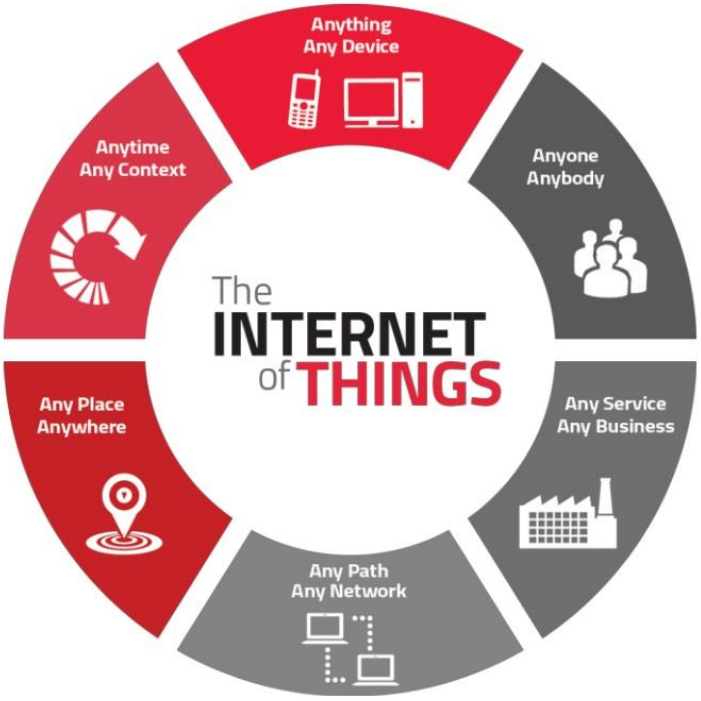

Figure 1: The IoT concept (URL 1).

IoT architecture consists of different layers of technologies. Sensor layer is the lowest layer and made up of smart objects integrated with sensors. The sensors enable the interconnection of the physical and digital words allowing real-time information to be collected and processed. Gateways and Networks layer is a robust and high performance wired or wireless network infrastructure as a transport medium in order to process produced massive volume of data by these tiny sensors. Current networks, often tied with very different protocols, have been used to support machine-to-machine networks and their applications. The management service layer renders the processing of information possible through analytics, security controls, process modeling, and management of devices. Lastly, the IoT application layer covers smart environments in domains such as: transportation, building, city, lifestyle, retail, agriculture, factory, supply chain, emergency, healthcare, user interaction, culture and tourism, environment and energy (Vermesan & Friess, 2014).

Literature Review

Jiang et al. (2013) introduced wireless network and built a security supervision system based on the IoT, which is an effective way to solve a series of problems in the present construction site safety supervision. The construction safety supervision system based on the IoT is constituted by construction site monitoring device, the construction site wireless signal transmission, server platform where site lead, and access internet network.

Sui et al. (2014) researched the monitoring and safety early warning technology of bridge health aiming at the bridge safety, based on the perception, transmission, knowledge, and application of IoT. The system of the monitoring and safety early warning of bridge health consists of data acquisition system in the outfield, the service system of data center, and application system. The general idea of constructing the model of monitoring and safety early warning for the bridge health is evaluating different working state according to the different categories of bridge structure (double curved arch bridge, rigid arch bridge, beam bridge) and the monitoring value in different parts, to make an objective assessment and early warning.

Zhong et al. (2014) proposed a practical application combining a WSN and the IoT in the construction industry, named as Safety Management System for Tower Crane Groups (SMS-TC) (Fig. 2).

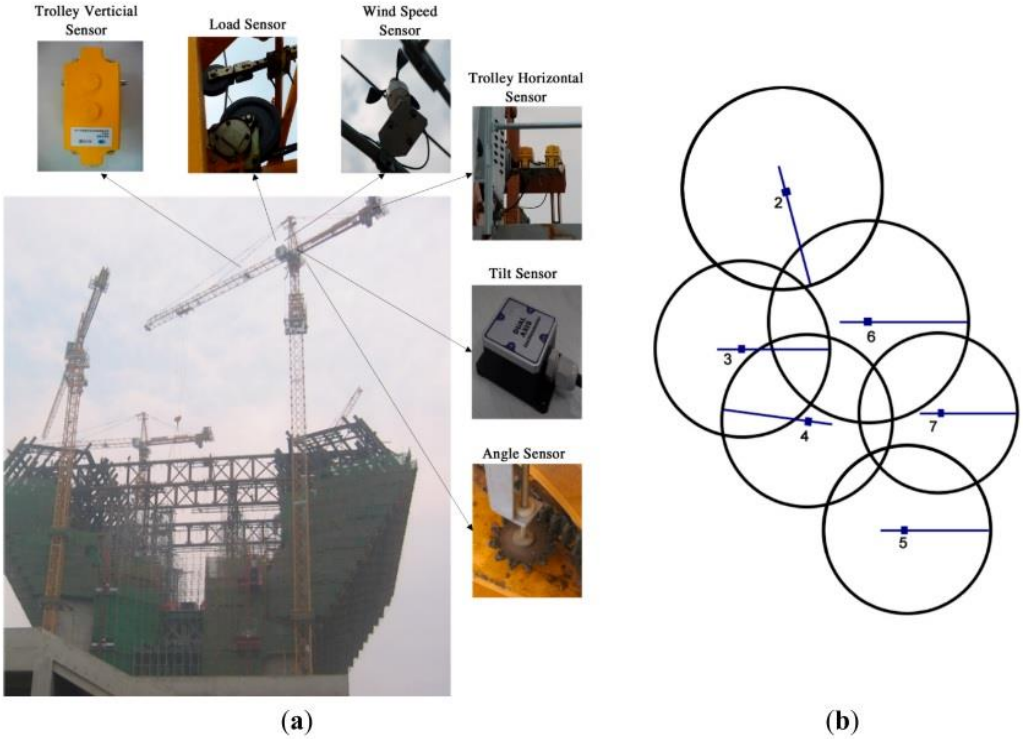

Figure 2: (a) The tower crane group in the worksite of Famen Temple Dagoba (FTD) and the actual assembled positions for six types of sensors; and (b) Schematic plan of a tower crane group. Number 2-7 represent six tower cranes with their netIDs.

In this system, there are three layers of the IoT, (i) perception layer, (ii) network layer, and (iii) application Layer. A set of customized sensors were utilized to obtain the complex real-time status of each tower crane. The WSN was used to fulfill wireless communication

between each tower crane and the Local Monitoring Terminal (LMT) at the ground worksite, which can avoid interruptions during the construction process and realize high-speed stable communication among the tower crane group. Based on the global status data of the whole group, an anti-collision algorithm was executed to ensure the safety of each tower crane during construction. As a system with mechanics, electrics, algorithms and network communications all in one, SMS-TC could be considered as a practical application that demonstrates the promising prospects of WSN and IoT in China's building industry and engineering in the near future.

Zhou and Ding (2017) described a new safety barrier early warning system for hazard energy on construction site using IoT technologies. They developed an IoT-based hazard energy monitoring framework to collect safety status data and isolate hazard energy with safety barriers (early warnings and warnings) efficiently and dynamically for underground metro construction (Fig. 3). The IoT-based safety barrier warning system was designed for collecting, analyzing, and managing multisource information, automating monitoring and warning, and minimizing the hazard energy coupling by using IoT. The portable warning device integrated with IoT tag was installed on the safety helmet, which is designed by RFID-based positioning technology.

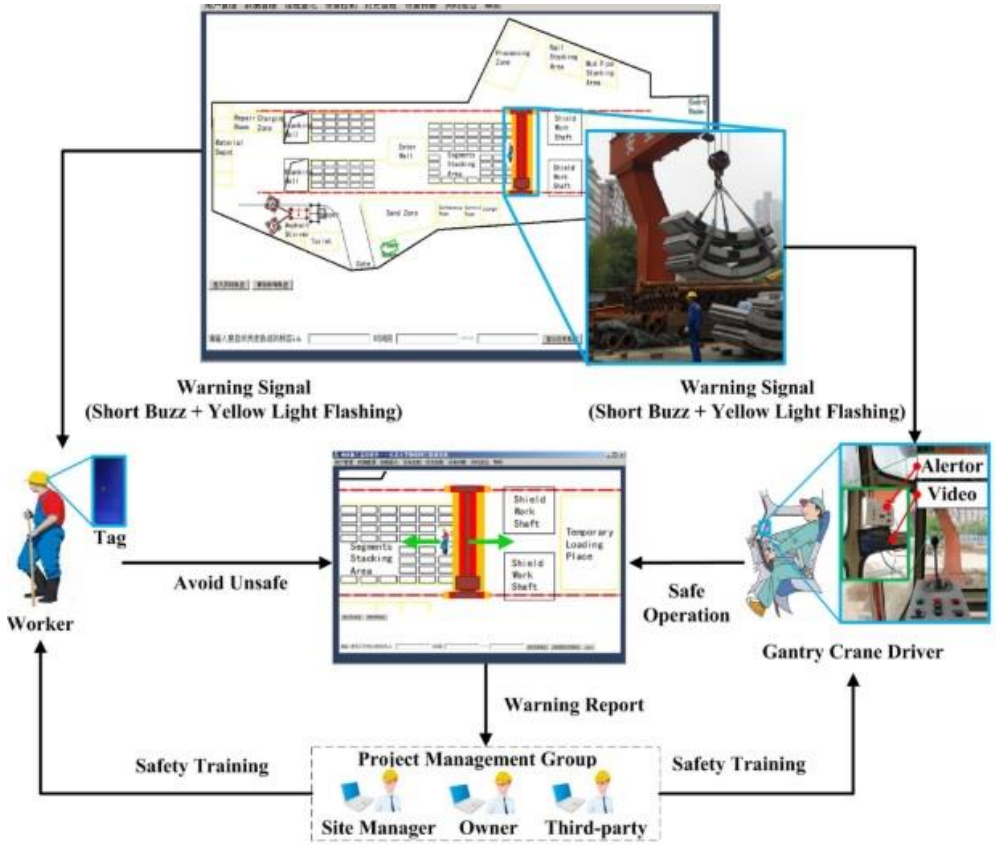

Figure 3: Early warning and alarming process (e.g. gantry crane).

The identified hazard energies and their coupling mechanisms were analyzed to provide safety barrier strategies and scenarios for avoiding unsafe behaviors and unsafe status of construction equipment and workers' environment. This system not only gathers the monitoring data of workers and "things" in real-time, but also generates the early warning

signals as spatiotemporal safety barriers to participants on and off construction site automatically.

Cheung et al. (2018) integrated BIM and WSN technologies to enhance the safety management of hazardous gas in an underground construction site, where the hazardous gas concentrations and environmental conditions (temperature & humidity) of different site regions were collected and integrated on the site BIM model. The corresponding model components will dynamically display all conditions collected from sensor nodes with changing colors and indicate the safety status, which enables the complete safety status to be mastered on an "active" BIM model. In particular, the WSN-integrated BIM model provides a visual and active platform for monitoring, the risk status of different site regions can be efficiently mastered by a colored and spatial display interface, and the real time safety status of different regions also provides important reference information for evacuation or rescue in emergency events.

Lam et al. (2018) presented a new concept in improving safety in construction and civil engineering works using IoT technologies. The IoT monitoring system consists of 4 building blocks, (i) sensing unit, (ii) communication backbone, (iii) server, and (iv) user devices. Sensing units continuously take site measurements and send them to a communication coordinator (CC) at the site in an encrypted digital format. The communication backbone of the system consists of the CC and the communication channel between the coordinator and server, and between the server and user devices. The CC manages sensing units at the site and transmits sensor measurements to the server either through WiFi or cellular network. After storage and analysis of data, the server sends the latest measurements and also warning signals to users' devices to enable users to always be aware of real time site conditions. With support from the industry and government in adopting IoT technologies, the system was gradually being accepted into the local industry. Codes of practice and regulations pertaining to construction and civil engineering works will then be updated to keep up with the latest technology. In the long run, implementation of the monitoring system in the industry was expected to greatly enhance construction safety, preventing injuries and casualties due to structural failures while at the same time minimizing the associated economic losses.

Su et al. (2018) studied a monitoring method for scaffold shoring system during concrete formwork with the IoT technology, and then the method was applied to practical formwork project to verify its validity. Four parameters were monitored during concrete placement, (i) slab settlement, (ii) overall lateral displacement, (iii) column axial force and (iv) column tilting angle. In the monitoring system, all these parameters were measured by sensors and transmitted with IoT technology. With the characteristic of the IoT technology, the monitoring system was designed to consist of wireless sensors, wireless monitor, wireless alarm, intelligent monitoring cloud platform and the wireless monitoring mobile client. In the practical application, the breaking of a slab was detected by the monitoring system, proving the validity and reliability of the IoT based monitoring system to ensure safety during concrete placement.

Zhou et al. (2019) aimed (i) to design a CPS-based SMS (CPS-SMS) for blind hoisting in underground construction to prevent accidents given the complex environment and challenges in hoisting and (ii) to apply this novel system on a real construction site and determine the potential value or practical improvements of the results after implementing the proposed system. The main advantage of this system was portability and agility. Several types of sensors were adopted for data acquisition and transition to detect and monitor the hoisting at

the construction site in real time. Various balancing and optimizing designs have been implemented in different aspects of system equipment, which involves power dissipation, accuracy, volume, weight, installation, protection, deployment, debugging, operation, and maintenance, to successfully use these IoT sensors and devices. To be specific, the safety risks relative to the blind hoisting in underground construction has a significant impact on the overall safety performance on the construction site. The CPS-SMS was designed for blind hoisting in metro and underground construction, including safety warning sensing, transmission, analysis, and control. For verifying the applicability, the Sanyang Road tunnel of Wuhan Yangtze Metro Tunnel in China was used as a case study. To date, the CPS-based safety monitoring system has shown promise in the real-time monitoring of blind hoisting. CPS offers an opportunity to address the safety issues and risks associated with blind hoisting in underground construction. In particular, CPS applications have potential in the simulation and procedures of underground hoisting and can help improve the safety and avoid hoisting failures.

Kim et al. (2019) proposed an IoT-based construction site safety management system that can effectively prevent safety accidents of field workers in both large-scale and small- scale construction sites. The proposed system has been developed with a prototype using sensors, smartphone, management server, and short and wide-range wireless communication systems such as Zigbee, WiFi, and Long-Term Evolution (LTE), etc. Moreover, the system can setup, suspend, and release the hazard zones and provide the access information of field workers and outsiders through a manager's smart application. Furthermore, the system was designed considering the system requirements, in which the system consists of IoT, worker safety check devices, the mobile gateway, the safety management server, and the safety manager application. It was expected that the developed prototype may drastically reduce the number of accidents when applied to the construction sites.

Zhang et al. (2019) studied to implement real-time alarming, monitoring, and locating for non-hard-hat use (NHU) in construction by applying nonintrusive sensors, and mobile, web, cloud, and other modern information techniques (Fig. 4).

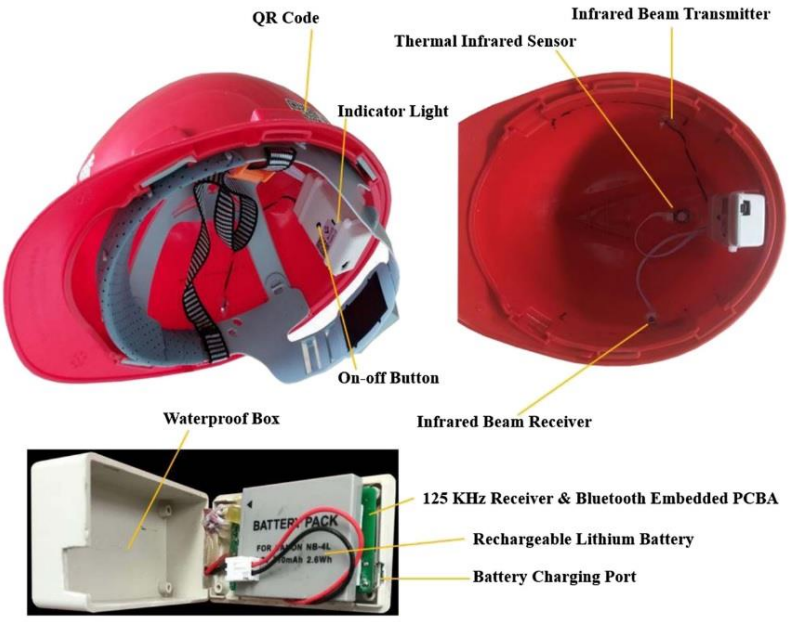

Figure 4: Major components of the NHU detector.

A smart hard-hat system was developed to automatically detect and locate NHU and provide real-time targeted warnings to both man- agers and workers when NHU occurs. The smart hard-hat system consists of a network of waterproof and rechargeable RFID triggers, a waterproof and rechargeable NHU detector, and active RFID receiver in a hard hat, a smartphone app, a web app, and a cloud server. An IoT-based smart hard-hat system was developed for NHU detection and locating in the construction industry.

Mehata et al. (2019) worked to build wearable devices such as smart band and helmet for monitoring the construction workers and to provide them a safer and secure working environment. The devices may help in keeping track of the pulse, and body temperature of the worker. Moreover, care was also taken to provide emergency alert during any slip or fall of the worker. There were various factors to be examined while designing the proposed system for seamless functioning of the device. These include (i) comfortability, (ii) portability (iii) reliability. The proposed system ensures the good fall detection taking into account of the complex conditions to provide safety of the workers and to monitor their health. However, in the other case (after exercise) the displayed output had a slight variation than the expected results.

Park et al. (2019) proposed a system that monitors workers' situation and informs about a dangerous situation such as falls for the safety of construction site workers using sensors acquired from IoT devices based on the deep learning system implemented in previous research. They categorized two situations changing heat or humidity (it related to worker's heatstroke or frostbite) and a worker's falls as the most important and usual safety issues in common construction sites. And then implemented SensorTag for detecting two features. They constructed a deep learning framework for experiments and used tensorflow-gpu1.13.1 at the back end of the framework. In the neural network library, Keras 2.24 was used. For the data set used for the test, SGAD obtained from the sensor tag was divided into x, y, and z-axes and used as input. The total number of records acquired was 500. To that end, they constructed a Sub 1 GHz sensor network which is suitable for construction sites with various radio interference factors. Based on the data obtained it was hoped that objective safety guideline will be established to workers at the construction site using environment and activity data. In addition, they built a service that provides appropriate post-response when notified of workers' perceived dangerous movements, through worker's fall detection using deep learning.

Guzman and Mezovari (2019) demonstrated the design of a scalable, driverless bulldozer prototype using IoT-based technologies. They illustrated the design process of the overall system and enhanced a preliminary version with new GPS tracking capabilities and remote monitoring functions. Generalizing from this particular case to the generic design of IoT-based cyber-physical systems, they recommend a preliminary safety and security risk assessment from the early stages of the design process to promote a safe design. Using the CPS master diagram, designers and engineers can identify and protect the security vulnerabilities as well as the human use cases that could potentially lead to hazardous scenarios.

Lam et al. (2019) introduced a falsework monitoring system utilizing IoT to detect and report abnormalities prior to the occurrence of an accident. IoT monitoring system is capable to provide continuous and real-time measurements, with both the load and inclination data actively monitored. The design was able to allow both common types of falsework for construction and demolition supports to be fitted, thus maximizing potential usage.

Okpala et al. (2020) was set at exploring the perceived opportunities and barriers for the use of wearable sensing devices (WSDs) in enhancing the effectiveness of construction safety management systems (SMS). First, a literature review was conducted to identify the perceived opportunities and barriers for the use of IoT (particularly WSDs) for implementing SMS in construction. Second, based on the identified opportunities and barriers, an online survey was created and distributed to construction professionals in the US construction industry to assess the usefulness of WSDs in SMS. The integration of WSDs could play an essential role in enhancing construction SMS. This study also highlights the key benefit and challenges to the adoption of WSDs for construction safety management. It is believed that WSDs can be integrated successfully into construction SMS based on their attributes for multi-parameter monitoring of safety performance.

Chung et al. (2020) evaluated the effectiveness and weakness of mandatory basic safety training in Hong Kong. Firstly, a questionnaire survey was conducted and over 80% of questionnaire respondents were able to pass the quiz. Then, using criteria weighting calculation calculated through AHP analysis, the weakness of respondents were located. After that, an IoT network model design was created for a real-time construction site safety monitoring system and suggested the basic infrastructure of the system, operation flowchart, and the optimal sensors' locations. This research provides a guideline for further investigation of innovative IoT networks' application networks and the data collection methods from the IoT sensors.

Yeo et al. (2020) targeted to develop a method to evaluate the effectiveness of IoT-based technologies in preventing accidents on construction sites. They proposed a method to quantify the effectiveness of an IoT-based technology in preventing different types of accidents occurring on construction sites. The applicability of this method was tested with two different IoT technologies. The technologies considered in this study were technology automatically identifying hazardous areas and technology monitoring the worker's heart rate with a photoplethysmography sensor on a real-time basis. According to the findings, practitioners can quantify the effectiveness of certain IoT technologies which can be utilized for construction works.

Yang et al. (2020) proposed a personal protective equipment (PPE) tool pair system for on-site construction safety. The PPE-Tool pair system was established at three levels: sensing level, application level and storage level. The sensing level consists of three modules: (i) PPE module was made up of a human sensor and a Wi-Fi sender. They detect whether the user was wearing suitable PPE and broadcast the information via wireless technology; (ii) the non-power hand tool module contains a Wi-Fi receiver, a processor, a speaker, or a vibrator. When the receiver receives the signals from PPE modules, the processor immediately checks safety regulations and determines whether a warning should be raised by the speaker or the vibrator; and (iii) the power tool module was another version of the non-power hand tool module without self-power and was embedded on the motherboard of the power tool. The application level refers to the mobile devices and applications, providing a customized interface for monitoring and management. At the storage level, the collected data are uploaded and saved on a cloud server by WiFi or GPRS so that any user can access the historical records online. This system ensures that all required PPE were properly equipped by users prior to using dangerous construction hand tools. Such a system for protection was composed of a wearing sensor, a battery, and a Wi-Fi module; each tool consists of a buzzer, a vibration motor, and a Wi-Fi module (Fig. 5).

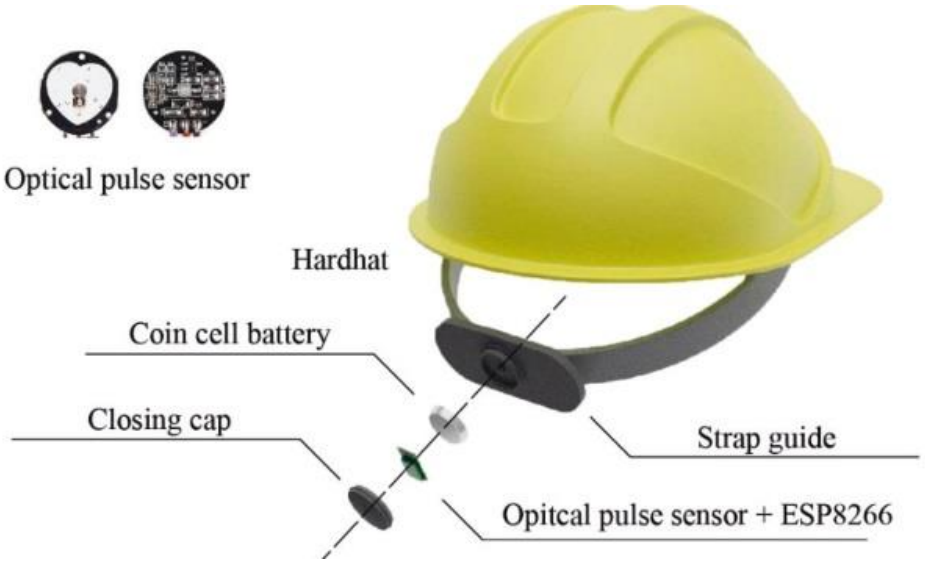

Figure 5: The sketch of helmet for wearing detection.

Yuan et al. (2021) focused on how to use IoT technologies to monitor the project implementation process in prefabricated building (PB) construction, which will help optimize the construction schedule and ensure the quality and safety of PB construction. Design changes affect component production, and many quality and safety risk control issues must be faced during on-site assembly. Applying IoT technologies to managing the whole process of PB construction will greatly improve construction efficiency. The IoT monitoring in the off-site manufacturing phase focuses on increasing the visibility of the manufacturing process and monitoring the manufacturing capabilities. Different from traditional construction, the main safety risk factors in the on-site assembly process of PB construction are the component installation risk, environmental risk, hoisting risk, and technology risk. This system can reduce safety risk at PB construction.

Prabha et al. (2021) utilized IoT to create a framework that will provide them with a better and more stable working environment. They suggest a method for predicting incidents before they happen. The proposed system consists of four modules. The modules are (i) database connectivity (ii) motion sensing (iii) alarm Intimation and (iv) webpage retrieval. If the worker reaches the hazardous zone, the sensor will alert the device. The message is then sent to the APR by the Arduino microcontroller. APR then sends out a voice-based warning to alert the staff and avoid the accident. The message will also be posted on a website. It senses any movement inside the hazardous zone and alerts them using APR. APR offers a voice-based warning system, in which a voice message was recorded and played whenever an alarm was required. This voice-based warning was more effective and helpful in relaying messages to staff, which can help them better understand the situation and avoid an accident.

Del Carmen Rey-Merchan et al. (2021) demonstrated an IoT infrastructure combined with Fuzzy Markup Language on JFML as an effective tool to prevent fall from height at construction environments. Several sensors and actuators, a broker based on the MQTT protocol, an instance of JFML and a FML file have been used to define the system. Concretely, they proposed to use the MQTT protocol to send data from sensors over the IoT architecture. They also used distance and proximity sensors, altimeters and anemometers to provide real time input data in a construction scenario and a color led to represent the output as the level of fall from height risk.

Khan et al. (2022) introduced an integration of vision and the IoT to develop an intelligent smart safety hook to monitor construction workers within the risk zone (scaffolding) and ensure compliance to PPEs. The proposed system was experimented and deployed on a single fall from height scenario, i.e., fall from scaffolding. This system relies on automated vision and an IoT-based system while providing an accurate, efficient, and fast solution. Through the development of WBMP and BCS, the site manager can readily monitor multiple workers' safe or unsafe behavior in real-time and later reward them for complying with the safety regulations. The obtained results show that this system provides an effective and timely communication platform to alert the safety manager in case of any unsafe behavior.

Discussion and Conclusion

Past studies reveal that IoT has a potential to be utilized in order to reduce health and safety problems in the construction industry. Sensors and monitoring systems enable researchers to develop IoT-based precaution applications to minimize work incidents. In this respect, smart PPEs, autonomous and GPS tracked construction equipment, false work detection systems, prefabricated building production, temperature and humidity conditions, and workers' heart beat and pulse monitoring systems were studied by several researches. Up to date, most of the IoT-based safety precautions seemed to be a single-case scaled. However, past studies reveals promising results for future studies and applications in terms of IoT-based health and safety practices.

Consequently, by applying the IoT technology, the construction industry may benefit from its application practices in a positive manner. The system of IoT can be integrated with different applications which are already in use in construction. From the perspective of IoT technology, wireless connection, sensors, smart devices, GPS tracking systems, and tags are most critical factors in order to develop a successful system to minimize or eliminate occupational incidents in the construction industry. Thus, past studies are expected to guide both industrial practitioners and academic researchers to adopt the IoT technology and to improve the health and safety performance of the construction industry.

Abstract

The acceleration of the worldwide transition to Industry 4.0 has increased the digitalization process. This digital process has many functional tools such as blockchain, artificial intelligence, and big data. The construction sector is attempting to benefit from the structure of this process that is called Construction 4.0. One of the emerging and popular tools in digitalization in the construction industry is blockchain technology. Blockchain holds data and transactions by providing decentralized, traceable, and immutable digital networks. It can be used for solving various problems in different knowledge areas of construction management such as payment methods, supply chain management, information management, facility management, contract management. Although blockchain is an emerging technology for various knowledge areas, academic studies are at their pre-mature level and sporadic. This condition enables the adaptability and utilization of blockchain in construction. Therefore, this research aims to classify and present blockchain research in terms of the knowledge areas and integration between other digital tools. For this purpose, blockchain and its related technologies have examined by systematic-bibliometric review was conducted in Scopus, Sci-direct and Web of Science database and analyzed by using VoSviewer. The outcome was classified by thematic clusters to perceive and utilize blockchain applications in construction management comprehensively. Presenting integrative perspective provides the original value to study.

Keywords: *blockchain, construction, digitalization.*

Introduction

Digitalization process has gained momentum in all sectors through Industry 4.0. Industry 4.0 is the digital transformation of manufacturing and related industries and value creation processes (Pech & Vrchota, 2022). The applications of digitalization can be defined big data analytics, artificial intelligence (AI), Internet of Things (IoT), cyber security, blockchain, cloud computing, machine learning, autonomous robots, and additive manufacturing. To certain extent, these technologies have already changed most industries, still there are industries are far away from adopting the full potential of the 4IR (4th Industrial Revolution). (Begic & Galic, 2021). Construction industry, the one of the leading sectors in worldwide, lags behind other sectors in adapting to the digitalization process (McKinsey & Company, 2018). Several existing digital technologies such as Building Information Modelling (BIM) and Mixed Reality (MR) lack to experience the digital transformation era.

The rate of annual increase of productivity by digitalization is 2.8% globally; where is rate increases to 3.6% in the production sector. Nevertheless, the construction industry's productivity rate in the last 20 years is 1% (McKinsey & Company, 2020). Therefore, digitalization opportunities in the construction industry, have the potential to increase productivity and cost reduction. It is predicted that the digital transformation studies to be carried out in the construction sector will provide a 14-15% increase in productivity, 15-40% cost reduction, effective time & conflict management, and young – skilled new workforce creation (McKinsey & Company, 2020). In addition, it is argued that digital transformations in the construction industry can increase the value of the industry by up to $1.6 trillion. (McKinsey Global, 2020; Forbes, 2021). Moreover, trust in the construction industry is crucial. In some cases, trust relations between the various stakeholders such as information exchange and contract documents cannot be managed efficiently. Poor communication and collaborative information sharing are one of the causes of many failed projects worldwide (Schepper et al., 2014). Different digitalization tools can assist to overcome these issues. One of the emerging and popular tools in digitalization in the construction industry is blockchain technology. Blockchain is a distributed data storing mechanism to replicate, share, and synchronize data spread across different geographical locations, such as multiple sites, countries, or organizations (Hewavitharana et al., 2019). These features make this technology attractive for the construction processes to become more efficient, traceable, transparent, and accountable across all stages of the project life-cycle (Institution of Civil Engineers, 2018).

Current research on blockchain technology has been executed in different sectors such as healthcare, and finance. In construction literature, blockchain research has been clustered construction management knowledge areas such as supply chain management, information management, contract management, facility management, payment management, project management, delivery, regulations and compliance, dispute management, and technological systems. Blockchain-enabled technologies such as BIM, IoT are popular research trends in these management areas. However, although blockchain and blockchain-enabled technologies are on the rise, academic studies are pre-mature and disconnected from each other. For this problem, this paper aims to identify five popular themes of blockchain applications in construction and its relations with knowledge areas through systematic-bibliometric review. These popular themes were selected as supply chain management, payment management, information management, facility management, and contract management from the prominent nodes of the 'blockchain' main keyword's science mapping by VOSviewer. Each theme was defined as a cluster and analyzed to understand current capabilities, technological tools combined with blockchain, and future developments. For this study, Web of Science, Scopus and Sci-direct databases were combined and examined together; thematic science-mapping and citation analysis were conducted through VOSviewer software.

Blockchain Technology and Its Applications

Blockchain is a distributed database (ledger) that maintains a list of records (transactions, information, etc.) (Dakhli et al., 2019). Each block can have some records limited by the megabyte. Unlike traditional transactions which rely on the central authentication such as banking system, blockchain is a decentralized P2P (person to person) network connected via a consensus protocol, which means transactions on the network are validated and shared among all participating nodes (computers) in the network (Koulouri-Fyrigou, 2019). The algorithmic hash key of each blocks defines the trust relationship by offering secure solutions. Any user of

the blockchain can easily trace any previous transactions by accessing any node in the distributed network, and all of the transactions are recorded with a timestamp. In the blockchain, although the view of existing data and adding new data is possible, changing the information that is already there is impossible. Because if any node in the network discovers an exchange, it checks consensus protocol and, if necessary, replaces itself with the consensus. Blockchains have many benefits; reducing costs and time, lowering the barriers to entry in several sectors, providing security in technological systems (Turk & Klinc, 2017). To understand the concept of blockchain, the study was clustered around the main keyword "blockchain" by including all industries. The research areas using the "blockchain" keyword in Scopus can be seen in Figure 1. According to Figure 1, the most researched areas of blockchain are seen as Computer Science (37,2%), Engineering (20,5%) in 27,133 papers. Besides, China can be seen as a pioneer country in blockchain literature (<7k documents), it is followed by the USA with <4k documents.

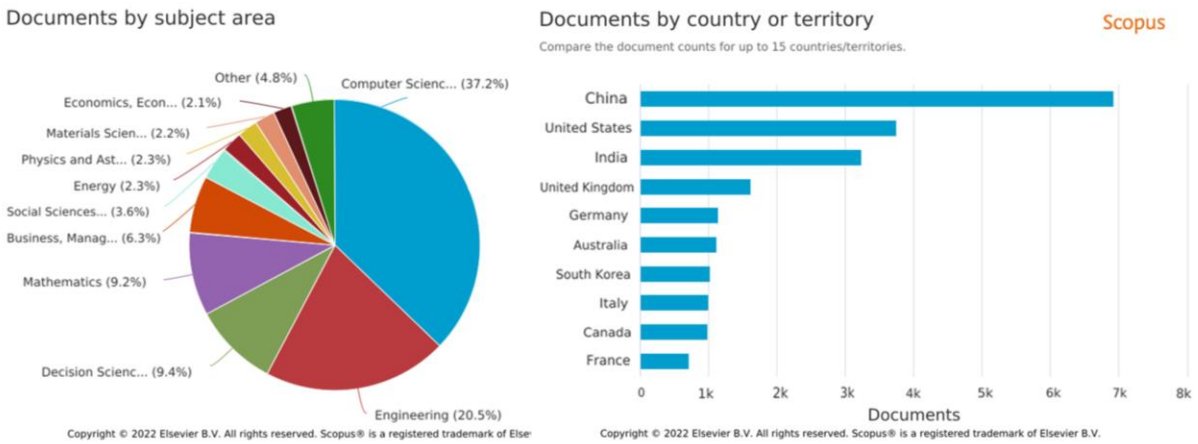

Figure 1: The research areas of Blockchain (a) and their country distributions (b).

As can be seen in Figure 2, blockchain technology has widespread research network by the other technological tools such as IoT, big data, BIM, cloud computing, machine learning, smart contracts. Also, it is seen that the most of the relevant digital tools are similar to the selected management themes. In order to understand the reflections of these relationships in the construction industry, the sub-keyword 'construction' was added as a focus to each theme.

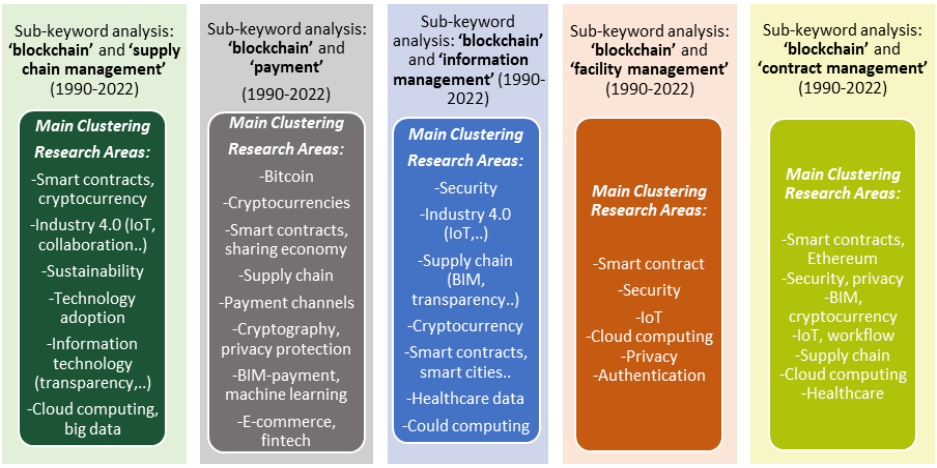

Figure 2: The clustering of sub-keywords about blockchain technologies by VOSviewer science mapping.

Research Methodology

The approach of a systematic-bibliometric literature review was selected for this paper to perceive the current level of research of blockchain and its applications in construction industry, and to guide development of research questions to further the body of knowledge. Systematic reviews allow a researcher to identify gaps in the research used to direct further investigation; offer background to support framework development in the case of new research; and support or challenge theoretical hypotheses (Tranfield et al., 2003).

All blockchain applications literature from 1990-2022 were collected through Web of Science, Scopus, and Sci-direct databases. The collections were created with 27,133 papers in Scopus, 19,833 papers in Web of Science, 9,754 papers in Science-direct by 'blockchain' main keyword. These papers were analyzed according to their sectors, countries and related research areas that were defined as sub-keywords. These sub-keywords' relations were shown in VOSviewer science-mapping by clustering. For VOSviewer science mapping, three different databases were combined so that the combination contributes to the originality of the study. Science mapping is a methodology that combines quantitative analysis, classification, and visualization to identify the composition and inter-relationships between bibliographic objects (Andersen & Swami, 2021). Besides, it presents the cluster analysis of the keywords & occurrence, time, country and journals according to the imported data. In the systematic-bibliometric research process shown in Figure 3, in the first stage, the main keyword 'blockchain' was examined according to the prominent nodes in VOSviewer science mapping that was in the scope of the main keyword analysis. The prominent studies in this process were grouped by five sub-keywords of management areas in all sectors: supply chain management, payment management, information management, facility management, and contract management. These prominent nodes were identified as five popular themes in the research. It can be inferred that the most researched sub-keyword related with blockchain is information and contract management regardless their sectors. At the result of this step, thematic science mapping by VOSviewer was created to identify the relationships with blockchain-related technologies. In the following stage, sub-keywords were disaggregated by the focused keyword which was the construction. These clusters were shown by VOSviewer's science mapping. Besides, bibliometric analysis was conducted through the number of citations and journals for each theme. Papers' contents and types of each theme were compared and discussed. In the last step, a discussion of the findings and gaps in the literature, the limitations of this study in terms of its utility and recommendations were performed.

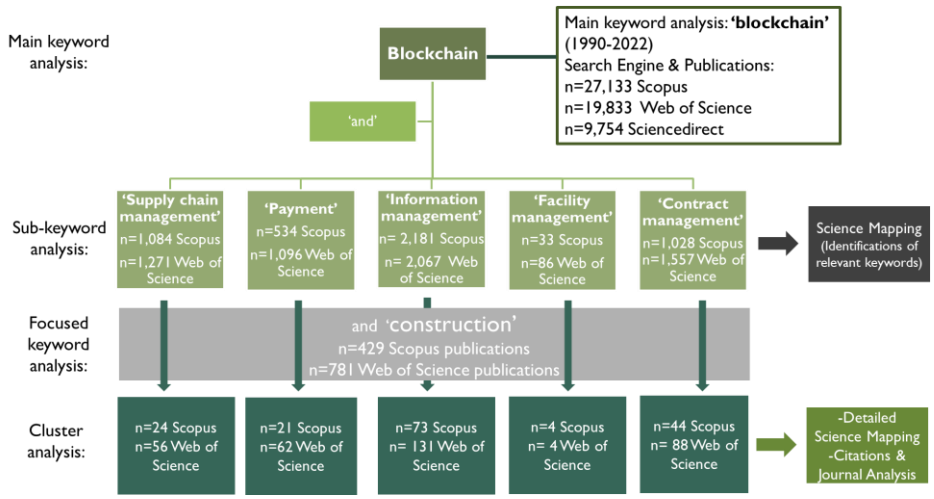

Figure 3: An overview of the literature review and research process.

In the first stage of the research that was executed with the keywords of blockchain and construction, 429 publications were found in Scopus and Sci-direct, 781 publications were investigated in Web of Science that can be seen in Figure 3. According to these findings, science mappings including blockchain-related keywords & occurrence and timeline were created and shown in Figure 4 and Figure 5.

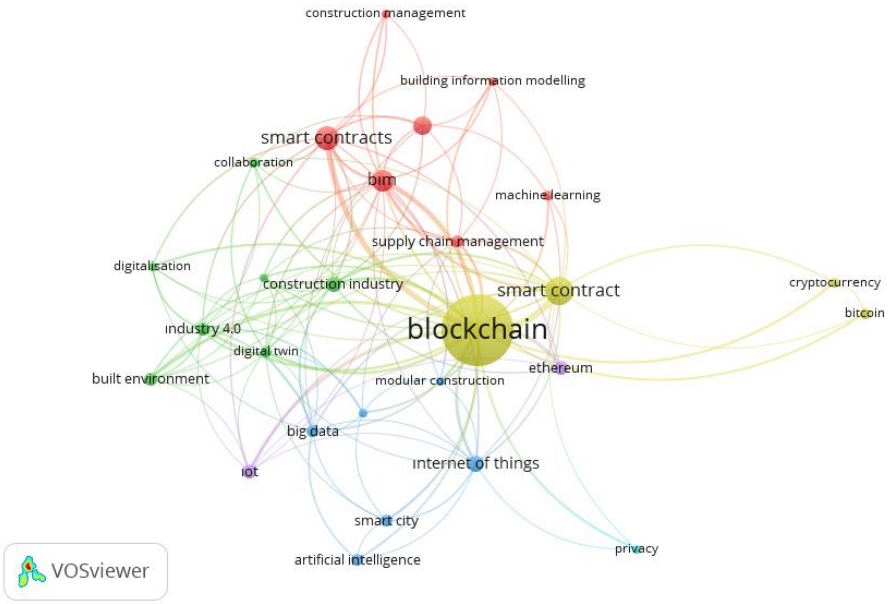

Figure 4: The science mapping of blockchain-related keywords & occurrence by VOSviewer.

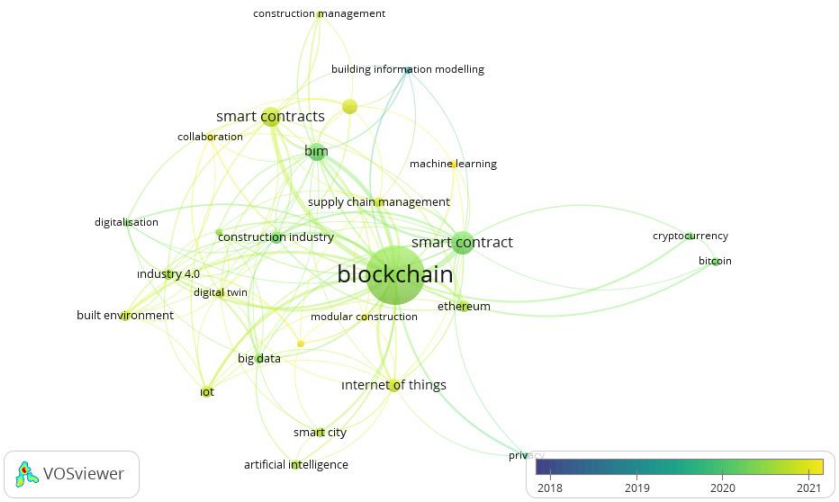

Figure 5: The timeline science mapping of blockchain-related keywords by VOSviewer.

As can be seen in Figure 4, smart contracts, BIM and IoT have wide bibliometric network in construction literature according to the size of nodes. Besides, Figure 4 presents the research clusters that are shown in different colors help to discover the relationships between the keywords. For example, it can be understood that smart contracts are associated with cryptocurrencies and BIM in construction. Figure 5 shows the timeline of popular researches related with blockchain technology. According to this bibliographic network, yellow nodes represent the trending topic in construction in nowadays such as IoT, digital twin, machine learning. In the next section, this bibliographic analysis was deepened by selecting five popular cluster themes; supply chain management, payment management, information management, facility management, contract management in construction.

Findings
